Specify the protocol type to be inspected. This keyword allows you to specify the traffic type by protocol rather than by port. If the decoder has the capability to identify the protocol on any port, the signature can be used to detect the attack no matter what port the service is running on. Currently, HTTP, SIP, SSL, and SSH protocols can be identified on any port based on the content.

Content keywords

byte_jump

Syntax: `--byte_jump <bytes_to_convert>, <offset>[, multiplier][, relative] [, big] [, little] [, string] [, hex] [, dec] [, oct] [, align];`

Description:

Use the byte_jump option to extract a number of bytes from a packet, convert them to their numeric representation, and jump the match reference up that many bytes (for further pattern matching or byte testing). This keyword allows relative pattern matches to take into account numerical values found in network data.

The available keyword options include:

- `<bytes_to_convert>`: The number of bytes to examine from the packet.
- `<offset>`: The number of bytes into the payload to start processing.
- `[multiplier]`: multiplier is optional. It must be a numerical value when present. The converted value multiplied by the number is the result to be skipped.
- `relative`: Use an offset relative to last pattern match.
- `big`: Process the data as big endian (default).
- `little`: Process the data as little endian.string: The data is a string in the packet.
- `hex`: The converted string data is represented in hexadecimal notation.
- `dec`: The converted string data is represented in decimal notation.
- `oct`: The converted string data is represented in octal notation.
- `align`: Round up the number of converted bytes to the next 32-bit boundary.

byte_test

Syntax: `--byte_test <bytes_to_convert>, <operator>, <value>, <offset>[, relative] [, big] [, little] [, string] [, hex] [, dec] [, oct];`

Description:

Use the byte_test keyword to compare a byte field against a specific value (with operator). This keyword is capable of testing binary values or converting representative byte strings to their binary equivalent and testing them. The available keyword options include:

- `<bytes_to_convert>`: The number of bytes to compare.
- `<operator>`: The operation to perform when comparing the value (<,>,=,!,&).
- `<value>`: The value to compare the converted value against.
- `<offset>`: The number of bytes into the payload to start processing.
- `relative`: Use an offset relative to last pattern match.
- `big`: Process the data as big endian (default).
- `little`: Process the data as little endian.string: The data is a string in the packet.
- `hex`: The converted string data is represented in hexadecimal notation.
- `dec`: The converted string data is represented in decimal notation.
- `oct`: The converted string data is represented in octal notation.

depth

Syntax: `--depth <depth_int>;`

Description:

Use the depth keyword to search for the contents within the specified number of bytes after the starting point defined by the offset keyword. If no offset is specified, the offset is assumed to be equal to 0.

If the value of the depth keyword is smaller than the length of the value of the content keyword, this signature will never be matched.

The depth must be between 0 and 65535.

distance

Syntax: `--distance <dist_int>;`

Description:

Use the distance keyword to search for the contents within the specified number of bytes relative to the end of the previously matched contents. If the within keyword is not specified, continue looking for a match until the end of the payload.

The distance must be between 0 and 65535.

content

Syntax: --content [!]"<content_str>";

Description:

Deprecated, see pattern and context keywords. Use the content keyword to search for the content string in the packet payload. The content string must be enclosed in double quotes.

To have the FortiGate search for a packet that does not contain the specified context string, add an exclamation mark (!) before the content string.

Multiple content items can be specified in one rule. The value can contain mixed text and binary data. The binary data is generally enclosed within the pipe (|) character.

The double quote ("), pipe sign(|) and colon(:) characters must be escaped using a back slash if specified in a content string.

If the value of the content keyword is greater than the length of the value of the depth keyword, this signature will never be matched.

context

Syntax: `--context {uri | header | body | host};`

Description:

Specify the protocol field to look for the pattern. If context is not specified for a pattern, the FortiGate unit searches for the pattern anywhere in the packet buffer.

The available context variables are:

`uri`: Search for the pattern in the HTTP URI line.

`header`: Search for the pattern in HTTP header lines or SMTP/POP3/SMTP control messages.

`body`: Search for the pattern in HTTP body or SMTP/POP3/SMTP email body.

`host`: Search for the pattern in HTTP HOST line.

no_case

Syntax: `--no_case;`

Description:

Use the no-case keyword to force the FortiGate unit to perform a case-insensitive pattern match.

offset

Syntax: `--offset <offset_int>;`

Description:

Use the offset keyword to look for the contents after the specified number of bytes into the payload. The specified number of bytes is an absolute value in the payload. Follow the offset keyword with the depth keyword to stop looking for a match after a specified number of bytes. If no depth is specified, the FortiGate unit continues looking for a match until the end of the payload. The offset must be between 0 and 65535.

pattern

Syntax: `--pattern [!]"<pattern_str>";`

Description:

The FortiGate unit will search for the specified pattern. A pattern keyword normally is followed by a context keyword to define where to look for the pattern in the packet. If a context keyword is not present, the FortiGate unit looks for the pattern anywhere in the packet buffer. To have the FortiGate search for a packet that does not contain the specified URI, add an exclamation mark (!) before the URI.

Example: `--pattern "/level/" --pattern "|E8 D9FF FFFF|/bin/sh" --pattern !"|20|RTSP/"`

pcre

Syntax: `--pcre [!]"/<regex>/[ismxAEGRUB]";`

Description:

Similarly to the pattern keyword, use the pcre keyword to specify a pattern using Perl-compatible regular expressions (PCRE). A pcre keyword can be followed by a context keyword to define where to look for the pattern in the packet. If no context keyword is present, the FortiGate unit looks for the pattern anywhere in the packet buffer. For more information about PCRE syntax, go to http://www.pcre.org.

The switches include:

- `i`: Case insensitive.
- s: Include newlines in the dot metacharacter.
- m: By default, the string is treated as one big line of characters. ^ and $ match at the beginning and ending of the string. When m is set, ^ and $ match immediately following or immediately before any newline in the buffer, as well as the very start and very end of the buffer.
- `x`: White space data characters in the pattern are ignored except when escaped or inside a character class.
- `A`: The pattern must match only at the start of the buffer (same as ^).
- `E`: Set $ to match only at the end of the subject string. Without E, $ also matches immediately before the final character if it is a newline (but not before any other newlines).
- `G`: Invert the “greediness” of the quantifiers so that they are not greedy by default, but become greedy if followed by ?.
- `R`: Match relative to the end of the last pattern match. (Similar to distance:0;).
- U: Deprecated, see the context keyword. Match the decoded URI buffers.

uri

Syntax: `--uri [!]"<uri_str>";`

Description:

Deprecated, see pattern and context keywords. Use the uri keyword to search for the URI in the packet payload. The URI must be enclosed in double quotes ("). To have the FortiGate unit search for a packet that does not contain the specified URI, add an exclamation mark (!) before the URI. Multiple content items can be specified in one rule. The value can contain mixed text and binary data. The binary data is generally enclosed within the pipe (|) character. The double quote ("), pipe sign (|) and colon (:) characters must be escaped using a back slash (\) if specified in a URI string.

within

Syntax: `--within <within_int>;`

Description:

Use this together with the distance keyword to search for the contents within the specified number of bytes of the payload. The within value must be between 0 and 65535.

IP header keywords

dst_addr

Syntax: `--dst_addr [!]<ipv4>;`

Description:

Use the dst_addr keyword to search for the destination IP address. To have the FortiGate search for a packet that does not contain the specified address, add an exclamation mark (!) before the IP address. You can define up to 28 IP addresses or CIDR blocks. Enclose the comma separated list in square brackets.

Example: `dst_addr [172.20.0.0/16, 10.1.0.0/16,192.168.0.0/16]`

ip_id

Syntax: `--ip_id <field_int>;`

Description:

Check the IP ID field for the specified value.

ip_option

Syntax: `--ip_option {rr | eol | nop | ts | sec | lsrr | ssrr | satid | any};`

Description:

Use the ip_option keyword to check various IP option settings.

The available options include:

- `rr`: Check if IP RR (record route) option is present.
- `eol`: Check if IP EOL (end of list) option is present.
- `nop`: Check if IP NOP (no op) option is present.
- `ts`: Check if IP TS (time stamp) option is present.
- `sec`: Check if IP SEC (IP security) option is present.
- `lsrr`: Check if IP LSRR (loose source routing) option is present.
- `ssrr`: Check if IP SSRR (strict source routing) option is present.
- `satid`: Check if IP SATID (stream identifier) option is present.
- `any`: Check if IP any option is present.

ip_tos

Syntax: `--ip_tos <field_int>;`

Description:

Check the IP TOS field for the specified value.

ip_ttl

Syntax: `--ip_ttl [< | >] <ttl_int>;`

Description:

Check the IP time-to-live value against the specified value. Optionally, you can check for an IP time-to-live greater-than (>) or less-than (<) the specified value with the appropriate symbol.

protocol

Syntax: `--protocol {<protocol_int> | tcp | udp | icmp};`

Description:

Check the IP protocol header.

Example: `--protocol tcp;`

src_addr

Syntax: `--src_addr [!]<ipv4>;`

Description:

Use the src_addr keyword to search for the source IP address. To have the FortiGate unit search for a packet that does not contain the specified address, add an exclamation mark (!) before the IP address. You can define up to 28 IP addresses or CIDR blocks. Enclose the comma separated list in square brackets.

Example: `src_addr 192.168.13.0/24`

TCP header keywords

ack

Syntax: `--ack <ack_int>;`

Description:

Check for the specified TCP acknowledge number.

dst_port

Syntax: `--dst_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>};`

Description:

Use the dst_port keyword to specify the destination port number.

You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

seq

Syntax: `--seq <seq_int>;`

Description:

Check for the specified TCP sequence number.

src_port

Syntax: `--src_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>};`

Description:

Use the src_port keyword to specify the source port number.

You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

tcp_flags

Syntax: `--tcp_flags <SAFRUP120>[!|*|+] [,<SAFRUP120>];`

Description:

Specify the TCP flags to match in a packet.

- `S`: Match the SYN flag.
- `A`: Match the ACK flag.
- `F`: Match the FIN flag.
- `R`: Match the RST flag.
- `U`: Match the URG flag.
- `P`: Match the PSH flag.
- `1`: Match Reserved bit 1.
- `2`: Match Reserved bit 2.
- `0`: Match No TCP flags set.
- `!`: Match if the specified bits are not set.
- `*`: Match if any of the specified bits are set.
- `+`: Match on the specified bits, plus any others.

The first part if the value (<SAFRUP120>) defines the bits that must be present for a successful match.

Example:

`--tcp_flags AP` only matches the case where both A and P bits are set.

The second part (`[,<SAFRUP120>]`) is optional, and defines the additional bits that can be present for a match.

For example `tcp_flags S,12` matches the following combinations of flags: S, S and 1, S and 2, S and 1 and 2. The modifiers !, * and + cannot be used in the second part.

window_size

Syntax: `--window_size [!]<window_int>;`

Description:

Check for the specified TCP window size. You can specify the window size as a hexadecimal or decimal integer. A hexadecimal value must be preceded by 0x. To have the FortiGate search for the absence of the specified window size, add an exclamation mark (!) before the window size.

UDP header keywords

dst_port

Syntax: `--dst_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>};`

Description:

Specify the destination port number.

You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

src_port

Syntax: `--src_port [!]{<port_int> | :<port_int> | <port_int>: | <port_int>:<port_int>};`

Description:

Specify the destination port number.

You can specify a single port or port range:

- `<port_int>` is a single port.
- `:<port_int>` includes the specified port and all lower numbered ports.
- `<port_int>:` includes the specified port and all higher numbered ports.
- `<port_int>:<port_int>` includes the two specified ports and all ports in between.

ICMP keywords

icmp_code

Syntax: `--icmp_code <code_int>;`

Description:

Specify the ICMP code to match.

icmp_id

Syntax: `--icmp_id <id_int>;`

Description:

Check for the specified ICMP ID value.

icmp_seq

Syntax: `--icmp_seq <seq_int>;`

Description:

Check for the specified ICMP sequence value.

icmp_type

Syntax: `--icmp_type <type_int>;`

Description:

Specify the ICMP type to match.

Other keywords

data_size

Syntax: `--data_size {<size_int> | <<size_int> | ><size_int>};`

Description:

Test the packet payload size. With data_size specified, packet reassembly is turned off automatically. So a signature with data_size and only_stream values set is wrong.

- <size_int> is a particular packet size.
- <<size_int> is a packet smaller than the specified size.
- ><size_int> is a packet larger than the specified size.

Example: `--data_size <300;`

data_at

Syntax: `--data_at <offset_int>[, relative];`

Description:

Verify that the payload has data at a specified offset, optionally looking for data relative to the end of the previous content match.

rate

Syntax: `--rate <matches_int>,<time_int>;`

Description:

Instead of generating log entries every time the signature is detected, use this keyword to generate a log entry only if the signature is detected a specified number of times within a specified time period.

- `<matches_int>` is the number of times a signature must be detected.
- `<time_int>` is the length of time in which the signature must be detected, in seconds.

For example, if a custom signature detects a pattern, a log entry will be created every time the signature is detected. If `--rate 100,10;` is added to the signature, a log entry will be created if the signature is detected 100 times in the previous 10 seconds. Use this command with `--track` to further limit log entries to when the specified number of detections occur within a certain time period involving the same source or destination address rather than all addresses.

rpc_num

Syntax: `--rpc_num <app_int>[, <ver_int> | *][, <proc_int> | *>];`

Description:

Check for RPC application, version, and procedure numbers in SUNRPC CALL requests. The * wild card can be used for version and procedure numbers.

same_ip

Syntax: `--same_ip;`

Description:

Check that the source and the destination have the same IP addresses.

track

Syntax: `--track {SRC_IP |DST_IP |DHCP_CLIENT |DNS_DOMAIN}[,block_int];`

Description:

When used with `--rate`, this keyword narrows the custom signature rate totals to individual addresses.

- `SRC_IP`: tracks the packet's source IP.
- `DST_IP`: tracks the packet's destination IP.
- `DHCP_CLIENT`: tracks the DHCP client's MAC address.
- `DNS_DOMAIN`: counts the number of any specific domain name.
- `block_int` has the FortiGate unit block connections for the specified number of seconds, from the client or to the server, depending on which is specified.

For example, if `--rate 100,10` is added to the signature, a log entry will be created if the signature is detected 100 times in the previous 10 seconds. The FortiGate unit maintains a single total, regardless of source and destination address.

If the same custom signature also includes `--track client`; matches are totaled separately for each source address. A log entry is added when the signature is detected 100 times in 10 seconds within traffic from the same source address.

The `--track` keyword can also be used without `--rate`. If an integer is specified, the client or server will be blocked for the specified number of seconds every time the signature is detected.

Creating a custom signature to block access to example.com

In this first example, you will create a custom signature to block access to the example.com URL.

This example describes the use of the custom signature syntax to block access to a URL. To create the custom signature entry in the FortiGate unit web-based manager, see “Creating a custom IPS signature” on page 2080.

1. Enter the custom signature basic format

   All custom signatures have a header and at least one keyword/value pair. The header is always the same:

   ```
   F-SBID( )
   ```

   The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

2. Choose a name for the custom signature

   Every custom signature requires a name, so it is a good practice to assign a name before adding any other keywords.

   Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

   ```
   F-SBID( --name "Block.example.com"; )
   ```

   The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic. You must specify a pattern that the FortiGate unit will search for.

3. Add a signature pattern

   Use the `--pattern` keyword to specify what the FortiGate unit will search for:

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com"; )
   ```

   The signature will now detect the example.com URL appearing in network traffic. The custom signature should only detect the URL in HTTP traffic, however. Any other traffic with the URL should be allowed to pass. For example, an email message to or from example.com should not be stopped.

4. Specify the service

   Use the `--service` keyword to limit the effect of the custom signature to only the HTTP protocol.

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com";
        --service HTTP; )
   ```

   The FortiGate unit will limit its search for the pattern to the HTTP protocol. Even though the HTTP protocol uses only TCP traffic, the FortiGate will search for HTTP protocol communication in TCP, UDP, and ICMP traffic. This is a waste of system resources that you can avoid by limiting the search further, as shown below.

5. Specify the traffic type.

   Use the `--protocol tcp keyword to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.`

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com";
        --service HTTP; --protocol tcp; )
   ```

   The FortiGate unit will limit its search for the pattern to TCP traffic and ignore UDP and ICMP network traffic.

6. Ignore case sensitivity

   By default, patterns are case sensitive. If a user directed his or her browser to Example.com, the custom signature would not recognize the URL as a match.

   Use the `--no_case` keyword to make the pattern matching case insensitive.

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com";
        --service HTTP; --no_case; )
   ```

   Unlike all of the other keywords in this example, the `--no_case` keyword has no value. Only the keyword is required.

7. Limit pattern scans to only traffic sent from the client

   The `--flow` command can be used to further limit the network traffic being scanned to only that send by the client or by the server.

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com";
        --service HTTP; --no_case; --flow from_client; )
   ```

   Web servers do not contact clients until clients first open a communication session. Therefore, using the `--flow from_client` command will force the FortiGate to ignore all

traffic from the server. Since the majority of HTTP traffic flows from the server to the client, this will save considerable system resources and still maintain protection.

8. Specify the context

   When the client browser tries to contact example.com, a DNS is first consulted to get the example.com server IP address. The IP address is then specified in the URL field of the HTTP communication. The domain name will still appear in the host field, so this custom signature will not function without the `--context host` keyword/value pair.

   ```
   F-SBID( --name "Block.example.com"; --pattern "example.com";
        --service HTTP; --no_case; --flow from_client;
        --context host; )
   ```

Creating a custom signature to block the SMTP “vrfy” command

The SMTP “vrfy” command can be used to verify the existence of a single email address or to list all of the valid email accounts on an email server. A spammer could potentially use this command to obtain a list of all valid email users and direct spam to their inboxes.

In this example, you will create a custom signature to block the use of the vrfy command. Since the custom signature blocks the vrfy command from coming through the FortiGate unit, the administrator can still use the command on the internal network.

This example describes the use of the custom signature syntax to block the vrfy command. To create the custom signature entry in the FortiGate unit web-based manager, see “Creating a custom IPS signature” on page 2080.

1. Enter the custom signature basic format

   All custom signatures have a header and at least one keyword/value pair. The header is always the same:

   ```
   F-SBID( )
   ```

   The keyword/value pairs appear within the parentheses and each pair is followed by a semicolon.

2. Choose a name for the custom signature

   Every custom signature requires a name, so it is a good practice to assign a name before you add any other keywords.

   Use the `--name` keyword to assign the custom signature a name. The name value follows the keyword after a space. Enclose the name value in double-quotes:

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; )
   ```

   The signature, as it appears here, will not do anything if you try to use it. It has a name, but does not look for any patterns in network traffic. You must specify a pattern that the FortiGate unit will search for.

3. Add a signature pattern

   Use the `--pattern` keyword to specify what the FortiGate unit will search for:

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy"; )
   ```

   The signature will now detect the vrfy command appearing in network traffic. The custom signature should only detect the command in SMTP traffic, however. Any other traffic with the pattern should be allowed to pass. For example, an email message discussing the vrfy command should not be stopped.

4. Specify the service

   Use the `--service` keyword to limit the effect of the custom signature to only the HTTP protocol.

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy";
        --service SMTP; )
   ```

   The FortiGate unit will limit its search for the pattern to the SMTP protocol.

   Even though the SMTP protocol uses only TCP traffic, the FortiGate will search for SMTP protocol communication in TCP, UDP, and ICMP traffic. This is a waste of system resources that you can avoid by limiting the search further, as shown below.

5. Specify the traffic type.

   Use the `--protocol tcp keyword to limit the effect of the custom signature to only TCP traffic. This will save system resources by not unnecessarily scanning UDP and ICMP traffic.`

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy";
        --service SMTP; --protocol tcp; )
   ```

   The FortiGate unit will limit its search for the pattern to TCP traffic and ignore the pattern in UDP and ICMP network traffic.

6. Ignore case sensitivity

   By default, patterns are case sensitive. If a user directed his or her browser to Example.com, the custom signature would not recognize the URL as a match.

   Use the `--no_case` keyword to make the pattern matching case insensitive.

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy";
        --service SMTP; --no_case; )
   ```

   Unlike all of the other keywords in this example, the `--no_case` keyword has no value. Only the keyword is required.

7. Specify the context

   The SMTP vrfy command will appear in the SMTP header. The `--context host` keyword/value pair allows you to limit the pattern search to only the header.

   ```
   F-SBID( --name "Block.SMTP.VRFY.CMD"; --pattern "vrfy";
        --service SMTP; --no_case; --context header; )
   ```

Web filter

This section describes FortiGate web filtering for HTTP traffic. The three main parts of the web filtering function, the Web Content Filter, the URL Filter, and the FortiGuard Web Filtering Service interact with each other to provide maximum control over what the Internet user can view as well as protection to your network from many Internet content threats. Web Content Filter blocks web pages containing words or patterns that you specify. URL filtering uses URLs and URL patterns to block or exempt web pages from specific sources. FortiGuard Web Filtering provides many additional categories you can use to filter web traffic.

This section describes the Web Content Filter and URL Filter functions. For information on FortiGuard Web Filtering, see "FortiGuard Web Filter" on page 133

The following topics are included in this section:

Web filter concepts

Web filtering is a means of controlling the content that an Internet user is able to view. With the popularity of web applications, the need to monitor and control web access is becoming a key component of secure content management systems that employ antivirus, web filtering, and messaging security. Important reasons for controlling web content include:

- lost productivity because employees are accessing the web for non-business reasons
- network congestion — when valuable bandwidth is used for non-business purposes, legitimate business applications suffer
- loss or exposure of confidential information through chat sites, non-approved email systems, instant messaging, and peer-to-peer file sharing
- increased exposure to web-based threats as employees surf non-business-related web sites
- legal liability when employees access/download inappropriate and offensive material
- copyright infringement caused by employees downloading and/or distributing copyrighted material.

As the number and severity of threats increase on the World Wide Web, the risk potential increases within a company's network as well. Casual non-business related web surfing has caused many businesses countless hours of legal litigation as hostile environments have been created by employees who download and view offensive content. Web-based attacks and

threats are also becoming increasingly sophisticated. Threats and web-based applications that cause additional problems for corporations include:

- spyware/grayware
- phishing
- pharming
- instant messaging
- peer-to-peer file sharing
- streaming media
- blended network attacks.

Spyware, also known as grayware, is a type of computer program that attaches itself to a user's operating system. It does this without the user's consent or knowledge. It usually ends up on a computer because of something the user does such as clicking on a button in a pop-up window. Spyware can track the user's Internet usage, cause unwanted pop-up windows, and even direct the user to a host web site. For further information, visit the FortiGuard Center.

Some of the most common ways of grayware infection include:

- downloading shareware, freeware, or other forms of file-sharing services
- clicking on pop-up advertising
- visiting legitimate web sites infected with grayware.

Phishing is the term used to describe attacks that use web technology to trick users into revealing personal or financial information. Phishing attacks use web sites and email that claim to be from legitimate financial institutions to trick the viewer into believing that they are legitimate. Although phishing is initiated by spam email, getting the user to access the attacker's web site is always the next step.

Pharming is a next generation threat that is designed to identify and extract financial, and other key pieces of information for identity theft. Pharming is much more dangerous than phishing because it is designed to be completely hidden from the end user. Unlike phishing attacks that send out spam email requiring the user to click to a fraudulent URL, pharming attacks require no action from the user outside of their regular web surfing activities. Pharming attacks succeed by redirecting users from legitimate web sites to similar fraudulent web sites that have been created to look and feel like the authentic web site.

Instant messaging presents a number of problems. Instant messaging can be used to infect computers with spyware and viruses. Phishing attacks can be made using instant messaging. There is also a danger that employees may use instant messaging to release sensitive information to an outsider.

Peer-to-peer (P2P) networks are used for file sharing. Such files may contain viruses. Peer-to-peer applications take up valuable network resources and may lower employee productivity but also have legal implications with the downloading of copyrighted or sensitive company material.

Streaming media is a method of delivering multimedia, usually in the form of audio or video to Internet users. Viewing streaming media impacts legitimate business by using valuable bandwidth.

Blended network threats are rising and the sophistication of network threats is increasing with each new attack. Attackers learn from each previous successful attack and enhance and update attack code to become more dangerous and fast spreading. Blended attacks use a combination of methods to spread and cause damage. Using virus or network worm techniques combined with known system vulnerabilities, blended threats can quickly spread through email, web sites, and Trojan applications. Examples of blended threats include Nimda, Code Red, Slammer, and Blaster. Blended attacks can be designed to perform different types of attacks,

which include disrupting network services, destroying or stealing information, and installing stealthy backdoor applications to grant remote access.

Different ways of controlling access

The methods available for monitoring and controlling Internet access range from manual and educational methods to fully automated systems designed to scan, inspect, rate and control web activity.

Common web access control mechanisms include:

- establishing and implementing a well-written usage policy in the organization on proper Internet, email, and computer conduct
- installing monitoring tools that record and report on Internet usage
- implementing policy-based tools that capture, rate, and block URLs.

The final method is the focus of this topic. The following information shows how the filters interact and how to use them to your advantage.

Order of web filtering

The FortiGate unit applies web filters in a specific order:

1. URL filter
2. FortiGuard Web Filter
3. web content filter
4. web script filter
5. antivirus scanning.

If you have blocked a FortiGuard Web Filter category but want certain users to have access to URLs within that pattern, you can use the *Override* within the FortiGuard Web Filter. This will allow you to specify which users have access to which blocked URLs and how long they have that access. For example, if you want a user to be able to access www.example.com for one hour, you can use the override to set up the exemption. Any user listed in an override must fill out an online authentication form that is presented when they try to access a blocked URL before the FortiGate unit will grant access to it. For more information, see "FortiGuard Web Filter" on page 133.

Inspections Modes

Proxy

Proxy-based inspection involves buffering the traffic and examining it as a whole before determining an action. The process of having the whole of the data to analyze allow this process to include more points of data to analyze than the flow-based or DNS methods.

The advantage of a proxy-based method is that the inspection can be more thorough than the other methods, resulting in fewer false positive or negative results in the analysis of the data.

Flow-based

The Flow-based inspection method examines the file as it passes through the FortiGate unit without any buffering. As each packet of the traffic arrives it is process and forwarded without waiting for the complete file or web page, etc.

The advantage of the flow-based method is that the user sees a faster response time for HTTP requests and there is less chance of a time-out error due to the server at the other end responding slowly.

The disadvantages of this method are that there is a higher probability of a false positive or negative in the analysis of the data and that a number of points of analysis that can be used in the proxy-based method are not available in the flow-based inspection method. There is also fewer actions available to choose from based on the categorization of the website by FortiGuard services.

DNS

The DNS inspection method uses the same categories as the FortiGuard Service. It is lightweight in terms of resource usage because it doesn't involve any proxy-based or flow-based inspection.

A DNS request is typically the first part of any new session to a new website. This inspection method takes advantage of that and places the results of the categorization of websites right on the FortiGuard DNS servers. When the FortiGate resolves a URL, in addition to the IP address of the website it also receives a domain rating.

In the same way that the flow-based inspection method had fewer filters and points of analysis than the proxy-based inspection method, DNS has fewer settings still. All of its inspection is based on the IP address, the domain name and the rating provided by the FortiGuard DNS server.

FortiGuard Web Filtering Service

FortiGuard Web Filter is a managed web filtering solution available by subscription from Fortinet. FortiGuard Web Filter enhances the web filtering features supplied with your FortiGate unit by sorting billions of web pages into a wide range of categories users can allow or block. The FortiGate unit accesses the nearest FortiGuard Web Filter Service Point to determine the category of a requested web page, and then applies the security policy configured for that user or interface.

FortiGuard Web Filter includes over 45 million individual ratings of web sites that apply to more than two billion pages. Pages are sorted and rated into several dozen categories administrators can allow or block. Categories may be added or updated as the Internet evolves. To make configuration simpler, you can also choose to allow or block entire groups of categories. Blocked pages are replaced with a message indicating that the page is not accessible according to the Internet usage policy.

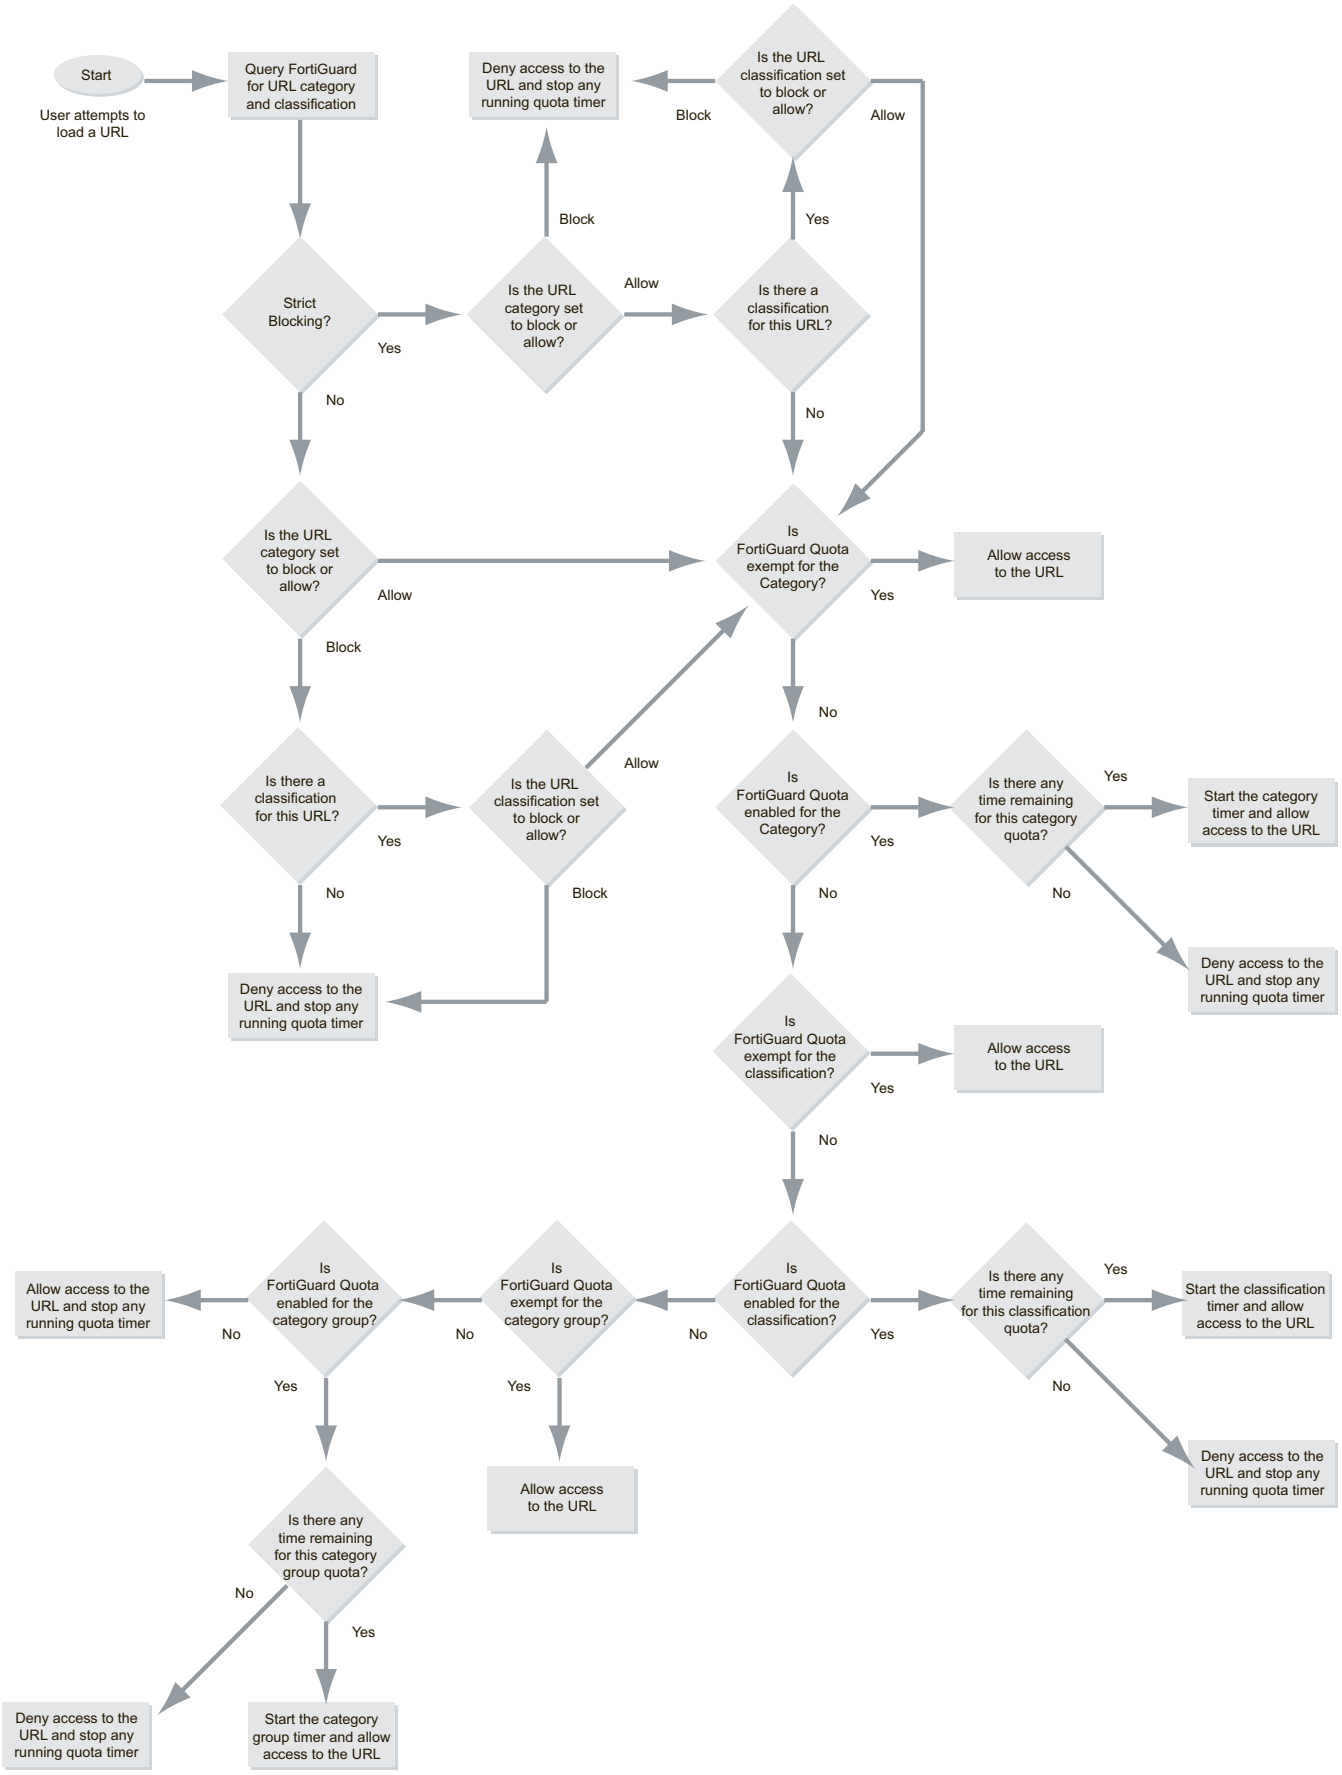
FortiGuard Web Filter ratings are performed by a combination of proprietary methods including text analysis, exploitation of the web structure, and human raters. Users can notify the FortiGuard Web Filter Service Points if they feel a web page is not categorized correctly, so that the service can update the categories in a timely fashion.

Before you begin to use the FortiGuard Web Filter options you should verify that you have a valid subscription to the service for your FortiGate firewall.

FortiGuard Web Filter and your FortiGate unit

When FortiGuard Web Filter is enabled in a web filter profile, the setting is applied to all firewall policies that use this profile. When a request for a web page appears in traffic controlled by one of these firewall policies, the URL is sent to the nearest FortiGuard server. The URL category is returned. If the category is blocked, the FortiGate unit provides a replacement message in place of the requested page. If the category is not blocked, the page request is sent to the requested URL as normal.

Figure 311: Webfiltering flowchart



Enabling FortiGuard Web Filter

FortiGuard Web Filter is enabled and configured within web filter profiles by enabling FortiGuard Categories. The service is engaged by turning on the Web Filter profile and selecting a profile that has FortiGuard Categories enabled on one or more active policies being run by the firewall.

There is also a system wide setting for the enabling or disabling of FortiGuard Web Filter that is only in the CLI.

```
config system fortiguard
   set webfilter-force-off
```

The two options on this setting are enable or disable. The syntax of the settings name is “force-off” so in order to enable FortiGuard Webfilter you have to choose disable for the setting and enable if you want to turn it off.

General configuration steps

1. Go to Security Profiles > Web Filter > Profile.
2. Select the Edit icon of the web filter profile in which you want to enable FortiGuard Web Filter, or select Create New to add a new web filter profile.
3. Select an Inspection Mode.
4. If you are using FortiGuard Categories, enable the feature, select the categories and select the action to be performed.
5. The categories allow you to block or allow access to general or more specific web site categories. Configure access as required.
6. Save the filter and web filter profile.
7. To complete the configuration, you need to select the security policy controlling the network traffic you want to restrict. Then, in the security policy, enable Web Filter and select the appropriate web filter profile from the list.

Configuring FortiGuard Web Filter settings

FortiGuard Web Filter includes a number of settings that allow you to determine various aspects of the filtering behavior.

To configure FortiGuard Web Filter settings

1. Go to *Security Profiles* > *Web Filter* > *Profile*.
2. Select the web filter profile in which you want to enable FortiGuard Web Filter from the drop down list in the Edit Web Filter Profile window title bar, or select *Create New* to add a new web filter profile.
3. The category groups are listed in a table. You can expand each category group to view and configure every category within the groups. If you change the setting of a category group, all categories within the group inherit the change.
4. Select the category groups and categories to which you want to apply an action.

5. Select an action from the *Change Action for Selected Categories* drop-down list immediately below the category table. Five actions are available:

- *Allow* permits access to the sites within the category.
- *Monitor* permits and logs access to sites in the category. You may also enable user quotas when enabling the monitor action.
- *Warning* presents the user with a message, allowing them to continue if they choose.
- *Authenticate* requires a user authenticate with the FortiGate unit before being allowed access to the category or category group.
- *Block* prevents access to sites within the category. Users attempting to access a blocked site will receive a replacement message explaining that access to the site is blocked.

6. Select *OK*.

In older versions of FortiOS there was a character limitation for the URL of 2048 bytes or approximately 321 characters. If the URL you were trying to reach was longer the URL sent to FortiGuard would be truncated and the service would be unable to categorize the site. Starting in version 5 of the firmware the parsed URL has been increase to 4Kilobytes, effectively doubling the length of a URL capable of being categorized.

To configure the FortiGuard Web Filter categories

1. Go to *Security Profiles* > *Web Filter* > *Profiles*.
2. Select the web filter profile in which you want to enable FortiGuard Web Filter from the drop down list in the Edit Web Filter Profile window title bar, or select *Create New* to add a new web filter profile.
3. Select *Create New*.
4. Select a *Filter Type* of *Category*.
5. Select the required category groups. You may also expand the category groups to select individual categories.
6. Select the *Monitor* action.
7. Enable *Enforce Quota* to activate the quota for the selected categories and category groups.
8. Select *Hours*, *Minutes*, or *Seconds* and enter the number of hours, minutes, or seconds. This is the daily quota allowance for each user.
9. Select *OK*.
10. Select *Apply*.

Apply the web filter profile to an identity-based security policy. All the users subject to that policy are restricted by the quotas.

If you look at your logs carefully, you may notice that not every URL connection in the log shows a category. They are left blank. If you take one of those URL and enter it in the FortiGuard website designed to show the category for a URL it will successfully categorize it.

The reason for this is that to optimize speed throughput and reduce the load on the FortiGuard servers the FortiGate does not determine a category rating on scripts and css files.

Configuring FortiGuard Web Filter usage quotas

In addition to using category and classification blocks and overrides to limit user access to URLs, you can set a daily timed access quota by category, category group, or classification.

Quotas allow access for a specified length of time, calculated separately for each user. Quotas are reset every day at midnight.

Users must authenticate with the FortiGate unit. The quota is applied to each user individually so the FortiGate must be able to identify each user. One way to do this is to configure a security policy using the identity based policy feature. Apply the web filter profile in which you have configured FortiGuard Web Filter and FortiGuard Web Filter quotas to such a security policy.

The use of FortiGuard Web Filter quotas requires that users authenticate to gain web access. The quotas are ignored if applied to a security policy in which user authentication is not required.

When a user first attempts to access a URL, they're prompted to authenticate with the FortiGate unit. When they provide their user name and password, the FortiGate unit recognizes them, determines their quota allowances, and monitors their web use. The category and classification of each page they visit is checked and FortiGate unit adjusts the user's remaining available quota for the category or classification.

Editing the web filter profile resets the quota timers for all users.

1. Select the *Monitor* action.
2. Enable *Enforce Quota* to activate the quota for the selected categories and category groups.
3. Select *Hours*, *Minutes*, or *Seconds* and enter the number of hours, minutes, or seconds. This is the daily quota allowance for each user.
4. Select *OK*.
5. Select *Apply*.

Apply the web filter profile to an identity-based security policy. All the users subject to that policy are restricted by the quotas.

Quota hierarchy

You can apply quotas to categories and category groups. Only one quota per user can be active at any one time. The one used depends on how you configure the FortiGuard Web Filter.

When a user visits a URL, the FortiGate unit queries the FortiGuard servers for the category of the URL. From highest to lowest, the relative priority of the quotas are:

1. Category
2. Category group

Overriding FortiGuard website categorization

In most things there is an exception to the rule. When it comes to the rules about who is allowed to go to which websites in spite of the rules or in this case, policies, it seems that there are more exceptions than to most rules. There are numerous valid reasons and scenarios for exceptions so it follows that there needs to be a way to accommodate this exceptions.

The different methods of override

There are actually two different ways to override web filtering behavior based on FortiGuard categorization of a websites. The second method has 2 variations in implementation and each of the three has a different level of granularity.

1. Using Alternate Categories

   Rating Override

   This method manually assigns a specific website to a different Fortinet category or a locally created category.

2. Using Alternate Profiles

   Administrative Override or Allow Blocked Override

   In this method all of the traffic going through the FortiGate unit, using identity based policies and a Web Filtering profile has the option where configured users or IP addresses can use an alternative Web Filter profile when attempting to access blocked websites.

Using Alternate Categories

Rating Overrides

There are two approached to overriding the FortiGuard Web Filtering. The first is an identity based method that can be configured using a combination of identity based policies and specifically designed webfilter profiles. This has been addressed in the Firewall Handbook.

The second method is the system wide approach that locally (on the FortiGate Firewall) reassigns a URL to a different FortiGuard Category and even subcategory. This is where you can set assign a specific URL to the FortiGuard Category that you want to you can also set the URL to one of the Local Categories that you have created

The Rating Overrides option is available because different people will have different criteria for how they categorize websites. Even is the criteria is the same an organization may have reason to block the bulk of a category but need to be able to access specific URLs that are assigned to that category.

A hypothetical example could be that a website, example.com is categorized as being in the Sub-Category Pornography. The law offices of Barrister, Solicitor and Lawyer do not want their employees looking at pornography at work so they have used the FortiGuard Webfilter to block access to sites that have been assigned to the Category “Pornography”. However, the owners of example.com are clients of the law office and they are aware that example.com is for artists that specialize in nudes and erotic images. In this case to approaches can be taken. The first is that the Rating Override function can be used to assign example.com to Nudity and Risque instead of Pornography for the purposes of matching the criteria that the law office goes by or the site can be assigned to a Custom Category that is not blocked because the site belongs to one of their clients and they always want to be able to access the site.

Another hypothetical example from the other side of the coin. A private school has decided that a company that specializes in the online selling of books that could be considered inappropriate for children because of their violent subject matter, should not be accessible to anyone in the school. The categorization by Fortinet of the site example2.com is General Interest - Business with the subcategory of Shopping and Auction, which is a category that is allowed at the school. In this case they school could reassign the site to the Category Adult Material which is a blocked category.

Local Categories

User-defined categories can be created to allow users to block groups of URLs on a per-profile basis. The categories defined here appear in the global URL category list when configuring a web filter profile. Users can rate URLs based on the local categories.

Users can create user-defined categories then specify the URLs that belong to the category. This allows users to block groups of web sites on a per profile basis. The ratings are included in the global URL list with associated categories and compared in the same way the URL block list is processed.

The local assignment of a category overrides the FortiGuard server ratings and appear in reports as “Local” Categories or “Custom” Categories depending on the context.

Local categories are configured in the CLI.

To create a Local Category:

```
config webfilter ftgd-local-cat
  edit local_category_1
    set id 140
    end
```

There is also a way to create a new category in the Web Based Manager.

Go to *Security Profiles* > *Web Filter* > *Rating Overrides*. In the process creating a new override, you can choose to override that URL to the *Category* “Custom Categories”. When you are choosing the *Sub-Category* from the drop down menu, the last item in the list will be *Create New*. If you select this item you will be given the option to fill out a field called *Category Name*. Just type in the name of the new category from this point on it will be listed in the *Custom Categories* of the *Rating Overrides* and as one of the Local Categories in the FortiGuard Webfilter.

Configuring Rating Overrides

1. Go to *Security Profiles* > *Web Filter* > *Rating Overrides.*
2. Select Create New
3. Type in the URL field the URL of the Website that you wish to recategorize.
4. Select the Lookup Rating button to verify the current categorization that is being assigned to the URL.
5. Change the Category field to one of the more applicable options from the drop down menu.
6. Change the Sub-Category field to a more narrowly defined option within the main category.
7. Select OK.

It is usually recommended that you choose a category that you know will be addressed in existing Webfilter profiles so that you will not need to engage in further configuration.

Using Alternate Profiles

Allow Blocked Overrides or Web Overrides

Depending on which patch level you are on of Firmware Version 5 you will have one of 2 options for the implementation of the alternate profile approach to overriding a Web Filter profile that blocks access to a URL.

Before FortiOS 5 Patch 4

The only feature available was referred to as "Allow Blocked Override". The configuration settings for this feature where found in the individual Web Filter profiles by going to the Advanced section near the bottom of the configuration window.

Starting with FortiOS Patch 4

The Administrative Override feature for Web Filtering was added and is found by going to *Security Profiles* > *Web Filter* > *Web Overrides*. This opening window will display a listing of all of the overrides of this type. The editing window referred to the configuration as an Administrative Override.

The Concept

When a Web filter profile is overridden it does not necessarily remove all control and restrictions that were previously imposed by the Web Filter. The idea is to replace a restrictive filter with a different one. In practice, it makes sense that this will likely be a profile that is less restrictive the the original one but there is nothing that forces this. The degree to which that the alternate profile is less restrictive is open. It can be as much as letting the user access everything on the Internet or as little as allowing only one addition website. The usual practice though is to have as few alternate profiles as are needed to allow approved people to access what they need during periods when an exception to the normal rules is needed but still having enough control that the organizations web usage policies are not compromised.

You are not restricted to having only one alternative profile as an option to the existing profile. The new profile depends on the credentials or IP address making the connection. For example, John connecting through the "Standard" profile could get the "Allow_Streaming_Video" profile while George would get the "Allow_Social_Networking_Sites" profile.

The other thing to take into account is the time factor on these overrides. They are not indefinite. The longest that an override can be enabled is for 1 year less a minute. Often these overrides are set up for short periods of time for specific reasons such as a project. Having the time limitation means that the System Administrator does not have to remember to go back and turn the feature off after the project is finished.

Identity or Address

In either case what these override features do is, for specified users, user groups or IP addresses, allow sites blocked by Web Filtering profiles to be overridden for a specified length of time. The drawback of this method of override is that it takes more planning and preparation than the rating override method. The advantage is that once this has been set up, this method requires very little in the way of administrative overhead to maintain.

When planning to use the alternative profile approach keep in mind the following: In Boolean terms, one of the following "AND" conditions has to be met before overriding the Web Filter is possible

Based on the IP address:

- The Web Filter profile must be specified as allowing overrides
- AND the user's computer is one of the IP addresses specified
- AND the time is within the expiration time frame.

While the conditions are fewer for this situation there is less control over who has the ability to bypass the filtering configured for the site. All someone has to do is get on a computers that is allowed to override the Web Filter and they have access.

Based on user or user group:

- The Web Filter profile must be specified as allowing overrides
- AND the policy the traffic is going through must be identity based
- AND the user's credentials matches the identity credentials specified
- AND the time is within the expiration time frame.

This method is the one most likely to be used as it gives more control in that the user has to have the correct credential and more versatile because the user can use the feature from any computer that uses the correct policy to get out on the Internet.

Settings

When using an alternate profile approach to Web Filter overrides the following settings are used to determine authentication and outcome. Not every setting is used in both methods but enough of them are common to describe them collectively.

Apply to Group(s)

This is found in the Allow Blocked Overrides configuration. Individual users can not be selected. You can select one or more of the User Groups that are recognized my the FortiGate unit, whether they are local to the system or from a third part authentication device such as a AD server through FSSO.

Original Profile

This is found in the Administrative Override configuration. In the Allow Blocked Overrides setting the configuration is right inside the profile so there was no need to specify which profile was the original one, but the Administrative Override setup is done separately from the profiles themselves.

Assign to Profile or New Profile

Despite the difference in the name of the field, this is the same thing in both variations of the feature. You select from the drop down menu the alternate Web Filter Profile that you wish to set up for this override.

Scope or Scope Range

When setting up the override in the "Allow Blocked Overrides" variation you are given a drop down menu next to the field name Scope while in the Administrative Override configuration you are asked to select a radio button next to the same options. In both cases this is just a way of selecting which form of credentials will be required to approve the overriding of the existing Web Filter profile.

When the Web Filter Block Override message page appears it will display a field named "Scope:" and depending on the selection, it will show the type of credentials used to determine whether or not the override is allowed. The available options are:

User

This means that the authentication for permission to override will be based on whether or not the user is using a specific user account.

User Group

This means that the authentication for permission to override will be based on whether on not the user account supplied as a credential is a member of the specified User Group.

IP

This means that the authentication for permission to override will be based on the IP address of the computer that was used to authenticate. This would be used with computers that have multiple users. Example: If Paul logs on to the computer, engages the override using

his credentials and then logs off, if the scope was based on the IP address of the computer, anybody logging in with any account on that computer would now be using the alternate override Web Filter profile.

When entering an IP address in the Administrative Override version, only individual IP addresses are allowed.

Differences between IP and Identity based scope

- Using the IP scope does not require the use of an Identity based policy.
- When using the Administrative Override variation and IP scope, you may not see a warning message when you change from using the original Web Filter profile to using the alternate profile. There is no requirement for credentials from the user so, if allowed, the page will just come up in the browser.

Ask

This option is available only in the "Allowed Blocked Overrides" variation and when used configures the message page to ask which scope the user wished to use. Normally, when the page appears the scope options are greyed out an not editable, but by using the ask option the option is dark and the user can choose from the choice of:

- User
- User Group
- IP Address

Duration Mode

This option is available only in the "Allowed Blocked Overrides" variation. The Administrative Override sets a specified time frame that is always used for that override. The available options from the drop down menu are:

Constant

Using this setting will mean that what ever is set as the duration will be the length of time that the override will be in effect. If the Duration variable is set to 15 minutes the length of the override will always be 15 minutes. The option will be visible in the Override message page but the setting will be greyed out.

Ask

Uusing this setting will give the person the option of setting the duration to the override when it is engaged. The duration time which is greyed out if the Constant setting is used will be dark and editable. The user can set the duration in terms of Day, Hours and or Minutes.

Duration

Duration is on of the areas where the two variations takes a different approach, on two aspects of the setting. As already indicated the "Administrative Override" only uses a static time frame there is no option for the user to select on the fly how long it will last. The other way in which the two variation differ is that the "Allow Blocked Overrides" starts the clock when the user logs in with his credentials. For example, if the duration is 1 hour and John initiates an override at 2:00 p.m. on January 1, at the end of that hour he will revert back to using the original profile but he can go back and re-authenticate and and start the process over again. The Administrative override variation starts the clock from when the override was configured, which is why is shows an expiration date and time when your are configuring it.

This option, which is available when the Duration Mode is set to Constant is the time in minutes that the override will last when engaged by the user.

When setting up a constant duration in the Web Based Interface, minutes is the only option for units of time. To set a longer time frame or to use the units of hours or days you can use the CLI.

```
config webfilter profile
  edit <name of webfilter profile>
    config override
      set ovrd-dur <###d##h##m>
      end
```

When configuring the duration you don't have to set a value for a unit you are not using. If you are not using days or hours you can use

```
      set ovrd-dur 30m
```

instead of

```
      set ovrd-dur 0d0h30m
```

However, each of the units of time variable has their own maximum level

```
###d cannot be more than 364
##h cannot be more than 23
##m cannot be more than 59
```

So the maximum length that the override duration can be set to is 364 days, 23 hours, and 59 minutes(a minute shy of 1 year)

SafeSearch

SafeSearch is a feature of popular search sites that prevents explicit web sites and images from appearing in search results. Although SafeSearch is a useful tool, especially in educational environments, the resourceful user may be able to simply turn it off. Enabling SafeSearch for the supported search sites enforces its use by rewriting the search URL to include the code to indicate the use of the SafeSearch feature. For example, on a Google search it would mean adding the string “&safe=active” to the URL in the search.

The search sites supported are:

- Google
- Yahoo
- Bing
- Yandex

Enabling SafeSearch — CLI

```
config webfilter profile
  edit default
    config web
      set safe-search url
    end
  end
```

This enforces the use of SafeSearch in traffic controlled by the firewall policies using the web filter you configure.

YouTube Education Filter

YouTube for Schools is a way to access educational videos from inside a school network. This YouTube feature gives schools the ability to access a broad set of educational videos on the YouTube EDU channel and to select the specific videos that are accessible from within the school network.

Before using this feature you must create a google account for your school and sign up for YouTube for Schools. The Youtube Schools account provides a unique ID registration key. This ID becomes part of the filter that is used to access YouTube EDU's educational videos in schools even if other YouTube content is blocked by the policy.

More details can be found by going to:

http://www.youtube.com/schools

Enabling YouTube Education Filter in CLI

```
config webfilter profile
  edit default
    config web
      set safe-search url header
      set youtube-edu-filter-id ABCD1234567890abcdef
      end
  end
```

Deep Scanning Restrictions

This section doesn't have a label such as "Deep Scanning Restrictions" but there are two settings in the profile that relate to the topic. In the profile, they appear as:

- *Enable HTTPS URL Scan Only*
- *Categories Exempt from Deep Scanning*...

Enable HTTPS URL Scan Only

When Deep Scanning is turned on traffic that is encrypted using SSL is scanned for issues just as unencrypted traffic is. However, scanning encrypted traffic puts a larger load on the resources of the FortiGate unit.

Even if the scanning of the contents of the traffic is not a requirement many administrator prefer to scan the URLs being sent over HTTPS so that users cannot bypass the blocking of access to a site by putting "https://" as a prefix to a URL. The setting restricts the deep scanning of the traffic to the URL destination which is in the header. This way the resources tied up in decrypting the traffic a are minimized, yet the administrator can still enforce policy regarding access to prohibited websites

Categories Exempt from Deep Scanning

For the purposes of personal privacy, there are 3 categories that can be exempted from deep scanning by the FortiGate unit. They are Banking, Health Care and Personal Privacy.

When HTTPS URL Scan Only is enabled you will notice that the option to exclude these categories from deep scanning is removed. This is because if only the URL is being scanned then the contents of the traffic is not being scanned anyway so there is no need to exclude it.

Web Site Filter

You can allow or block access to specific URLs by adding them to the Web Site Filter list. You add the URLs by using patterns containing text and regular expressions. The FortiGate unit allows or blocks web pages matching any specified URLs or patterns and displays a replacement message instead.

URL blocking does not block access to other services that users can access with a web browser. For example, URL blocking does not block access to ftp:// ftp.example.com. Instead, use firewall policies to deny ftp connections.

When adding a URL to the URL filter list, follow these rules:

- Type a top-level URL or IP address to control access to all pages on a web site. For example, `www.example.com` or `192.168.144.155` controls access to all pages at this web site.
- Enter a top-level URL followed by the path and file name to control access to a single page on a web site. For example, `www.example.com/news.html` or `192.168.144.155/news.html` controls access to the news page on this web site.
- To control access to all pages with a URL that ends with example.com, add `example.com` to the filter list. For example, adding example.com controls access to www.example.com, mail.example.com, www.finance.example.com, and so on.
- Control access to all URLs that match patterns using text and regular expressions (or wildcard characters). For example, `example.*` matches example.com, example.org, example.net and so on.

URLs with an action set to exempt or monitor are not scanned for viruses. If users on the network download files through the FortiGate unit from a trusted web site, add the URL of this web site to the URL filter list with an action to pass it so the FortiGate unit does not virus scan files downloaded from this URL.

URL formats

When adding a URL to the URL filter list, follow these rules:

How URL formats are detected when using HTTPS

If your unit does not support SSL content scanning and inspection or if you have selected the *URL filtering* option in web content profile for *HTTPS content filtering mode* under *Protocol Recognition*, filter HTTPS traffic by entering a top level domain name, for example, `www.example.com`. HTTPS URL filtering of encrypted sessions works by extracting the CN from the server certificate during the SSL negotiation. Since the CN only contains the domain name of the site being accessed, web filtering of encrypted HTTPS sessions can only filter by domain names.

If your unit supports SSL content scanning and inspection and if you have selected Deep Scan, you can filter HTTPS traffic in the same way as HTTP traffic.

How URL formats are detected when using HTTP

URLs with an action set to exempt are not scanned for viruses. If users on the network download files through the unit from trusted web site, add the URL of this web site to the URL

filter list with an action set to exempt so the unit does not virus scan files downloaded from this URL.

- Type a top-level URL or IP address to control access to all pages on a web site. For example, `www.example.com` or `192.168.144.155` controls access to all pages at this web site.
- Enter a top-level URL followed by the path and filename to control access to a single page on a web site. For example, `www.example.com/news.html` or `192.168.144.155/news.html` controls the news page on this web site.
- To control access to all pages with a URL that ends with `example.com`, add `example.com` to the filter list. For example, adding `example.com` controls access to `www.example.com`, `mail.example.com`, `www.finance.example.com`, and so on.
- Control access to all URLs that match patterns created using text and regular expressions (or wildcard characters). For example, `example.*` matches `example.com`, `example.org`, `example.net` and so on.
- Fortinet URL filtering supports standard regular expressions.

If virtual domains are enabled on the unit, web filtering features are configured globally. To access these features, select *Global Configuration* on the main menu.

Web Site Filter actions

You can select one of four actions for how traffic will be treated as it attempts to reach a site in the list.

Block

Attempts to access any URLs matching the URL pattern are denied. The user will be presented with a replacement message.

Allow

Any attempt to access a URL that matches a URL pattern with an allow action is permitted. The traffic is passed to the remaining antivirus proxy operations, including FortiGuard Web Filter, web content filter, web script filters, and antivirus scanning.

Allow is the default action. If a URL does not appear in the URL list, it is permitted.

Monitor

Traffic to, and reply traffic from, sites matching a URL pattern with a monitor be allowed through in the same way as the “Allow” action. The difference with the Monitor action being that a log message will be generated each time a matching traffic session is established. The requests will also be subject to all other Security Profiles inspections that would normally be applied to the traffic.

Exempt

Exempt allows trusted traffic to bypass the antivirus proxy operations, but it functions slightly differently. In general, if you’re not certain that you need to use the *Exempt* action, use *Monitor*.

HTTP 1.1 connections are persistent unless declared otherwise. This means the connections will remain in place until closed or the connection times out. When a client loads a web page, the client opens a connection to the web server. If the client follows a link to another page on

the same site before the connection times out, the same connection is used to request and receive the page data.

When you add a URL pattern to a URL filter list and apply the *Exempt* action, traffic sent to and replies traffic from sites matching the URL pattern will bypass all antivirus proxy operations. The connection itself inherits the exemption. This means that all subsequent reuse of the existing connection will also bypass all antivirus proxy operations. When the connection times out, the exemption is cancelled.

For example, consider a URL filter list that includes `example.com/files` configured with the Exempt action. A user opens a web browser and downloads a file from the URL `example.com/sample.zip`. This URL does not match the URL pattern so it is scanned for viruses. The user then downloads `example.com/files/beautiful.exe` and since this URL does match the pattern, the connection itself inherits the exempt action. The user then downloads `example.com/virus.zip`. Although this URL does not match the exempt URL pattern, a previously visited URL did, and since the connection inherited the exempt action and was re-used to download a file, the file is not scanned.

If the user next goes to an entirely different server, like `example.org/photos`, the connection to the current server cannot be reused. A new connection to example.org is established. This connection is not exempt. Unless the user goes back to example.com before the connection to that server times out, the server will close the connection. If the user returns after the connection is closed, a new connection to example.com is created and it is not exempt until the user visits a URL that matches the URL pattern.

Web servers typically have short time-out periods. A browser will download multiple components of a web page as quickly as possible by opening multiple connections. A web page that includes three photos will load more quickly if the browser opens four connections to the server and downloads the page and the three photos at the same time. A short time-out period on the connections will close the connections faster, allowing the server to avoid unnecessarily allocating resources for a long period. The HTTP session time-out is set by the server and will vary with the server software, version, and configuration.

Using the *Exempt* action can have unintended consequences in certain circumstances. You have a web site at example.com and since you control the site, you trust the contents and configure `example.com` as exempt. But example.com is hosted on a shared server with a dozen other different sites, each with a unique domain name. Because of the shared hosting, they also share the same IP address. If you visit example.com, your connection your site becomes exempt from any antivirus proxy operations. Visits to any of the 12 other sites on the same server will reuse the same connection and the data you receive is exempt from scanned.

Use of the *Exempt* action is not suitable for configuration in which connections through the FortiGate unit use an external proxy. For example, you use proxy.example.net for all outgoing web access. Also, as in the first example, URL filter list that includes a URL pattern of `example.com/files` configured with the *Exempt* action. Users are protected by the antivirus protection of the FortiGate unit until a user visits a URL that matches the of `example.com/files` URL pattern. The pattern is configured with the *Exempt* action so the connection to the server inherits the exemption. With a proxy however, the connection is from the user to the proxy. Therefore, the user is entirely unprotected until the connection times out, no matter what site he visits.

Ensure you are aware of the network topology involving any URLs to which you apply the Exempt action.

Status

The Web Site Filter has the option to either enable or disable individual web sites in the list. This allows for the temporary removal of the actions against a site so that it can be later reengaged without having to rewrite the configuration.

Configuring a Web Site Filter

To create a URL Filter list

1. Go to *Security Profiles* > *Web Filter* > *Profiles.*
2. Select the Web Filter Profile that you which to add the Web Site Filter to.
3. About half way down the Edit Web Filter Profile page check the box next to Enable Web Site Filter.
4. Select *Create New.*
5. Enter a URL for the website.
6. Enter optional comments to describe it.
7. Select *OK.*

Configuring a URL filter list

Each URL filter list can have up to 5000 entries. For this example, the URL www.example*.com will be used. You configure the list by adding one or more URLs to it.

To add a URL to a URL filter list

1. Go to *Security Profiles* > *Web Filter* > *URL Filter.*
2. Select an existing list and choose *Edit*.
3. Select *Create New*.
4. Enter the URL, without the “http”, for example: `www.example*.com`.
5. Select a *Type*: *Simple*, *Wildcard* or *Regular Expression*.
6. In this example, select Wildcard.
7. Select the *Action* to take against matching URLs: Exempt, Block, Allow, or Monitor.
8. Select *Enable*.
9. Select *OK.*

Web content filter

You can control web content by blocking access to web pages containing specific words or patterns. This helps to prevent access to pages with questionable material. You can also add words, phrases, patterns, wild cards and Perl regular expressions to match content on web pages. You can add multiple web content filter lists and then select the best web content filter list for each web filter profile.

Enabling web content filtering involves three separate parts of the FortiGate configuration.

- The security policy allows certain network traffic based on the sender, receiver, interface, traffic type, and time of day.
- The web filter profile specifies what sort of web filtering is applied.
- The web content filter list contains blocked and exempt patterns.

The web content filter feature scans the content of every web page that is accepted by a security policy. The system administrator can specify banned words and phrases and attach a numerical value, or score, to the importance of those words and phrases. When the web content filter scan detects banned content, it adds the scores of banned words and phrases in the page. If the sum is higher than a threshold set in the web filter profile, the FortiGate unit blocks the page.

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create a web content filter list.
2. Add patterns of words, phrases, wildcards, and regular expressions that match the content to be blocked or exempted.
3. You can add the patterns in any order to the list. You need to add at least one pattern that blocks content.
4. In a web filter profile, enable the web content filter and select a web content filter list from the options list.

To complete the configuration, you need to select a security policy or create a new one. Then, in the security policy, enable *Webfilter* and select the appropriate web filter profile from the list.

Creating a web filter content list

You can create multiple content lists and then select the best one for each web filter profile. Creating your own web content lists can be accomplished only using the CLI.

This example shows how to create a web content list called inappropriate language, with two entries, offensive and rude.

To create a web filter content list

```
config webfilter content
  edit 3
    set name "inappropriate language"
    config entries
      edit offensive
        set action block
        set lang western
        set pattern-type wildcard
        set score 15
        set status enable
      next
      edit rude
        set action block
        set lang western
        set pattern-type wildcard
        set score 5
        set status enable
      end
    end
end
```

How content is evaluated

Every time the web content filter detects banned content on a web page, it adds the score for that content to the sum of scores for that web page. You set this score when you create a new pattern to block the content. The score can be any number from zero to 99999. Higher scores indicate more offensive content. When the sum of scores equals or exceeds the threshold score, the web page is blocked. The default score for web content filter is 10 and the default

threshold is 10. This means that by default a web page is blocked by a single match. Blocked pages are replaced with a message indicating that the page is not accessible according to the Internet usage policy.

Banned words or phrases are evaluated according to the following rules:

- The score for each word or phrase is counted only once, even if that word or phrase appears many times in the web page.
- The score for any word in a phrase without quotation marks is counted.
- The score for a phrase in quotation marks is counted only if it appears exactly as written.

The following table describes how these rules are applied to the contents of a web page. Consider the following, a web page that contains only this sentence: “The score for each word or phrase is counted only once, even if that word or phrase appears many times in the web page.”

Table 95: Banned Pattern Rules

Banned pattern	Assigned score	Score added to the sum for the entire page	Threshold score	Comment
word	20	20	20	Appears twice but only counted once. Web page is blocked.
word phrase	20	40	20	Each word appears twice but only counted once giving a total score of 40. Web page is blocked
word sentence	20	20	20	“word” appears twice, “sentence” does not appear, but since any word in a phrase without quotation marks is counted, the score for this pattern is 20. Web page is blocked.
“word sentence”	20	0	20	“This phrase does not appear exactly as written. Web page is allowed.
“word or phrase”	20	20	20	This phrase appears twice but is counted only once. Web page is blocked.

Enabling the web content filter and setting the content threshold

When you enable the web content filter, the web filter will block any web pages when the sum of scores for banned content on that page exceeds the content block threshold. The threshold will be disregarded for any exemptions within the web filter list.

To enable the web content filter and set the content block threshold

1. Go to *Security Profiles* > *Web Filter* > *Profiles.*
2. Select the *Create New* icon on the Edit Web Filter Profile window title bar.

3. In the *Name* field, enter the name of the new web filter profile.
4. Optionally, you may also enter a comment. The comment can remind you of the details of the sensor.
5. Select the *Inspection Method*.

   Proxy-based detection involves buffering the file and examining it as a whole. Advantages of proxy-based detection include a more thorough examination of attachments, especially archive formats and nesting.

   Flow-based detection examines the file as it passes through the FortiGate unit without any buffering. Advantages of flow-based detection include speed and no interruption of detection during conserve mode.
6. Expand the *Advanced Filter* heading.
7. Enable *Web Content Filter*.
8. Select the required web filter content list from the *Web Content Filter* drop-down list.
9. Select *Apply*.

The web filter profile configured with web content filtering is ready to be added to a firewall profile.

Advanced web filter configurations

Allow websites when a rating error occurs

Enable to allow access to web pages that return a rating error from the FortiGuard Web Filter service.

If your FortiGate unit cannot contact the FortiGuard service temporarily, this setting determines what access the FortiGate unit allows until contact is re-established. If enabled, users will have full unfiltered access to all web sites. If disabled, users will not be allowed access to any web sites.

ActiveX filter

Enable to filter ActiveX scripts from web traffic. Web sites using ActiveX may not function properly with this filter enabled.

Block HTTP redirects by rating

Enable to block HTTP redirects.

Many web sites use HTTP redirects legitimately but in some cases, redirects may be designed specifically to circumvent web filtering, as the initial web page could have a different rating than the destination web page of the redirect.

This option is not supported for HTTPS.

Block Invalid URLs

Select to block web sites when their SSL certificate CN field does not contain a valid domain name.

FortiGate units always validate the CN field, regardless of whether this option is enabled. However, if this option is not selected, the following behavior occurs:

- If the request is made directly to the web server, rather than a web server proxy, the FortiGate unit queries for FortiGuard Web Filtering category or class ratings using the IP address only, not the domain name.
- If the request is to a web server proxy, the real IP address of the web server is not known. Therefore, rating queries by either or both the IP address and the domain name is not reliable. In this case, the FortiGate unit does not perform FortiGuard Web Filtering.

Cookie filter

Enable to filter cookies from web traffic. Web sites using cookies may not function properly with this enabled.

Provide Details for Blocked HTTP 4xx and 5xx Errors

Enable to have the FortiGate unit display its own replacement message for 400 and 500-series HTTP errors. If the server error is allowed through, malicious or objectionable sites can use these common error pages to circumvent web filtering.

HTTP POST action

Select the action to take with HTTP POST traffic. HTTP POST is the command used by your browser when you send information, such as a form you have filled-out or a file you are uploading, to a web server.

The available actions include:

Normal	Allow use of the HTTP POST command as normal.
Comfort	Use client comforting to slowly send data to the web server as the FortiGate unit scans the file. Use this option to prevent a server time-out when scanning or other filtering is enabled for outgoing traffic. The client comforting settings used are those defined in the Proxy Options profile selected in the security policy. For more information, see "Configuring client comforting" on page 2040.
Block	Block the HTTP POST command. This will limit users from sending information and files to web sites. When the post request is blocked, the FortiGate unit sends the http-post-block replacement message to the web browser attempting to use the command.

Java applet filter

Enable to filter java applets from web traffic. Web sites using java applets may not function properly with this filter enabled.

Rate Images by URL

Enable to have the FortiGate retrieve ratings for individual images in addition to web sites. Images in a blocked category are not displayed even if they are part of a site in an allowed category.

Blocked images are replaced on the originating web pages with blank place-holders. Rated image file types include GIF, JPEG, PNG, BMP, and TIFF.

Rate URLs by Domain and IP Address

Enable to have the FortiGate unit request the rating of the site by URL and IP address separately, providing additional security against attempts to bypass the FortiGuard Web Filter.

If the rating determined by the domain name and the rating determined by the IP address defer the Action that is enforce will be determined by a weighting assigned to the different categories. The higher weighted category will take precedence in determining the action. This will have the side effect that sometimes the Action will be determined by the classification based on the domain name and other times it will be determined by the classification that is based on the IP address.

FortiGuard Web Filter ratings for IP addresses are not updated as quickly as ratings for URLs. This can sometimes cause the FortiGate unit to allow access to sites that should be blocked, or to block sites that should be allowed.

An example of how this would work would be if a URL's rating based on the domain name indicated that it belonged in the category Lingerie and Swimsuit, which is allowed but the category assigned to the IP address was Pornography which has an action of Block, because the Pornography category has a higher weight the effective action is Block.

Web resume download block

Enable to prevent the resumption of a file download where it was previously interrupted. With this filter enabled, any attempt to restart an aborted download will download the file from the beginning rather than resuming from where it left off.

This prevents the unintentional download of viruses hidden in fragmented files.

Note that some types of files, such as PDF, fragment files to increase download speed and enabling this option can cause download interruptions. Enabling this option may also break certain applications that use the Range Header in the HTTP protocol, such as YUM, a Linux update manager.

Working with the Interface

In order to find out the status of your configuration it helps to understand the interface. In the Web filtering section there are a number of pages that you will need to be able to read.

Profile page

Lists each web filter profile that you created. On this page, you can edit, delete or create a new web filter profile. You are redirected to this page when you select *View List* on the Edit Web Filter Profile page.

Note: Web filtering overrides are profile-based, allowing a rule to be created that changes the web filter profile that applies to a user. An override link appears in all related blocked pages. This is available only in the CLI.

New Web Filter Profile page

Provides settings for configuring a web filter profile. Advanced features, such as web content filtering and FortiGuard web filtering, is configured in the CLI.

This page appears when you select *Create New* on the Edit Web Filter Profile page. If you are on the Profile page, and you select *Create New*, you will be redirected to the New Web Filter Profile page.

Note: Logging is enabled in the CLI.

The following explains the web filtering options in the Web Filtering menu. If your unit supports SSL content scanning and inspection you can also configure web filtering for HTTPS traffic.

If you want to configure advanced settings, such as web content filter, you must configure them within the CLI. Advanced settings also includes overrides.

This topic includes the following:

Profile

The Profile menu allows you to configure a web filter profile to apply to a firewall policy. A profile is specific information that defines how the traffic within a policy is examined and what action may be taken based on the examination.

Web profile configuration settings

The following are web filter profile configuration settings in *Security Profiles* > *Web Filter* > *Profiles*. If you want to configure advanced settings, such as FortiGuard web filtering overrides, you must configure these settings within the CLI.

Profile page	
Lists each web filter profile that you created. On this page, you can edit, delete or create a new web filter profile. You are redirected to this page when you select *View List* on the Edit Web Filter Profile page. **Note:** Web filtering overrides are profile-based, allowing a rule to be created that changes the web filter profile that applies to a user. An override link appears in all related blocked pages. This is available only in the CLI.	
Create New	Creates a new web filter profile. When you select *Create New*, you are automatically redirected to the New Web Filter Profile page.
Edit	Modifies settings within a web filter profile. When you select *Edit*, you are automatically redirected to the Edit Web Filter Profile page.

Delete	Removes a web filter profile from within the list on the Profile page. To remove multiple web filter profiles from within the list, on the Profile page, in each of the rows of the file filter lists you want removed, select the check box and then select *Delete*. To remove all web filter profiles from the list, on the Profile page, select the check box in the check box column and then select *Delete*.
Name	The name of the web filter profile.
Comments	A description given to the web filter profile. This is an optional setting.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a firewall policy; on the Profile page (*Security Profiles* > *Antivirus* > *Profile*), 1 appears in *Ref.*. To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy, and that firewall policy's settings appear within the table.

New Web Filter Profile page

Provides settings for configuring a web filter profile. Advanced features, such as web content filtering and FortiGuard web filtering, is configured in the CLI.

This page appears when you select *Create New* on the Edit Web Filter Profile page. If you are on the Profiile page, and you select *Create New*, you will be redirected to the New Web Filter Profile page.

Note: Logging is enabled in the CLI.

Name	Enter a name for the web filter profile. If you want to edit the name at any time, select the profile and enter a new name in the *Name* field. Select *Apply* to save the change.

Comments	Enter a description for the web filter profile. This is optional. If you want to edit the description at any time, select the profile and enter the new description in the *Comments* field. Select *Apply* to save the change.
Inspection mode	Select to enable either flow-based web filtering or proxy-based. Flow-based web filtering is a non-proxy solution, which provides high concurrent session, high session rate, and low-latency web filtering service.
FortiGuard Categories	A list of FortiGuard category groups and categories that are used to rate web sites. Selecting a category group will automatically select all of the categories within the group. For example, if you select Security Risk, you can see that all of the categories within are selected if you expand the group. You can however, select or deselect categories within groups as required.
Show	Select an action to view all of the categories that are currently configured with the selected action.
Change Action for Selected Categories to	Select an action, and all of the selected categories will have the selected action applied. Selected category groups will have the action applied to all categories within the group.
Quota on Categories	Users can have their web browsing time limited by category through the use of quotas. Quotas can be applied only to categories that are configured with the Monitor action. If you create a quota for a single category, every authenticated user subject to the security policy in which the web filter profile is applied is limited in browsing web sites in the category to the duration you specify. If you create a single quota that includes multiple categories, the quota will apply to the categories as a whole. Quotas are ignored for unauthenticated users. To enforce quotas, configure the security policy to require authentication.
Enable Safe Search (Support Search Engines: Google, Yahoo and Bing)	When enabled, the supported search engines exclude offensive material from search results.
HTTPS Scanning	Available only on models that support HTTPS. Select to have all of the web filtering specified in the web filter profile to HTTPS traffic as well as HTTP traffic.
Advanced Filter	Expand this heading for advanced web filtering options.
Web URL Filter	Enable to block access to URLs listed in the selected URL list.

Web Resume Download Block	Enable to prevent the resumption of a file download where it was previously interrupted. With this filter enabled, any attempt to restart an aborted download will download the file from the beginning rather than resuming from where it left off. This prevents the unintentional download of viruses hidden in fragmented files. Note that some types of files, such as PDF, fragment files to increase download speed and enabling this option can cause download interruptions. Enabling this option may also break certain applications that use the Range Header in the HTTP protocol, such as YUM, a Linux update manager.
Block Invalid URLs	Select to block web sites when their SSL certificate CN field does not contain a valid domain name. FortiGate units always validate the CN field, regardless of whether this option is enabled. However, if this option is not selected, the following behavior occurs: • If the request is made directly to the web server, rather than a web server proxy, the FortiGate unit queries for FortiGuard Web Filtering category or class ratings using the IP address only, not the domain name. • If the request is to a web server proxy, the real IP address of the web server is not known. Therefore, rating queries by either or both the IP address and the domain name is not reliable. In this case, the FortiGate unit does not perform FortiGuard Web Filtering.
HTTP POST Action	Select the action to take with HTTP POST traffic. HTTP POST is the command used by your browser when you send information, such as a form you have filled-out or a file you are uploading, to a web server. The available actions include: • Normal: Allow use of the HTTP POST command as normal. • Comfort: Use client comforting to slowly send data to the web server as the FortiGate unit scans the file. Use this option to prevent a server time-out when scanning or other filtering is enabled for outgoing traffic. The client comforting settings used are those defined in the Proxy Options profile selected in the security policy. • Block: Block the HTTP POST command. This will limit users from sending information and files to web sites. When the post request is blocked, the FortiGate unit sends the http-post-block replacement message to the web browser attempting to use the command.
Remove Java Applet Filter	Enable to filter java applets from web traffic. Web sites using java applets may not function properly with this filter enabled.
Remove ActiveX Filter	Enable to filter ActiveX scripts from web traffic. Web sites using ActiveX may not function properly with this filter enabled.

Remove Cookie Filter	Enable to filter cookies from web traffic. Web sites using cookies may not function properly with this enabled.
Search Engine Keyword Filter	Enter the keywords that you want to monitor when users enter those same or similar keywords during a search within the supported search engines.
Web Content Filter	Enable to block access to web pages that include the words included in the selected web content filter list.
Provide Details for Blocked HTTP 4xx and 5xx Errors	Enable to have the FortiGate unit display its own replacement message for 400 and 500-series HTTP errors. If the server error is allowed through, malicious or objectionable sites can use these common error pages to circumvent web filtering.
Rate Images by URL (Blocked images will be replaced with blanks)	Enable to have the FortiGate retrieve ratings for individual images in addition to web sites. Images in a blocked category are not displayed even if they are part of a site in an allowed category. Blocked images are replaced on the originating web pages with blank place-holders. Rated image file types include GIF, JPEG, PNG, BMP, and TIFF.
Allow Websites When a Rating Error Occurs	Enable to allow access to web pages that return a rating error from the FortiGuard Web Filter service. If your FortiGate unit cannot contact the FortiGuard service temporarily, this setting determines what access the FortiGate unit allows until contact is re-established. If enabled, users will have full unfiltered access to all web sites. If disabled, users will not be allowed access to any web sites.
Rate URLs by Domain and IP Address	Enable to have the FortiGate unit request the rating of the site by URL and IP address separately, providing additional security against attempts to bypass the FortiGuard Web Filter. FortiGuard Web Filter ratings for IP addresses are not updated as quickly as ratings for URLs. This can sometimes cause the FortiGate unit to allow access to sites that should be blocked, or to block sites that should be allowed.
Block HTTP Redirects by Rating	Enable to block HTTP redirects. Many web sites use HTTP redirects legitimately but in some cases, redirects may be designed specifically to circumvent web filtering, as the initial web page could have a different rating than the destination web page of the redirect. This option is not supported for HTTPS.

URL Filter

Allow or block access to specific URLs by adding them to the URL filter list. Add patterns using text and regular expressions (or wildcard characters) to allow or block URLs. The unit allows or blocks web pages matching any specified URLs or patterns and displays a replacement message.

You can add multiple URL filter lists and then select the best URL filter list for each profile.

You can add the following to block or exempt URLs:

- complete URLs
- IP addresses
- partial URLs to allow or block all sub-domains

Each URL filter list can have up to 5000 entries.

URL filter configuration settings

The following are URL filter configuration settings in *Security Profiles* > *Web Filter* > *URL Filter*.

URL blocking does not block access to other services that users can access with a web browser. For example, URL blocking does not block access to `ftp://ftp.example.com`. Instead, use firewall policies to deny FTP connections.

URL Filter page	
Lists each URL filter that you created. On this page, you can edit, delete or create a new URL filter.	
Create New	Creates a new URL filter list. When you select *Create New*, you are automatically redirected to the New List page. This page provides a name field and comment field. You must enter a name to go to the URL Filter Settings page.
Edit	Modifies settings within a URL filter list. When you select *Edit*, you are automatically redirected to the URL Filter Settings page.
Delete	Removes the URL filter list from the list on the URL Filter page. The *Delete* icon is only available if the URL filter list is not selected in any profiles. To remove multiple URL filter list from within the list, on the URL Filter page, in each of the rows of the file filter lists you want removed, select the check box and then select *Delete*. To remove all URL filter list from the list, on the URL Filter page, select the check box in the check box column and then select *Delete*.
Name	The available URL filter lists.
# Entries	The number of URL patterns in each URL filter list.
MMS Profiles (FortiOS Carrier only)	The name of the MMS profile
Comments	Optional description of each URL filter list.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a firewall policy; on the Profile page (*Security Profiles* > *AntiVirus* > *Profiles*), 1 appears in *Ref.*. To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a firewall policy, and that firewall policy's settings appear within the table.

URL Filter Settings page

Provides settings for configuring URLs that make up the URL filter, and also lists the URLs that you created. You are automatically redirected to this page from the New List Page. If you are editing a URL filter, you are automatically redirected to this page.

Name	If you are editing an existing URL filter setting and want to change the name, enter a new name in this field. You must select *OK* to save the change.
Comments	If you are editing an existing URL filter setting and want to change or add a description, enter the new text in this field. You must select *OK* to save these changes.
Create New	Adds a URL address and filter settings to the list. When you select *Create New*, you are automatically redirected to the New URL Filter list.
Edit	Modifies the settings within a URL filter.
Delete	Removes an entry from the list. To remove multiple URL filters from within the list, on the URL Filter Settings page, in each of the rows of the filters you want removed, select the check box and then select *Delete*. To remove all URL filters from the list, on the URL Filter Settings page, select the check box in the check box column and then select *Delete*.
Enable	Enables a filter in the list.
Disable	Disables a filter in the list.

Move To	Moves the URL to any position in the list. When you select *Move To*, the Move URL Filter window appears. To move a URL, select the new position *Before* or *After*, which will place the current URL entry before or after the entry you enter in the *(URL)* field. For example, 1example.com is being moved after 3example.com, so 3example.com is entered in the *(URL)* field.
Remove All Entries	Removes all filter entries within the list on the URL Filter Settings page.
Enable	Indicates whether the URL is enable or disabled. A green check mark indicates that the URL is enabled; a gray check mark indicates that the URL is disabled.
URL	The URL address.
Action	The type of action the unit will take when there is a match.
Type	The type of URL. For example, the type of URL is *Regex*.

New URL Filter page

Provides settings for configuring a URL to add to the filter list.

URL	Enter the URL.
Type	Select a type from the drop-down list: *Simple*, *Regex* (regular expression), or *Wildcard*.
Action	Select an action the unit will take. • *Allow* – any attempt to access a URL that matches a URL pattern with an allow action is permitted. • *Exempt* – similar to *Pass* in that it allows trusted traffic to bypass the antivirus proxy operations, but it functions slightly differently; ensure you are aware of the network topology involving URLs that you applied the Exemption action. Additional information about the Exempt action is found in the Security Profiles chapter of the FortiOS Handbook. • *Block* – attempts to access any URLs matching the URL pattern are denied; user is presented with a replacement message. • *Pass* – traffic to, and replay traffic from sites that match a URL pattern with a pass action will bypass all antivirus proxy operations, including FortiGuard Web Filter, web content filter, web script filters, and antivirus scanning. Make sure you trust the content of any site you pass, otherwise there may be a security risk.
Enable	Select to enable the URL. By default, the URL is enabled.

Type a top-level domain suffix (for example, “com” without the leading period) to block access to all URLs with this suffix.

Web filtering example

Web filtering is particularly important for protecting school-aged children. There are legal issues associated with improper web filtering as well as a moral responsibility not to allow children to view inappropriate material. The key is to design a web filtering system in such a way that students and staff do not fall under the same web filter profile in the FortiGate configuration. This is important because the staff may need to access websites that are off-limits to the students.

School district

The background for this scenario is a school district with more than 2300 students and 500 faculty and staff in a preschool, three elementary schools, a middle school, a high school, and a continuing education center. Each elementary school has a computer lab and the high school has three computer labs with connections to the Internet. Such easy access to the Internet ensures that every student touches a computer every day.

With such a diverse group of Internet users, it was not possible for the school district to set different Internet access levels. This meant that faculty and staff were unable to view websites that the school district had blocked. Another issue was the students' use of proxy sites to circumvent the previous web filtering system. A proxy server acts as a go-between for users seeking to view web pages from another server. If the proxy server has not been blocked by the school district, the students can access the blocked website.

When determining what websites are appropriate for each school, the district examined a number of factors, such as community standards and different needs of each school based on the age of the students.

The district decided to configure the FortiGate web filtering options to block content of an inappropriate nature and to allow each individual school to modify the options to suit the age of the students. This way, each individual school was able to add or remove blocked sites almost immediately and have greater control over their students' Internet usage.

In this simplified example of the scenario, the district wants to block any websites with the word ***example*** on them, as well as the website www.example.com. The first task is to create web content filter lists for the students and the teachers.

To create a web content filter list for the students

```
config webfilter content
   edit 5
      set name "Student Web Content List"
      config entries
         edit example
            set action block
            set status enable
      end
   end
```

It might be more efficient if the Teacher Web Content List included the same blocked content as the student list. From time to time a teacher might have to view a blocked page. It would then be a matter of changing the *Action* from *Block* to *Allow* as the situation required.

To create a web content filter list for the teachers

```
config webfilter content
  edit 5
    set name "Teacher Web Content List"
    config entries
      edit example
        set action exempt
        set status enable
    end
  end
```

URL filter lists with filters to block unwanted web sites must be created for the students and teachers. For this example the URL *www.example.com* will be used.

To create a URL filter for the students

1. Go to *Security Profiles* > *Web Filter* > *URL Filter*.
2. Select *Create New*.
3. Enter `Student URL List` as the URL filter *Name*.
4. Enter optional comments to describe the contents of the list.
5. Select *OK*.

   The URL filter for the students has been created. Now it must be configured.
6. Select *Create New*.
7. Enter `example.com` in the URL field.
8. Select *Simple* from the *Type* list.
9. Select *Block* from the *Action* list.
10. Select *Enable.*
11. Select *OK*.
12. Select *OK*.

The teachers should be able to view the students' blocked content, however, so an addition URL filter is needed.

To create a URL filter for the teachers

1. Go to *Security Profiles* > *Web Filter* > *URL Filter*.
2. Select *Create New*.
3. Enter `Teacher URL List` as the URL filter *Name*.
4. Enter optional comments to describe the list.
5. Select *OK*.

   The URL filter for the students has been created. Now it must be configured.
6. Select *Create New*.
7. Enter `www.example.com` in the *URL* field.
8. Select *Simple* from the *Type* list.
9. Select *Exempt* from the *Action* list.
10. Select *Enable*.
11. Select *OK*.
12. Select *OK*.

A web filter profile must be created for the students and the teachers.

To create a web filter profile for the students

1. Go to *Security Profiles* > *Web Filter* > *Profiles*.
2. Select the *Create New* icon in the Edit Web Filter window title bar.
3. Enter `Students` as the *Profile Name*.
4. Enter optional comments to identify the profile.
5. Expand the *Advanced Filter* heading.
6. Enable *Web Content Filter*.
7. Select *Student Web Content List* from the *Web Content Filter* drop-down list.
8. Enable *Web URL Filter*.
9. Select *Student URL List* from the *Web URL Filter* drop-down list.
10. Enable *Web Resume Download Block*.

    Selecting this setting will block downloading parts of a file that have already been downloaded and prevent the unintentional download of virus files hidden in fragmented files. Note that some types of files, such as PDFs, are fragmented to increase download speed, and that selecting this option can cause download interruptions with these types.
11. Select *OK*.

To create a security policy for the students

1. Go to *Policy* > *Policy* > *Policy.*
2. Select *Create New*.
3. Enable *Web Filter*.
4. Select *Students* from the web filter drop-down list.
5. Enter optional comments.
6. Select *OK*.

To create a web filter profile for the teachers

1. Go to *Security Profiles* > *Web Filter* > *Profiles*.
2. Select the *Create New* icon in the Edit Web Filter window title bar.
3. Enter `Teachers` as the *Profile Name*.
4. Enter optional comments to identify the profile.
5. Expand the *Advanced Filter* heading.
6. Enable *Web Content Filter*.
7. Select *Teacher Web Content List* from the *Web Content Filter* drop-down list.
8. Enable *Web URL Filter*.
9. Select *Teacher URL List* from the *Web URL Filter* drop-down list.
10. Enable *Web Resume Download Block*.
11. Select *OK*.

To create a security policy for Teachers

1. Go to *Policy* > *Policy* > *Policy.*
2. Select *Create New*.
3. Enable *Web Filter*.
4. Select *Teachers* from the web filter drop-down list.
5. Enter optional comments.

Select *OK*.

Data leak prevention

The FortiGate data leak prevention (DLP) system allows you to prevent sensitive data from leaving your network. When you define sensitive data patterns, data matching these patterns will be blocked, or logged and allowed, when passing through the FortiGate unit. You configure the DLP system by creating individual filters based on file type, file size, a regular expression, an advanced rule, or a compound rule, in a DLP sensor and assign the sensor to a security policy.

Although the primary use of the DLP feature is to stop sensitive data from leaving your network, it can also be used to prevent unwanted data from entering your network and to archive some or all of the content passing through the FortiGate unit.

This section describes how to configure the DLP settings.

The following topics are included:

Data leak prevention concepts

Data leak prevention examines network traffic for data patterns you specify. You define whatever patterns you want the FortiGate unit to look for in network traffic. The DLP feature is broken down into a number of parts.

DLP sensor

A DLP sensor is a package of filters. To use DLP, you must enable it in a security policy and select the DLP sensor to use. The traffic controlled by the security policy will be searched for the patterns defined in the filters contained in the DLP sensor. Matching traffic will be passed or blocked according to how you configured the filters.

DLP filter

Each DLP sensor has one or more filters configured within it. Filters can examine traffic for known files using DLP fingerprints, for files of a particular type or name, for files larger than a specified size, for data matching a specified regular expression, or for traffic matching an advanced rule or compound rule.

You can configure the action taken when a match is detected. The actions include:

- None
- Log Only,
- Block
- Quarantine User,
- Quarantine IP address
- Quarantine Interface

Log Only is enabled by default.

Fingerprint

Fingerprint scanning allows you to create a library of files for the FortiGate unit to examine. It will create checksum fingerprints so each file can be easily identified. Then, when files appear in network traffic, the FortiGate will generate a checksum fingerprint and compare it to those in the fingerprint database. A match triggers the configured action.

File filter

File filters use file filter lists to examine network traffic for files that match either file names or file types. For example, you can create a file filter list that will find files called secret.* and also all JPEG graphic files. You can create multiple file filter lists and use them in filters in multiple DLP sensors as required.

File size

This filter-type checks for files exceeding a configured size. All files larger than the specified size are subject to the configured action.

Regular expression

The FortiGate unit checks network traffic for the regular expression specified in a regular expression filter. The regular expression library used by Fortinet is a variation of a library called PCRE (Perl Compatible Regular Expressions). A number of these filters can be added to a sensor making a sort of ‘dictionary’ subset within the sensor.

Some other, more limited DLP implementations, use a list of words in a text file to define what words are searched for. While the format used here is slightly different than what some people are used to, the resulting effect is similar. Each Regular Expression filter can be thought of as a more versatile word to be searched against. In this dictionary (or sensor), the list of words is not limited to just predefined words. It can include expressions that can accommodate complex variations on those words and even target phrases. Another advantage of the individual filter model of this dictionary over the list is that each word can be assigned its own action, making this implementation much more granular.

Watermark

Watermarking is essentially marking files with a digital pattern to mark the file as being proprietary to a specific company. Fortinet has a utility that will apply a digital watermark to files. The utility adds a small (approx. 100 byte) pattern to the file that is recognised by the DLP Watermark filter. the pattern is invisible to the end user.

When watermarking a file it should be verified that the pattern matches up to a category found on the FortiGate firewall. For example, if you are going to watermark a file with the sensitivity

level of “Secret” you should verify that “Secret” is a sensitivity level that has been assigned in the FortiGate unit.

Software Versions

Before planning on using watermarking software it is always best to verify that the software will work with your OS. Currently the utility was only available for the Linux and Windows operating systems.

The Linux version can be found in one of 3 command line executable programs.

- watermark_linux_amd64
- watermark_linux_arm
- watermark_linux_x86

The Windows version is part of the FortiExplorer software.

File types

The Watermark tool does not work with every file type. The following file types are supported by the watermark tool:

- .txt
- .pdf
- .doc
- .xls
- .ppt
- .docx
- .pptx
- .xlsx

Currently the DLP only works with Fortinet’s watermarking software.

Using the FortiExplorer Watermark tool

The FortiExplorer software can be downloaded from the Fortinet Support Site.

1. Choose whether to "Apply Watermark To:"
   - Select File
   - Entire Directory
2. Fill in the fields:
   - ***a.*** *Select File*

     This Field has a browse icon next to it which will allow the user to browse to and select a single file or directory to apply the water mark to.
   - ***b.*** *Sensitivity Level*

     This field is a drop down menu that lists the available sensitivity levels that the FortiGate can scan for
   - ***c.*** *Identifier*

     This is a unique identifier string of characters to identify the company that the document belongs to.
   - ***d.*** *Output Directory*

     This Field has a browse icon next to it which will allow the user to browse to a directory where the altered file will be placed. If the output directory is the same as the source

directory the original file will be overwritten. If the output directory is different than the source directory then the watermarked version of the file will be place there and the unaltered original will be left in the source directory.

3. Select *Apply Watermark* to start the process.

You should get output in the window similar to this:

```
> fortinet-watermark-win.exe -v -f "C:\Users\TestUser\Documents\test
    document.txt" -i "123456ABC" -l "Private" -o
    "C:\Users\TestUser\Watermarked Documents"
   Creating watermark. Pattern:
   =-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=identifier=123456ABC
    sensitivity=Private=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=
   --> 'C:\Users\TestUser\Documents\test document.txt'
   Inserted watermark size 231
   ------------------------------------------------------------
   1 file(s) processed. (success = 1, failure = 0)
```

Installation of the watermark utility on Linux

Add the watermark file to a location on the system that is in the $PATH.

To see what the path is use the command

```
echo $PATH
```

Example results:

```
/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin:/usr/ga
    mes
```

for example you could move or copy the file to the :/bin directory.

Permissions on the watermark file:

Check the existing permissions:

The command in Linux for listing file along with the permissions is:

```
ls -l
```

Run the check to see if the permission status. The results may be something along these lines:

```
-rw-r--r-- 1 root root 2053868 Jan 10 11:44 watermark
```

You will see that in this case it has no executable permissions

To change the permissions on the watermark file:

It will be assume for this command that the utility is in the bin directory and that you have ownership level access.

```
chmod o+x /bin/watermark
```

To verify the change:

```
ls -l wa*
-rw-r--r-x 1 root root 2053868 Jan 10 11:44 watermark
```

You can see how the x for executable has been added to the permissions for the *others* group.

Syntax of the Watermark utility

The tool is executed in a Linux environment by passing in files or directories of files to insert a watermark.

USAGE:

```
watermark <options> -f <file name> -i <identifier> -l <sensitivity
     level>
watermark <options> -d <directory> -i <identifier> -l <sensitivity
     level>
```

Options:

```
-h print help
-v verbose information
-I inplace watermarking (don't copy file)
-o output directory
-e encode <to non-readable>
-a add additional watermark (by default replaces watermarks existing
     watermarks)
-D delete all watermarks
```

Using the watermark utility

Now if you are in your home directory and you want to watermark a file in the Documents directory you could plan out the command like this:

watermark [because that is the executable to be used]

-v [so that you can get as much feedback as possible]

-I [because you don't want a new file you just want to watermark the existing one]

-f [because you only want to change the one file not the entire directory]

filename.pdf [the name of the file]

-i 123456 [to set the identifier to 123456 - this is a required setting

-l Private [to set the sensitivity level to “Private”]

Now at the command prompt enter all of these components in order:

```
watermark -v -I -f filename.pdf -i 12345 -l Private
Creating watermark.  Pattern:
=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=identifier=12345
     sensitivity=Private=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=
Watermarking file: 'filename.pdf'
Inserted watermark size 148
```

Enable data leak prevention

DLP examines your network traffic for data patterns you specify. The FortiGate unit then performs an action based on the which pattern is found and a configuration set for each filter trigger.

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create a DLP sensor.

   New DLP sensors are empty. You must create one or more filters in a sensor before it can examine network traffic.

2. Add one or more filters to the DLP sensor.

   Each filter searches for a specific data pattern. When a pattern in the active DLP sensor appears in the traffic, the FortiGate unit takes the action configured in the matching filter. Because the order of filters within a sensor cannot be changed, you must configure DLP in sequence.
3. Add the DLP sensor to one or more firewall policies that control the traffic to be examined.

Creating a DLP sensor

DLP sensors are collections of filters. You must also specify an action for the filter when you create it in a sensor. Once a DLP sensor is configured, you can select it a security policy profile. Any traffic handled by the security policy will be examined according to the DLP sensor configuration.

To create a DLP sensor

1. Go to *Security Profiles* > *Data Leak Prevention* > *Sensor*.
2. Select the *Create New* icon on the Edit DLP Sensor window title bar.
3. In the *Name* field, enter the name of the new DLP sensor.
4. Optionally, you may also enter a comment. The comment appears in the DLP sensor list and can remind you of the details of the sensor.
5. Select *OK*.

   The DLP sensor is created and the sensor configuration window appears.
6. Select OK.

A newly created sensor is empty, containing no filters. Without filters, the DLP sensor will do nothing.

Adding filters to a DLP sensor

Once you have created a DLP sensor, you need to add filters.

1. To add filters to a DLP sensor
2. Go to *Security Profiles* > *Data Leak Prevention*> *Sensor*.
3. Select the Sensor in the Edit DLP Sensor window title bar drop-down list.
4. Select *Create New*.
5. Enter a filter name.
6. Select the type of filter. You can choose either Messages or Files. Depending on which of these two are chosen different options will be available

Message filter will have these configuration options:

- [radio button] Containing: [drop down menu including: Credit Card # or SSN]
- [radio button] Regular Expression [input field]
- [radio button] Encrypted

Examine the following Services:

Web Access

- HTTP-POST

Email

- [check box] SMTP
- [check box] POP3

- [check box] IMAP
- [check box] MAPI

Others

- [check box] NNTP

Action [from drop down menu]

- None
- Log Only,
- Block
- Quarantine User,
- Quarantine IP address
- Quarantine Interface

Files filter will have these options:

- [radio button] Containing: drop down menu including: Credit Card # or SSN
- [radio button] File Size >= [ ]kb
- [radio button] File Type included in [drop down menu of File Filters]
- [radio button] File Finger Print : [drop down menu]
- [radio button] Watermark Sensitivity: [drop down menu] and Corporate Identifier [id field]
- [radio button] Regular Expression [input field]
- [radio button] Encrypted

Examine the following Services:

Web Access

- [check box] HTTP-POST
- [check box] HTTP-GET

Email

- [check box] SMTP
- [check box] POP3
- [check box] IMAP
- [check box] MAPI

Others

- [check box] FTP
- [check box] NNTP

Action [from drop down menu]

- None
- Log Only,
- Block
- Quarantine User,
- Quarantine IP address
- Quarantine Interface

Table 96: Option explanations

Option	Description
Containing..	the predefined settings for this filter are: • Credit Card numbers - The number formats used by American Express, Visa, and Mastercard credit cards are detected. • Social Security Numbers.
Regular Expression	Network traffic is examined for the pattern described by the regular expression.
Encrypted	This filter is triggered by encrypted files.
File Size	Enter a file size in kilobytes. Files larger than the specified size are treated according to the selected action.
File Type	Select a file filter list that includes the file patterns and file types the network traffic will be examined for. Files matching the types or patterns in the selected list are treated according to the selected action. To create a file filter list, see “Creating a file filter list” on page 2141.
File Finger Print	A fingerprint filter checks files in traffic against those in the FortiGate unit document fingerprint database. A match triggers the configured action. You must configure a document source or uploaded documents to the FortiGate unit for fingerprint scanning to work. For more information about document fingerprinting, see “Fingerprint” on page 2131.
Watermark Sensitivity	If you are using watermarking on your files you can use this filter to check for watermarks that correspond to sensitivity categories that you have set up. The Corporate Identifier is to make sure that you are only blocking watermarks that your company has place on the files, not watermarks with the same name by other companies.
Services	Configure the filter to examine the traffic over the selected services. This setting gives you a tool to optimized the resources of the FortiGate unit by only using processing cycles on the relevant traffic. Just check the boxes associated with the service / protocol that you want to have checked for filter triggers.

Table 97: Action Options

Action	Description
None	No action is taken if filter even if filter is triggered
Log Only	The FortiGate unit will take no action on network traffic matching a rule with this action. The filter match is logged, however. Other matching filters in the same sensor may still operate on matching traffic.
Block	Traffic matching a filter with the block action will not be delivered. The matching message or download is replaced with the data leak prevention replacement message.

Table 97: Action Options

Action	Description
Quarantine User	If the user is authenticated, this action blocks all traffic to or from the user using the protocol that triggered the rule and adds the user to the Banned User list. If the user is not authenticated, this action blocks all traffic of the protocol that triggered the rule from the user's IP address. If the banned user is using HTTP, FTP, or NNTP (or HTTPS if the FortiGate unit supports SSL content scanning and inspection) the FortiGate unit displays the "Banned by data leak prevention" replacement message. If the user is using IM, the IM and P2P "Banned by data leak prevention" message replaces the banned IM message and this message is forwarded to the recipient. If the user is using IMAP, POP3, or SMTP (or IMAPS, POP3S, SMTPS if your FortiGate unit supports SSL content scanning and inspection) the Mail "Banned by data leak prevention" message replaces the banned email message and this message is forwarded to the recipient. These replacement messages also replace all subsequent communication attempts until the user is removed from the banned user list. If this action is chosen the additional field for [ ] minutes will appear so that a time limit can be set for the duration of the quarantine. This field cannot be left blank.
Quarantine IP Address	This action blocks access for any IP address that sends traffic matching a filter with this action. The IP address is added to the Banned User list. The FortiGate unit displays the "NAC Quarantine DLP Message" replacement message for all connection attempts from this IP address until the IP address is removed from the banned user list. If this action is chosen the additional field for [ ] minutes will appear so that a time limit can be set for the duration of the quarantine. This field cannot be left blank.
Quarantine Interface	This action blocks access to the network for all users connecting to the interface that received traffic matching a filter with this action. The FortiGate unit displays the "NAC Quarantine DLP Message" replacement message for all connection attempts to the interface until the interface is removed from the banned user list. If this action is chosen the additional field for [ ] minutes will appear so that a time limit can be set for the duration of the quarantine. This field cannot be left blank.

Quarantine User, *Quarantine IP*, and *Quarantine Interface* provide functionality similar to NAC quarantine. However, these DLP actions block users and IP addresses at the application layer while NAC quarantine blocks IP addresses and interfaces at the network layer.

7. Select OK.
8. Repeat Steps 6 and 7 for each filter.
9. Select Apply to confirm the settings of the sensor.

If you have configured DLP to block IP addresses and if the FortiGate unit receives sessions that have passed through a NAT device, all traffic from that NAT device — not just traffic from individual users — could be blocked. You can avoid this problem by implementing authentication.

To view or modify the replacement message text, go to *System* > *Config* > *Replacement Message*.

DLP document fingerprinting

One of the DLP techniques to detect sensitive data is fingerprinting (also called document fingerprinting). Most DLP techniques rely on you providing a characteristic of the file you want to detect, whether it's the file type, the file name, or part of the file contents. Fingerprinting is different in that you provide the file itself. The FortiGate unit then generates a checksum fingerprint and stores it. The FortiGate unit generates a fingerprint for all files detected in network traffic, and it is compared to all of the fingerprints stored in its fingerprint database. If a match is found, the configured action is taken.

The document fingerprint feature requires a FortiGate unit with internal storage. The document fingerprinting menu item does not appear on models without internal storage.

Any type of file can be detected by DLP fingerprinting and fingerprints can be saved for each revision of your files as they are updated.

To use fingerprinting you select the documents to be fingerprinted and then add fingerprinting filters to DLP sensors and add the sensors to firewall policies that accept the traffic to which to apply fingerprinting.

Fingerprinted Documents

The FortiGate unit must have access to the documents for which it generates fingerprints. One method is to manually upload documents to be fingerprinted directly to the FortiGate unit. The other is to allow the FortiGate unit to access a network share that contains the documents to be fingerprinted.

If only a few documents are to be fingerprinted, a manual upload may be the easiest solution. If many documents require fingerprinting, or if the fingerprinted documents are frequently revised, using a network share makes user access easier to manage.

To configure manual document fingerprints

1. Go to *Security Profiles* > *Data Leak Prevention* > *Document Fingerprinting*.
2. In the Manual Document Fingerprints section, select *Create New*.
3. Select the file to be fingerprinted.
4. Choose a Sensitivity level. The default choices are *Critical*, *Private* and *Warning*, but more can be added in the CLI.
5. If the file is an archive containing other files, select *Process files inside archive* if you also want the individual files inside the archive to have fingerprints generated in addition to the archive itself.
6. Select *OK*.

   The file is uploaded and a fingerprint generated.

To configure a fingerprint document source

1. Go to *Security Profiles* > *Data Leak Prevention* > *Document Fingerprinting*.
2. In the Document Sources section, select *Create New*.

3. Configure the settings:

Name	Enter a descriptive name for the document source.
Server Type	This refers to the type of server share that is being accessed. The default is Windows Share but this will also work on Samba shares.
Server Address	Enter the IP address of the server.
User Name **Password**	Enter the user name and password of the account the FortiGate unit uses to access the server network share.
Path	Enter the path to the document folder.
Filename Pattern	You may enter a filename pattern to restrict fingerprinting to only those files that match the pattern. To fingerprint all files, enter an asterisk (“*”).
Sensitivity Level	Select a sensitivity level. The sensitivity is a tag for your reference that is included in the log files. It does not change how fingerprinting works.
Scan Periodically	To have the files on the document source scanned on a regular basis, select this option. This is useful if files are added or changed regularly. Once selected, you can choose Daily, Weekly, or Monthly update options, and enter the time of day the files are fingerprinted.
Advanced	Expand the Advanced heading for additional options.
Fingerprint files in subdirectories	By default, only the files in the specified path are fingerprinted. Files in subdirectories are ignored. Select this option to fingerprint files in subdirectories of the specified path.
Remove fingerprints for deleted files	Select this option to retain the fingerprints of files deleted from the document source. If this option is disabled, fingerprints for deleted files will be removed when the document source is rescanned.
Keep previous fingerprints for modified files	Select this option to retain the fingerprints of previous revisions of updated files. If this option is disabled, fingerprints for previous version of files will be deleted when a new fingerprint is generated.

4. Select *OK*.

File filter

File filter is a DLP option that allows you to block files based on their file name or their type.

- **File patterns** are a means of filtering based purely on the names of files. They may include wildcards (*). For example, blocking *.scr will stop all files with an scr file extension, which is

commonly used for Windows screen saver files. Files trying to pass themselves off as Windows screen saver files by adopting the file-naming convention will also be stopped.

- Files can specify the full or partial file name, the full or partial file extension, or any combination. File pattern entries are not case sensitive. For example, adding `*.exe` to the file pattern list also blocks any files ending with `.EXE`.
- Files are compared to the enabled file patterns from top to bottom, in list order.
- In addition to the built-in patterns, you can specify more file patterns to block. For details, see "Creating a file filter list" on page 2141.
- **File types** are a means of filtering based on an examination of the file contents, regardless of the file name. If you block the file type *Archive (zip)*, all zip archives are blocked even if they are renamed with a different file extension. The FortiGate examines the file contents to determine what type of file it is and then acts accordingly.

The FortiGate unit can take either of the following actions toward the files that match a configured file pattern or type:

- **Block**: the file is blocked and a replacement message is sent to the user. If both file pattern filtering and virus scan are enabled, the FortiGate unit blocks files that match the enabled file filter and does not scan these files for viruses.
- **Allow**: the file is allowed to pass.

The FortiGate unit also writes a message to the Security log and sends an alert email message if configured to do so.

File filter does not detect files within archives. You can use file filter to block or allow the archives themselves, but not the contents of the archives.

General configuration steps

The following steps provide an overview of file filter configuration. For best results, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create a file filter list.
2. Create one or more file patterns or file types to populate the file filter list.
3. Enable the file filter list by adding it to a filter in a DLP sensor.
4. Select the DLP sensor in a security policy.

Creating a file filter list

Before your FortiGate unit can filter files by pattern or type, you must create a file filter list. The action triggered by the contents of a file filter list will be decided in the sensor so it is important to make sure that when you are building a list that you intend for the same action to be applied to all of the entries in the same list.

To create a file filter list

1. Go to *Security Profiles* > *Data Leak Prevention* > *File Filter*.
2. Select *Create New*.
3. Enter a *Name* for the new file filter list.
4. Select *OK*.

The new list is created and the edit file filter list window appears. The new list is empty. You need to populate it with one or more file patterns or file types.

Creating a file pattern

A file pattern allows you to block or allow files based on the file name. File patterns are created within file filter lists.

To create a file pattern

1. Go to *Security Profiles* > *Data Leak Prevention* > *File Filter*.
2. Select a file filter list.
3. Select the *Edit* icon.
4. Select *Create New*.
5. Select *File Name Pattern* as the *Filter Type*.
6. Enter the pattern in the *Pattern* field. The file pattern can be an exact file name or can include wildcards (*). The file pattern is limited to a maximum of 80 characters.
7. Select *OK*.

Creating a file type

A file type allows you to block or allow files based on the kind of file. File types are created within file filter lists.

To create a file type

1. Go to *Security Profiles* > *Data Leak Prevention* > *File Filter*.
2. Select the *Edit* icon of the file filter list to which you will add the file type.
3. Select *Create New*.
4. Select *File Type* as the *Filter Type*.
5. Select the kind of file from the *File Type* list.
6. Select *OK*.

DLP can detect the following file types:

- Archive (arj)
- Archive (bzip)
- Archive (bzip2)
- Archive (cab)
- Archive (gzip)
- Archive (Archive (lzh)
- Archive (rar)
- Archive (tar)
- Archive (zip)
- Audio (wav)
- Audio (wma)
- BMP (bmp)
- Batch File (bat)
- Common Console Document (msc)
- Encoded Data (base64)

- Encoded Data (binhex)
- Encoded Data (mime)
- Encoded Data (uue)
- Executable (elf)
- Executable (exe)
- GIF Image (gif)
- HTML Application (hta)
- HTML File (html)
- Ignored File Type (ignored)
- JPEG Image (jpeg)
- Java Application Descriptor (jad)
- Java Class File (class)
- Java Compiled Bytecode (cod)
- JavaScript File (javascript)
- Microsoft Office (msoffice)
- PDF (pdf)
- PNG Image (png)
- Packer (aspack)
- Packer (fsg)
- Packer (petite)
- Packer (upx)
- PalmOS Application (prc)
- Real Media Streaming (rm)
- Symbian Installer System File (sis)
- TIFF Image (tiff)
- Torrent (torrent)
- Unknown File Type (unknown)
- Video (mov)
- Video (mpeg)
- Windows Help File (hlp)
- activemime (activemime)

The “unknown” type is any file type that is not listed in the table. The “ignored” type is the traffic the unit typically does not scan. This includes primarily streaming audio and video.

Preconfigured sensors

A number of preconfigured sensors are provided with your FortiGate unit. These can be edited or added to more closely match your needs.

Some of the preconfigured sensors with filters ready to go are:

- Credit-Card - This sensor logs the traffic, both files and messages, that contain credit card numbers in the formates used by American Express, MasterCard and Visa.
- Large-File - This sensor logs the traffic consisting of files larger than 5120 kB or approximately 5 MB.
- SSN-Sensor - This sensor logs the traffic, both files and messages, that contain Social Security Numbers with the exception of those that are WebEx invitation emails.

These rules affect only unencrypted traffic types. If you are using a FortiGate unit that can decrypt and examine encrypted traffic, you can enable those traffic types in these rules to extend their functionality if required.

Before using the rules, examine them closely to ensure you understand how they will affect the traffic on your network.

DLP archiving

DLP is typically used to prevent sensitive information from getting out of your company network, but it can also be used to record network use. This is called DLP archiving. The DLP engine examines email, FTP, IM, NNTP, and web traffic. Enabling archiving for rules when you add them to sensors directs the FortiGate unit to record all occurrences of these traffic types when they are detected by the sensor.

Since the archive setting is configured for each rule in a sensor, you can have a single sensor that archives only the things you want.

You can archive Email, FTP, HTTP, IM, and session control content:

- Email content includes IMAP, POP3, and SMTP sessions. Email content can also include email messages tagged as spam by Email filtering. If your unit supports SSL content scanning and inspection, Email content can also include IMAPS, POP3S, and SMTPS sessions.
- HTTP content includes HTTP sessions. If your unit supports SSL content scanning and inspection HTTP content can also include HTTPS sessions.
- IM content includes AIM, ICQ, MSN, and Yahoo! sessions.

DLP archiving comes in two forms: *Summary Only*, and *Full*.

Summary archiving records information about the supported traffic types. For example, when an email message is detected, the sender, recipient, message subject, and total size are recorded. When a user accesses the Web, every URL the user visits recorded. The result is a summary of all activity the sensor detected.

For more detailed records, full archiving is necessary. When an email message is detected, the message itself, including any attachments, is archived. When a user accesses the Web, every page the user visits is archived. Far more detailed than a summary, full DLP archives require more storage space and processing.

Because both types of DLP archiving require additional resources, DLP archives are saved to a FortiAnalyzer unit or the FortiGuard Analysis and Management Service (subscription required).

You can use DLP archiving to collect and view historical logs that have been archived to a FortiAnalyzer unit or the FortiGuard Analysis and Management Service. DLP archiving is available for FortiAnalyzer when you add a FortiAnalyzer unit to the Fortinet configuration. The FortiGuard Analysis server becomes available when you subscribe to the FortiGuard Analysis and Management Service.

Two sample DLP sensors are provided with DLP archiving capabilities enabled. If you select the `Content_Summary` sensor in a security policy, it will save a summary DLP archive of all traffic the security policy handles. Similarly, the `Content_Archive` sensor will save a full DLP archive of all traffic handled the security policy you apply it to. These two sensors are configured to detect all traffic of the supported types and archive them.

DLP archiving is set in the CLI only.

To set the archive to Full

```
config dlp sensor
  edit <name of sensor>
    set full-archive-proto smtp pop3 imap http ftp nntp aim icq msn
        yahoo mapi
    end
```

To set the archive to Summary Only

```
config dlp sensor
  edit <name of sensor>
    set summary-proto smtp pop3 imap http ftp nntp aim icq msn yahoo
        mapi
    end
```

DLP examples

Blocking content with credit card numbers

When the objective is to block credit card numbers one of the important things to remember is that 2 filters will need to be used in the sensor.

In the default Credit-Card sensor, you will notice a few things.

- The Action is set to Log Only
- In the Files filter not all of the services are being examined.

If you wish to block as much content as possible with credit card numbers in it instead of just logging most the traffic that has it, the existing sensor will have to be edited.

Security Profile > *Data Leak Prevention* > *Sensor.*

Use the drop down menu to select Credit-Card.

1. Edit the first filter.
   a. Change the Action to Block
   b. Make sure all of the services are being examined.
   c. Select OK
2. Repeat for the second filter
3. Select Apply
4. Edit the appropriate policies so that under *Security Profiles*, *DLP* is turned on and the *Credit-Card* sensor is selected.

Blocking emails larger than 15 MB and logging emails from 5 MB to 15 MB

Because the designated size is over 10 MB the proxy options cannot be used to block the file size. Multiple filters will have to be used in this case and the order that they are used is important. Because there is no mechanism to move the filters within the sensor the order that they are added to the sensor is important.

Security Profile > *Data Leak Prevention* > *Sensor.*

Create a new sensor

Use the following values

Name	large_emails
Comment	<optional>

Once the Sensor has been created a new filter will need to be added.

Create New

Use the following values

Filter:

- Choice between *Meassages* and *Files*: choose *Files.*
- Choose radio button to the left of *File Size*
- In the field for the file size type 15360
  1MB = 1024kB, 15 MB = 15 x 1024kB = 15360kB

Examine the following Services

SMTP	enabled
POP3	enabled
IMAP	enabled
HTTP	not enabled
FTP	not enabled
AIM	not enabled
ICQ	not enabled
MSN	not enabled
Yahoo!	not enabled
NNTP	not enabled
MAPI	not enabled

Action

- From the drop down menu choose Block

Select OK

A second filter will need to be added.

Create New

Use the following values

Filter:

- Choice between Meassages and Files: choose Files
- Choose radio button to the left of *File Size*
- In the field for the file size type 1024

Examine the following Services

SMTP	enabled
POP3	enabled
IMAP	enabled
HTTP	not enabled
FTP	not enabled
AIM	not enabled
ICQ	not enabled
MSN	not enabled
Yahoo!	not enabled
NNTP	not enabled
MAPI	not enabled

Action

- From the drop down menu choose *Log Only*.

Select OK

Select Apply

Add the sensor to the appropriate policy.

The reason that the block filter is placed first is because the filters are applied in sequence and once the traffic triggers a filter the action is applied and then the traffic is passed on to the next test. If the Log Only filter which checks for anything over 1MB is triggered this would include traffic over 15MB, so a 16 MB file would only be logged. In the described order, the 16 MB file will be blocked and the 3 MB file will be logged.

Selective blocking based on a finger print

The following is a fairly complex example but shows what can be done by combining various components in the correct configuration.

The company has a number of copyrighted documents that it does not want “escaping” to the Internet but it does want to be able to send those documents to the printers for turning into hardcopy.

The policies and procedures regarding this issue state that:

- Only members of the group *Senior_Editors* can send copyrighted material to the printers.
- Every member of the company by default is included in the group *employees*.
- Even permitted transmission of copyrighted material should be recorded.
- All of the printers IP addresses are in a group called *approved_printers*.
- There is a file share called copyrighted where any file that is copyrighted is required to have a copy stored.
- It doesn't happen often but for legal reasons sometimes these files can be changed, but all versions of a file in this directory need to be secured.
- All network connections to the Internet must have Antivirus enabled using at least the default profile.
- The SSL/SSH Inspection profile used will be *default*.

It is assumed for the purposes of this example that:

- Any addresses or address groups have been created.
- User accounts and groups have been created.
- The account used by the FortiGate is fgtaccess.
- The Copyrighted sensitivity level needs to be created.
- The copyrighted material is stored at \\192.168.27.50\books\copyrighted\

Sensitivity Level Addition

```
config dlp fp-sensitivity
  edit copyrighted
  end
```

Finger print configuration

Security Profile > *Data Leak Prevention* > *Document Fingerprinting.*

In the *Document Sources* section *select Create New*

Use the following field values

Name	copyrighted_material
Server Type	Windows Share
Server Address	192.168.27.50
User Name	fgtaccess
Password	******
Path	books/copyrighted/
Filename Pattern	*.pdf
Sensitivity	copyrighted
Scan Periodically	enabled
<Frequency>	Daily, Hour: 2, Min: 0
Advanced	

Fingerprint files in subdirectories	enabled
Remove fingerprints for deleted files	not enabled
Keep previous fingerprints for modified files	enabled

Create DLP Sensors

Security Profile > Data Leak Prevention > Sensor

Create a new sensor. This can be done one of two ways.

- In the menu bar at the top on the right hand, use the Create New icon (circle with + symbol inside).
- In the menu bar at the top on the right hand, use the View List icon to go to the list window and use the Create New icon on the top left of that page.

Two Sensors need to be created. One for blocking the transmission of copyrighted material and a second for allowing the passing of copyrighted material under specific circumstances.

Configuration for the first sensor that blocks transmission.

Use the following field values:

Name	block_copyrighted
Comment	<optional>

Once the Sensor has been created a new filter will need to be added.

Create New

Use the following values

Filter:

- Choice between Meassages and Files: choose Files
- Choose radio button to the left of File Finger Print
- From the drop down for File Finger Print choose “copyrighted”

Examine the following Services

SMTP	enabled
POP3	enabled
IMAP	enabled
HTTP	enabled
FTP	enabled
AIM	enabled
ICQ	enabled
MSN	enabled

Yahoo!	enabled
NNTP	enabled
MAPI	enabled

Action

- From the drop down menu choose Block

Configuration for the second sensor that allows transmission.

Use the following field values:

Name	allow_copyrighted
Comment	<optional>

Once the Sensor has been created a new filter will need to be added.

This will be identical to the filter in the block_copyrighted sensor except that the action will be *Log Only*.

Create policies and attach DLP sensors

Policy to allow transmission of copyrighted material

Policy > Policy > Policy

Create New

Use the following values in the Policy:

Policy Type	Firewall
Policy Subtype	User Identity
Incoming Interface	LAN
Source Address	all
Outgoing Interface	wan1
Enable NAT	enabled -- Use Destination Interface Address
Enable Web cache	<optional>
Enable WAN Optimization	<optional>
Skip this policy for unauthenticated user	do not enable
Disclaimer	<optional>
Customize authentication Messages	<optional>

Configure Authentication Rules:

Destination Address	approved_printers
Group(s)	Senior_Editors
User(s)	<optional>
Schedule	always
Service	ALL
Action	ACCEPT
Log Allowed Traffic	<optional>
Security Profiles	
Antivirus	<ON> default
Webfilter	<optional>
Application Control	<optional>
IPS	<optional>
Email Filter	<optional>
DLP Sensor	<ON> Copyrighted
VoIP	<optional>
ICAP	<optional>
Proxy Options	
SSL/SSH Inspection	<ON>
Traffic Shaping	<optional>

This policy should be place as close to the beginning of the list of policies so the it is among the first tested against.

Policy to block transmission of copyrighted material

This will in effect be the default template for all following policies in that they will have to use the DLP profile that blocks the transmission of the copyrighted material.

Policy > *Policy* > *Policy*

Create New or *Edit* the existing policies.

The fields should include what ever values you need to accomplish your requirements are but each policy should include the DLP sensor block_copyrighted or if a different DLP configuration is required it should include a filter that blocks *copyrighted* fingerprinted file.

If you need to create a policy that is identity based make sure that there is an Authentication rule for the group *employees* that uses the DLP sensor that blocks copyrighted material.

Application control

Using the application control Security Profile feature, your FortiGate unit can detect and take action against network traffic depending on the application generating the traffic. Based on FortiGate Intrusion Protection protocol decoders, application control is a user-friendly and powerful way to use Intrusion Protection features to log and manage the behavior of application traffic passing through the FortiGate unit. Application control uses IPS protocol decoders that can analyze network traffic to detect application traffic even if the traffic uses non-standard ports or protocols.

The FortiGate unit can recognize the network traffic generated by a large number of applications. You can create application control sensors that specify the action to take with the traffic of the applications you need to manage and the network on which they are active, and then add application control sensors to the firewall policies that control the network traffic you need to monitor.

Fortinet is constantly increasing the list of applications that application control can detect by adding applications to the FortiGuard Application Control Database. Because intrusion protection protocol decoders are used for application control, the application control database is part of the FortiGuard Intrusion Protection System Database and both of these databases have the same version number.

You can find the version of the application control database that is installed on your unit, by going to the *License Information* dashboard widget and find IPS Definitions version.

You can go to the FortiGuard Application Control List to see the complete list of applications supported by FortiGuard. This web page lists all of the supported applications. You can select any application name to see details about the application.

If you enable virtual domains (VDOMs) on the Fortinet unit, you need to configure application control separately for each virtual domain.

The following topics are included in this section:

Application control concepts

You can control network traffic generally by the source or destination address, or by the port, the quantity or similar attributes of the traffic itself in the security policy. If you want to control the flow of traffic from a specific application, these methods may not be sufficient to precisely define the traffic. To address this problem, the application control feature examines the traffic itself for signatures unique to the application generating it. Application control does not require knowledge of any server addresses or ports. The FortiGate unit includes signatures for over 1000 applications, services, and protocols.

Updated and new application signatures are delivered to your FortiGate unit as part of your FortiGuard Application Control Service subscription. Fortinet is constantly increasing the

number of applications that application control can detect by adding applications to the FortiGuard Application Control Database. Because intrusion protection protocol decoders are used for application control, the application control database is part of the FortiGuard Intrusion Protection System Database and both of these databases have the same version number.

To view the version of the application control database installed on your FortiGate unit, go to the *License Information* dashboard widget and find the *IPS Definitions* version.

To see the complete list of applications supported by FortiGuard Application Control go to the FortiGuard Application Control List. This web page lists all of the supported applications. You can select any application name to see details about the application.

Application considerations

Some applications behave differently from most others. You should be aware of these differences before using application control to regulate their use.

Automatically allowing basic applications

A common practice is to block applications by category, because the alternative is to list each specific traffic on an individual basis. While listing the applications individually gives a great deal of granularity it does tend to allow for missing some of them. On the other hand, blocking by category has the drawback of blocking some traffic that was not intended to be blocked.

There are a number of basic applications that you may want to be allowed on a default basis. For example, DNS. If you were to block the category Network Services you would end up blocking your web browsing, unless your users are members of a very limited group that do their web browsing by using IP addresses instead of URLs. Without DNS the systems will not be able to resolve URLs into IP addresses.

Using a set of options in the CLI the FortiGate unit can be configured to automatically allow the following types of traffic, regardless of whether or not their category is blocked:

- DNS
- ICMP
- Generic HTTP Web browsing
- Generic SSL communications

Syntax

```
config application list
  edit appcontrol
    set options allow-dns allow-icmp allow-http allow-ssl
  end
```

As the example indicates, DNS is vitally important to multiple other types of traffic so by default it is set to be allowed, however the other settings must be specifically enabled.

IM applications

The Application Control function for a number of IM application is not in the Web Based Manager, in the CLI of the FortiGate unit. These applications are:

- AIM
- ICQ
- MSN
- Yahoo

These applications are controlled by either permitting or denying the users from logging in to the service. Individual IM accounts are configured as to whether or not they are permitted and then there is a global policy for how to action unknown users, by the application, and whether to add the user to the black list or the white list.

The configuration details for these settings can be found in the CLI Reference guide under the heading of imp2p.

Skype

Based on the NAT firewall type, Skype takes advantage of several NAT firewall traversal methods, such as STUN (Simple Traversal of UDP through NAT), ICE (Interactive Connectivity Establishment) and TURN (Traversal Using Relay NAT), to make the connection.

The Skype client may try to log in with either UDP or TCP, on different ports, especially well-known service ports, such as HTTP (80) and HTTPS (443), because these ports are normally allowed in firewall settings. A client who has previously logged in successfully could start with the known good approach, then fall back on another approach if the known one fails.

The Skype client could also employ Connection Relay. This means if a reachable host is already connected to the Skype network, other clients can connect through this host. This makes any connected host not only a client but also a relay server.

Application traffic shaping

You can apply traffic shaping for application list entries you configure to pass. Traffic shaping enables you to limit or guarantee the bandwidth available to the application or applications specified in an application list entry. You can also prioritize traffic by using traffic shaping.

You can create or edit traffic shapers by going to *Firewall Objects* > *Traffic Shaper* > *Shared*. Per-IP traffic shapers are not available for use in application traffic shaping.

For more information about traffic shaping, see “Traffic shaping methods” on page 2243.

Direction of traffic shaping

When Traffic Shaping is enabled the direction that traffic shaping will be applied must also be chosen.

Forward direction traffic shaping refers to the direction of the initial connection. This would be the direction described by the policy that the Application Control Sensor is assigned to. If the policy has an Incoming Interface of LAN and an Outgoing Interface of wan1 then any Forward Direction Traffic Shaping profile will apply to network traffic heading in that direction only. If the connection used by that policy involved a response that included a download of Gigabytes of traffic the shaper would not be applied to that traffic.

Reverse Direction Traffic Shaping is applied to traffic that is flowing in the opposite direction indicated by the direction of the policy. If the policy has an Incoming Interface of LAN and an Outgoing Interface of wan1 then the shaper would only be applied to the traffic that was coming from the wan1 interface to the LAN interface.

For example, if you find that your network bandwidth is being overwhelmed by streaming HTTP video, one solution is to limit the bandwidth by applying a traffic shaper to an application control entry that allows the HTTP.Video application. Your users access the Web using a security policy that allows HTTP traffic from the internal interface to the external interface. Firewall policies are required to initiate communication so even though web sites respond to requests, a policy to allow traffic from the external interface to the internal interface is not required for your users to access the Web. The internal to external policy allows them to open communication sessions to web servers, and the external servers can reply using the existing session.

If you enable *Traffic Shaping* and select the Forward Direction shaper in an application sensor specified in the security policy, the problem will continue. The reason is the shaper you select for *Traffic Shaping* is applied only to the application traffic moving in the direction stated in the security policy. In this case, that is from the internal interface to the external interface. The security policy allows the user to visit the web site and start the video, but the video itself is streamed from the server to the user, or from the external interface to the internal interface. This is the reverse of the direction specified in the security policy. To solve the problem, you must enable *Reverse Direction Traffic Shaping* and select the appropriate shaper.

Shaper re-use

Shapers are created independently of firewall policies and application sensors so you are free to reuse the same shapers in multiple list entries and policies. Shared shapers can be configured to apply separately to each security policy or across all policies. This means that if a shaper is configured to guaranteed 1000 KB/s bandwidth, each security policy using the shaper will have its own 1000 KB/s reserved, or all of the policies using the shaper will share a pool if 1000 KB/s, depending on how it is configured.

The same thing happens when a shaper is used in application sensors. If an application sensor using a shaper is applied to two separate policies, how the bandwidth is limited or guaranteed depends on whether the shaper is set to apply separately to each policy or across all policies. In fact, if a shaper is applied directly to one security policy, and it is also included in an application sensor that is applied to another security policy, the same issue occurs. How the bandwidth is limited or guaranteed depends on the shaper configuration.

If a shaper is used more than once within a single application sensor, all of the applications using the shaper are restricted to the maximum bandwidth or share the same guaranteed bandwidth.

For example, you want to limit the bandwidth used by Skype and Facebook chat to no more than 100 KB/s. Create a shaper, enable *Maximum Bandwidth*, and enter 100. Then create an application sensor with an entry for Skype and another entry for Facebook chat. Apply the shaper to each entry and select the application sensor in the security policy that allows your users to access both services.

This configuration uses the same shaper for each entry, so Skype ***and*** Facebook chat traffic are limited to no more than 100 KB/s in total. That is, traffic from both applications is added and the total is limited to 100 KB/s. If you want to limit Skype traffic to 100 KB/s and Facebook chat traffic to 100 KB/s, you must use separate shapers for each application control entry.

Application control monitor

The application monitor enables you to gain an insight into the applications generating traffic on your network. When monitor is enabled in an application sensor entry and the list is selected in

a security policy, all the detected traffic required to populate the selected charts is logged to the SQL database on the FortiGate unit hard drive. The charts are available for display in the executive summary section of the log and report menu.

Because the application monitor relies on a SQL database, the feature is available only on FortiGate units with an internal hard drive.

While the monitor charts are similar to the top application usage dashboard widget, it offers several advantages. The widget data is stored in memory so when you restart the FortiGate unit, the data is cleared. Application monitor data is stored on the hard drive and restarting the system does not affect old monitor data.

Application monitor allows you to choose to compile data for any or all of three charts: top ten applications by bandwidth use, top ten media users by bandwidth, and top ten P2P users by bandwidth. Further, there is a chart of each type for the traffic handled by each security policy with application monitor enabled. The top application usage dashboard widget shows only the bandwidth used by the top applications since the last system restart.

Application Control monitor

Once you have configured application control and associated the sensors with firewall policies, you can monitor the results. The applications that will be reported on the ones that are included in sensors that are assigned to firewall policies.

Security Profile > *Monitor* > Application Monitor.

Here you will find some widgets that include charts:

- Top Applications by Bandwidth
- Top Applications by Session Count
- Top IP/User for <application>

The number of “Top” can be set to the value of 5, 10 or 15 on any of these widgets.

Enable application control

Application control examines your network traffic for traffic generated by the applications you want it to control.

General configuration steps

Follow the configuration procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Create an application sensor.
2. Configure the sensor to include the signatures for the application traffic you want the FortiGate unit to detect. Configure each entry to allow or pass the traffic.
3. Enable application control in a security policy and select the application sensor.

Creating an application sensor

You need to create an application sensor before you can enable application control.

To create an application sensor

1. Go to *Security Profiles* > *Application Control* > *Application Sensor*.
2. Select the *Create New* icon in the title bar of the *Edit Application Sensor* window.
3. In the *Name* field, enter the name of the new application sensor.
4. Optionally, you may also enter a comment.
5. Select *OK*.

The application sensor is created and the sensor configuration window appears. A newly created application sensor is empty. Without applications, the application sensor will have no effect.

Adding applications to an application sensor

Once you have created an application sensor, you need to need to define the applications that you want to control.

You can add applications using application entries and application filters. Entries allow you to choose individual applications. Filters allow you to choose application attributes and all the applications with matching attributes are included in the filter.

The sequence of the entries in the table is significant. The entries are checked against the traffic in sequence, from top to bottom. If a match is found and the action is *Block* or *Reset*, the action is performed and further checking is stopped. If the action is *Monitor* the traffic is checked against all of the signatures in the sensor and the best match to the signature is the one that is logged.

To add an application entry to an application sensor

1. Go to *Security Profiles* > *Application Control* > *Application Sensors*.
2. Select an application sensor from the drop-down list in the Edit Application Sensor window title bar.
3. Select the *Create New* icon in the sensor area and this will bring up a new window entitled *New Application Filter*.
4. Choose the format of the filter. There are two types of entries that can be added to a sensor. The type of entry is detemined by the selection of the sensor type. The choices are either *Filter Based* or *Specify Applications*.
   - Filter Based

     This option is for choosing groups of similar applications based on the filters of Category, Popularity, Technology and Risk. Once the parameters of the 4 filter types have been chosen every application that falls in to that filtered list will be included in the list that the Application Control engine will use to filter the network traffic.
   - Specify Applications

     This option is good for a more granular approach to picking appliction to be filtered. It will allow for the use of the same filters that were used in the *Filter Based* option to develop a list of applications to be filtered but the Specify Applications option can be selective of which applications in that list are actually filtered. They are selected individually.

   The difference in the Web-based Manager, when alternating between the Sensor Types, is that when the Filter Based option is chosen the Filter Options section will appear by default. If the Specify Applications sensor type is chosen you can click on the [Filter Options] link to make it appear and use it to narrow down the list of possible applications but it does not show up by default. The other difference is that with the Specify Applications option you are

given an additional field at the top of the Application List that allow you to type out the name of an application to search for it in that manner.

To use the search field, located above the application list, start typing any portion of the application name. The mail list of application will adjust accordingly.

5. Narrow down the list of applications to be filtered. This will depend a little on which *Sensor Type* was chosen. If the Filter Based option was chosen, by default, the top section of the window will show the properties by which the list of application filters can be filtered into a more managable list. These properties are broken into 4 sections representing the properties of Category, Popularity, Technology and Risk. Between the property filter section and the Action section of the window there is a listing of the individual application filters that have been configured into the appliance.

   Each of these individual application filters is assigned values in each of the 4 properties. The values that can be assigned to these properties are listed in the 4 sections. By enabling the check boxes next to the propterties in the sections the list can be narrowed down until it only includes the subset of the individual application filters that you wish to make up the sensor entry or Application Filter.

   When choosing a property, if the specific value is unknown do not disable the property section as this will cause the list of individual application filters to be empty.

   The properties have been broken down into the following sections:

   a. Category

      These are the types of application that are available to filter by:

Table 98: Property Values listed in Category section along with ID#

Category Name	Category ID#
Botnet	19
eMail	21
File.Sharing	24
Game	8
General.Interest	12
IM	1
Media	5
Network.Service	15
P2P	2
Proxy	6
Remote.Access	7
Social.Networking	23
Storage.Backup	22
Update	17
VoIP	3
Web.Surfing	25

there is also a category designation reserved for future use.

These categories should cover the bulk of application based network traffic. If you wanted to disallow the use of Peer to Peer (P2P) applications because you didn't want your users tieing up your bandwidth with torrent downloads you would select the P2P category and set the Action to Block

b. Popularity

Popularity is broken down into 5 levels of popularity represented by stars. 5 stars representing the most popular applications and 1 star representing applications that are the least popular. The Popularity property works well when trying to narrow down the list of one of the categories. Using the previous category example of P2P traffic but you wanted to monitor the activity of the most popular applications, which numbers about 30 as opposed to over 100, you would choose P2P from Category and the 5 star popularity.

c. Technology

Technology is broken down into 3 technology models as well as the more basic Network-Protocol which would can be used as a catch all for anything not covered by the more narrowly defined technologies of:

- Browser-Based
- Client-Server
- Peer -to-Peer

d. Risk

The Risk property does not indicate the level of risk but the type of impact that is likely to occur by allowing the traffic from that application to occur. The Risk list is broken down into the following

- Botnet
- Excessive-Bandwidth
- None

6. Pick the individual applications if using the Specify Applications Sensor type.

From the list of possible applications highlight the application by selecting the application.If you choose an application in error you can unhighlight or desellect the application by clicking on it again.

If the Filter Based sensor type is being used this will not be an option.

7. Select the *Action* the FortiGate unit will take when it detects network traffic from the application:

- *Monitor* allows the application traffic to flow normally and log all occurrences.

  If you set the action to *Monitor*, you have the option of enabling traffic shaping for the application or applications specified in this application list entry. For more information about application control traffic shaping, see "Enabling application traffic shaping" on page 2161
- *Block* will stop all traffic from the application and log all occurrences.
- *Reset* will reset the network connection on the session that the specified application traffic was detected on.
- *Traffic Shaping* will allow a Traffic Shaping profile to be applied to the applicatin traffic that triggered the sensor.

  Choosing the Traffic shaping action will cause to appear the secondary options of:
  - Forward Direction Traffic Shaping with a checkbox
  - Reverse Direction Traffic Shaping with a checkbox

  If the checkbox is enable for these options a dropdown menu will appear next to that option that will allow you to choose one of the existing Traffic Shaping profiles. If you are

going to want to use Traffic Shaping as an action in Application Control it is best to set up any of the Traffic Shaping profiles that you will want in advance.

Viewing and searching the application list

Go to *Security Profiles* > *Application Control* > *Application List* to view the list of applications the FortiGate unit recognizes. You may find applications by paging manually through the list, apply filters, or by using the search field.

Searching manually

Applications are displayed in a paged list, with 50 applications per page. The bottom of the screen shows the current page and the total number of pages. You can enter a page number and press enter, to skip directly to that page. Previous Page and Next Page buttons move you through the list, one page at a time. The First Page and Last Page button take you to the beginning or end of the list.

Applying application list filters

You can enter criteria for one or more columns, and only the applications matching all the conditions you specify will be listed.

To apply filters

1. Go to *Security Profiles* > *Application Control* > *Application List*.
2. Goto the column you intend to filter by and select the filter icon in the heading to the left of the column name.
3. A small window will appear which will have a field for the value to intend to filter by and a checkbox for *NOT* so that you can choose to view all of the values except the one you enter into the field. You can also input multiple values if you separate them using commas.
4. Select *Apply*.
5. Continue to add more filters to narrow your search, if required.
6. Select *OK*.

Creating a New Custom Application Signature

If you have to deal with an application that is not already in the *Application List* you have the option to create a new one.

Creating a new Application Filter

1. Go to *Security Profiles* > *Application Control* > *Application List*.
2. Select *Create New.*
3. The *New Custom Application Signature* window will appear.
4. In the *Name* field give the new signature a unique name.
5. In the *Comments* field give a brief discription of the application or what you intend to filter by.
6. In the *Signature* field include the signature that you intend to base your application filtering on. For more details on how to design a signature see “Creating a custom IPS signature” on page 2080
7. As an optional step you can select the Submit Signature link to submit your newly created signature to Fortiguard for possible inclusion in future predefined application lists.
8.

Enabling application traffic shaping

Enabling traffic shaping in an application sensor involves selecting the required shaper. You can create or edit shapers in *Firewall Objects* > *Traffic Shaper* > *Shared*.

To enable traffic shaping

1. Go to *Security Profiles* > *Application Control* > *Application Sensors*.
2. Select an application sensor from the drop-down list in the Edit Application Sensor window title bar.
3. Select the application control list entry and choose *Edit*.
4. Select *Traffic Shaping* and choose the required traffic shaper from the list.

   If the action is set to *Block*, the traffic shaping option is not available. Only allowed traffic can be shaped.
5. Select *Reverse Direction Traffic Shaping* and choose the required traffic shaper from the list if traffic flowing in the opposite direction also requires shaping.
6. Select *OK*.

Any security policy with this application sensor selected will shape application traffic according to the applications specified in the list entry and the shaper configuration.

Application control examples

Blocking all instant messaging

Instant messaging use is not permitted at the Example Corporation. Application control helps enforce this policy.

First you will create an application sensor with a single entry that includes all instant messaging applications. You will set the list action to block.

To create the application sensor

1. Go to *Security Profiles* > *Application Control* > *Application Sensors*.
2. Select the *Create New* icon in the title bar of the *Edit Application Sensor* window.
3. In the *Name* field, enter `no_IM` for the application sensor name.
4. Select *OK*.
5. Select the *Create New* icon in the sensor.
6. For the Sensor Type select *Filter Based*.
7. For *Category*, select only *IM*.
8. For *Popularity*, *Technology* and *Risk*, make sure that all of the options are selected.
9. For *Action*, select *Block*.
10. Select *OK* to save the new filter.
11. Select *Apply* to save the sensor.

Next you will assign the sensor to a policy.

To enable application control and select the application sensor

1. Go to *Policy* > *Policy* > *Policy*.
2. Select the security policy that allows the network users to access the Internet and choose *Edit*.

3. Under the heading *Security Profiles* toggle the button next to *Application Control* to turn it on.
4. In the drop down menu field next to the *Application Control* select the *no_IM* application sensor.
5. Select *OK*.

No IM use will be allowed by the security policy. If other firewall policies handle traffic that users could use for IM, enable application control with the *no IM* application sensor for those as well.

Allowing only software updates

Some departments at Example Corporation do not require access to the Internet to perform their duties. Management therefore decided to block their Internet access. Software updates quickly became an issue because automatic updates will not function without Internet access and manual application of updates is time-consuming.

The solution is configuring application control to allow only automatic software updates to access the Internet.

To create an application sensor — web-based manager

1. Go to *Security Profiles* > *Application Control* > *Application Sensors*.
2. Select the *Create New* icon in the title bar of the *Edit Application Sensor* window.
3. In the *Name* field, enter `Updates_Only` as the application sensor name.
4. Select *OK*.
5. Select the *Create New* icon in the sensor.
6. For the Sensor Type select *Filter Based*.
7. Enable only *Update* in the *Category* list.
8. Select *Monitor* from the *Action* list.
9. Select *OK* to save the filter to the sensor.

   The filter just finished filter will allow all software update application traffic.
10. Select the application filter *All Other Known Applications*.
11. Select *Edit*.
12. Select *Block* from the *Action* list.
13. Select *OK*.

    The filter just finished filter will block all traffic from recognized applications that are not specified in this application sensor.
14. Select the *All Other Unknown Applications* entry.
15. Select *Edit*.
16. Select *Block* from the *Action* list.
17. Select *OK*.

    The filter just finished filter will block all traffic from applications that are not recognized by the application control feature.
18. Select *Apply* to save the application sensor.

To create an application sensor — CLI

```
config application list
  edit Updates_Only
    config entries
      edit 1
        set category 17
        set action pass
      end
    set other-application-action block
    set unknown-application-action block
  end
```

You will notice that there are some differences in the naming convention between the Web Based Interface and the CLI. For instance the *Action* in the CLI is "`pass`" and the *Action* in the Web Based Manager is "*Monitor".*

Selecting the application sensor in a security policy

An application sensor directs the FortiGate unit to scan network traffic only when it is selected in a security policy. When an application sensor is selected in a security policy, its settings are applied to all the traffic the security policy handles.

To select the application sensor in a security policy — web-based manager

1. Go to *Policy* > *Policy* > *Policy*.
2. Select a policy.
3. Select the *Edit* icon.
4. Under the heading *Security Profiles* toggle the button next to *Application Control* to turn it on.
5. In the drop down menu field next to the *Application Control* select the `Updates_only` list.
6. Select *OK*.

To select the application sensor in a security policy — CLI

```
config firewall policy
  edit 1
    set utm-status enable
    set profile-protocol-options default
    set application-list Updates_Only
  end
```

Traffic handled by the security policy you modified will be scanned for application traffic. Software updates are permitted and all other application traffic is blocked.

ICAP

ICAP is the acronym for Internet Content Adaptation Protocol The purpose of the feature is to off load work that would normally take place on the firewall to a separate server specifically set up for the specialized processing of the incoming traffic. This takes some of the resource strain off of the FortiGate firewall leaving it to concentrate its resources on things that only it can do.

Off-loading value-added services from Web servers to ICAP servers allows those same web servers to be scaled according to raw HTTP throughput versus having to handle these extra tasks.

ICAP servers are focused on a specific function, for example:

- Ad insertion
- Virus scanning
- Content translation
- HTTP header or URL manipulation
- Language translation
- Content filtering

ICAP does not appear by default in the web-based manager. You must enable it in *System* > *Config* > *Features* to display ICAP in the web-based manager.

The following topics are included in this section:

The Protocol

The protocol is a lightweight member of the TCP/IP suite of protocols. It is an Application layer protocol and its specifications are set out in RFC 3507. The default TCP that is assigned to it is 1344. Its purpose is to support HTTP content adaptation by providing simple object-based content vectoring for HTTP services. ICAP is usually used to implement virus scanning and content filters in transparent HTTP proxy caches. Content Adaptation refers to performing the particular value added service, or content manipulation, for an associated client request/response.

Essentially it allows an ICAP client, in this case the FortiGate firewall, to pass HTTP messages to an ICAP server like a remote procedure call for the purposes of some sort of transformation or other processing adaptation. Once the ICAP server has finished processing the the content, the modified content is sent back to the client.

The messages going back and forth between the client and server are typically HTTP requests or HTTP responses. While ICAP is a request/response protocol similar in semantics and usage

to HTTP/1.1 it is not HTTP nor does it run over HTTP, as such it cannot be treated as if it were HTTP. For instance ICAP messages can not be forwarded by HTTP surrogates.

Offloading using ICAP

If you enable ICAP in a security policy, HTTP traffic intercepted by the policy is transferred to an ICAP server in the ICAP profile added to the policy. Responses from the ICAP server are returned to the FortiGate unit which forwards them to an HTTP client or server.

You can offload HTTP responses or HTTP requests (or both) to the same or different ICAP servers.

If the FortiGate unit supports HTTPS inspection, HTTPS traffic intercepted by a policy that includes an ICAP profile is also offloaded to the ICAP server in the same way as HTTP traffic.

When configuring ICAP on the FortiGate unit, you must configure an ICAP profile that contains the ICAP server information; this profile is then applied to a security policy.

Configuration Settings

There are 2 sections where ICAP is configured:

Servers

The available settings to be configured regarding the profile are

IP Type (in the GUI) or IP address version (in the CLI)

The options for this field in the GUI are 2 radio buttons labelled “IPv4” and “IPv4”. In the CLI the approach is slightly different. There is a field “ip-version” that can be set to “4” or “6”.

IP address

depending on whether you’ve set the IP version to 4 or 6 will determine the format that the content of this field will be set into. In the GUI it looks like the same field with a different format but in the CLI it is actually 2 different fields named “ip-address” and ip6-address.

Maximum Connections

This value refers to the maximum number of concurrent connections that can be made to the ICAP server. The default setting is 100. This setting can only be configured in the CLI.

The syntax is:

```
config icap server
  edit <icap_server_name>
    set max-connections <integer>
    end
```

Port

this is the TCP port used for the ICAP traffic. The range can be from 1 to 65535. The default value is 1344.

Profiles

Enable Request Processing

Enabling this setting allows the ICAP server to process request messages.

If enabled this setting will also require:

- *Server* - This is the name of the ICAP server. It is chosen from the drop down menu in the field. The servers are configure in the Security Profiles > ICAP > Server section.
- *Path* - This is the path on the server to the processing compent. For instance if the Windows share name was “Processes” and the directory within the share was “Content-Filter” the path would be “/Processes/Content-Filter/”
- *On Failure* - There are 2 options. You can choose by the use of radio buttons either *Error* or *Bypass*.

Enable Response Processing

Enabling this setting allows the ICAP server to process response messages.

If enabled this setting will also require:

- *Server* - This is the name of the ICAP server. It is chosen from the drop down menu in the field. The servers are configure in the Security Profiles > ICAP > Server section.
- *Path* - This is the path on the server to the processing compent. For instance if the Windows share name was “Processes” and the directory within the share was “Content-Filter” the path would be “/Processes/Content-Filter/”

On Failure - There are 2 options. You can choose by the use of radio buttons either *Error* or *Bypass*.

Enable Streaming Media Bypass

Enabling this setting allows streaming media to ignore offloading to the ICAP server.

Example ICAP sequence

This example is for an ICAP server performing web URL filtering on HTTP requests

1. A user opens a web browser and sends an HTTP request to connect to a web server.
2. The FortiGate unit intercepts the HTTP request and forwards it to an ICAP server.
3. The ICAP server receives the request and determines if the request is for URL that should be blocked or allowed.
   - If the URL should be blocked the ICAP server sends a response to the FortiGate unit. The FortiGate unit returns this response to the user’s web browser. This response could be a message informing the user that their request was blocked.
   - If the URL should be allowed the ICAP server sends a request to the FortiGate unit. The FortiGate unit forwards the request to the web server that the user originally attempted to connect to.
   - When configuring ICAP on the FortiGate unit, you must configure an ICAP profile that contains the ICAP server information; this profile is then applied to a security policy.

Example Scenerio

Information relavent to the following example:

- The ICAP server is designed to do proprietary content filtering specific to the organization so it will have to receive the messages and sent back appropriate responses.
- The content filter is a required security precaution so it if the message cannot be processed it is not allowed through.
- Resources on both the Fortigate and the ICAP server are considerable so the maximum connections setting will set at a double the default value to analyse the impact on performance.
- The ICAP server's IP address is 172.16.100. 55.
- The path to the processing component is "/proprietary_code/content-filter/".
- Streaming media is not something that the filter considers, but is allowed through the policy so processing it would be a waste of resources.
- The ICAP profile is to be added to an existing firewall policy.
- It is assumed that the display of the policies has already been configured to show the column "ID".

1. Enter the following to configure the ICAP server:

Go to *Security Profiles* > *ICAP* > *Server*.

Use the following values:

Name	content-filtration-server4
IP Type	4
IP Address	172.16.100.55
Port	1344

Use the CLI to set the max-connections value.

```
config icap server
  edit content-filtration-server4
    set max-connections 200
    end
```

2. Enter the following to configure the ICAP profile to then apply to a security policy:

Use the following values:

Name	Prop-Content-Filtration
Enable Request Processing	enable
Server	content-filtration-server4
Path	/proprietary_code/content-filter/
On Failure	Error
Enable Response Processing	enable
Server	content-filtration-server4

Path	/proprietary_code/content-filter/
On Failure	Error
Enable Streaming Media Bypass	enable

3. Apply the ICAP profile to policy:

The purposes of this particular ICAP profile is to filter the content of the traffic coming through the firewall via policy ID#17

a. Go to *Policy* > *Policy* > *Policy.*

b. Open the existing policy ID# 17 for editing.

c. Go to the section *Security Profiles.*

d. Select the button next to *ICAP* so that it indicates that it's status is *ON*.

e. Select the field with the profile name and use the drop down menu to select *Prop-Content-Filtration.*

f. Select *OK*.

Other Security Profiles considerations

The following topics are included in this section:

Profile Groups

One of the options when adding Security profiles to policies is the use of the Profile Groups feature. This works much the same way as an address group or a service group. You assign a selection of Security profiles to the Group and assign the group to a policy. This can be very convenient in an environment that has a large number of policies because instead of deciding each time you make a policy which Security profiles are going to be used you can have a small selection of Profile groups and every policy is assigned one of those groups. If changes need to be make, rather than going into each policy to make individual changes you only have to make changes to the group and the changes automatically propagate through to all of the policies that are using the Profile Group. It makes Security Profiles administration much simpler to implement, simpler to administrate and simpler to remember what Security Profiles features are being assigned to policies.

To refine the application of Security Profiles even further you can use the Profile Group in combination with Identity based policies and User Groups so that depending upon which User group a person belongs to that can be assigned a common set of Security profiles. A good example of this would a school environment. Staff and students are going to have significantly different permissions and restrictions associated with them. Staff will be allow access to websites that children are not (Web Filter). Staff will be allowed to transmit certain data under certain circumstances while students cannot transmit that type of data at all (DLP). Staff might have access to applications to communicate with colleagues in real time while students might be denied social networking access to get them from being distracted from their studies (Application Control). There are a number of permutations and possibilities made simpler and easier to administrate using these features together.

Creating a new group

Security profiles that can be grouped

When setting up a Profile Group you can assign to a group, or not as you want, the following Profile types:

- AntiVirus
- Web Filter
- Application Control
- IPS
- Email Filter
- DLP Sensor
- VoIP
- ICAP

Because the Security profiles need to use one, if you are assigning a Security profile to a policy you must assign a Proxy Option profile.

Using the Web-based Manager

To keep the interface simpler and less cluttered, by default, some versions of the firmware only display a default profile for each of the profile types and a default Profile Group. By going into the Admin Settings section and enabling the display of Multiple Security Profiles the option to have multiple Profile Groups in the Web Based Manager is also enabled.

1. Go to Security Profiles --> Profile Group --> Profile Group
2. Select Create New
3. Give the New Profile group a name.
4. Select the Security Profiles.
   a. Use the check-boxes to determine whether or not a particular Security profile will be assigned.
   b. Use the drop-down menu to determine which Security profile will be used.
   c. Select a Proxy Option profile.

      The Default Proxy Option Profile will be added by default if another profile is not selected.
5. Select OK.

Using the CLI

In the CLI enter the commands:

```
config firewall profile-group
  edit <profile_group_name>
    set profile-protocol-options <protocol_options_name>
    set av-profile <name_of_av-profile>
    set webfilter-profile <name_of_webfilter-profile>
    set spamfilter-profile <name_of_spamfilter-profile>
    set dlp-sensor <name_of_dlp-sensor>
    set ips-sensor <name_of_ips-sensor>
    set application-list <name_of_application-list>
    set voip-profile <name_of_voip-profile>
    set icap-profile <name_of_icap-profile>
    set deep-inspection-options <name_of_deep-inspection-options>
  next
end
```

Adding a Profile Group to a policy

Using the CLI

1. Go to the Firewall policy that you wish to associate the Profile Group
   a. For an Address Firewall policy:
   ```
   config firewall policy
     edit <policyID>
   ```
   b. For an Identity based policy
   ```
   config firewall policy
     edit <policyID>
       config identity-based-policy
         edit <policy_id>
   ```
2. To assign a Profile Group to a security policy the following additional settings need to be added to the policy configuration.
   ```
   set utm-status enable
   set profile-type group
   set profile-group <name of the profile group>
   end
   ```

When adding a Profile Group to a policy there are 2 potential points of confusion:

1. Depending on your interpretation, there may be some confusion on the profile-type setting.
   - `group` indicates the use of a profile group.
   - `single` indicates the use of individual Security profiles.
2. In the CLI, the context, or placement in the "syntax tree" of configuration settings, can make some options available or unavailable depending on other settings.

   In an Address Policy you only have to go down 2 "levels" to have the options for configuring the Profile Groups available.

   When an Identity policy is being used the Profile Group options are not available at the same level. You have to go down a further 2 levels, to inside the Authentication rule that is nested within the overall umbrella of the Firewall Policy. This is where the Profile Group settings will be available to you.

Security Profiles and Virtual domains (VDOMs)

If you enable virtual domains (VDOMs) on your FortiGate unit, all Security Profiles configuration is limited to the VDOM in which you configure it.

While configuration is not shared, the various databases used by Security Profiles features are shared. The FortiGuard antivirus and IPS databases and database updates are shared. The FortiGuard web filter and spam filter features contact the FortiGuard distribution network and access the same information when checking email for spam and web site categories and classification.

Conserve mode

FortiGate units perform all Security Profiles processing in physical RAM. Since each model has a limited amount of memory, conserve mode is activated when the remaining free memory is nearly exhausted or the AV proxy has reached the maximum number of sessions it can service. While conserve mode is active, the AV proxy does not accept new sessions.

The AV proxy

Most content inspection the FortiGate unit performs requires that the files, email messages, URLs, and web pages be buffered and examined as a whole. The AV proxy performs this function, and because it may be buffering many files at the same time, it uses a significant amount of memory. Conserve mode is designed to prevent all the component features of the FortiGate unit from trying to use more memory than it has. Because the AV proxy uses so much memory, conserve mode effectively disables it in most circumstances. As a result, the content inspection features that use the AV proxy are also disabled in conserve mode.

All of the Security Profiles features use the AV proxy with the exception of IPS, application control, DoS as well as flow-based antivirus, DLP, and web filter scanning. These features continue to operate normally when the FortiGate unit enters conserve mode.

Entering and exiting conserve mode

A FortiGate unit will enter conserve mode because it is nearly out of physical memory, or because the AV proxy has reached the maximum number of sessions it can service. The memory threshold that triggers conserve mode varies by model, but it is about 20% free memory. When memory use rises to the point where less than 20% of the physical memory is free, the FortiGate unit enters conserve mode.

The FortiGate unit will leave conserve mode only when the available physical memory exceeds about 30%. When exiting conserve mode, all new sessions configured to be scanned with features requiring the AV proxy will be scanned as normal, with the exception of a unit configured with the one-shot option.

Conserve mode effects

What happens when the FortiGate unit enters conserve mode depends on how you have `av-failopen` configured. There are four options:

off

The off setting forces the FortiGate unit to stop all traffic that is configured for content inspection by Security Profiles features that use the AV proxy. New sessions are not allowed but

current sessions continue to be processed normally unless they request more memory. Sessions requesting more memory are terminated.

For example, if a security policy is configured to use antivirus scanning, the traffic it permits is blocked while in conserve mode. A policy with IPS scanning enabled continues as normal. A policy with both IPS and antivirus scanning is blocked because antivirus scanning requires the AV proxy.

Use the off setting when security is more important than a loss of access while the problem is rectified.

pass

The pass setting allows traffic to bypass the AV proxy and continue to its destination. Since the traffic is bypassing the proxy, no Security Profiles scanning that requires the AV proxy is performed. Security Profiles scanning that does not require the AV proxy continues normally.

Use the pass setting when access is more important than security while the problem is rectified.

Pass is the default setting.

one-shot

The one-shot setting is similar to pass in that traffic is allowed when conserve mode is active. The difference is that a system configured for one-shot will force new sessions to bypass the AV proxy even after it leaves conserve mode. The FortiGate unit resumes use of the AV proxy only when the `av-failopen` setting is changed or the unit is restarted.

idledrop

The idledrop setting will recover memory and session space by terminating all the sessions associated with the host that has the most sessions open. The FortiGate may force this session termination a number of times, until enough memory is available to allow it to leave conserve mode.

The idledrop setting is primarily designed for situations in which malware may continue to open sessions until the AV proxy cannot accept more new sessions, triggering conserve mode. If your FortiGate unit is operating near capacity, this setting could cause the termination of valid sessions. Use this option with caution.

Configuring the av-failopen command

You can configure the av-failopen command using the CLI.

```
config system global
  set av-failopen {off | pass | one-shot | idledrop}
end
```

The default setting is pass.

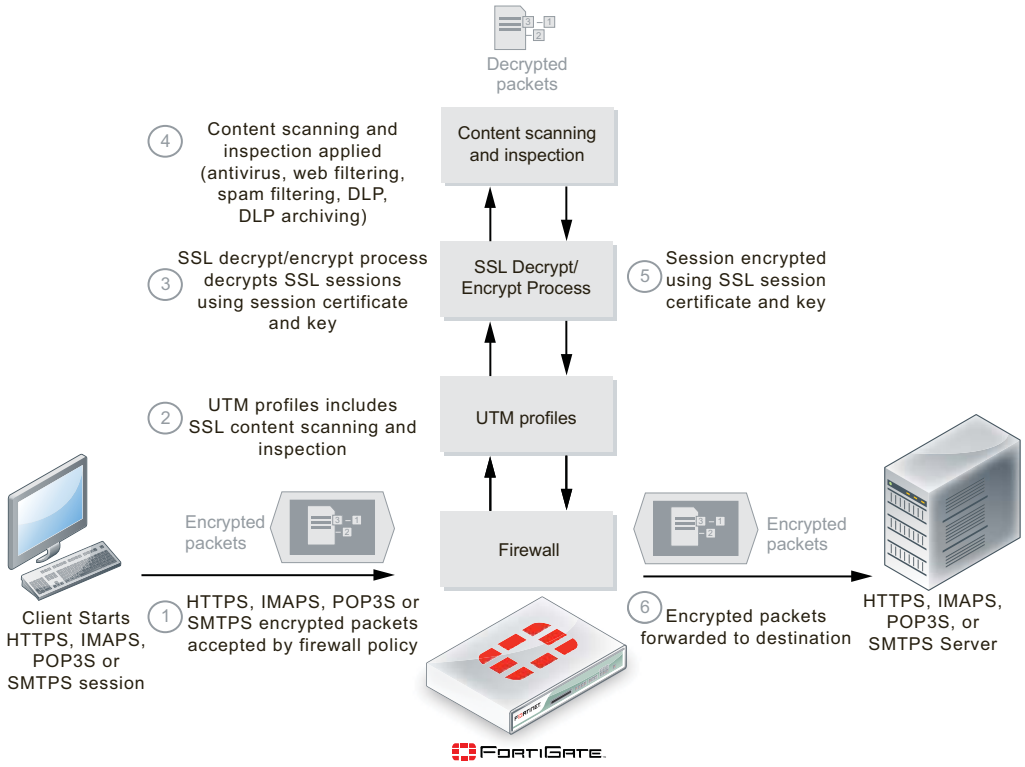
SSL content scanning and inspection

If your FortiGate model supports SSL content scanning and inspection, you can apply antivirus scanning, web filtering, FortiGuard Web Filtering, and email filtering to encrypted traffic. You can

also apply DLP and DLP archiving to HTTPS, IMAPS, POP3S, and SMTPS traffic. To perform SSL content scanning and inspection, the FortiGate unit does the following:

- intercepts and decrypts HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions between clients and servers (FortiGate SSL acceleration speeds up decryption)
- applies content inspection to decrypted content, including:
- HTTPS, IMAPS, POP3S, and SMTPS Antivirus, DLP, and DLP archiving
- HTTPS web filtering and FortiGuard web filtering
- IMAPS, POP3S, and SMTPS email filtering
- encrypts the sessions and forwards them to their destinations.

Figure 312: FortiGate SSL content scanning and inspection packet flow



Setting up certificates to avoid client warnings

To use SSL content scanning and inspection, you need to set up and use a certificate that supports it. FortiGate SSL content scanning and inspection intercepts the SSL keys that are passed between clients and servers during SSL session handshakes and then substitutes spoofed keys. Two encrypted SSL sessions are set up, one between the client and the FortiGate unit, and a second one between the FortiGate unit and the server. Inside the FortiGate unit the packets are decrypted.

While the SSL sessions are being set up, the client and server communicate in clear text to exchange SSL session keys. The session keys are based on the client and server certificates. The FortiGate SSL decrypt/encrypt process intercepts these keys and uses a built-in signing CA certificate named Fortinet_CA_SSLProxy to create keys to send to the client and the server. This signing CA certificate is used only by the SSL decrypt/encrypt process. The SSL decrypt/encrypt process then sets up encrypted SSL sessions with the client and server and uses these keys to decrypt the SSL traffic to apply content scanning and inspection.

Some client programs (for example, web browsers) can detect this key replacement and will display a security warning message. The traffic is still encrypted and secure, but the security warning indicates that a key substitution has occurred.

You can stop these security warnings by importing the signing CA certificate used by the server into the FortiGate unit SSL content scanning and inspection configuration. Then the FortiGate unit creates keys that appear to come from the server and not the FortiGate unit.

You can add one signing CA certificate for SSL content scanning and inspection. The CA certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported for SSL content scanning and encryption.

You can replace the default signing CA certificate, Fortinet_CA_SSLProxy, with another signing CA certificate. To do this, you need the signing CA certificate file, the CA certificate key file, and the CA certificate password.

To add a signing CA certificate for SSL content scanning and inspection

1. Obtain a copy of the signing CA certificate file, the CA certificate key file, and the password for the CA certificate.
2. Go to *System* > *Certificates* > *Local Certificates* and select *Import*.
3. Set *Type* to *Certificate*.
4. For *Certificate file,* use the *Browse* button to select the signing CA certificate file.
5. For *Key file,* use the *Browse* button to select the CA certificate key file.
6. Enter the CA certificate *Password*.
7. Select *OK*.

   The CA certificate is added to the *Local Certificates* list. In this example the signing CA certificate name is Example_CA. This name comes from the certificate file and key file name. If you want the certificate to have a different name, change these file names.
8. Add the imported signing CA certificate to the SSL content scanning and inspection configuration. Use the following CLI command if the certificate name is Example_CA.

   ```
   config firewall ssl setting
     set caname Example_CA
   end
   ```

   The Example_CA signing CA certificate will now be used by SSL content scanning and inspection for establishing encrypted SSL sessions.

SSL content scanning and inspection settings

If SSL content scanning and inspection is available on your FortiGate unit, you can configure SSL settings. The following table provides an overview of the options available and where to find further instruction:

Table 99: SSL content scanning and inspection settings

Setting	Description
Predefined firewall services	The IMAPS, POP3S and SMTPS predefined services. You can select these services in a security policy and a DoS policy.
Protocol recognition	The TCP port numbers that the FortiGate unit inspects for HTTPS, IMAPS, POP3S, and SMTPS. Go to *Policy* > *Policy* > *Proxy Options*. Add or edit a Proxy Options profile, configure HTTPS, IMAPS, POP3S, SMTPS, and FTPS. Using *Proxy Options*, you can also configure the FortiGate unit to perform URL filtering of HTTPS or to use SSL content scanning and inspection to decrypt HTTPS so that the FortiGate unit can also apply antivirus and DLP content inspection and DLP archiving to HTTPS. Using SSL content scanning and inspection to decrypt HTTPS also allows you to apply more web filtering and FortiGuard Web Filtering options to HTTPS. To enable full SSL content scanning of web filtering, select *Enable Deep Scanning* under HTTPS in the Proxy Options profile.
Antivirus	Antivirus options including virus scanning and file filtering for HTTPS, IMAPS, POP3S, and SMTPS. Go to *AntiVirus* > *Profile*. Add or edit a profile and configure *Virus Scan* for HTTPS, IMAPS, POP3S, and SMTPS.
Antivirus quarantine	Antivirus quarantine options to quarantine files in HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions. Go to *Security Profiles* > *AntiVirus* > *Quarantine*. You can quarantine infected files, suspicious files, and blocked files found in HTTPS, IMAPS, POP3S, SMTPS, and FTPS sessions.
Web filtering	Web filtering options for HTTPS: • Web Content Filter • Web URL Filter • ActiveX Filter • Cookie Filter • Java Applet Filter • Web Resume Download Block • Block invalid URLs Go to *Security Profiles* > *Web Filter* > *Profile*. Add or edit a web filter profile and configure web filtering for HTTPS.

Table 99: SSL content scanning and inspection settings (continued)

Setting	Description
FortiGuard Web Filtering	FortiGuard Web Filtering options for HTTPS: • Enable FortiGuard Web Filtering • Enable FortiGuard Web Filtering Overrides • Provide Details for Blocked HTTP 4xx and 5xx Errors • Rate Images by URL (Blocked images will be replaced with blanks) • Allow Websites When a Rating Error Occurs • Strict Blocking • Rate URLs by Domain and IP Address • Block HTTP Redirects by Rating Go to *Security Profiles* > *Web Filter* > *Profile*. Add or edit a profile and configure FortiGuard Web Filtering for HTTPS.
Email filtering	Email filtering options for IMAPS, POP3S, and SMTPS: • FortiGuard Email Filtering IP Address Check, URL check, E-mail Checksum Check, and Spam Submission • IP Address BWL Check • E-mail Address BWL Check • Return S-mail DNS Check • Banned Word Check • Spam Action • Tag Location • Tag Format Go to *Security Profiles* > *Email Filter* > *Profile*. Add or edit a profile and configure email filtering for IMAPS, POP3S, and SMTPS.
Data Leak Prevention	DLP for HTTPS, IMAPS, POP3S, and SMTPS. To apply DLP, follow the steps below: • Go to *Security Profiles* > *Data Leak Prevention* > *Sensor,* create a new DLP sensor or edit an existing one and then add any combination of the DLP advanced rules, DLP compound rules, file filters, a Regular Expressions, and file size limits to a DLP sensor. • Go to *Policy* > *Policy* > *Proxy Options*. Add or edit a profile and select *Enable Deep Scan* under HTTPS. • Go to *Policy* > *Policy* > *Policy*, edit the required policy, enable *DLP Sensor* and select the DLP sensor. • Go to *Policy* > *Policy* > *Policy*, edit the required policy, enable *Proxy Options* and select a profile that has *Enable Deep Scan* selected under HTTPS. **Note**: If no Proxy Options profile is selected, or if *Enable Deep Scan* is not selected within the Proxy Options profile, DLP rules ***cannot*** inspect HTTPS.

Table 99: SSL content scanning and inspection settings (continued)

Setting	Description
DLP archiving	DLP archiving for HTTPS, IMAPS, POP3S, and SMTPS. Add DLP Rules for the protocol to be archived.
Monitor DLP content information on the system dashboard	DLP archive information on the Log and Archive Statistics widget on the system dashboard for HTTPS, IMAPS, POP3S, and SMTPS. Go to *Policy* > *Policy* > *Proxy Options.* Add or edit a profile. For each protocol you want monitored on the dashboard, enable *Monitor Content Information for Dashboard*. These options display meta-information on the Statistics dashboard widget.

Exeptions

Periodically, you will come across situations were SSL and certificates will interfer with the smooth operation of an application or website. For instance, there is a popular application called Dropbox that does not work when deep SSL inspection is enabled. The reason for this is that the trusted certificate authority that is recognised by Dropbox is imbedded in the software and Dropbox cannot be reconfigured to recognise the FortiGate certificates that are used when deep SSL inspection is implimented.

One way to by-pass the deep inspection for Dropbox is to add dropbox.com to a local category in webfiltering and add that local category to the `ftgd-wf-ssl-exempt` list in the webfilter profile. This way any connections with dropbox.com will be exempt from deep SSL inspection.

Whenever an exception is found, the reason that it causes an issue will have to be determined in order to figure out a way to accommodate that application or website.

Monitoring Security Profiles activity

The first two steps in monitoring activity covered by Security profiles is make sure that logging is enabled on the FortiGate and that the policies are configured to collect those logs as traffic goes through them.

Check the Logging and Reporting handbook for configuration of such details as to whether the logs are stored locally on a disk or in memory, or use a remote service of some kind such as a FortiAnalyzer or SNMP server. The important thing is that the storing of logs is taking place somewhere. This is configured by going to Log & Report > Log Config > Log Setting. If you are going to log locally you will also have to enable logging locally in the CLI.

The next step is to get the firewall policies to collect traffic logs. In the configuration of policies there are 3 logging options:

- No log
- Log Security events
- Log all Sessions

Make sure that either Log Security events or Log all sessions is selected.

There are two ways to view the Security Profiles activity based on the collected logs. The first gives you an overview based on a sampling of logs over time. This is good for spotting trends and giving you an idea of the overall impact of a type of Security Profiles threat. For instance you can see if you are a lot of your users are trying to get to sites that you have blocked or which email protocol is receiving the most blocked email.

Go to *Security Profiles* > *Monitor.* From here you can choose information from the differnt types of Security profile that you have running.

From the AV Monitor, you can see information relating to the Antivirus Profile.

- What are the Top Viruses coming through the FortiGate unit, listing:
  - Virus name,
  - Last time it was detected
  - A count of how many times it was detected.

From the Web Monitor you can find information relating to Web filtering. You can choose:

- Report by FortiGuard Webfilter Category
  - Top blocked Categories (pie chart and graph)
  - Total blocked requests
- Report by Webfilter Technicue
  - Pie chart of requests (allowed, etc.)
  - Blocked Requests (Bar chart)
  - Spam
  - Banned Word
  - Virus Archive
  - FortiGuard
  - URL Filter
  - Fragmented
  - DLP

From the Application Monitor you can get an idea of which applications are being used over your network and who is using them by looking at the charts:

- Top Application by Bandwidth
- Top Applications by Session Count
- Top IP/User for…

From the Intrusion Monitor you can determine what are the Top Attacks against your network. The report will list:

- Attack Name
- Last time the attack was detected
- A count of how many times the attack was used

From the Email Monitor

- Total Emails (pie chart)
- Blocked Emails, broken down by
  - Protocol used
  - Reason/technique used to block

From the Archive & Data Leak Monitor you can see what is the:

- Top DLP usage by policy
- Total Dropped Archives

From the FortiGuard Quota you can monitor the status of quotas by seeing which ones are in effect listing:

- User name
- Webfilter Profile
- Used Quota

The second way to look at the logs of the Security Profiles activity is to look at the individual logs. This is useful for trouble shooting and verification of what is being tracked and how because individual log display more information about what happened to the traffic in question.

To look at the logs go to Log and Report > Traffic Log > Forward Traffic and search for individual logged events. In order to see just the Security Profiles based events you may have to first display a column that relates to Security Profiles such as Security Action, Security Event or Security Sub type. Once the appropriate column is displayed in the log window you can then filter based on the criteria that you are searching on. For instance if you were looking for examples of where your DLP profile stopped some traffic from getting out you could go to the Security event column and then filter for the event “dlp”. The log page will now only display dlp events. You could not further refine your filter until you were only looking at the logs that relate to the events they you are trying to track.

Configuring packet logging options

You can use a number of CLI commands to further configure packet logging.

Limiting memory use

When logging to memory, you can define the maximum amount of memory used to store logged packets.

```
config ips settings
  set packet-log-memory 256
end
```

The acceptable range is from 64 to 8192 kilobytes. This command affects only logging to memory.

Limiting disk use

When logging to the FortiGate unit internal hard disk, you can define the maximum amount of space used to store logged packets.

```
config ips settings
  set ips-packet-quota 256
end
```

The acceptable range is from 0 to 4294967295 megabytes. This command affects only logging to disk.

Configuring how many packets are captured

Since the packet containing the signature is sometimes not sufficient to troubleshoot a problem, you can specify how many packets are captured before and after the packet containing the IPS signature match.

```
config ips settings
  packet-log-history
  packet-log-post-attack
end
```

The `packet-log-history` command specifies how many packets are captured before and including the one in which the IPS signature is detected. If the value is more than `1`, the packet containing the signature is saved in the packet log, as well as those preceding it, with the total number of logged packets equalling the `packet-log-history` setting. For example, if `packet-log-history` is set to `7`, the FortiGate unit will save the packet containing the IPS signature match and the six before it.

The acceptable range for `packet-log-history` is from 1 to 255. The default is 1.

Setting `packet-log-history` to a value larger than `1` can affect the performance of the FortiGate unit because network traffic must be buffered. The performance penalty depends on the model, the setting, and the traffic load.

The `packet-log-post-attack` command specifies how many packets are logged after the one in which the IPS signature is detected. For example, if `packet-log-post-attack` is set to `10`, the FortiGate unit will save the ten packets following the one containing the IPS signature match.

The acceptable range for `packet-log-post-attack` is from 0 to 255. The default is 0.

Using wildcards and Perl regular expressions

Many Security Profiles feature list entries can include wildcards or Perl regular expressions.

For more information about using Perl regular expressions, see http://perldoc.perl.org/perlretut.html.

Regular expression vs. wildcard match pattern

A wildcard character is a special character that represents one or more other characters. The most commonly used wildcard characters are the asterisk (*), which typically represents zero or more characters in a string of characters, and the question mark (?), which typically represents any one character.

In Perl regular expressions, the '.' character refers to any single character. It is similar to the '?' character in wildcard match pattern. As a result:

- example.com not only matches example.com but also examplea.com, exampleb.com, examplec.com, and so on.

To add a question mark (`?`) character to a regular expression from the FortiGate CLI, enter Ctrl+V followed by ?. To add a single backslash character (\) to a regular expression from the CLI you must add precede it with another backslash character. For example, `example\\.com`.

To match a special character such as '.' and '*' use the escape character '\'. For example:

- To match example.com, the regular expression should be: example\.com

In Perl regular expressions, '*' means match 0 or more times of the character before it, not 0 or more times of any character. For example:

- exam*.com matches exammmm.com but does not match example.com

To match any character 0 or more times, use '.*' where '.' means any character and the '*' means 0 or more times. For example, the wildcard match pattern exam*.com should therefore be exam.*\.com.

Word boundary

In Perl regular expressions, the pattern does not have an implicit word boundary. For example, the regular expression “test” not only matches the word “test” but also any word that contains “test” such as “atest”, “mytest”, “testimony”, “atestb”. The notation “\b” specifies the word boundary. To match exactly the word “test”, the expression should be \btest\b.

Case sensitivity

Regular expression pattern matching is case sensitive in the web and Email Filter filters. To make a word or phrase case insensitive, use the regular expression `/i`. For example, `/bad language/i` will block all instances of “bad language”, regardless of case.

Perl regular expression formats

Table 100 lists and describes some example Perl regular expressions.

Table 100: Perl regular expression formats

Expression	Matches
abc	“abc” (the exact character sequence, but anywhere in the string)
^abc	“abc” at the beginning of the string
abc$	“abc” at the end of the string
a|b	Either “a” or “b”
^abc|abc$	The string “abc” at the beginning or at the end of the string
ab{2,4}c	“a” followed by two, three or four “b”s followed by a “c”
ab{2,}c	“a” followed by at least two “b”s followed by a “c”
ab*c	“a” followed by any number (zero or more) of “b”s followed by a “c”
ab+c	“a” followed by one or more b's followed by a c
ab?c	“a” followed by an optional “b” followed by a” c”; that is, either “abc” or ”ac”
a.c	“a” followed by any single character (not newline) followed by a” c “
a\.c	“a.c” exactly
[abc]	Any one of “a”, “b” and “c”
[Aa]bc	Either of “Abc” and “abc”
[abc]+	Any (nonempty) string of “a”s, “b”s and “c”s (such as “a”, “abba”, ”acbabcacaa”)
[^abc]+	Any (nonempty) string which does not contain any of “a”, “b”, and “c” (such as “defg”)
`\d\d`	Any two decimal digits, such as 42; same as \d{2}
/i	Makes the pattern case insensitive. For example, `/bad language/i` blocks any instance of `bad language` regardless of case.

Table 100: Perl regular expression formats (continued)

\w+	A “word”: A nonempty sequence of alphanumeric characters and low lines (underscores), such as foo and 12bar8 and foo_1
100\s*mk	The strings “100” and “mk” optionally separated by any amount of white space (spaces, tabs, newlines)
abc\b	“abc” when followed by a word boundary (for example, in “abc!” but not in “abcd”)
perl\B	“perl” when not followed by a word boundary (for example, in “perlert” but not in “perl stuff”)
\x	Tells the regular expression parser to ignore white space that is neither preceded by a backslash character nor within a character class. Use this to break up a regular expression into (slightly) more readable parts.
/x	Used to add regular expressions within other text. If the first character in a pattern is forward slash '/', the '/' is treated as the delimiter. The pattern must contain a second '/'. The pattern between ‘/’ will be taken as a regular expressions, and anything after the second ‘/’ will be parsed as a list of regular expression options ('i', 'x', etc). An error occurs if the second '/' is missing. In regular expressions, the leading and trailing space is treated as part of the regular expression.

Examples of regular expressions

Block any word in a phrase

/block|any|word/

Block purposely misspelled words

Spammers often insert other characters between the letters of a word to fool spam blocking software.

/^.*v.*i.*a.*g.*r.*o.*$/i

/cr[eéèêë][\+\-*=<>\.\,;!\?%&§@\^°\$£€\{\}()\[\]\|_01]dit/i

Block common spam phrases

The following phrases are some examples of common phrases found in spam messages.

/try it for free/i

/student loans/i

/you’re already approved/i

/special[\+\-*=<>\.\,;!\?%&~#§@\^°\$£€\{\}()\[\]\|_1]offer/i

Monitor interface reference

The Monitor submenus allow you to view the Security Profiles activity occurring on your network. You must have Security Profiles and sensors applied to firewall policies, as well as logging enabled for the profiles and sensors, for the monitors to display any information regarding this activity.

This topic contains the following:

AV Monitor

The AV Monitor submenu allows you to view statistical information regarding viruses that were detected on your unit from *Security Profiles* > *Monitor* > *AV Monitor*. The information displays in a bar chart as well as in a table below the bar chart. The table contains detailed information.

You must have antivirus logging enabled for this within the profile itself, as well as within log settings and an antivirus profile is applied to a firewall policy.

AV Monitor page

Displays monitored information about viruses that were detected by the unit.

Tip: To view information about a specific virus, select a bar within the chart; the virus FortiGuard definition displays.

Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Top Viruses (all policies) since <yyyy-mm-dd hh:mm:ss>	The top viruses detected by the unit using all firewall policies.
#	The order that the viruses are listed in the table.
Virus Name	The name of the virus.
Last Detected	The last time that the virus was detected.
Count	The number of times the virus has been detected.

Intrusion Monitor

The Intrusion Monitor submenu allows you to view statistical information regarding attacks that were detected on your unit from *Security Profiles* > *Monitor* > *Intrusion Monitor*. The information

displays in a bar chart as well as in a table below the bar chart. The table contains detailed information.

Intrusion Monitor page	
Displays monitored information about attacks that were detected by the unit. **Tip:** To view information about a specific attack, select a bar within the chart; the attack FortiGuard definition displays.	
Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Top Attacks (all policies) since <yyyy-mm-dd hh:mm:ss>	A bar chart displaying the top attacks detected by the unit.
#	The order that the attacks are listed in the table.
Attack Name	The name of the attack.
Last Detected	The last time that the attack was detected.
Count	The number of times the attack has been detected.

Web Monitor

The Web Monitor submenu allows you to view statistical information regarding the web activity from *Security Profiles* > *Monitor* > *Web Monitor*. The information displays in both a pie chart and a bar chart .

Web Monitor page	
Displays monitored information about web activity detected by the unit.	
Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Report By	Select whether to view the web filter monitored information by web filter technique or by FortiGuard web filter category. If you choose FortiGuard web filter category, you are viewing the information that was gathered from the category settings for FortiGuard web filter from the web filter profile.
Web Monitor since <yyyy-mm-dd hh:mm:ss>	
Total Requests (HTTP)	A pie chart representing the total requests detected.

Blocked Requests (HTTP)	A bar chart representing the total blocked requests detected. The information is broken down to spam, banned words, file filter, viruses, archives, FortiGuard, URL filter, and fragmented.
Total Web Requests (HTTP): <number>	The total number of web requests over HTTP that occurred.

Email Monitor

The Email Monitor submenu allows you to view statistical information regarding email filtering from *Security Profiles* > *Monitor* > *Email Monitor*. The information displays in both a pie chart and bar chart.

Email Monitor page	
Displays monitored information about email filter activity detected by the unit.	
Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Total Emails	A pie chart representing the total number of emails scanned by the unit.
Blocked Emails	A bar chart representing the total number of blocked emails, broken down by protocol. The colors indicate the type of scanning that occurred.
Total Emails: <number>	The total number of email messages detected by the unit.

Archive & Data Leak Monitor

The Archive & Data Leak Monitor submenu allows you to view statistical information regarding log archives, as well as DLP usage. This page displays the information in a bar chart in *Security Profiles* > *Monitor* > *Archive & Data Leak Monitor*.

Archive & Data Leak Monitor page	
Displays monitored information about archive and DLP activity detected by the unit.	
Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Report By:	Select what type of DLP information you want to view. You can view DLP usage by DLP sensor, firewall policy usage, or by protocol.
Top DLP Usage by DLP Sensor <yyyy-mm-dd hh:mm:ss>	The bar chart that displays DLP usage monitored using DLP sensor information.

Top DLP Usage by Policy <yyyy-mm-dd hh:mm:ss>	The bar chart that displays DLP usage monitored using firewall policy traffic information.
Top DLP Usage by Protocol <yyyy-mm-dd hh:mm:ss>	The bar chart that displays DLP usage monitored using protocol information.
Total Dropped Archives: <number>	The total number of dropped DLP archives.

Application Monitor

The Application Monitor submenu allows you to view statistical information regarding application usage in *Security Profiles* > *Monitor* > *Application Monitor*.

Application Monitor page

Displays monitored information about the application usage detected by the unit.

Tip: To view top source IP addresses for a specific application, select a bar in the chart to view that application's source IP addresses.

Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Top Application Usage by <yyyy-mm-dd hh:mm:ss>	The bar chart that displays the top applications being used detected by the unit.
Resolve Host Name	Appears after selecting a bar for a specific application, for example SSL. Select to resolve the host name. **Tip:** Hover your mouse over the bar to view the address and total MB (or KB) used for that application.
Report By:	Appears after selecting a bar for a specific application, for example, SSL. Select to view the detailed information by destination address, or source address.
Display User Name	Appears after selecting *Source Address* from the drop-down list beside *Report By*. Select to display user names.

FortiGuard Quota

The FortiGuard Quota submenu allows you to view statistical information regarding quota usage by users in *Security Profiles* > *Monitor* > *FortiGuard Quota*.

FortiGuard Quota page	
Lists the users and the amount of quota that they have used.	
Page Controls	Use to navigate through the list.
User Name	The user name of the user that has FortiGuard quota enabled for them.
Webfilter Profile	The web filter profile that was used for detecting users' FortiGuard quota usage.
Used Quota	The amount of used quota by a user.

Endpoint Monitor

You can view monitored endpoints in *Security Profiles* > *Monitor* > *Endpoint Monitor*. An endpoint is added to the list when it uses a security policy that has *Endpoint Security* enabled.

Endpoint Monitor page	
Provides information about endpoints, such as endpoint traffic. Note: The pie chart displays information in percent and indicates which is non-compliant and which is compliant.	
Refresh	Updates the list, providing current endpoints that are being monitored.
Report By	Select to view endpoint information by traffic, status or application usage. When you select *Status*, a pie chart appears along with information about the total endpoints (*Total Endpoints*). When you select *Traffic* or *Application usage*, a bar chart appears; select a bar to view detailed information.

Chapter 16 SSL VPN for FortiOS 5.0

- Introduction to SSL VPN provides useful general information about VPN and SSL, how the FortiGate unit implements them, and gives guidance on how to choose between SSL and IPsec.
- Basic Configuration explains how to configure the FortiGate unit and the web portal. Along with these configuration details, this chapter also explains how to grant unique access permissions, configure the SSL virtual interface (`ssl.root`), and describes the SSL VPN OS Patch Check feature that allows a client with a specific OS patch to access SSL VPN services.
- The SSL VPN client provides an overview of the FortiClient software required for tunnel mode, where to obtain the software, install it and the configuration information required for remote users to connect to the internal network.
- Setup examples explores several configuration scenarios with step-by-step instructions. While the information provided is enough to set up the described SSL VPN configurations, these scenarios are not the only possible SSL VPN setups.

Introduction to SSL VPN

Over the past several years, as organizations have grown and become more complex, secure remote access to network resources has become critical for day-to-day operations. In addition, businesses are expected to provide clients with efficient, convenient services including knowledge bases and customer portals. Employees travelling across the country or around the world require timely and comprehensive access to network resources. As a result of the growing need for providing remote/mobile clients with easy, cost-effective and secure access to a multitude of resources, the concept of a Virtual Private Network was developed.

SSL VPNs establish connectivity using SSL, which functions at Levels 4 - 5 (Transport and Session). Information is encapsulated at Levels 6 - 7 (Presentation and Application), and SSL VPNs communicate at the highest levels in the OSI model. SSL is not strictly a Virtual Private Network (VPN) technology allows clients to connect to remote networks in a secure way. A VPN is a secure logical network created from physically separate networks. VPNs use encryption and other security methods to ensure that only authorized users can access the network. VPNs also ensure that the data transmitted between computers cannot be intercepted by unauthorized users. When data is encoded and transmitted over the Internet, the data is said to be sent through a “VPN tunnel”. A VPN tunnel is a non-application oriented tunnel that allows the users and networks to exchange a wide range of traffic regardless of application or protocol.

The advantages of a VPN over an actual physical private network are two-fold. Rather than utilizing expensive leased lines or other infrastructure, you use the relatively inexpensive, high-bandwidth Internet. Perhaps more important though is the universal availability of the Internet - in most areas, access to the Internet is readily obtainable without any special arrangements or long wait times.

SSL (Secure Sockets Layer) as HTTPS is supported by most web browsers for exchanging sensitive information securely between a web server and a client. SSL establishes an encrypted link, ensuring that all data passed between the web server and the browser remains private and secure. SSL protection is initiated automatically when a user (client) connects to a web server that is SSL-enabled. Once the successful connection is established, the browser encrypts all the information before it leaves the computer. When the information reaches its destination, it is decrypted using a secret (private) key. Any data sent back is first encrypted, and is decrypted when it reaches the client.

FortiOS supports the SSL and TLS versions defined below.

Version	RFC
SSL 2.0	RFC 6176
SSL 3.0	RFC 6101
TLS 1.0	RFC 2246
TLS 1.1	RFC 4346
TLS 1.2	RFC 5246

Table 101. SSL and TLS version support table.

SSL VPN modes of operation

When a remote client connects to the FortiGate unit, the FortiGate unit authenticates the user based on user name, password, and authentication domain. A successful login determines the access rights of remote users according to user group. The user group settings specify whether the connection will operate in web-only mode or tunnel mode.

Web-only mode

Web-only mode provides remote users with a fast and efficient way to access server applications from any thin client computer equipped with a web browser. Web-only mode offers true clientless network access using any web browser that has built-in SSL encryption and the Sun Java runtime environment.

Support for SSL VPN web-only mode is built into the FortiOS operating system. The feature comprises of an SSL daemon running on the FortiGate unit, and a web portal, which provides users with access to network services and resources including HTTP/HTTPS, telnet, FTP, SMB/CIFS, VNC, RDP and SSH.

In web-only mode, the FortiGate unit acts as a secure HTTP/HTTPS gateway and authenticates remote users as members of a user group. After successful authentication, the FortiGate unit redirects the web browser to the web portal home page and the user can access the server applications behind the FortiGate unit.

When the FortiGate unit provides services in web-only mode, a secure connection between the remote client and the FortiGate unit is established through the SSL VPN security in the FortiGate unit and the SSL security in the web browser. After the connection has been established, the FortiGate unit provides access to selected services and network resources through a web portal.

FortiGate SSL VPN web portals have a 1- or 2-column page layout and portal functionality is provided through small applets called widgets. Widget windows can be moved or minimized. The controls within each widget depend on its function. There are predefined web portals and the administrator can create additional portals.

Configuring the FortiGate unit involves selecting the appropriate web portal configuration in the user group settings. These configuration settings determine which server applications can be accessed. SSL encryption is used to ensure traffic confidentiality.

For information about client operating system and browser requirements, see the Release Notes for your FortiGate firmware.

Tunnel mode

Tunnel mode offers remote users the freedom to connect to the internal network using the traditional means of web-based access from laptop computers, as well as from airport kiosks, hotel business centers, and Internet cafés. If the applications on the client computers used by your user community vary greatly, you can deploy a dedicated SSL VPN client to any remote client through its web browser. The SSL VPN client encrypts all traffic from the remote client computer and sends it to the FortiGate unit through an SSL VPN tunnel over the HTTPS link between the web browser and the FortiGate unit. Another option is split tunneling, which ensures that only the traffic for the private network is sent to the SSL VPN gateway. Internet traffic is sent through the usual unencrypted route. This conserves bandwidth and alleviates bottlenecks.

In tunnel mode, remote clients connect to the FortiGate unit and the web portal login page using Microsoft Internet Explorer, Firefox, Chrome, Mac OS, or Linux. The FortiGate unit acts as a secure HTTP/HTTPS gateway and authenticates remote users as members of a user group. After successful authentication, the FortiGate unit redirects the web browser to the web portal

home page dictated by the user group authentication settings. If the user does not have the SSL VPN client installed, they will be prompted to download the SSL VPN client (an ActiveX or Java plugin) and install it using controls provided through the web portal. SSL VPN tunnel mode can also be initiated from a standalone application on Windows, Mac OS, and Linux.

When the user initiates a VPN connection with the FortiGate unit through the SSL VPN client, the FortiGate unit establishes a tunnel with the client and assigns the client a virtual IP address from a range of reserved addresses. The client uses the assigned IP address as its source address for the duration of the connection. After the tunnel has been established, the user can access the network behind the FortiGate unit.

Configuring the FortiGate unit to establish a tunnel with remote clients involves enabling the feature through SSL VPN configuration settings and selecting the appropriate web portal configuration for tunnel-mode access in the user group settings. The security policy and protection profiles on the FortiGate unit ensure that inbound traffic is screened and processed securely.

The user account used to install the SSL VPN client on the remote computer must have administrator privileges.

If you are using Windows Vista, you must disable UAC (User Account Control) before installing the SSL VPN tunnel client. This UAC setting must be disabled before the SSL VPN tunnel client is installed. IE7 in Windows Vista runs in Protected Mode by default. To install SSL VPN client ActiveX, you need to launch IE7 by using 'Run as administrator' (right-click the IE7 icon and select 'Run as administrator').

For information about client operating system requirements, see the Release Notes for your FortiGate firmware. For information on configuring tunnel mode, see “Tunnel mode and split tunneling” on page 2203.

Port forwarding mode

While tunnel mode provides a Layer 3 tunnel that users can run any application over it, the user needs to install the tunnel client, and have the required administrative rights to do so. In some situations, this may not be desirable, yet the simple web mode does not provide enough flexibility for application support. For example, using an email client that needs to communicate with a POP3 server. The port forward mode, or proxy mode, provides this middle ground between web mode and tunnel mode.

SSL VPN port forwarding listens on local ports on the user’s computer. When it receives data from a client application, the port forward module encrypts and sends the data to the FortiGate unit, which then forwards the traffic to the application server.

The port forward module is implemented with a Java applet, which is downloaded and runs on the user’s computer. The applet provides the up-to-date status information such as addressing and bytes sent and received.

On the user end, the user logs into the FortiGate SSL VPN portal, and selects a port forward bookmark configured for a specific application. The bookmark defines the server address and port as well as which port to listen to on the user's computer.

The user must configure the application on the PC to point to the local proxy instead of the application server. For information on this configuration change, see the application documentation.

This mode only supports client/server applications that are using a static TCP port. It will not support client/server applications using dynamic ports or traffic over UDP.

For information on configuring a port forward tunnel, see "Port forward tunnel" on page 2203.

Application support

With Citrix application servers, the server downloads an ICA configuration file to the user's PC. The client application uses this information to connect to the Citrix server. The FortiGate unit will read this file and append a SOCKS entry to set the SOCKS proxy to localhost. The Citrix client will then be able to connect to the SSL VPN port forward module to provide the connection. When configuring the port forwarding module, an selection is available for Citrix servers.

For Windows Remote Desktop Connections, when selecting the RDP option, the tunnel will launch the RDP client and connect to the local loopback address after the port forward module has been initiated.

SSL VPN and IPv6

FortiOS supports SSL VPN using IPv6 addressing using IPv6 configurations for security policies and addressing including:

- Policy matching for IPv6 addresses
- Support for DNS resolving in SSL VPN
- Support IPv6 for ping
- FTP applications
- SMB
- Support IPV6 for all the java applets (Telnet, VNC, RDP and so on)

Traveling and security

Because SSL VPN provides a means for "on-the-go" users to dial in to the network while away from the office, you need to ensure that wherever and however they choose to dial in is secure, and not potentially compromising the corporate network.

When setting up the portal, you can include two options to ensure corporate data is safe; a host check for antivirus software, and a cache cleaner.

Host check

You can enable a host integrity checker to scan the remote client. The integrity checker probes the remote client computer to verify that it is safe before access is granted. Security attributes recorded on the client computer (for example, in the Windows registry, in specific files, or held in memory due to running processes) are examined and uploaded to the FortiGate unit.

For more information, see "Host check" on page 2212.

Cache cleaning

You can enable a cache cleaner to remove any sensitive data that would otherwise remain on the remote computer after the session ends. For example, all cache entries, browser history, cookies, encrypted information related to user authentication, and any temporary data generated during the session are removed from the remote computer. If the client's browser cannot install and run the cache cleaner, the user is not allowed to access the SSL-VPN portal.

For more information, see "Configuring cache cleaning" on page 2214.

Basic Configuration

Configuring SSL VPN involves a number of configurations within FortiOS that you need to complete to make it all come together. This chapter describes the components required, and how and where to configure them to set up the FortiGate unit as an SSL VPN server. The configurations and steps are high level, to show you the procedures needed, and where in FortiOS they are located. For real-world examples, see the chapter, "Setup examples" on page 2221.

There are three or four key steps to configuring an SSL VPN tunnel. The first three in the points below are mandatory, while the other is optional. This chapter will outline these four key steps, as well as additional configuration you can do for tighter security and monitoring.

The key steps are:

- Create user accounts and user groups for the remote clients.
  ("User accounts and groups" on page 2195)
- Create a web portal to define user access to network resources.
  ("Configuring SSL VPN web portals" on page 2199)
- Configure the security policies.
  ("Configuring security policies" on page 2204)
- For tunnel-mode operation, add routing to ensure that client tunnel-mode packets reach the SSL VPN interface.
  ("Routing in tunnel mode" on page 2211)
- Setup logging of SSL VPN activities.
  ("SSL VPN logs" on page 2216)

User accounts and groups

The first step for an SSL VPN tunnel is to add the users and user groups that will access the tunnel. You may already have users defined for other authentication-based security policies. These users and groups are identified when creating the security policy when defining the authentication rules.

The user group is associated with the web portal that the user sees after logging in. You can use one policy for multiple groups, or multiple policies to handle differences between the groups such as access to different services, or different schedules.

To create a user account

- in the web-based manager, go to *User & Device* > *User* > *User Definition*, and select *Create New.*
- in the CLI, use the commands in `config user local`.

All users accessing the SSL tunnel must be in a firewall user group. User names can be up to 64 characters long.

To create user groups

- in the web-based manager, go to *User & Device* > *User* > *User Groups* and select *Create New*.
- in the CLI, use the commands in `config user group`.

Authentication

Remote users must be authenticated before they can request services and/or access network resources through the web portal. The authentication process can use a password defined on the FortiGate unit or optionally use established external authentication mechanisms such as RADIUS or LDAP.

To authenticate users, you can use a plain text password on the FortiGate unit (Local domain), forward authentication requests to an external RADIUS, LDAP or TACACS+ server, or utilize PKI certificates.

For information about how to create RADIUS, LDAP, TACACS+ or PKI user accounts and certificates, see the *Authentication* chapter of *The Handbook*.

FortiOS supports LDAP password renewal notification and updates through SSL VPN. Configuration is enabled using the CLI commands:

```
config user ldap
  edit <username>
    set password-expiry-warning enable
    set password-renewal enable
end
```

MAC host check

When a remote client attempts to log in to the portal, you can have the FortiGate unit check against the client's MAC address to ensure that only a specific computer or device is connecting to the tunnel. This can ensure better security should a password be compromised.

MAC addresses can be tied to specific portals and can be either the entire MAC address or a subset of it. MAC host checking is configured in the CLI using the commands:

```
conf vpn ssl web portal
  edit portal
    set mac-addr-check enable
    set mac-addr-action allow
      config mac-addr-check-rule
        edit "rule1"
          set mac-addr-list 01:01:01:01:01:01 08:00:27:d4:06:5d
          set mac-addr-mask 48
      end
  end
```

IP addresses for users

After the FortiGate unit authenticates a request for a tunnel-mode connection, the FortiGate unit assigns the SSL VPN client an IP address for the session. The address is assigned from an address range (IP Pool) which is a firewall address that defines an IP address range.

Take care to prevent overlapping IP addresses. Do not assign to clients any IP addresses that are already in use on the private network. As a precaution, consider assigning IP addresses from a network that is not commonly used (for example, 10.254.254.0/24).

To set tunnel-mode client IP address range - web-based manager

1. Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New*.
2. Enter an *Name*, for example, `SSL_VPN_tunnel_range`.
3. Select a *Type* of *IP Range*.
4. In the *Subnet/IP Range* field, enter the starting and ending IP addresses that you want to assign to SSL VPN clients, for example `10.254.254.[80-100]`.
5. In *Interface*, select *Any*.
6. Select *OK*.

To set tunnel-mode client IP address range - CLI

If your SSL VPN tunnel range is for example 10.254.254.80 - 10.254.254.100, you could enter

```
config firewall address
  edit SSL_tunnel_users
    set type iprange
    set end-ip 10.254.254.100
    set start-ip 10.254.254.80
  end
end
```

You can select the tunnel-mode IP Pools in two places:

- The *VPN* > *SSL* > *Config* page *IP Pools* setting applies to all web portals that do not specify their own IP Pools.
- The web portal Tunnel Mode widget IP Pools setting, if used, applies only to the web portal and overrides the setting in *VPN* > *SSL* > *Config*. See "Tunnel mode and split tunneling" on page 2203.

Authentication of remote users

When remote users connect to the SSL VPN tunnel, they must perform authentication before being able to use the internal network resources. This can be as simple as assigning users with their own passwords, connecting to an LDAP server or using more secure options. FortiOS provides a number of options for authentication as well as security option for those connected users.

The web portal can include bookmarks to connect to internal network resources. A web (HTTP/HTTPS) bookmark can include login credentials so that the FortiGate unit automatically logs the user into the web site. This means that the user logs into the SSL VPN and then does not have to enter any more credentials to visit preconfigured web sites.

Both the administrator and the end user can configure bookmarks, including SSO bookmarks. To add bookmarks as a web portal user, see "Adding bookmarks" on page 2202.

Setting the client authentication timeout

The client authentication timeout controls how long an authenticated user will remain connected. When this time expires, the system forces the remote client to authenticate again. As with the idle timeout, a shorter period of time is more secure. The default value is 28800 seconds (8 hours). You can only modify this timeout value in the CLI.

For example, to change the authentication timeout to 18 000 seconds, enter the following commands:

```
config vpn ssl settings
  set auth-timeout 18000
end
```

You can also set the idle timeout for the client, to define how long the user does not access the remote resources before they are logged out. For information see "SSL connection configuration" on page 2200.

Allow one time login per user

You can set the SSL VPN tunnel such that each user can only log into the tunnel one time concurrently per user per login. That is, once logged into the portal, they cannot go to another system and log in with the same credentials again.

To do this, go to *VPN* > *SSL* > *Portal* and select to disable *Allow Multiple Concurrent Sessions for Each User*. It is enabled by default.

To configure in the CLI, enter the commands:

```
config vpn ssl web portal
  edit <portal_name>
    set limit-user-logins enable
end
```

Once set, once the user has logged in, no other user can use the same login credentials.

Strong authentication with security certificates

The FortiGate unit supports strong (two-factor) authentication through X.509 security certificates (version 1 or 3). The FortiGate unit can require clients to authenticate using a certificate. Similarly, the client can require the FortiGate unit to authenticate using a certificate.

For information about obtaining and installing certificates, see the *Authentication* chapter of *The Handbook*.

You can select the *Require Client Certificate* option in *SSL VPN config* so that clients must authenticate using certificates. The client browser must have a local certificate installed, and the FortiGate unit must have the corresponding CA certificate installed.

When the remote client initiates a connection, the FortiGate unit prompts the client browser for its client-side certificate as part of the authentication process.

To require client authentication by security certificates - web-based manager

1. Go to *VPN* > *SSL* > *Config*.
2. Select *Require Client Certificate*.
3. Select *Apply*.

To require client authentication by security certificates - CLI

```
config vpn ssl settings
  set reqclientcert enable
end
```

If your SSL VPN clients require strong authentication, the FortiGate unit must offer a CA certificate that the client browser has installed.

In the FortiGate unit SSL VPN settings, you can select which certificate the FortiGate offers to authenticate itself. By default, the FortiGate unit offers its factory installed (self-signed) certificate from Fortinet to remote clients when they connect.

To enable FortiGate unit authentication by certificate - web-based manager

1. Go to *VPN* > *SSL* > *Config*.
2. From the *Server Certificate* list, select the certificate that the FortiGate unit uses to identify itself to SSL VPN clients.
3. Select *Apply*.

To enable FortiGate unit authentication by certificate - CLI

For example, to use the `example_cert` certificate

```
config vpn ssl settings
  set servercert example_cert
end
```

FortiOS will check the server certificate to verify that the certificate is valid. Only valid server certificates should be used.

NSA Suite B cryptography support

FortiOS supports the use of ECDSA Local Certificates for SSL VPN Suite B. The National Security Agency (NSA) developed Suite B algorithms in 2005 to serve as a cryptographic base for both classified and unclassified information at an interoperable level.

FortiOS allows you to import, generate, and use ECDSA certificates defined by the Suite B cryptography set. To generate ECDSA certificates, use the following command in the CLI:

```
exec vpn certificate local generate ec
```

Configuring SSL VPN web portals

The SSL VPN portal enables remote users to access internal network resources through a secure channel using a web browser. FortiGate administrators can configure log in privileges for system users and which network resources are available to the users.

This step in the configuration of the SSL VPN tunnel sets up the infrastructure; the addressing, encryption, and certificates needed to make the initial connection to the FortiGate unit. This step also is where you set up what the remote user sees when the connection is successful. The portal view defines what resources are available to the remote users and what functionality they have on the network.

SSL connection configuration

To configure the basic SSL VPN settings for encryption and log in options, go to *VPN* > *SSL* > *Config.*

IP Pools	Select *Edit* to select the range or subnet firewall addresses that represent IP address ranges reserved for tunnel-mode SSL VPN clients.
Server Certificate	Select the signed server certificate to use for authentication. If you leave the default setting (Self-Signed), the FortiGate unit offers its factory installed certificate from Fortinet, to remote clients when they connect.
Require Client Certificate	Select to use group certificates for authenticating remote clients. When the remote client initiates a connection, the FortiGate unit prompts the client for its client-side certificate as part of the authentication process. For information on using PKI to provide client certificate authentication, see the *Authentication Guide*.
Encryption Key Algorithm	Select the algorithm for creating a secure SSL connection between the remote client web browser and the FortiGate unit. This will depend on what the web browser of the client can support. The FortiGate unit supports a range of cryptographic cipher suites to match the capabilities of various web browsers. The web browser and the FortiGate unit negotiate a cipher suite before any information is transmitted over the SSL link.
Idle Timeout	Type the period of time (in seconds) that the connection can remain idle before the user must log in again. The range is from 10 to 28800 seconds. Setting the value to 0 will disable the idle connection timeout. This setting applies to the SSL VPN session. The interface does not time out when web application sessions or tunnels are up. You can also set the authentication timeout for the client, to define how long the user can remain connected to the network. For information see "Setting the client authentication timeout" on page 2197.
Login Port	Enter the port number for HTTPS access.
Enable Endpoint Registration	Select so that FortiClient registers with the FortiGate unit when connecting. If you configured a registration key by going to *System* > *Config* > *Advanced*, the remote user is prompted to enter the key. This only occurs on the first connection to the FortiGate unit.
Advanced (DNS and WINS Servers)	Enter up to two DNS servers and/or two WINS servers to be provided for the use of clients.

Portal configuration

The portal configuration determines what the remote user sees when they log in to the portal. Both the system administrator and the user have the ability to customize the SSL VPN portal.

To view the portals settings page, go to *VPN* > *SSL* > *Portal*.

There are three pre-defined default web portal configurations available:

- *full-access*
- *tunnel-access*
- *web-access*

Each web portal type include similar configuration options. Select between the different portals by selecting one from the drop-down list in the upper right corner of the window. You can also create a custom portal by selecting the plus sign next to the portal drop-down list.

Name	The name for the portal
Portal Message	This is a text header that appears on the top of the web portal.
Theme	A color styling for the web portal.
Page Layout	Select one or two column layouts for the widgets that appear on the web portal page.
Enable Tunnel Mode	If your web portal provides tunnel mode access, you need to configure the *Tunnel Mode* widget. These settings determine how tunnel mode clients are assigned IP addresses.
Enable Split Tunneling	Select so that the VPN carries only the traffic for the networks behind the FortiGate unit. The user's other traffic follows its normal route.
IP Pools	Select an IP Pool for users to acquire an IP address when connecting to the portal. There is always a default pool available if you do not create your own.
Client Options	These options affect how the FortiClient application behaves when connected to the FortiGate VPN tunnel. When enabled, a check box for the corresponding option appears on the VPN login screen in FortiClient, and is not enabled by default. **Save Password** - When enabled, if the user selects this option, their password is stored on the user's computer and will automatically populate each time they connect to the VPN. **Auto Connect** - When enabled, if the user selects this option, when the FortiClient application is launched, for example after a reboot or system startup, FortiClient will automatically attempt to connect to the VPN tunnel. **Always Up (Keep Alive)** - When enabled, if the user selects this option, the FortiClient connection will not shut down. When not selected, during periods of inactivity, FortiClient will attempt to stay connected every three minutes for a maximum of 10 minutes.
Enable Web Mode	Select to enable web mode access.
Applications	Select the applications the user can access when connected over the VPN portal.
Include Session Info	Select to display the Session Information widget on the portal page. The *Session Information* widget displays the login name of the user, the amount of time the user has been logged in and the inbound and outbound traffic statistics.

Include Connection Tool	Select to display the Connection Tool widget on the portal page. Use the *Connection Tool* widget to connect to a internal network resource without adding a bookmark to the bookmark list. You select the type of resource and specify the URL or IP address of the host computer.
Include Bookmarks	Select to include bookmarks on the web portal. Bookmarks are used as links to internal network resources. When a bookmark is selected from a bookmark list, a pop-up window appears with the web page. Telnet, VNC, and RDP require a browser plug-in. FTP and Samba replace the bookmarks page with an HTML file-browser.
Prompt Mobile Users to Download FortiClient App	If a remote user is using web browser to connects to the SSL VPN in web mode they are prompted to download the FortiClient Application. The remote user can accept or reject the notification. If the user accepts, they are redirected to the FortiClient web site.
Allow Multiple Concurrent Sessions for Each User	You can set the SSL VPN tunnel such that each user can only log into the tunnel one time concurrently per user per login. That is, once logged into the portal, they cannot go to another system and log in with the same credentials again. To prevent multiple logins, clear the check box.

Adding bookmarks

A web bookmark can include login credentials to automatically log the SSL VPN user into the web site. When the administrator configures bookmarks, the web site credentials must be the same as the user's SSL VPN credentials. Users configuring their own bookmarks can specify alternative credentials for the web site.

To add a bookmark

1. On the *VPN* > *SSL* > *Portal* page, ensure *Include Bookmarks* is enabled.
2. Select *Create New* and enter the following information:

Category	Select a category, or group, to include the bookmark. If this is the first bookmark added, you will be prompted to add a category. Otherwise, select *Create* from the drop-down list.
Name	Enter a name for the bookmark.
Type	Select the type of link from the drop-down list. Telnet, VNC, and RDP require a browser plug-in. FTP and Samba replace the bookmarks page with an HTML file-browser.
Location	Enter the IP address source.
SSO	Select if you wish to use single sign-on for any links that require authentication. When including a link using SSO, ensure to use the entire url. For example, http://10.10.1.0/login, rather than just the IP address.
Description	Enter a brief description of the link.

Select *OK*.

For more configuration options, see “Additional configuration options” on page 2210.

Personal bookmarks

The administrator has be ability to view bookmarks the remote client has added to their SSL VPN login in the bookmarks widget. This enables the administrator to monitor and, if needed, remove unwanted bookmarks that do not meet with corporate policy.

To view and maintain remote client bookmarks, go to *VPN* > *SSL* > *Personal Bookmarks*.

On mid-range and high end FortiGate units, this feature is enabled by default. On low-end FortiGate units, it must be enabled.

To enable personal bookmarks

1. Go to *System* > *Config* > *Features*.
2. In the *Display Options on GUI* section, select *SSPVPN Personal Bookmark Management*.
3. Select *Apply*.

Custom login screen

You can create a custom log in for your remote SSL VPN users. When configured with a security policy, when the user connects to the SSL VPN portal, a custom log in screen appears. With this screen, you can define the address, customize the look and define how many users are can connect at any one time to the portal.

When adding the URL Path, you only need to enter the subdirectory or site. The FortiGate unit will complete the remainder of the address. For example, if the sub site is corpusers, only enter `corpusers`. The final URL that appears is http://172.20.120.230/corpusers. The login port is separately configured by going to *VPN* > *SSL* > *Config*.

When configuring with the security policy, when you create *SSL VPN Authentication Rules*, you can select the specific portal login screen.

Tunnel mode and split tunneling

If you want your web portal to have tunnel mode access, select *Tunnel Mode* when creating a new portal. Enable *Split Tunneling* so that the VPN carries only the traffic for the networks behind the FortiGate unit. The user’s other traffic follows its normal route.

Port forward tunnel

Port forwarding provides a method of connecting to application servers without configuring a tunnel mode connection, and requiring the installation of tunnel mode client. Set up the portal as described at “Configuring SSL VPN web portals” on page 2199. To configure the application, create a bookmark with the *Type* of *PortForward*.

Ensure that *Port Forward* is enabled in the *Applications* list.

The Connection tool widget

The *Connection Tool* widget enables a user to connect to resources when isn’t a bookmark. Ensure that what you want remote users to connect to is enabled in the *Applications* list of the *General* settings, by selecting the *Settings* button in the portal configuration window.

To configure the Connection Tool widget - CLI

To change, for example, the full-access portal Connection Tool widget to allow all application types except Telnet, you would enter:

```
config vpn ssl web portal
  edit full-access
    config widget
      edit 3
        set allow-apps ftp rdp smb ssh vnc web
      end
    end
  end
```

Configuring security policies

You will need at least one SSL VPN security policy. This is an identity-based policy that authenticates users and enables them to access the SSL VPN web portal. The SSL VPN user groups named in the policy determine who can authenticate and which web portal they will use. From the web portal, users can access protected resources or download the SSL VPN tunnel client application.

This section contains the procedures needed to configure security policies for web-only mode operation and tunnel-mode operation. These procedures assume that you have already completed the procedures outlined in “User accounts and groups” on page 2195.

If you will provide tunnel mode access, you will need a second security policy — an ACCEPT tunnel mode policy to permit traffic to flow between the SSL VPN tunnel and the protected networks.

Firewall addresses

Before you can create security policies, you need to define the firewall addresses you will use in those policies. For both web-only and tunnel mode operation, you need to create firewall addresses for all of the destination networks and servers to which the SSL VPN client will be able to connect.

For tunnel mode, you will already have defined firewall addresses for the IP address ranges that the FortiGate unit will assign to SSL VPN clients.

The source address for your SSL VPN security policies will be the predefined “all” address. Both the address and the netmask are `0.0.0.0`. The “all” address is used because VPN clients will be connecting from various addresses, not just one or two known networks. For improved security, if clients will be connecting from one or two known locations you should configure firewall addresses for those locations, instead of using the “all” address.

To create a firewall address, in the web-based manager, go to *Firewall Objects* > *Address* > *Address*, and select *Create New.*

Create an SSL VPN security policy

At minimum, you need one SSL VPN security policy to authenticate users and provide access to the protected networks. You will need additional security policies only if you have multiple web portals that provide access to different resources. You can use one policy for multiple groups, or multiple policies to handle differences between the groups such as access to different services, or different schedules.

The SSL VPN security policy specifies:

- the remote address that corresponds to the IP address of the remote user.
- the local protected subnet address that corresponds to the IP address or addresses that remote clients need to access.

  The local protected subnet address may correspond to an entire private network, a range of private IP addresses, or the private IP address of a server or host.
- the level of SSL encryption to use and the authentication method.
- which SSL VPN user groups can use the security policy.
- the times (schedule) and types of services that users can access.
- the UTM features and logging that are applied to the connection.

Do not use ALL as the destination address. If you do, you will see the “Destination address of Split Tunneling policy is invalid” error when you enable Split Tunneling

To create an SSL-VPN security policy - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select *Create New.*
2. Select the *Policy Type* as *SSL*.
3. Enter the following information:

Incoming Interface	Select the name of the FortiGate network interface to that connects to the Internet.
Remote Address	Select *all*.
Local Interface	Select the FortiGate network interface that connects to the protected network.
Local Protected Subnet	Select the firewall address you created that represents the networks and servers to which the SSL VPN clients will connect. If you want to associate multiple firewall addresses or address groups with the *Destination Interface/Zone*, from *Destination Address*, select the plus symbol. In the dialog box, move the firewall addresses or address groups from the *Available Addresses* section to the *Members* section, then select *OK*.
SSL Client Certificate Restrictive	Select to allow access only to holders of a (shared) group certificate. The holders of the group certificate must be members of an SSL VPN user group, and the name of that user group must be present in the Allowed field. See “Strong authentication with security certificates” on page 2198.
Cipher Strength	Select the bit level of SSL encryption. The web browser on the remote client must be capable of matching the level that you select.

4. Under *Configure SSL-VPN Authentication Rules*, select *Create New*.

Add a user group to the policy. The New SSL VPN Authentication Rule window opens on top of the security policy. Enter the following information and then select OK. You can select Add again to add more groups.

Group(s)	Select user groups that can connect to the SSL VPN tunnel.
User(s)	Select individual users that can connect to the SSL VPN tunnel.
Schedule	Select always.
SSL-VPN Portal	Select the portal the users connect to.
Custom Login	Select to choose a configured login screen. For more information, see "Custom login screen" on page 2203.

Your identity-based policies are listed in the security policy table. The FortiGate unit searches the table from the top down to find a policy to match the client's user group. Using the move icon in each row, you can change the order of the policies in the table to ensure the best policy will be matched first. You can also use the icons to edit or delete policies.

To create an SSL VPN security policy - CLI

To create the security policy by entering the following CLI commands.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr OfficeLAN
    set action ssl-vpn
    set nat enable
    config identity-based-policy
      edit 0
        set groups SSL-VPN
        set schedule always
        set service ALL
        set sslvpn-poprtal <portal_name>
      end
  end
```

Create a tunnel mode security policy

If your SSL VPN will provide tunnel mode operation, you need to create a security policy to enable traffic to pass between the SSL VPN virtual interface and the protected networks. This is in addition to the SSL VPN security policy that you created in the preceding section.

The SSL VPN virtual interface is the FortiGate unit end of the SSL tunnel that connects to the remote client. It is named `ssl.<vdom_name>`. In the root VDOM, for example, it is named `ssl.root`. If VDOMs are not enabled on your FortiGate unit, the SSL VPN virtual interface is also named ssl.root.

To configure the tunnel mode security policy - web-based manager

1. Go to *Policy* > *Policy*> *Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.

3. Enter the following information and select *OK*.

Incoming Interface	Select the virtual SSL VPN interface, such as *ssl.root.*
Source Address	Select the firewall address you created that represents the IP address range assigned to SSL VPN clients, such as SSL_VPN_tunnel_users.
Outgoing Interface	Select the interface that connects to the protected network.
Destination Address	Select the firewall address that represents the networks and servers the SSL VPN clients will connect to. To select multiple firewall addresses or address groups, select the plus sign next to the drop-down list.
Service	Select service in the left list and use the right arrow button to move them to the right list. Select the ALL service to allow the user group access to all services.
Action	Select *Accept*.
Enable NAT	Select *Enable NAT.* (Optional)

To configure the tunnel mode security policy - CLI

```
config firewall policy
  edit <id>
    set srcintf ssl.root
    set dstintf <dst_interface_name>
    set srcaddr <tunnel_ip_address>
    set dstaddr <protected_network_address_name>
    set schedule always
    set service ALL
    set nat enable
  end
```

This policy enables the SSL VPN client to initiate communication with hosts on the protected network. If you want to enable hosts on the protected network to initiate communication with the SSL VPN client, you should create another Accept policy like the preceding one but with the source and destination settings reversed.

You must also add a static route for tunnel mode operation.

Routing for tunnel mode

If you your SSL VPN operates in tunnel mode, you must add a static route so that replies from the protected network can reach the remote SSL VPN client.

To add the tunnel mode route - web-based manager

1. Go to *Router* > *Static* > *Static Routes* and select *Create New*.

   For low-end FortiGate units, go to *System* > *Network* > *Routing* and select *Create New*.
2. Enter the *Destination IP/Mask* of the tunnel IP address that you assigned to the users of the web portal.
3. Select the SSL VPN virtual interface for the *Device*.
4. Select *OK*.

To add the tunnel mode route - CLI

If you assigned 10.11.254.0/24 as the tunnel IP range, you would enter:

```
config router static
  edit <id>
    set device ssl.root
    set dst 10.11.254.0/24
    set gateway <gateway_IP>
end
```

Split tunnel Internet browsing policy

With split tunneling disabled, all of the SSL VPN client's requests are sent through the SSL VPN tunnel. But the tunnel mode security policy provides access only to the protected networks behind the FortiGate unit. Clients will receive no response if they attempt to access Internet resources. You can enable clients to connect to the Internet through the FortiGate unit.

To add an Internet browsing policy

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information and select *OK*.

Incoming Interface	Select the virtual SSL VPN interface, *ssl.root*, for example.
Source Address	Select the firewall address you created that represents the IP address range assigned to SSL VPN clients.
Outgoing Interface	Select the FortiGate network interface that connects to the Internet.
Destination Address	Select *all*.
Action	Select *Accept*.
Enable NAT	Select *Enable*.

To configure the Internet browsing security policy - CLI

To enable browsing the Internet through port1, you would enter:

```
config firewall policy
  edit 0
    set srcintf ssl.root
    set dstintf port1
    set srcaddr SSL_tunne_users
    set dstaddr all
    set schedule always
    set service ALL
    set nat enable
end
```

Enabling a connection to an IPsec VPN

You might want to provide your SSL VPN clients access to another network, such as a branch office, that is connected by an IPsec VPN. To do this, you need only to add the appropriate security policy. For information about route-based and policy-based IPsec VPNs, see the *IPsec VPN Guide*.

Route-based connection

To configure interconnection with a route-based IPsec VPN - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information and select *OK*.

Incoming Interface	Select the virtual SSL VPN interface, *ssl.root*, for example.
Source Address	Select the firewall address that represents the IP address range assigned to SSL VPN clients.
Outgoing Interface	Select the virtual IPsec interface for your IPsec VPN.
Destination Address	Select the address of the IPsec VPN remote protected subnet.
Action	Select *ACCEPT*.
Enable NAT	Enable.

To configure interconnection with a route-based IPsec VPN - CLI

If, for example, you want to enable SSL VPN users to connect to the private network (address name OfficeAnet) through the toOfficeA IPsec VPN, you would enter:

```
config firewall policy
  edit 0
    set srcintf ssl.root
    set dstintf toOfficeA
    set srcaddr SSL_tunnel_users
    set dstaddr OfficeAnet
    set action accept
    set nat enable
    set schedule always
    set service ALL
end
```

Policy-based connection

To configure interconnection with a policy-based IPsec VPN - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Select the *Policy Type* as *VPN* and leave the *Policy Subtype* as *IPsec*.

3. Enter the following information and select *OK*.

Local Interface	Select the virtual SSL VPN interface, *ssl.root*, for example.
Local Protected Subnet	Select the firewall address that represents the IP address range assigned to SSL VPN clients.
Outgoing VPN Interface	Select the FortiGate network interface that connects to the Internet.
Remote Protected Subnet	Select the address of the IPsec VPN remote protected subnet.
VPN tunnel	Select the Phase 1 configuration name of your IPsec VPN.
Allow traffic to be initiated from the remote site	Enable
NAT inbound	Enable

4. Configure inbound NAT from the CLI:

```
config firewall policy
  edit 0
    set natinbound enable
  end
```

To configure interconnection with a policy-based IPsec VPN - CLI

If, for example, you want to enable SSL VPN users to connect to the private network (address name OfficeAnet) through the OfficeA IPsec VPN, you would enter:

```
config firewall policy
  edit 0
    set srcintf ssl.root
    set dstintf port1
    set srcaddr SSL_tunnel_users
    set dstaddr OfficeAnet
    set action ipsec
    set schedule always
    set service ALL
    set inbound enable
    set outbound enable
    set natinbound enable
    set vpntunnel toOfficeA
end
```

In this example, port1 is connected to the Internet.

Additional configuration options

Beyond the basics of setting up the SSL VPN, you can configure a number of other options that can help to ensure your internal network is secure and limit the possibility of attacks and viruses entering the network from an outside source.

Routing in tunnel mode

If are creating a SSL VPN connection in tunnel mode, you need to add a static route so that replies from the protected network can reach the remote SSL VPN client.

To add the tunnel mode route - web-based manager

1. Go to *Router* > *Static* > *Static Routes* and select *Create New*.

   For low-end FortiGate units, go to *System* > *Network* > *Routing* and select *Create New*.
2. Enter the *Destination IP/Mask* of the tunnel IP address that you assigned to the users of the web portal.
3. Select the SSL VPN virtual interface for the *Device*.
4. Select *OK*.

To add the tunnel mode route - CLI

If you assigned 10.11.254.0/24 as the tunnel IP range, you would enter:

```
config router static
  edit <id>
    set device ssl.root
    set dst 10.11.254.0/24
    set gateway <gateway_IP>
end
```

Changing the port number for web portal connections

You can specify a different TCP port number for users to access the web portal login page through the HTTPS link. By default, the port number is 443 and users can access the web portal login page using the following default URL:

`https://<FortiGate_IP_address>:443/remote/login`

where `<FortiGate_IP_address>` is the IP address of the FortiGate interface that accepts connections from remote users.

To change the SSL VPN port - web-based manager

1. If *Current VDOM* appears at the bottom left of the screen, select *Global* from the list of VDOMs.
2. Go to *VPN* > *SSL* > *Config*.
3. Type an unused port number in *Login Port*, and select *Apply*.

To change the SSL VPN port - CLI

This is a global setting. For example, to set the SSL VPN port to 10443, enter:

```
config global
  config system global
    set sslvpn-sport 10443
end
```

SSL offloading

Configuring SSL offloading that allows or denies client renegotiation, is configured in the CLI. This helps to resolve the issues that affect all SSL and TLS servers that support renegotiation, identified by the Common Vulnerabilities and Exposures system in CVE-2009-3555. The IETF is currently working on a TLS protocol change that will permanently resolve the issue. The SSL

offloading renegotiation feature is considered a workaround until the IETF permanently resolves the issue.

The CLI command is `ssl-client-renegotiation` and is found in `config firewall vip` command.

Customizing the web portal login page

The default web portal login page shows only the *Name* and *Password* fields and the Login button, centred in the web browser window. You can customize the page with your company name or other information.

The login page is a form of replacement message, in HTML format. You can modify the content to display a customized message. Note that there are specific fields that must remain in the code to ensure the page appears correctly in the user's browser.

Before you begin, copy the default web portal login page text to a separate text file for safe-keeping. Afterward, if needed you can restore the text to the original version.

To configure the SSL VPN login page - web-based manager

1. If you want to edit the global login page and *Current VDOM* appears at the bottom left of the screen, select *Global* from the list of VDOMs.
2. Go to *System* > *Config* > *Replacement Messages*.
3. Expand the *SSL VPN* row and select *SSL VPN login page*.
4. Edit the HTML text. Note the following content that must remain on the page:
   - The login page must contain a form with `ACTION="%%SSL_ACT%%"` and `METHOD="%%SSL_METHOD%%"`
   - The form must contain the `%%SSL_LOGIN%%` tag to provide the login form.
   - The form must contain the `%%SSL_HIDDEN%%` tag.

Host check

When you enable AV, FW, or AV-FW host checking in the web portal Security Control settings, each client is checked for security software that is recognized by the Windows Security Center. As an alternative, you can create a custom host check that looks for security software selected from the Host Check list. For more information, see "Portal configuration" on page 2200.

The Host Check list includes default entries for many security software products.

Host integrity checking is only possible with client computers running Microsoft Windows platforms.

To configure host checking - CLI

To configure the full-access portal to check for AV and firewall software on client Windows computers, you would enter the following:

```
config vpn ssl web portal
  edit full-access
    set host-check av-fw
end
```

To configure the full-access portal to perform a custom host check for FortiClient Host Security AV and firewall software, you would enter the following:

```
config vpn ssl web portal
  edit full-access
    set host-check custom
    set host-check-policy FortiClient-AV FortiClient-FW
end
```

Creating a custom host check list

You can add your own software requirements to the host check list using the CLI. Host integrity checking is only possible with client computers running Microsoft Windows platforms. Enter the following commands:

```
config vpn ssl web host-check-software
  edit <software_name>
    set guid <guid_value>
    set type <av | fw>
    set version <version_number>
end
```

Enter the Globally Unique IDentifier (GUID) for the host check application, if known. Windows uses GUIDs to identify applications in the Windows Registry. The GUID can be found in the Windows registry in the HKEY_CLASSES_ROOT section.

To get the exact versioning, in Windows right-click on the .EXE file of the application and select Properties. Select the *Version* tab.

Windows OS check

The Windows patch check enables you to define the minimum Windows version and patch level allowed when connecting to the SSL VPN portal. When the user attempts to connect to the web portal, FortiOS performs a query on the version of Windows the user has installed. If it does not match the minimum requirement, the connection is denied. The Windows patch check is configured in the CLI.

The following example shows how you would add an OS check to the g1portal web portal. This OS check accepts all Windows XP users and Windows 2000 users running patch level 3.

To specify the acceptable patch level, you set the `latest-patch-level` and the `tolerance`. The lowest acceptable patch level is `latest-patch-level` minus `tolerance`. In this case, `latest-patch-level` is 3 and `tolerance` is 1, so 2 is the lowest acceptable patch level.

```
config vpn ssl web portal
  edit g1portal
    set os-check enable
    config os-check-list windows-2000
      set action check-up-to-date
      set latest-patch-level 3
      set tolerance 1
    end
    config os-check-list windows-xp
      set action allow
    end
  end
```

Configuring cache cleaning

When the SSL VPN session ends, the client browser cache may retain some information. To enhance security, cache cleaning clears this information just before the SSL VPN session ends.

The cache cleaner is effective only if the session terminates normally. The cache is not cleaned if the session ends due to a malfunction, such as a power failure.

To enable cache cleaning

To enable cache cleaning on the full-access portal, you would enter:

```
config vpn ssl web portal
  edit full-access
    set cache-cleaner enable
  end
```

Cache cleaning requires a browser plug-in. If the user does not have the plug-in, it is automatically downloaded to the client computer.

Configuring virtual desktop

Available for Windows XP, Windows Vista, and Windows 7 client PCs, the virtual desktop feature completely isolates the SSL VPN session from the client computer's desktop environment. All data is encrypted, including cached user credentials, browser history, cookies, temporary files, and user files created during the session. When the SSL VPN session ends normally, the files are deleted. If the session ends due to a malfunction, files might remain, but they are encrypted, so the information is protected.

When the user starts an SSL VPN session which has virtual desktop enabled, the virtual desktop replaces the user's normal desktop. When the virtual desktop exits, the user's normal desktop is restored.

Virtual desktop requires the Fortinet cache cleaner plug in. If the plug in is not present, it is automatically downloaded to the client computer.

To enable virtual desktop

To enable virtual desktop on the full-access portal and apply the application control list List1, for example, you would enter:

```
config vpn ssl web portal
  edit full-access
    set virtual-desktop enable
    set virtual-desktop-app-list List1
  end
```

Configuring virtual desktop application control

You can control which applications users can run on their virtual desktop. To do this, you create an Application Control List of either allowed or blocked applications. When you configure the web portal, you select the list to use. Configure the application control list in the CLI.

To create an Application Control List - CLI

If you want to add BannedApp to List1, a list of blocked applications, you would enter:

```
config vpn ssl web virtual-desktop-app-list
  edit "List1"
    set action block
    config apps
      edit "BannedApp"
        set md5s "06321103A343B04DF9283B80D1E00F6B"
      end
  end
```

Configuring client OS Check

The SSLVPN client OS Check feature can determine if clients are running the Windows 2000, Windows XP, Windows Vista or Windows 7 operating system. You can configure the OS Check to do any of the following:

- allow the client access
- allow the client access only if the operating system has been updated to a specified patch (service pack) version
- deny the client access

The OS Check has no effect on clients running other operating systems.

To configure OS Check

OS Check is configurable only in the CLI.

```
config vpn ssl web portal
  edit <portal_name>
    set os-check enable
    config os-check-list {windows-2000 | windows-xp
         | windows-vista | windows-7}
      set action {allow | check-up-to-date | deny}
      set latest-patch-level {disable | 0 - 255}
      set tolerance {tolerance_num}
    end
  end
```

Adding WINS and DNS services for clients

You can specify the WINS or DNS servers that are made available to SSL-VPN clients.

DNS servers provide the IP addresses that browsers need to access web sites. For Internet sites, you can specify the DNS server that your FortiGate unit uses. If SSL VPN users will access intranet sites using URLs, you need to provide them access to the intranet's DNS server. You specify a primary and a secondary DNS server.

A WINS server provides IP addresses for named servers in a Windows domain. If SSL VPN users will access a Windows network, you need to provide them access to the domain WINS server. You specify a primary and a secondary WINS server.

To specify WINS and DNS services for clients - web-based manager

1. Go to *VPN* > *SSL* > *Config*.
2. Select the *Expand Arrow* to display the *Advanced* section.
3. Enter the IP addresses of DNS servers in the *DNS Server* fields as needed.
4. Enter the IP addresses of WINS servers in the *WINS Server* fields as needed.
5. Select *Apply*.

To specify WINS and DNS services for clients - CLI

```
config vpn ssl settings
  set dns-server1 <address_ipv4>
  set dns-server2 <address_ipv4>
  set wins-server1 <address_ipv4>
  set wins-server2 <address_ipv4>
end
```

Setting the idle timeout setting

The idle timeout setting controls how long the connection can remain idle before the system forces the remote user to log in again. For security, keep the default value of 300 seconds (5 minutes) or less.

To set the idle timeout - web-based manager

1. Go to *VPN* > *SSL* > *Config*.
2. In the *Idle Timeout* field, enter the timeout value.

   The valid range is from 10 to 28800 seconds.
3. Select *Apply*.

To set the idle timeout - CLI

```
config vpn ssl settings
  set idle-timeout <seconds_int>
end
```

SSL VPN logs

Logging is available for SSP VPN traffic so you can monitor users connected to the FortiGate unit and their activity. For more information on configuring logs on the FortiGate unit, see the *Logging and Reporting* chapter of *The Handbook*.

To enable logging of SSL VPN events - web-based manager

1. Go to *Log&Report* > *Log Config* > *Log Settings*.

2. Select *Enable*, and select *VPN activity event*.
3. Select *Apply*.

To view the SSL VPN log data, in the web-based manager, go to *Log&Report* > *Log & Archive Access* and select either the *Event Log* or *Traffic Log*.

In event log entries, look for the sub-types “sslvpn-session” and “sslvpn-user”.

For information about how to interpret log messages, see the *FortiGate Log Message Reference*.

Monitoring active SSL VPN sessions

You can go to *User & Device* > *Monitor* to view a list of active SSL VPN sessions. The list displays the user name of the remote user, the IP address of the remote client, and the time the connection was made. You can also see which services are being provided, and delete an active web session from the FortiGate unit.

To monitor SSL VPNs - web-based manager

To view the list of active SSL VPN sessions, go to *VPN* > *SSL-VPN* > *Monitor*.

When a tunnel-mode user is connected, the *Description* field displays the IP address that the FortiGate unit assigned to the remote host.

If required, you can end a session/connection by selecting its check box and then selecting the *Delete* icon.

Troubleshooting

Here is a list of common SSL VPN problems and the likely solutions.

No response from SSL VPN URL	Check SSL VPN port assignment (default 10443). Verify the SSL VPN security policy.
Error: “The web page cannot be found.”	Check URL: `https://<FortiGate_IP>:<SSLVPN_port>/remote/login`
Tunnel connects, but there is no communication.	Check that there is a static route to direct packets destined for the tunnel users to the SSL VPN interface. See “Routing for tunnel mode” on page 2207.

Tunnel-mode connection shuts down after a few seconds	This issue occurs when there are multiple interfaces connected to the Internet, for example, a dual WAN configuration. Upgrade to the latest firmware then use the following CLI command:
	`config vpn ssl settings`
	`  set route-source-interface enable`
	`end`

Error: “Destination address of Split Tunneling policy is invalid.”	The SSL VPN security policy uses the ALL address as its destination. Specify the address of the protected network instead.
When trying to connect using FortiClient the error message “Unable to logon to the server. Your user name or password may not be configured properly for this connection. (-12)” appears. **When trying to login to the web portal, login and password are entered and login page will be sent back.**	Cookies must be enabled for SSL VPN to function in Web portal or with FortiClient. Access to the web portal or tunnel will fail if Internet Explorer has the privacy Internet Options set to High. If set to High, Internet Explorer will: Block cookies that do not have a compact privacy policy. Block cookies that use personally identifiable information without your explicit consent.

The SSL VPN client

The remote client connects to the SSL VPN tunnel in various ways, depending on the VPN configuration.

- Web mode requires nothing more than a web browser. Microsoft Internet Explorer, Firefox, and Apple Safari browsers are supported. For detailed information about supported browsers see the Release Notes for your FortiOS firmware.
- Tunnel mode establishes a connection to the remote protected network that any application can use. This requires FortiClient SSL VPN application that sends and receives data through the SSL VPN tunnel.

  If the client computer runs Microsoft Windows, they can download the tunnel mode client from the web portal Tunnel Mode widget. After installing the client, they can start and stop tunnel operation from the Tunnel Mode widget, or open the tunnel mode client as a standalone application. The tunnel mode client is available on the Start menu at *All Programs* > *FortiClient* > *FortiClient SSL VPN*.

  If the client computer runs Linux or Mac OS X, the user needs to download the tunnel mode client application from the Fortinet Support web site. See the Release Notes for your FortiOS firmware for the specific operating system versions that are supported. On Linux and Mac OS X platforms, tunnel mode operation cannot be initiated from the web portal Tunnel Mode widget. The remote user must use the standalone tunnel client application.
- The virtual desktop application creates a virtual desktop on a user's PC and monitors the data read/write activity of the web browser running inside the virtual desktop. When the application starts, it presents a ‘virtual desktop’ to the user. The user starts the web browser from within the virtual desktop and connects to the SSL VPN web portal. The browser file/directory operation is redirected to a new location, and the data is encrypted before it is written to the local disk. When the virtual desktop application exits normally, all the data written to the disk is removed. If the session terminates abnormally (power loss, system failure), the data left behind is encrypted and unusable to the user. The next time you start the virtual desktop, the encrypted data is removed.

FortiClient

Remote users can use FortiClient software to initiate an SSL VPN tunnel to connect to the internal network. FortiClient uses local port TCP 1024 to initiate an SSL encrypted connection to the FortiGate unit, on port TCP 443. When connection using FortiClient, the FortiGate unit authenticates the FortiClient SSL VPN request based on the user group options. The FortiGate unit establishes a tunnel with the client and assigns a virtual IP address to the client PC. Once the tunnel has been established, the user can access the network behind the FortiGate unit.

FortiClient software is available for download at www.forticlient.com and is available for Windows, Mac OS X, Apple iOS and Android.

Tunnel mode client configuration

The FortiClient SSL VPN tunnel client requires basic configuration by the remote user to connect to the SSL VPN tunnel. When distributing the FortiClient software, provide the following information for the remote user to enter once the client software has been started. Once entered, they can select *Connect* to begin a SSL VPN session.

Connection Name	If you have pre-configured the connection settings, select the connection from the list and then select *Connect*. Otherwise, enter the settings in the fields below.
Remote Gateway	Enter the IP address or FQDN of the FortiGate unit that hosts the SSL VPN.
Username	Enter your user name.
Client Certificate	Use this field if the SSL VPN requires a certificate for authentication. Select the required certificate from the drop-down list. The certificate must be installed in the Internet Explorer certificate store.

Setup examples

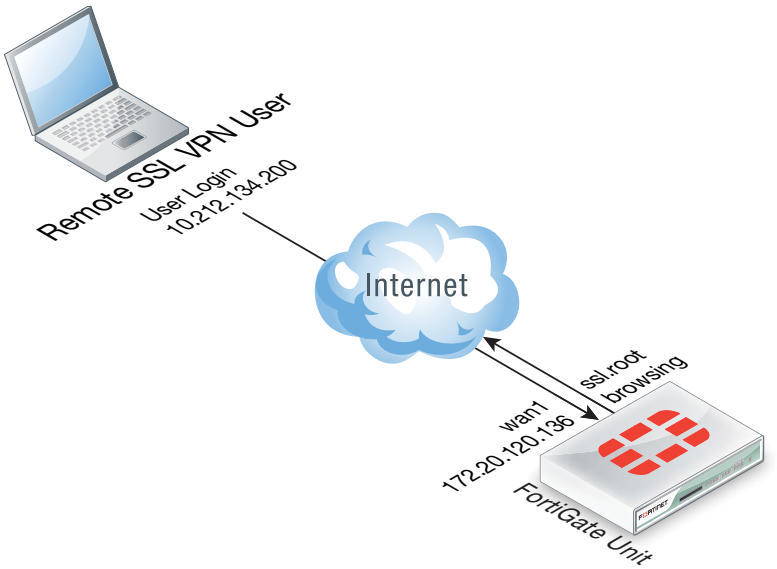
The examples in this chapter demonstrate the basic configurations needed for common connections to the SSL VPN tunnel and portals, applying the steps outlined in the chapter "Basic Configuration" on page 2195.

The example included are:

- Secure internet browsing
- Split Tunnel
- Multiple user groups with different access permissions example

Secure internet browsing

This example sets up an SSL VPN tunnel to provide remote users the ability to access the Internet while travelling, and ensure that they are not subjected to malware and other dangers, by using the corporate firewall to filter all of their Internet traffic. Essentially, the remote user will connect to the corporate FortiGate unit to surf the Internet.



Using SSL VPN and FortiClient SSL VPN software, you create a means to use the corporate FortiGate to browse the web safely.

Creating an SSL VPN IP pool and SSL VPN web portal

1. Go to *VPN* > *SSL* > *Config* and for *IP Pools* select *SSLVPN_TUNNEL_ADDR1*.
2. Create the SSL VPN portal to by going to *VPN* > *SSL* > *Portal* and selecting *tunnel-access* in the upper right-hand corner drop-down list box.
3. Select *OK*.

Creating the SSL VPN user and user group

Create the SSL VPN user and add the user to a user group configured for SSL VPN use.

1. Go to *User & Device* > *User* > *User Definition* and select *Create New* to add the user:

User Name	twhite
Password	password

2. Select *OK*.
3. Go to *User & Device* > *User* > *User Groups* and select *Create New* to add `twhite` to a group called SSL VPN:

Name	SSL Group
Type	Firewall

4. Move ***twhite*** to the *Members* list.
5. Select *OK*.

Creating a static route for the remote SSL VPN user

Create a static route to direct traffic destined for tunnel users to the SSL VPN tunnel.

1. Go to *Router* > *Static* > *Static* and select *Create New* to add the static route.

   For low-end FortiGate units, go to *System* > *Network* > *Routing* and select *Create New*.

Destination IP/Mask	10.212.134.0/255.255.255.0
Device	ssl.root

The *Destination IP/Mask* matches the network address of the remote SSL VPN user.

2. Select *OK*.

Creating security policies

Create an SSL VPN security policy with SSL VPN user authentication to allow SSL VPN traffic to enter the FortiGate unit. Create a normal security policy from ssl.root to wan1 to allow SSL VPN traffic to connect to the Internet.

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Select the *Policy Type* as *VPN* and the *Policy Subtype* as *SSL-VPN*.
3. to add the SSL VPN security policy:

Incoming Interface	wan1
Remote Address	all
Local Interface	ssl.root
Local Protected Subnet	all

4. Select *Create New* for Configure SSL-VPN Authentication Rules and add an authentication rule for the remote user:

Selected User Groups	Tunnel
Selected Services	All
Schedule	always
SSL-VPN Portal	tunnel-access

5. Select *OK*.
6. Select *Create New* to add a security policy that allows remote SSL VPN users to connect to the Internet
7. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.:

Incoming Interface	ssl.root
Source Address	all
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

8. Select *OK*.

Results

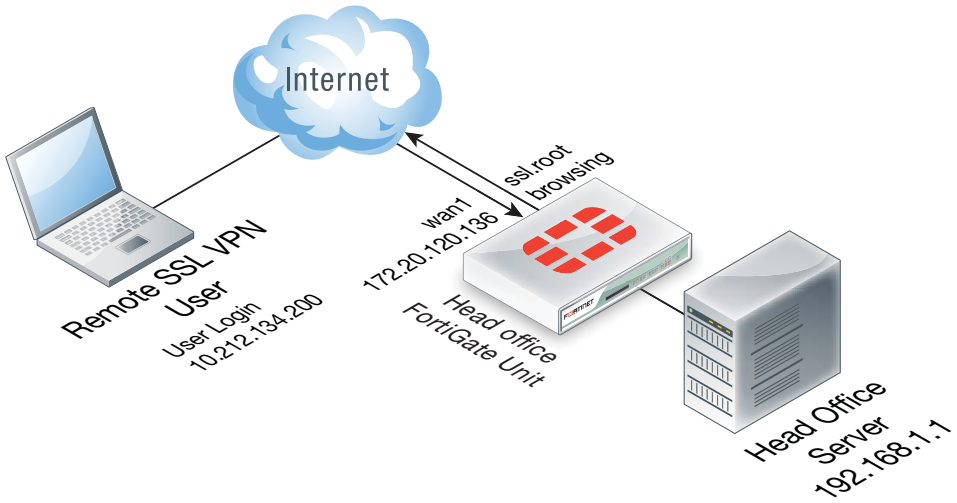
Using FortiClient SSLVPN application, log into the VPN using the address `https://172.20.120.136:443/` and log in as `twhite`. Once connected, you can browse the Internet.

From the FortiGate web-based manager go to *VPN* > *Monitor* > *SSL-VPN Monitor* to view the list of users connected using SSL VPN. The *Subsession* entry indicates the split tunnel which redirects to the Internet.

Split Tunnel

For this example, the remote users are configured to be able to securely access head office internal network servers, and browse the Internet through the head office firewall. This will enable the remote user to use the FortiGate security to connect to the internal network and the web.

This solution describes how to configure FortiGate SSL VPN split tunnelling using the FortiClient SSL VPN software, available from the Fortinet Support site.



Using split tunneling, all communication from remote SSL VPN users to the head office internal network and to the Internet uses an SSL VPN tunnel between the user's PC and the head office FortiGate unit. Connections to the Internet are routed back out the head office FortiGate unit to the Internet. Replies come back into the head office FortiGate unit before being routed back through the SSL VPN tunnel to the remote user.

Creating a firewall address for the head office server

1. Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* and add the head office server address:

Name	Head office server
Type	Subnet
Subnet / IP Range	192.168.1.12
Interface	Internal

2. Select *OK*.

Creating an SSL VPN IP pool and SSL VPN web portal

1. Go to *VPN* > *SSL* > *Config*.
2. *For IP Pools* select *SSLVPN_TUNNEL_ADDR1*.
3. Create the SSL VPN portal to by going to *VPN* > *SSL* > *Portal* and select the plus sign in the upper right of the window.
4. Enter the following:

Name	Connect to head office server
IP Pools	SSLVPN_TUNNEL_ADDR1
Enable Tunnel Mode	Enable
Split Tunneling	Enable

5. Select *OK*.

Creating the SSL VPN user and user group

Create the SSL VPN user and add the user to a user group.

1. Go to *User & Device* > *User* > *User Definition*, select *Create New* and add the user:

User Name	twhite
Password	password

2. Select *OK*.
3. Go to *User & Device* > *User* > *User Groups* and select *Create New* to add ***twhite*** to the SSL VPN user group:

Name	Tunnel
Type	Firewall

4. Move ***twhite*** to the *Members* list.
5. Select *OK*.

Creating a static route for the remote SSL VPN user

Create a static route to direct traffic destined for tunnel users to the SSL VPN tunnel.

1. Go to *Router* > *Static* > *Static* and select *Create New*
2. For low-end FortiGate units, go to *System* > *Network* > *Routing* and select *Create New*:

Destination IP/Mask	10.212.134.0/255.255.255.0
Device	ssl.root

3. Select *OK*.

Creating security policies

Create an SSL VPN security policy with SSL VPN user authentication to allow SSL VPN traffic to enter the FortiGate unit. Create a normal security policy from ssl.root to wan1 to allow SSL VPN traffic to connect to the Internet.

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Select the *Policy Type* of VPN and the *Policy Subtype* as SSL-VPN.
3. Complete the following:

Incoming Interface	wan1
Remote Address	all
Local Interface	internal
Local Protected Subnet	Head office server

4. Under *Configure SSL-VPN Authentication Rules* select *Create New* to add an authentication rule for the remote user:

Groups(s)	Tunnel
Service	ALL
Schedule	always

5. Select *OK*.

   Add a security policy that allows remote SSL VPN users to connect to the Internet.
6. Select *Create New*.
7. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
8. Complete the following and select *OK*:

Incoming Interface	ssl.root
Source Address	all
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

Results

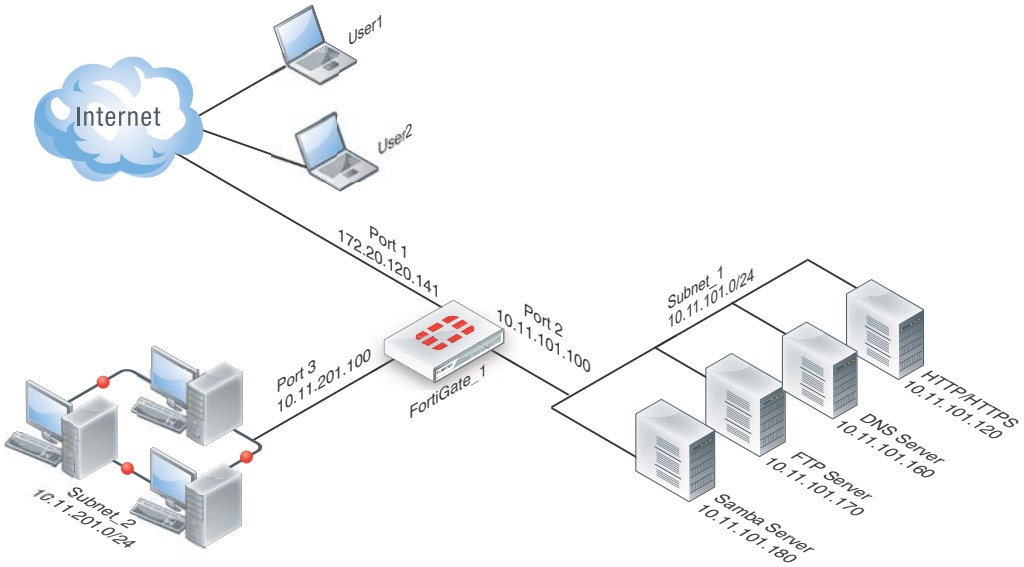
Using the FortiClient SSL VPN application on the remote PC, connect to the VPN using the address `https://172.20.120.136:443/` and log in with the `twhite` user account. Once connected, you can connect to the head office server or browse to web sites on the Internet.

From the web-based manager go to *VPN* > *Monitor* > *SSL-VPN Monitor* to view the list of users connected using SSL VPN. The *Subsession* entry indicates the split tunnel which redirects SSL VPN sessions to the Internet.

Multiple user groups with different access permissions example

You might need to provide access to several user groups with different access permissions. Consider the following example topology in which users on the Internet have controlled access to servers and workstations on private networks behind a FortiGate unit.

Figure 313:SSL VPN configuration for different access permissions by user group



In this example configuration, there are two users:

- user1 can access the servers on Subnet_1
- user2 can access the workstation PCs on Subnet_2

You could easily add more users to either user group to provide them access to the user group's assigned web portal.

General configuration steps

1. Create firewall addresses for
   - the destination networks
   - two non-overlapping tunnel IP address ranges that the FortiGate unit will assign to tunnel clients in the two user groups
2. Create two web portals.
3. Create two user accounts, user1 and user2.
4. Create two user groups. For each group, add a user as a member and select a web portal. In this example, user1 will belong to group1, which will be assigned to portal1.
5. Create security policies:
   - two SSL VPN security policies, one to each destination
   - two tunnel-mode policies to allow each group of users to reach its permitted destination network
6. Create the static route to direct packets for the users to the tunnel.

Creating the firewall addresses

Security policies do not accept direct entry of IP addresses and address ranges. You must define firewall addresses in advance.

Creating the destination addresses

SSL VPN users in this example can access either Subnet_1 or Subnet_2.

To define destination addresses - web-based manager

1. Go to *Firewall Objects* > *Address* > *Addresses.*
2. Select *Create New*, enter the following information, and select *OK*:

Name	Subnet_1
Type	Subnet
Subnet / IP Range	10.11.101.0/24
Interface	port2

3. Select *Create New*, enter the following information, and select *OK*:

Name	Subnet_2
Type	Subnet
Subnet / IP Range	10.11.201.0/24
Interface	port3

Creating the tunnel client range addresses

To accommodate the two groups of users, split an otherwise unused subnet into two ranges. The tunnel client addresses must not conflict with each other or with other addresses.

To define tunnel client addresses - web-based manager

1 Go to *Firewall Objects* > *Address* > *Addresses.*
2. Select *Create New*, enter the following information, and select *OK*:

Name	Tunnel_group1
Type	IP Range
Subnet / IP Range	10.11.254.[1-50]
Interface	Any

3. Select *Create New*, enter the following information, and select *OK*.

Name	Tunnel_group2
Type	IP Range
Subnet / IP Range	10.11.254.[51-100]
Interface	Any

Creating the web portals

To accommodate two different sets of access permissions, you need to create two web portals, portal1 and portal2, for example. Later, you will create two SSL VPN user groups, one to assign to portal1 and the other to assign to portal2.

To create the portal1 web portal

1. Go to *VPN* > *SSL* > *Portal* and select the plus icon in the upper right corner.
2. Enter `portal1` in the *Name* field.
3. In *Applications*, select all of the application types that the users can access.
4. In *IP Pools*, select *Tunnel_ group1*.
5. Select *OK*.

To create the portal2 web portal

1. Go to *VPN* > *SSL* > *Portal* and select the plus icon in the upper right corner.
2. Enter `portal2` in the *Name* field and select *OK*.
3. In *Applications*, select all of the application types that the users can access.
4. In *IP Pools*, select *Tunnel_ group2*
5. Select *OK*.

Later, you can configure these portals with bookmarks and enable connection tool capabilities for the convenience of your users.

Creating the user accounts and user groups

After enabling SSL VPN and creating the web portals that you need, you need to create the user accounts and then the user groups that require SSL VPN access.

Go to *User & Device* > *User* > *User Definition* and create user1 and user2 with password authentication. After you create the users, create the SSL VPN user groups.

To create the user groups - web-based manager

1. Go to *User & Device* > *User* > *User Groups*.
2. Select *Create New* and enter the following information:

Name	group1
Type	Firewall

3. From the *Available* list, select *user1* and move it to the *Members* list by selecting the right arrow button.
4. Select *OK*.
5. Repeat steps 2 through 4 to create group2, assigned to portal2, with user2 as its only member.

Creating the security policies

You need to define security policies to permit your SSL VPN clients, web-mode or tunnel-mode, to connect to the protected networks behind the FortiGate unit. Before you create the security policies, you must define the source and destination addresses to include in the policy. See “Creating the firewall addresses” on page 2227.

Two types of security policy are required:

- An SSL VPN policy enables clients to authenticate and permits a web-mode connection to the destination network. In this example, there are two destination networks, so there will be

two SSL VPN policies. The authentication, ensures that only authorized users access the destination network.

- A tunnel-mode policy is a regular ACCEPT security policy that enables traffic to flow between the SSL VPN tunnel interface and the protected network. Tunnel-mode policies are required if you want to provide tunnel-mode connections for your clients. In this example, there are two destination networks, so there will be two tunnel-mode policies.

To create the SSL VPN security policies - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select *Create New.*
2. Select the *Policy Type* of *VPN* and the *Policy Subtype* as *SSL-VPN*.
3. Enter the following information:

Incoming Interface	port1
Remote Address	All
Local Interface	port2
Local Protected Interface	Subnet_1

4. Under Configure *SSL-VPN Authentication Rules*, select *Create New* and enter the following information:

Group(s)	group1
Schedule	always
Service	ALL
SSL-VPN Portal	portal1

5. Select *OK*, and then select *OK* again.
6. Select *Create New.*
7. Select the *Policy Type* of *VPN* and the *Policy Subtype* as *SSL-VPN*.
8. Enter the following information:

Incoming Interface	port1
Remote Address	All
Local Interface	port3
Local Protected Interface	Subnet_2

9. Under Configure *SSL-VPN Authentication Rules*, select *Create New* and enter the following information:

Group(s)	group2
Schedule	always
Service	ALL
SSL-VPN Portal	portal1

10. Select *OK*, and then select *OK* again.

To create the tunnel-mode security policies - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following information, and select *OK*:

Incoming Interface	sslvpn tunnel interface (ssl.root)
Source Address	Tunnel_group1
Outgoing Interface	port2
Destination Address	Subnet_1
Action	ACCEPT
Enable NAT	Enable

4. Select *Create New.*
5. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
6. Enter the following information, and select *OK*:

Incoming Interface	sslvpn tunnel interface (ssl.root)
Source Address	Tunnel_group2
Outgoing Interface	port3
Destination Address	Subnet_2
Action	ACCEPT
Enable NAT	Enable

Create the static route to tunnel mode clients

Reply packets destined for tunnel mode clients must pass through the SSL VPN tunnel. You need to define a static route to accomplish this.

To add a route to SSL VPN tunnel mode clients - web-based manager

1. Go to *Router* > *Static* > *Static Routes* and select *Create New*.

   For low-end FortiGate units, go to *System* > *Network* > *Routing* and select *Create New*.

2. Enter the following information and select *OK*.

Destination IP/Mask	`10.11.254.0/24` This IP address range covers both ranges that you assigned to SSL VPN tunnel-mode users. See “Creating the tunnel client range addresses” on page 2228.
Device	Select the SSL VPN virtual interface, *ssl.root* for example.

In this example, the *IP Pools* field on the *VPN* > *SSL* > *Config* page is not used because each web portal specifies its own tunnel IP address range

Chapter 17 Traffic Shaping for FortiOS 5.0

With the ever-increasing demands on network systems for a number of protocols, including email, HTTP traffic both internally and externally to the internet, voice over IP, FTP, and more, slow traffic is becoming a reality. Important traffic may even be dropped or slowed to an unusable speed. Web traffic delays can result in a loss of revenue for businesses.

Traffic shaping attempts to normalize traffic peaks and bursts to prioritize certain flows over others. There is a physical limitation to the amount of data which can be buffered and to the length of time it can be buffered.

FortiGate units provide Quality of Service (QoS) by applying bandwidth limits and prioritization. Using traffic shaping, you can adjust how your FortiGate unit allocates resources to different traffic types to improve performance and stability of latency sensitive or bandwidth intensive network applications.

This document describes Quality of Service (QoS), traffic shaping, FortiGate traffic shaping algorithms, and includes configuration procedures for traffic shaping on FortiGate units.

This FortiOS Handbook chapter contains the following sections:

The purpose of traffic shaping describes traffic shaping theories and quality of service.

Traffic shaping methods lists different methods of applying traffic shaping within FortiOS, and explains how to use TOS and Differentiated Services.

Examples provides basic application scenarios for shapers.

Troubleshooting traffic shaping lists diagnose commands to use for determining if traffic shapers are working correctly.

The purpose of traffic shaping

Traffic shaping, or traffic management, controls the bandwidth available and sets the priority of traffic processed by the policy to control the volume of traffic for a specific period (bandwidth throttling) or rate the traffic is sent (rate limiting).

Traffic shaping attempts to normalize traffic peaks and bursts to prioritize certain flows over others. But there is a physical limitation to the amount of data which can be buffered and to the length of time. Once these thresholds have been surpassed, frames and packets will be dropped, and sessions will be affected in other ways.

A basic traffic shaping approach is to prioritize certain traffic flows over other traffic whose potential loss is less disadvantageous. This would mean that you accept certain sacrifices in performance and stability on low-priority traffic, to increase or guarantee performance and stability to high-priority traffic.

If, for example, you are applying bandwidth limitations to certain flows, you must accept the fact that these sessions can be limited and therefore negatively impacted.

Note that traffic shaping is effective for normal IP traffic at normal traffic rates. Traffic shaping is not effective during periods when traffic exceeds the capacity of the FortiGate unit. Because packets must be received by the FortiGate unit before they are subject to traffic shaping, if the FortiGate unit cannot process all of the traffic it receives, then dropped packets, delays, and latency are likely to occur.

To ensure that traffic shaping is working at its best, make sure that the interface Ethernet statistics show no errors, collisions or buffer overruns.

Accelerated interfaces (NPx network processors and CE) affect traffic shaping. For more information, see the *FortiGate Hardware* Guide.

Quality of Service

Quality of Service (QoS) is the capability to adjust some quality aspects of your overall network traffic. This can include such techniques as priority-based queuing and traffic policing. Because bandwidth is finite and because some types of traffic are slow, jitter or packet loss sensitive, bandwidth intensive, or operation critical, QoS can be a useful tool for optimizing the performance of the various applications on your network.

Before implementing QoS, organizations should first identify the types of traffic that are important to the organization, the types of traffic that use high amounts of bandwidth, and the types of traffic that are sensitive to latency or packet loss.

For example, a company might want to guarantee sufficient bandwidth for revenue producing e-commerce traffic. They need to ensure that transactions can be completed and that clients do not experience service delays and interruptions. At the same time, the company may need to ensure low latency for voice over IP (VoIP) traffic used by sales and customer support, while traffic latency and bursts may be less critical to the success of other network applications such as long term, resumable file transfers. Many organizations discover that QoS is especially important for managing their voice and streaming multi-media traffic. These types of traffic can rapidly consume bandwidth and are sensitive to latency.

Discovering the needs and relative importance of each traffic type on your network will help you to design an appropriate overall approach, including how you will configure each available QoS component technique. Some organizations discover that they only need to configure bandwidth limits for some services. Other organizations determine that they need to fully configure

interface and security policy bandwidth limits for all services, and prioritize queuing of critical services relative to traffic rate.

You can implement QoS on FortiGate units using the following techniques:

Traffic policing	Drops packets that do not conform to bandwidth limitations.
Traffic shaping	Ensures that the traffic may consume bandwidth at least at the guaranteed rate by assigning a greater priority queue if the guarantee is not being met. Also ensures that the traffic cannot consume bandwidth greater than the maximum at any given instant in time. Flows greater than the maximum rate are subject to traffic policing.
Queuing	Transmits packets in order of their assigned priority queue for that physical interface. All traffic in a higher priority traffic queue must be completely transmitted before traffic in lower priority queues will be transmitted.

When deciding how to configure QoS techniques, it can be helpful to know when FortiGate units employ each technique in the overall traffic processing flow, and the considerations that arise from those mechanisms.

Traffic policing

The FortiGate unit begins to process traffic as it arrives (ingress) and departs (egress) on an interface. In later phases of the network processing, such as enforcing maximum bandwidth use on sessions handled by a security policy, if the current rate for the destination interface or traffic regulated by that security policy is too high, the FortiGate unit may drop the packet. Time spent on prior processing, such as web filtering, decryption or IPS, is often wasted on packets that are not forwarded. This applies to VLAN interfaces and physical interfaces.

You can prevent this wasted effort on ingress by configuring the FortiGate unit to preemptively drop excess packets when they are received at the source interface, before most other traffic processing is performed:

```
config system interface
  edit <interface_name>
    set inbandwidth <rate_int>
  next
end
```

where `<rate_int>` is the bandwidth limit in Kb/s. Excess packets will be dropped. If `inbandwidth` is `0`, the rate is not limited.

A similar command is available that can be performed on egress as well using the CLI commands:

```
config system interface
  edit <interface_name>
    set outbandwidth <rate_int>
  next
end
```

As with ingress, setting the rate to 0 (zero) sets the rate to unlimited.

Rate limiting traffic accepted by the interface enables you to restrict incoming traffic to rates that, while no longer the full capacity of the interface, at the traffic shaping point in the processing are more likely to result in acceptable rates of outgoing traffic per destination

interface or all security policies. This conserves FortiGate processing resources for those packets that are more likely to be viable completely to the point of egress.

Excessive traffic policing can degrade network performance rather than improve it. For details on factors you may want to consider when configuring traffic policing, see “Important considerations” on page 2241.

Bandwidth guarantee, limit, and priority interactions

After packet acceptance, the FortiGate unit classifies traffic and may apply traffic policing at additional points during processing. It may also apply additional QoS techniques, such as prioritization and traffic shaping. Traffic shaping consists of a mixture of traffic policing to enforce bandwidth limits, and priority queue adjustment to assist packets in achieving the guaranteed rate.

If you have configured prioritization, the FortiGate unit prioritizes egressing packets by distributing them among FIFO (first in, first out) queues associated with each possible priority number. Each physical interface has six priority queues. Virtual interfaces do not have their own queues, and instead use the priority queues of the physical interface to which they are bound.

Each physical interface’s six queues are queue 0 to queue 5, where queue 0 is the highest priority queue. However, for the reasons described below, you may observe that your traffic uses only a subset of those six queues. Some traffic may always use a certain queue number. Some queuing may vary by the packet rate or mixture of services. Some queue numbers may be used only by through traffic for which you have configured traffic shaping in the security policy that applies to that traffic session. For example:

- Administrative access traffic will always use queue 0.
- Traffic matching security policies ***without*** traffic shaping may use queue 0, queue 1, or queue 2. Which queue will be used depends on the priority value you have configured for packets with that ToS (type of service) bit value, if you have configured ToS-based priorities.
- Traffic matching security policies ***with*** traffic shaping may use any queue. Which queue will be used depends on whether the packet rate is currently below the guaranteed bandwidth (queue 0), or above the guaranteed bandwidth. Packets at rates greater than the maximum bandwidth limit are dropped.
- If the global tos-based-priority is low (3), the priority in a traffic-shaper is medium (2) and a packet flows though a policy that refers to the shaper, the packet will be assigned the priority defined by the shaper, in this case medium (2).

Prioritization and traffic shaping behavior varies by your configuration, the service types and traffic volumes, and by whether the traffic is through traffic, or the traffic originates from or terminates at the FortiGate unit itself.

FortiGate traffic

Administrative access to the FortiGate through HTTPS or SSH, or IPsec tunnel negotiations, security policies do not apply, and therefore FortiGate units do not apply traffic shaping. Such traffic also uses the highest priority queue, queue 0. In other words:

packet priority = 0

Exceptions to this rule include traffic types that are connections related to a session governed by a security policy.

For example, if you have enabled scanning by FortiGuard antivirus, traffic from the sender technically terminates at the FortiGate proxy that scans that traffic type; the FortiGate unit initiates a second connection that transmits scanned content to its destination. Because the second connection’s traffic is technically originating from the FortiGate proxy and therefore the

FortiGate unit itself, it uses the highest priority queue, queue 0. However, this connection is logically associated with through traffic, and is therefore subject to possible bandwidth enforcement and guarantees in its governing security policy. In this way, it behaves partly like other through traffic.

Through traffic

For traffic passing through the FortiGate unit, the method a FortiGate unit uses to determine the priority queue varies by whether you have enabled Traffic Shaping. Packets may or may not use a priority queue directly or indirectly derived from the type of service (ToS) bit — sometimes used instead with differentiated services — in the packet's IP header.

If Traffic Shaping is not enabled in the security policy, the FortiGate unit neither limits nor guarantees bandwidth, and traffic for that session uses the priority queue determined directly by matching the ToS bit in its header with your configured values:

```
config system global
  set tos-based-priority {high | low | medium}
end
```

or, if you have configured a priority specifically for that TOS bit value:

```
config system tos-based-priority
  edit <id_int>
    set tos [0-15]
    set priority {high | low | medium}
  next
end
```

where `tos` is the value of the ToS bit in the packet's IP header, and `high` has a priority value of 0 and `low` is 2. Priority values configured in the second location will override the global ToS-based priority. In other words:

packet priority = ToS-based priority

For example, you might specify that packets with a ToS bit value of 2 should use queue 0, the highest priority queue:

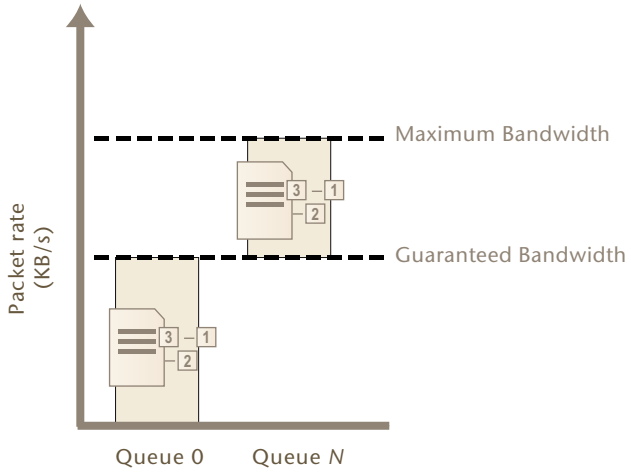
```
config system tos-based-priority
  edit 15
    set tos 2
    set priority high
  next
end
```

If Traffic Shaping is enabled in the security policy using shared traffic shapers, the FortiGate unit may instead or also subject packets to traffic policing, or priority queue increase in an effort to meet bandwidth guarantees configured in the shaper:

```
config firewall shaper traffic-shaper
  edit <shaper_name>
    ...
    set priority {high | medium | low}
    set maximum-bandwidth <rate>
    set guaranteed-bandwidth <rate>
end
```

where `high` has a priority value of 1 and `low` is 3, and `<rate>` is the bandwidth limit in kilobits per second.

Figure 314: Traffic queuing as packet rate increases



- If the current packet rate is less than Guaranteed Bandwidth, packets use priority queue 0. In other words:

  packet priority = 0

- If the current packet rate is greater than Guaranteed Bandwidth but less than Maximum Bandwidth, the FortiGate unit assigns a priority queue by adding the numerical value of the security policy-based priority, where the value of High is 1, and Low is 3, with the numerical value of the ToS-based priority, where `high` has a priority value of 0 and `low` is 2. Because the two values are added, depending on the your configured ToS-based priorities, packets in this category could use queues from queue 1 to queue 5. In other words:

  packet priority = ToS-based priority + security policy-based priority

  For example, if you have enabled Traffic Shaping in the security policy, and the security policy's Traffic Priority is Low (value 3), and the priority normally applied to packets with that ToS bit is `medium` (value 1), then packets have a total packet priority of 4, and use priority queue 4.

- If the current packet rate exceeds Maximum Bandwidth, excess packets are dropped.

Calculation and regulation of packet rates

Packet rates specified for Maximum Bandwidth or Guaranteed Bandwidth are:

```
rate = amount / time
```

where rate is expressed in kilobits per second (Kb/s).

Burst size at any given instant cannot exceed the amount configured in Maximum Bandwidth. Packets in excess are dropped. Packets deduct from the amount of bandwidth available to subsequent packets and available bandwidth regenerates at a fixed rate. As a result, bandwidth available to a given packet may be less than the configured rate, down to a minimum of 0 Kb/s.

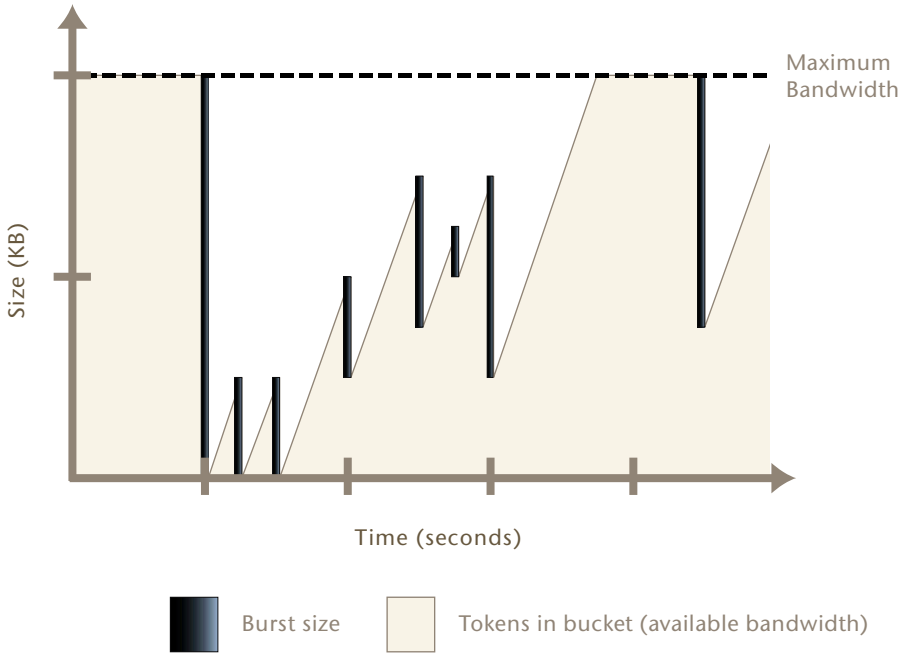
Rate calculation and behavior can alternatively be described using the token bucket metaphor, where:

- a traffic flow has an associated bucket, which represents burst size bounds, and is the size of your configured bandwidth limit
- the bucket receives tokens, which represent available bandwidth, at the fixed configured rate
- as time passes, tokens are added to the bucket, up to the capacity of the bucket; excess tokens are discarded
- when a packet arrives, the packet must deduct bandwidth tokens from the bucket equal to its packet size in order to egress
- packets cannot egress if there are insufficient tokens to pay for its egress; these nonconforming packets are dropped

Bursts are not redistributed over a longer interval, so bursts are propagated rather than smoothed, although their peak size is limited.

Maximum burst size is the capacity of the bucket (the configured bandwidth limit); actual size varies by the current number of tokens in the bucket, which may be less than bucket capacity, due to deductions from previous packets and the fixed rate at which tokens accumulate. A depleted bucket refills at the rate of your configured bandwidth limit. Bursts cannot borrow tokens from other time intervals. This behavior is illustrated in Figure 315 on page 2239.

Figure 315: Bursts and bandwidth limits over time



By limiting traffic peaks and token regeneration in this way, the available bandwidth at a given moment may be less than bucket capacity, but your limit on the total amount per time interval is ensured. That is, total bandwidth use during each interval of 1 second is at most the integral of your configured rate.

You may observe that external clients, such as FTP or BitTorrent clients, initially report rates between Maximum Bandwidth and twice that of Maximum Bandwidth, depending on the size of their initial burst. This is notably so when a connection is initiated following a period of no network activity.The apparent discrepancy in rates is caused by a difference of perspective when delimiting time intervals. A burst from the client may initially consume all tokens in the

bucket, and before the end of 1 second, as the bucket regenerates, be allowed to consume almost another bucket's worth of bandwidth. From the perspective of the client, this constitutes one time interval. From the perspective of the FortiGate unit, however, the bucket cannot accumulate tokens while full; therefore, the time interval for token regeneration begins ***after*** the initial burst, and does not contain the burst. These different points of reference result in an initial discrepancy equal to the size of the burst — the client's rate contains it, but the FortiGate unit's rate does not. If the connection is sustained to its limit and time progresses over an increasing number of intervals, however, this discrepancy decreases in importance relative to the bandwidth total, and the client's reported rate will eventually approach that of the FortiGate unit's configured rate limit.

For example, your Maximum Bandwidth might be 50 Kb/s and there has been no network activity for one or more seconds. The bucket is full. A burst from an FTP client immediately consumes 50 Kb. Because the bucket completely regenerates over 1 second, by the time almost another 1 second has elapsed from the initial burst, traffic can consume another 49.999 Kb, for a total of 99.999 Kb between the two points in time. From the vantage point of an external FTP client regulated by this bandwidth limit, it therefore initially appears that the bandwidth limit is 99.999 Kb/s, almost twice the configured limit of 50 Kb/s. However, bucket capacity only regenerates at your configured rate of 50 Kb/s, and so the connection can only consume a maximum of 50 Kb during each second thereafter. The result is that as bandwidth consumption is averaged over an increasing number of time intervals, each of which are limited to 50 Kb/s, the effects of the first interval's doubled bandwidth size diminishes proportionately, and the client's reported rate eventually approach your configured rate limit. This effect is illustrated in Table 102 on page 2240.

Table 102: Effects of a 50 Kb/s limit on client reported rates

Total size transferred (Kb)	Time (s)	Rate reported by client (Kb/s)
99.999 (50 + 49.999)	1	99.999
149.999	2	74.999
199.999	3	66.666
249.999	4	62.499
299.999	5	59.998
349.999	6	58.333
...	...	...

Guaranteed Bandwidth can also be described using a token bucket metaphor. However, because this feature attempts to achieve or exceed a rate rather than limit it, the FortiGate unit does not discard non-conforming packets, as it does for Maximum Bandwidth; instead, when the flow does not achieve the rate, the FortiGate unit increases the packets' priority queue, in an effort to increase the rate.

Guaranteed and maximum bandwidth rates apply to the bidirectional total for all sessions controlled by the security policy. For example, an FTP connection may entail two separate connections for the data and control portion of the session; some packets may be reply traffic rather than initiating traffic. All packets for both connections are counted when calculating the packet rate for comparison with the guaranteed and maximum bandwidth rate.

Important considerations

In essence, by implementing QoS, you trade some performance and/or stability from traffic X by discarding packets or introducing latency in order to improve performance and stability of traffic Y. The best traffic shaping configuration for your network will appropriately balance the needs of each traffic flow by considering not only the needs of your particular organization, but also the resiliency and other characteristics of each particular service.

For example, you may find that web browsing traffic is both more resistant to interruptions or latency and less business critical than UDP or VoIP traffic, and so you might implement less restrictive QoS measures on UDP or VoIP traffic than on HTTP traffic.

An appropriate QoS configuration will also take into account the physical limits of your network devices, and the interactions of the aforementioned QoS mechanisms, described in "Bandwidth guarantee, limit, and priority interactions" on page 2236.

You may choose to configure QoS differently based upon the hardware limits of your network and FortiGate unit. Traffic shaping may be less beneficial in extremely high-volume situations where traffic exceeds a network interface's or your FortiGate model's overall physical capacity. A FortiGate unit must have sufficient resources, such as memory and processing power, to process all traffic it receives, and to process it at the required rate; if it does not have this capacity, then dropped packets and increased latency are likely to occur. For example, if the total amount of memory available for queuing on a physical interface is frequently exceeded by your network's typical packet rates, frames and packets must be dropped. In such a situation, you might choose to implement QoS using a higher model FortiGate unit, or to configure an incoming bandwidth limit on each interface.

Incorrect traffic shaping configurations can actually further degrade certain network flows, because excessive discarding of packets or increased latency beyond points that can be gracefully handled by that protocol can create additional overhead at upper layers of the network, which may be attempting to recover from these errors. For example, a configuration might be too restrictive on the bandwidth accepted by an interface, and may therefore drop too many packets, resulting in the inability to complete or maintain a SIP call.

To optimize traffic shaping performance, first ensure that the network interface's Ethernet statistics are clean of errors, collisions, or buffer overruns. To check the interface, enter the following diagnose command to see the traffic statistics:

```
diagnose hardware deviceinfo nic <port_name>
```

If these are not clean, adjust FortiGate unit and settings of routers or other network devices that are connected to the FortiGate unit. For additional information, see "Troubleshooting traffic shaping" on page 2266.

Once Ethernet statistics are clean, you may want to use only some of the available FortiGate QoS techniques, or configure them differently, based upon the nature of FortiGate QoS mechanisms described in "Bandwidth guarantee, limit, and priority interactions" on page 2236. Configuration considerations include:

- For maximum bandwidth limits, ensure that bandwidth limits at the source interface and/or the security policy are not too low, which can cause the FortiGate unit to discard an excessive number of packets.
- For prioritization, consider the ratios of how packets are distributed between available queues, and which queue is used by which types of services. If you assign most packets to the same priority queue, it negates the effects of configuring prioritization. If you assign many high bandwidth services to high priority queues, lower priority queues may be starved for bandwidth and experience increased or indefinite latency. For example, you may want to prioritize a latency-sensitive service such as SIP over a bandwidth-intensive service such as

FTP. Consider also that bandwidth guarantees can affect the queue distribution, assigning packets to queue 0 instead of their typical queue in high-volume situations.

- You may or may not want to guarantee bandwidth, because it causes the FortiGate unit to assign packets to queue 0 if the guaranteed packet rate is not currently being met. Comparing queuing behavior for lower-bandwidth and higher-bandwidth situations, this would mean that effects of prioritization only become visible as traffic volumes rise and exceed their guarantees. Because of this, you might want only some services to use bandwidth guarantees, to avoid the possibility that in high-volume situations all traffic uses the same queue, thereby negating the effects of configuring prioritization.
- For prioritization, configure prioritization for all through traffic. You may want to configure prioritization by either ToS-based priority or security policy priority, but not both. This simplifies analysis and troubleshooting.

  Traffic subject to both security policy and ToS-based priorities will use a combined priority from both of those parts of the configuration, while traffic subject to only one of the prioritization methods will use only that priority. If you configure both methods, or if you configure either method for only a subset of your traffic, packets for which a combined priority applies will frequently receive a lower priority queue than packets for which you have only configured one priority method, or for which you have not configured prioritization.

  For example, if both ToS-based priority and security policy priority both dictate that a packet should receive a “medium” priority, in the absence of bandwidth guarantees, a packet will use queue 3, while if only ToS-based priority had been configured, the packet would have used queue 1, and if only security policy-based priority had been configured, the packet would have used queue 2. If no prioritization had been configured at all, the packet would have used queue 0.

For example alternative QoS implementations that illustrate these considerations, see “Examples” on page 2259

Traffic shaping methods

In FortiOS, there are three types of traffic shaping configuration. Each has a specific function, and all can be used together in varying configurations. Policy shaping enables you to define the maximum bandwidth and guaranteed bandwidth set for a security policy. Per-IP shaping enables you to define traffic control on a more granular level. Application traffic shaping goes further, enabling traffic controls on specific applications or application groupings.

This chapter describes the types of traffic shapers and how to configure them in the web-based manager and the CLI.

Traffic shaping options

When configuring traffic shaping for your network, there are three different methods to control the flow of network traffic to ensure that the desired traffic gets through while also limiting the bandwidth that users use for other less important or bandwidth consuming traffic. The three shaping options are:

- shared policy shaping - bandwidth management by security policies
- per-IP shaping - bandwidth management by user IP addresses
- application control shaping - bandwidth management by application

Shared policy shaping and per IP shaping are enabled within the security policy, while the application control shaping is configured in *Security Profiles* > *Application Control* > *Application Sensors,* and enabled in the security policy by enabling *Application Control* in the *Security Profiles* section.

The FortiGate unit offers three different traffic shaping options, all of which can be enabled at the same time within the same security policy. Generally speaking, the hierarchy for shapers in FortiOS is:

- Application Control shaper
- Security policy shaper
- Per-IP shaper

With this hierarchy, if an application control list has a traffic shaper defined, it will have precedence always over any other security policy shaper. For example, with the example above creating an application control for Facebook, the shaper defined for Facebook will supersede any security policy enabled traffic shapers. While the Facebook application may reach its maximum bandwidth, the user can still have the bandwidth room available from the shared shaper and, if enabled, the per-IP shaper.

Equally, any security policy shared shaper will have precedence over any per-IP shaper. However, traffic that exceeds any of these shapers will be dropped. For example, the policy shaper will take effect first, however, if the per-IP shaper limit is reached first, then traffic for that user will be dropped even if the shared shaper limit for the policy has not been exceeded.

Shared policy shaping

Traffic shaping by security policy enables you to control the maximum and/or guaranteed throughput for a selected security policy. When configuring a shaper, you can select to apply the bandwidth shaping per policy or for all policies. Depending on your selection, the FortiGate unit will apply the shaping rules differently.

Per policy

When selecting a shaper to be *per policy*, the FortiGate unit will apply the shaping rules defined to each security policy individually.

For example, the shaper is set to be per policy with a maximum bandwidth of 1000 Kb/s. There are four security policies monitoring traffic through the FortiGate unit. Three of these have the shaper enabled. Each security policy has the same maximum bandwidth of 1000 Kb/s.

Per policy traffic shaping is compatible with client/server (active-passive) transparent mode WAN optimization rules. Traffic shaping is ignored for peer-to-peer WAN optimization and for client/server WAN optimization not operating in transparent mode.

All policies

When selecting a shaper to be for all policies - *For All Policies Using This Shaper* - the FortiGate unit applies the shaping rules to all policies using the same shaper. For example, the shaper is set to be per policy with a maximum bandwidth of 1000 Kb/s. There are four security policies monitoring traffic through the FortiGate unit. All four have the shaper enabled. Each security policy must share the defined 1000 Kb/s, and is set on a first come, first served basis. For example, if policy 1 uses 800 Kb/s, the remaining three must share 200 Kb/s. As policy 1 uses less bandwidth, it is opened up to the other policies to use as required. Once used, any other policies will encounter latency until free bandwidth opens from a policy currently in use.

Maximum and guaranteed bandwidth

The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the shaper.

The *Maximum Bandwidth* can be set to a value of between 1 and 16776000 kbit/s. The Web-Based Manager gives an error if any value outside of this range is used, but in the CLI a value of 0 can be entered. Setting `maximum-bandwidth` to 0 (zero) prevents any traffic from going through the policy.

The guaranteed bandwidth ensures there is a consistent reserved bandwidth available for a given service or user. When setting the guaranteed bandwidth, ensure that the value is significantly less than the bandwidth capacity of the interface, otherwise no other traffic will pass through the interface or very little an potentially causing unwanted latency.

Traffic priority

Select a Traffic Priority of high, medium or low, so the FortiGate unit manages the relative priorities of different types of traffic. For example, a policy for connecting to a secure web server needed to support e-commerce traffic should be assigned a high traffic priority. Less important services should be assigned a low priority. The firewall provides bandwidth to low-priority connections only when bandwidth is not needed for high-priority connections.

Be sure to enable traffic shaping on all security policies. If you do not apply any traffic shaping rule to a policy, the policy is set to high priority by default. Distribute security policies over all three priority queues.

VLAN, VDOM and virtual interfaces

Policy-based traffic shaping does not use queues directly. It shapes the traffic and if the packet is allowed by the security policy, then a priority is assigned. That priority controls what queue the packet will be put in upon egress. VLANs, VDOMs, aggregate ports and other virtual devices do not have queues and as such, traffic is sent directly to the underlying physical device where it is queued and affected by the physical ports. This is also the case with IPsec connections.

Shared traffic shaper configuration settings

To configure a shared traffic shaper go to *Firewall Objects* > *Traffic Shaper* > *Shared* and select *Create New*.

Name	Enter a name for the traffic shaper.
Apply Shaper	When selecting a shaper to be *Per Policy*, the FortiGate unit will apply the shaping rules defined to each security policy individually. For example, the shaper is set to be per policy with a maximum bandwidth of 1000 Kb/s. There are four security policies monitoring traffic through the FortiGate unit. Three of these have the shaper enabled. Each security policy has the same maximum bandwidth of 1000 Kb/s. Per policy traffic shaping is compatible with client/server (active-passive) transparent mode WAN optimization rules. Traffic shaping is ignored for peer-to-peer WAN optimization and for client/server WAN optimization not operating in transparent mode. When selecting a shaper to be for all policies - *For All Policies Using This Shaper* - the FortiGate unit applies the shaping rules to all policies using the same shaper. For example, the shaper is set to be per policy with a maximum bandwidth of 1000 Kb/s. There are four security policies monitoring traffic through the FortiGate unit. All four have the shaper enabled. Each security policy must share the defined 1000 Kb/s, and is set on a first come, first served basis. For example, if policy 1 uses 800 Kb/s, the remaining three must share 200 Kb/s. As policy 1 uses less bandwidth, it is opened up to the other policies to use as required. Once used, any other policies will encounter latency until free bandwidth opens from a policy currently in use.
Traffic Priority	Select level of importance *Priority* so the FortiGate unit manages the relative priorities of different types of traffic. For example, a policy for connecting to a secure web server needed to support e-commerce traffic should be assigned a high traffic priority. Less important services should be assigned a low priority. If you do not apply any traffic shaping priority, the priority is set to high priority by default.

Maximum Bandwidth	The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the shaper. Setting *Maximum Bandwidth* to 0 (zero) provides unlimited bandwidth.
Guaranteed Bandwidth	The guaranteed bandwidth ensures there is a consistent reserved bandwidth available for a given service or user. When setting the guaranteed bandwidth, ensure that the value is significantly less than the bandwidth capacity of the interface, otherwise no other traffic will pass through the interface or very little and potentially causing unwanted latency. Setting *Guaranteed Bandwidth* to 0 (zero) provides unlimited bandwidth.
DSCP	Enter the number for the DSCP value. You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet. For more information, see "Differentiated Services".

Example

The following steps creates a Per Policy traffic shaper called "Throughput" with a maximum traffic amount of 720,000 Kb/s, and a guaranteed traffic of 150,000 Kb/s with a high traffic priority.

To create the shared shaper - web-based manager

1. Go to *Firewall Objects* > *Traffic Shaper* > *Shared* and select *Create New*.
2. Enter the *Name* `Throughput`.
3. Select *Per Policy*.
4. Select the *Maximum Bandwidth* check box and enter the value `120000`.
5. Select the *Guaranteed Bandwidth* check box and enter the value `150000`.
6. Set the *Traffic Priority* to *High*.
7. Select *OK*.

To create the shared shaper - CLI

```
config firewall shaper traffic-shaper
  edit Throughput
    set per-policy enable
    set maximum-bandwidth 720000
    set guaranteed-bandwidth 150000
    set priority high
end
```

Per-IP shaping

Traffic shaping by IP enables you to apply traffic shaping to all source IP addresses in the security policy. As well as controlling the maximum bandwidth users of a selected policy, you can also define the maximum number of concurrent sessions.

Per-IP traffic shaping enables you limit the behavior of every member of a policy to avoid one user from using all the available bandwidth - it now is shared within a group equally. Using a per-IP shaper avoids having to create multiple policies for every user you want to apply a shaper. Per-IP traffic shaping is not supported over NP2 interfaces.

Per-IP traffic shaping configuration settings

To configure per-IP traffic shaping go to *Firewall Objects* > *Traffic Shaper* > *Per-IP*. and select *Create New*.

Name	Enter a name for the per-IP traffic shaper.
Maximum Bandwidth	The maximum bandwidth instructs the security policy what the largest amount of traffic allowed using the policy. Depending on the service or the users included for the security policy, this number can provide a larger or smaller throughput depending on the priority you set for the shaper. Setting *Maximum Bandwidth* to 0 (zero) provides unlimited bandwidth.
Maximum Concurrent Connections	Enter the maximum allowed concurrent connection.
Forward DSCP Reverse DSCP	Enter the number for the DSCP value. You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet. For more information, see “Differentiated Services”.

Example

The following steps create a Per-IP traffic shaper called “Accounting” with a maximum traffic amount of 720,000 Kb/s, and the number of concurrent sessions of 200.

To create the shared shaper - web-based manager

1. Go to *Firewall Objects* > *Traffic Shaper* > *Per-IP*.
2. Select *Create New*.
3. Enter the *Name* `Accounting`.
4. Select the *Maximum Bandwidth* check box and enter the value `720000`.
5. Select the *Maximum Concurrent Sessions* check box and enter the value `200`.
6. Select *OK*.

To create the shared shaper - CLI

```
config firewall shaper per-ip-shaper
  edit Accounting
    set max-bandwidth 720000
    set max-concurrent-sessions 200
end
```

Adding Per-IP traffic shapers to a security policy

Per-IP traffic shaping is supported by IPv6 security policies. You can add any Per-IP traffic shaper to an IPv6 security policy in the CLI.5.020142014

To add a Per-IP traffic shaper to an IPv6 security policy - CLI

```
config firewall policy6
  edit 0
    set per-ip-shaper 'new-perip-shaper'
  end
```

Application control shaping

Traffic shaping is also possible for specific applications for both shared and per IP shaping. Through the *Security Profiles* > *Application Control* feature, you can configure a specific application's maximum bandwidth. When configuring the application control features, if the application is set to pass, you can set the traffic shaping options. The shapers available are those set up in the *Firewall Objects* > *Traffic Shaping* menu.

For more information on configuring application control shapers, see the *Security Profiles Guide*.

Example

This example sets the traffic shaping definition for Facebook to a medium priority, a default traffic shaper.

To add traffic shaping for Facebook - web-based manager

1. Go to *Security Profiles* > *Application Control* > *Application Sensors*.
2. Select the *Create New* "Plus" icon in the upper right corner of the screen to create a new application group, and enter the name `Web`.
3. Select *OK*.
4. Select *Create New*.
5. Deselect the check box for Category to unselect all categories and select *Social.Networking*.
6. Select *Traffic Shaping* and select medium-priority from the drop-down list.
7. Select *OK*.

To add traffic shaping for Facebook - CLI

```
config application list
  edit web
    config entries
      edit 1
        set category 23
        set application 17735
        set action pass
        set shaper medium-priority
      end
  end
end
```

Enabling in the security policy

All traffic shapers are enabled within a security policy, including the Application Control shapers. As such, the shapers are in effect after any DoS detection policies, and before any routing or packet scanning occurs.

Traffic shaping is also supported for IPv6 policies.

To enable traffic shaping - web-based manager

1. Go to *Policy* > *Policy* > *Policy*.
2. Select *Create New* or select an existing policy and select *Edit*.
3. Select *Traffic Shaping*.
4. Select the shaping option and select the shaper from the drop-down list.
5. Select *OK*.

Shapers applied in the security policy affect outbound or traffic to a destination. To affect inbound, or download, traffic, select *Shared Traffic Shaper Reverse Direction*. For more information, see “Reverse direction traffic shaping” on page 2249.

To enable traffic shaping - CLI

```
config firewall policy
  edit <policy_number>
    ...
    set traffic-shaper <shaper_name>
    set per-ip-shaper <shaper_name>
end
```

Reverse direction traffic shaping

The shaper you select for the security policy (shared shaper) will affect the traffic in the direction defined in the policy. For example, if the source port is port 1 and the destination is port 3, the shaping affects the flow in this direction only, that is, the upload or outbound direction. By selecting *Shared Traffic Shaper Reverse Direction*, you can define the traffic shaper for the policy in the opposite direction, that is, the download or inbound direction. In this example, from port 3 to port 1.

To add a reverse shaper

1. Go to *Policy* > *Policy* > *Policy*.

2. Select *Traffic Shaping*.
3. Select *Shared Traffic Shaper Reverse Direction* and select the shaper from the list.
4. Select *OK*.

Setting the reverse direction only

There may be instances where you only need to have the traffic shaping for incoming connections. That is, the “reverse” direction to the typical traffic shaper.

To add a reverse shaper - web-based manager

1. Go to *Policy* > *Policy* > *Policy*.
2. Select *Traffic Shaping*.
3. Select *Shared Traffic Shaper Reverse Direction* and select the shaper from the list.
4. Select *OK*.

To configure a reverse-only shaper - CLI

```
config firewall policy
  edit <policy_number>
    ...
    set traffic-shaper-reverse <shaper_name>
end
```

Application control shaper

Application control shapers are in effect within the application control profile. Within the security policy options, select *Application Control* and select the application from the list.

Type of Service priority

Type of service (ToS) is an 8-bit field in the IP header that enables you to determine how the IP datagram should be delivered, using criteria of Delay, Throughput, Priority, Reliability, and Cost. Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority ToS is 0, the highest is 7 when bits 3, 4, and 5 are all set to 1. There are 4 other bits that are seldom used or reserved that are not included here.

Together these bits are the tos variable of the `tos-based-priority` command. The router tries to match the ToS of the datagram to the ToS on one of the possible routes to the destination. If there is no match, the datagram is sent over a zero ToS route. Using increased quality may increase the cost of delivery because better performance may consume limited network resources.

Each bit represents the priority as per RFC 1349:

- 1000 - minimize delay
- 0100 - maximize throughput
- 0010 - maximize reliability
- 0001 - minimize monetary cost

The TOS value is set in the CLI using the commands:

```
config system tos-based-priority
  edit <sequence_number>
    set tos [0-15]
    set priority [high | medium | low]
end
```

Where `tos` is the value of the type of service bit in the IP datagram header with a value between 0 and 15, and `priority` is the priority of this type of service priority. These priority levels conform to the firewall traffic shaping priorities, as defined in RFC 1349.

For example, if you want to configure the FortiGate unit so that reliability is the first priority, set the tos value to 4.

```
config system tos-based-priority
  edit 1
    set tos 4
    set priority high
end
```

For a list of ToS values and their DSCP equivalents see "Tos and DSCP mapping" on page 2257.

Example

```
config system tos-based-priority
  edit 1
    set tos 1
    set priority low
  next
  edit 4
    set tos 4
    set priority medium
  next
  edit 6
    set tos 6
    set priority high
  next
end
```

TOS in FortiOS

Traffic shaping and TOS follow the following sequence:

- The CLI command `tos-based-priority` acts as a `tos-to-priority` mapping. FortiOS maps the TOS to a priority when it receives a packet.
- Traffic shaping settings adjust the packet's priority according the traffic.
- Deliver the packet based on its priority.

Differentiated Services

Differentiated Services describes a set of end-to-end Quality of Service (QoS) capabilities. End-to-end QoS is the ability of a network to deliver service required by specific network traffic

from one end of the network to another. By configuring differentiated services, you configure your network to deliver particular levels of service for different packets based on the QoS specified by each packet.

Differentiated Services (also called DiffServ) is defined by RFC 2474 and 2475 as enhancements to IP networking to enable scalable service discrimination in the IP network without the need for per-flow state and signaling at every hop. Routers that can understand differentiated services sort IP traffic into classes by inspecting the DS field in IPv4 header or the Traffic Class field in the IPv6 header.

You can use the FortiGate Differentiated Services feature to change the DSCP (Differentiated Services Code Point) value for all packets accepted by a policy. The network can use these DSCP values to classify, mark, shape, and police traffic, and to perform intelligent queuing. DSCP features are applied to traffic by configuring the routers on your network to apply different service levels to packets depending on the DSCP value of the packet.

If the differentiated services feature is not enabled, the FortiGate unit treats traffic as if the DSCP value is set to the default (00), and will not change IP packets' DSCP field. DSCP values are also not applied to traffic if the traffic originates from a FortiGate unit itself.

The FortiGate unit applies the DSCP value and IPsec encryption to the differentiated services (formerly TOS) field in the first word of the IP header. The typical first word of an IP header, with the default DSCP value, is 4500:

- 4 for IPv4
- 5 for a length of five words
- 00 for the default DSCP value

You can change the packet's DSCP field for traffic initiating a session (forward) or for reply traffic (reverse) and enable each direction separately and configure it in the security policy.

Changes to DSCP values in a security policy effect new sessions. If traffic must use the new DSCP values immediately, clear all existing sessions.

DSCP is enabled using the CLI command:

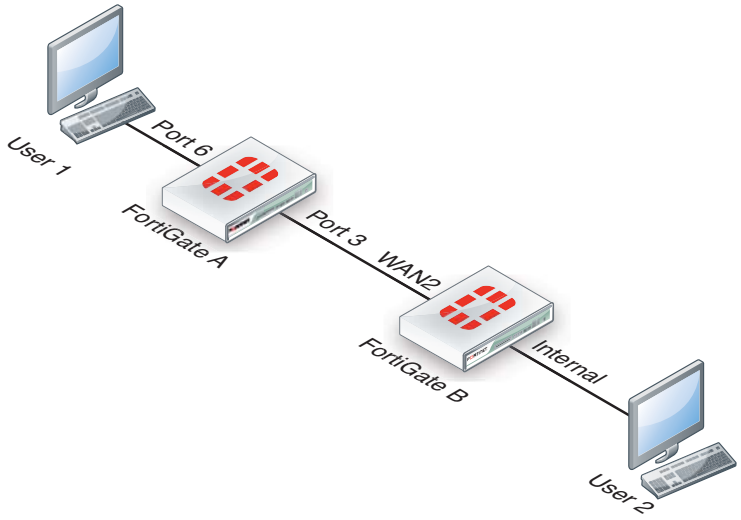
```
config firewall policy
  edit <policy_number>
    ...
    set diffserv-forward enable
    set diffservcode-forward <binary_integer>
    set diffserv-reverse enable
    set diffservcode-rev <binary_integer>
end
```

For more information on the different DCSP commands, see the examples below and the *CLI Reference*. If you only set `diffserv-forward` and `diffserv-reverse` without setting the corresponding `diffvercode` values, the FortiGate unit will reset the bits to zero.

For a list of DSCP values and their ToS equivalents see “Tos and DSCP mapping” on page 2257. DSCP values can also be defined within a shared shaper as a single value, and per-IP shaper for forward and reverse directions.

DSCP examples

For all the following DSCP examples, the FortiGate and client PC configuration is the following diagram and used firewall-based DSCP configurations.



Example

In this example, an ICMP ping is executed between User 1and FortiGate B, through a FortiGate unit. DSCP is disabled on FortiGate B, and FortiGate A contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf port6
    set dstintf port3
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-forward enable
    set diffservcode-forward 101110
end
```

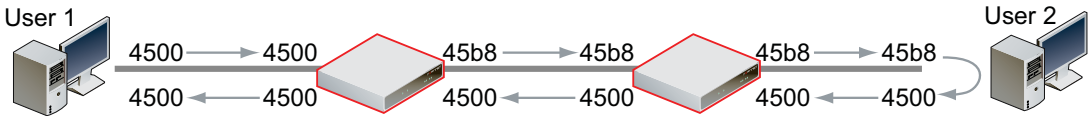
As a result, FortiGate A changes the DSCP field for outgoing traffic, but not to its reply traffic. The binary DSCP values used map to the following hexadecimal

TOS field values, which are observable by a sniffer (also known as a packet tracer):

- DSCP 000000 is TOS field 0x00
- DSCP 101110 is TOS field 0xb8, the recommended DSCP value for expedited forwarding (EF)

If you performed an ICMP ping between User 1 and User 2, the following output illustrates the IP headers for the request and the reply by sniffers on each of FortiGate unit's network

interfaces. The right-most two digits of each IP header are the TOS field, which contains the DSCP value.



Example

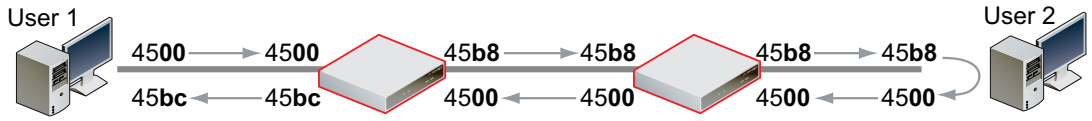
In this example, an ICMP ping is executed between User 1 and FortiGate B, through FortiGate A. DSCP is disabled on FortiGate B, and FortiGate A contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf port6
    set dstintf port3
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY"
    set diffserv-forward enable
    set diffserv-rev enable
    set diffservcode-forward 101110
    set diffservcode-rev 101111
end
```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic. The binary DSCP values in map to the following hexadecimal TOS field values, which are observable by a sniffer (also known as a packet tracer):

- DSCP 000000 is TOS field 0x**00**
- DSCP 101110 is TOS field 0x**b8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field 0x**bc**

If you performed an ICMP ping between User 1 and User 2, the output below illustrates the IP headers observed for the request and the reply by sniffers on each of FortiGate A's and FortiGate B's network interfaces. The right-most two digits of each IP header are the TOS field, which contains the DSCP value.



Example

In this example, an ICMP ping is executed between User 1 and FortiGate B, through FortiGate A. DSCP is enabled for both traffic directions on FortiGate A, and enabled only for reply traffic on FortiGate B. FortiGate A contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf port6
    set dstintf port3
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-forward enable
    set diffserv-rev enable
    set diffservcode-forward 101110
    set diffservcode-rev 101111
end
```

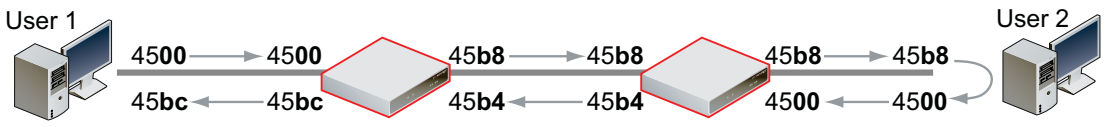
FortiGate B contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf wan2
    set dstintf internal
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-rev enable
    set diffservcode-rev 101101
end
```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic, and FortiGate B changes the DSCP field only for reply traffic. The binary DSCP values in this configuration map to the following hexadecimal TOS field values:

- DSCP 000000 is TOS field 0**x00**
- DSCP 101101 is TOS field 0**xb4**
- DSCP 101110 is TOS field 0**xb8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field 0**xbc**

If you performed an ICMP ping between User 1 and User 2, the output below illustrates the IP headers observed for the request and the reply by sniffers on each of FortiGate A's and FortiGate B's network interfaces. The right-most two digits of each IP header are the TOS field, which contains the DSCP value.



Example

In this example, HTTPS and DNS traffic is sent from User 1 to FortiGate B, through FortiGate A. DSCP is enabled for both traffic directions on FortiGate A, and enabled only for reply traffic on FortiGate B. FortiGate A contains the following configuration:

```
config firewall policy
  edit 2
    set srcintf port6
    set dstintf port3
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-forward enable
    set diffserv-rev enable
    set diffservcode-forward 101110
    set diffservcode-rev 101111
end
```

FortiGate B contains the following configuration:

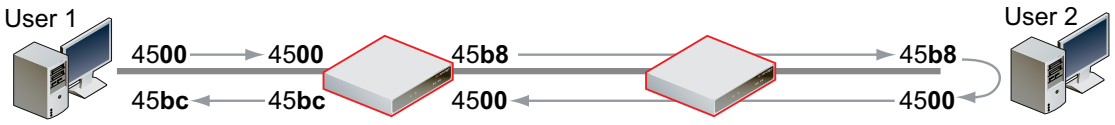
```
config firewall policy
  edit 2
    set srcintf wan2
    set dstintf internal
    set src addr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set diffserv-rev enable
    set diffservcode-rev 101101
end
```

As a result, FortiGate A changes the DSCP field for both outgoing traffic and its reply traffic, but FortiGate B changes the DSCP field only for reply traffic which passes through its internal interface. Since the example traffic does not pass through the internal interface, FortiGate B does not mark the packets. The binary DSCP values in this configuration map to the following hexadecimal TOS field values:

- DSCP 000000 is TOS field 0**x00**
- DSCP 101101 is TOS field 0**xb4**, which is configured on FortiGate B but not observed by the sniffer because the example traffic originates from the FortiGate unit itself, and therefore does not match that security policy.
- DSCP 101110 is TOS field 0**xb8**, the recommended DSCP value for expedited forwarding (EF)
- DSCP 101111 is TOS field 0**xbc**

If you sent HTTPS or DNS traffic from User 1 to FortiGate B, the following would illustrate the IP headers observed for the request and the reply by sniffers on each of FortiGate A's and

FortiGate B's network interfaces. The right-most two digits of each IP header are the TOS field, which contains the DSCP value.



Tos and DSCP mapping

The table below lists the mapping of DSCP and ToS hexadecimal values for QoS.

Table 103: ToS to DSCP mappings

Service Class	DSCP Bits	DSCP Value	ToS Value	ToS Hexidecimal
Network Control	111000	56-63	224	0xE0
Internetwork Control	110000	48-55	192	0xC0
Critical - Voice Data (RTP)	101110	46	184	0xB8
	101000	40	160	0xA0
Flash Override Video Data	100010	34	136	0x88
	100100	36	144	0x90
	100110	38	152	0x98
	100000	32	128	0x80
Flash Voice Control	011010	26	104	0x68
	011100	28	112	0x70
	011110	30	120	0x78
	011000	24	96	0x60
Immediate Deterministic (SNA)	010010	18	72	0x48
	010100	20	80	0x50
	010110	22	88	0x58
	010000	16	64	0x40
Priority Controlled Load	001010	10	40	0x28
	001100	12	48	0x30
	001110	14	56	0x38
	001000	8	32	0x20
Routine - Best Effort	000000	0	0	0x00
Routine - Penalty Box	000010	2	8	0x08

Traffic Shaper Monitor

You can view statistical information about traffic shapers and their bandwidth from *Firewall Objects* > *Monitor* > *Traffic Shaper Monitor*.

Refresh	Select to refresh the information on the page.
Reset	Select to reset the information to clear the current information from the page. New information is included on the page.
Report By	Select to display dropped packets or current bandwidth. The chart changes its name so you know what current information is displayed.
Traffic Shaper Usage Dropped packets	The bar chart displays the packets that were dropped by traffic shaper.
Traffic Shaper Usage Current Bandwidth	The bar chart displays the current bandwidth of traffic shapers.

Examples

While it is possible to configure QoS using a combination of security policies and in ToS-based priorities, and to distribute traffic over all six of the possible queues for each physical interface, the results of those configurations can be more difficult to analyze due to their complexity. In those cases, prioritization behavior can vary by several factors, including traffic volume, ToS (type of service) or differentiated services markings, and correlation of session to a security policy.

The following simple examples illustrate QoS configurations using either prioritization by security policy, or prioritization by ToS bit, but not both. The examples also assume you are not configuring traffic shaping for interfaces that receive hardware acceleration from network processing units (NPU).

QoS using priority from security policies

Configurations implementing QoS using the priority values defined in security policies are capable of applying bandwidth limits and guarantees.

In addition to configuring traffic shaping, you may also choose to limit bandwidth accepted by each interface. This can be useful in scenarios where bandwidth being received on source interfaces frequently exceeds the maximum bandwidth limit defined in the security policy. In this case, rather than wasting processing power on packets that will only be dropped later in the processing to enforce those limits, you may choose to preemptively police the traffic.

Note that if you implement QoS using security policies rather than ToS bit, the FortiGate unit applies QoS to all packets controlled by the policy. Control is less granular than prioritization by ToS bit, but has the benefits of correlating quality of service to a security policy, enabling you to distribute traffic over up to four of the possible 6 priority queues (queue 0 to queue 3), not requiring other devices in your network to set or respect the ToS bit, and of enabling you to configure bandwidth limits and guarantees.

In this example, we limit the bandwidth accepted by each source interface, limit the bandwidth used by sessions controlled by the security policy, and then configure prioritized queuing on the destination interface based upon the priority in the security policy, subject to alternative assignment to queue 0 when necessary to achieve the guaranteed packet rate.

To limit bandwidth accepted by an interface

In the CLI, enter the following commands:

```
config system interface
  edit <name_str>
    set inbandwidth <rate_int>
  next
end
```

where `<rate_int>` is the bandwidth limit in Kb/s. Excess packets will be dropped.

To configure bandwidth guarantees, limits, and priorities

1. Go to *Firewall Objects* > *Traffic Shaper* > *Shared*, and select *Create New*.
2. Enter a name for the shaper.

3. Enter the *Guaranteed Bandwidth*, if any.

   Bandwidth guarantees affect prioritization. While packet rates are less than this rate, they use priority queue 0. If this is not the effect you intend, consider entering a small guaranteed rate, or enter 0 to effectively disable bandwidth guarantees.
4. Enter a *Maximum Bandwidth*.

   Packets greater than this rate will be discarded.
5. Select the *Traffic Priority*.

   High has a priority value of 1, while Low is 3. While the current packet rate is below Guaranteed Bandwidth, the FortiGate unit will disregard this setting, and instead use priority queue 0.
6. Select *OK*.

Sample configuration

This sample configuration limits ingressing bandwidth to 500 Kb/s. It also applies separate traffic shapers to FTP and HTTP traffic. In addition to the interface bandwidth limit, HTTP traffic is subject to a security policy bandwidth limit of 200 Kb/s.

All egressing FTP traffic greater than 10 Kb/s is subject to a low priority queue (queue 3), while all egressing HTTP traffic greater than 100 Kb/s is subject to a medium priority queue (queue 2). That is, unless FTP traffic rates are lower than their guaranteed rate, and web traffic rates are greater than their guaranteed rate, FTP traffic is lower priority than web traffic.

Traffic less than these guaranteed bandwidth rates use the highest priority queue (queue 0).

Set the inbandwidth limits. This setting is only available in the CLI:

```
config system interface
  edit wan1
    set inbandwidth 500
  next
end
```

Create the traffic shapers or FTP and HTTP.

To configure the shapers - web-based manager

1. Go to *Firewall Objects* > *Traffic Shaper* > *Shared*, and select *Create New*.
2. Enter FTP for the name of the shaper.
3. Enter the *Guaranteed Bandwidth*, of 10 Kbps.
4. Enter a *Maximum Bandwidth* of 500 Kbps.
5. Select the *Traffic Priority* of *Low*.
6. Select *OK*.
7. Select *Create New*.
8. Enter `HTTP` for the name of the shaper.
9. Enter the *Guaranteed Bandwidth*, of 100 Kbps.
10. Enter a *Maximum Bandwidth* of 200 Kbps.
11. Select the *Traffic Priority of Medium*.
12. Select *OK*.

To configure the shapers - CLI

```
config firewall shaper traffic-shaper
  edit FTP
    set maximum-bandwidth 500
    set guaranteed-bandwidth 10
    set per-policy enable
    set priority low
    end
  next
  edit HTTP
    set maximum-bandwidth 200
    set guaranteed-bandwidth 100
    set per-policy enable
    set priority medium
end
```

QoS using priority from ToS or differentiated services

Configurations implementing QoS using the priority values defined in either global or specific ToS bit values are not capable of applying bandwidth limits and guarantees, but are capable of prioritizing traffic at per-packet levels, rather than uniformly to all services matched by the security policy.

In addition to configuring traffic prioritization, you may also choose to limit bandwidth being received by each interface. This can sometimes be useful in scenarios where you want to limit traffic levels, but do not want to configure traffic shaping within a security policy. This has the benefit of policing traffic at a point before the FortiGate unit performs most processing.

Note that if you implement QoS using ToS octet rather than security policies, the FortiGate unit applies QoS on a packet by packet basis, and priorities may be different for packets and services controlled by the same security policy. This is more granular control than prioritization by security policies, but has the drawbacks that quality of service is may not be uniform for multiple services controlled by the same security policy, packets will only use up to three of the six possible queues (queue 0 to queue 2), and bandwidth cannot be guaranteed. Other devices in your network must also be able to set or preserve ToS bits.

In this example, we limit the bandwidth accepted by each source interface, and then configure prioritized queuing on the destination interface based upon the value of the ToS bit located in the IP header of each accepted packet.

To limit bandwidth accepted by an interface, in the CLI, enter the following commands:

```
config system interface
  edit <name_str>
    set inbandwidth <rate_int>
  next
end
```

where `<rate_int>` is the bandwidth limit in Kb/s. Excess packets will be dropped.

To configure priorities, in the CLI, configure the global priority value using the following commands:

```
config system global
  set tos-based-priority {high | low | medium}
    end
```

where `high` has a priority value of 0 and `low` is 2.

If you want to prioritize some ToS bit values differently than the global ToS-based priority, configure the priority for packets with that ToS bit value using the following commands:

```
config system tos-based-priority
  edit <id_int>
    set tos [0-15]
    set priority {high | low | medium}
  next
end
```

where and `tos` is the value of the ToS bit in the packet's IP header, and `high` has a priority value of 0 and `low` is 2. Priority values configured in this location will override the global ToS-based priority.

Sample configuration

This sample configuration limits ingressing bandwidth to 500 Kb/s. It also queues egressing traffic based upon the ToS bit in the IP header of ingressing packets.

Unless specified for the packet's ToS bit value, packets use the low priority queue (queue 2). For ToS bit values 4 and 15, the priorities are specified as medium (value 1) and high (value 0), respectively.

```
config system interface
  edit wan1
    set inbandwidth 500
  next
end
config system global
  set tos-based-priority low
end
config system tos-based-priority
  edit 4
    set tos 4
    set priority medium
  next
  edit 15
    set tos 15
    set priority high
  next
end
```

Example setup for VoIP

In this example, there are three traffic shaping requirements for a network:

- Voice over IP (VoIP) requires a guaranteed, high-priority for bandwidth for telephone communications.
- FTP bursts must be contained so as not to consume any available bandwidth. As such this traffic needs to be throttled to a smaller amount.
- A consistent bandwidth requirement is needed for all other email and web-based traffic.

To enable this requirement, you need to create three separate shapers and three security policies for each traffic type.

For this example, the actual values are not actual values, they are used for the simplicity of the example.

Creating the traffic shapers

First create the traffic shapers that define the maximum and guaranteed bandwidth. The shared shapers will be used, some with per-policy and some all policies as shown in the table, to better control traffic.

VoIP shaper

The VoIP functionary is a key component to the business as a communication tool and as such requires a guaranteed bandwidth.

To create a VoIP shaper - web-based manager

1. Go to *Firewall Objects* > *Traffic Shaping* > *Shared*.
2. Enter the *Name* `voip`.
3. Select *Per Policy*.
4. Enter the *Maximum Bandwidth* of `1000` Kb/s
5. Enter the *Guaranteed Bandwidth* of `800` Kb/s.
6. Select a *Traffic Priority* of *High*.
7. Select *OK*.

To create a VoIP shaper - CLI

```
config firewall shaper traffic-shaper
  edit voip
    set maximum-bandwidth 1000
    set guaranteed-bandwidth 800
    set per-policy enable
    set priority high
end
```

This ensures that whatever number of policies use this shaper, the defined bandwidth will always be the same. At the same time, the bandwidth is continually guaranteed at 800 Kb/s but if available can be as much as 1000 Kb/s. Setting the priority to high ensures that the FortiGate unit always considers VoIP traffic as the most important.

FTP shaper

The FTP shaper sets the maximum bandwidth to use to avoid sudden spikes by sudden uploading or downloading of large files, and interfering with other more important traffic.

To create a FTP shaper - web-based manager

1. Go to *Firewall Objects* > *Traffic Shaping* > *Shared*.
2. Enter the *Name* `ftp`.
3. Select *For all Policies Using This Shaper*.
4. Enter the *Maximum Bandwidth* of `200` Kb/s
5. Enter the *Guaranteed Bandwidth* of `200` Kb/s.
6. Select a *Traffic Priority* of *Low*.
7. Select *OK*.

To create a FTP shaper - CLI

```
config firewall shaper traffic-shaper
  edit ftp
    set maximum-bandwidth 200
    set guaranteed-bandwidth 200
    set priority low
end
```

For this shaper, the maximum and guaranteed bandwidth are set low and to the same value. In this case, the bandwidth is restricted to a specific amount. By also setting the traffic priority low ensures more important traffic will be able to pass before FTP traffic.

Regular traffic shaper

The regular shaper sets the maximum bandwidth and guaranteed bandwidth for everyday business traffic such as web and email traffic.

To create a regular shaper - web-based manager

1. Go to *Firewall Objects* > *Traffic Shaping* > *Shared*.
2. Enter the *Name* `daily_traffic`.
3. Select *Per Policy*.
4. Enter the *Maximum Bandwidth* of `600` Kb/s
5. Enter the *Guaranteed Bandwidth* of `600` Kb/s.
6. Select a *Traffic Priority* of *Medium*.
7. Select *OK*.

To create a regular shaper - CLI

```
config firewall shaper traffic-shaper
  edit daily_traffic
    set maximum-bandwidth 600
    set guaranteed-bandwidth 600
    set per-policy enable
    set priority medium
end
```

For this shaper, the maximum and guaranteed bandwidth are set to a moderate value of 600 Kb/s. It is also set for per policy, which ensures each security policy for day-to-day business traffic has the same distribution of bandwidth.

Creating security policies

To employ the shaper, create security policies that use the shapers within the policies. Create a separate policy for each service and enable traffic shaping. For example, a policy for FTP traffic, a policy for SIP and so on.

For the following steps the VoIP traffic shaper is enabled as well as the reverse direction option. This ensures that return traffic for a VoIP call has the same guaranteed bandwidth as the outgoing call.

To enable traffic shaping in the security policy - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Leave the *Policy Type* as *Firewall* and leave the *Policy Subtype* as *Address*.
3. Enter the following:

Incoming interface	Internal
Source address	All
Outgoing interface	WAN1
Destination address	All
Schedule	always
Service	SIP
Action	ACCEPT

4. Select *Traffic Shaping*.
5. From the drop-down list, select the voip shaper created in the previous steps.
6. Select *Reverse Direction Traffic Shaping*.
7. Select *OK*.

To enable traffic shaping in the security policy - CLI

```
config firewall policy
  edit 6
    set srcintf internal
    set scraddr all
    set dstintf wan1
    set dstaddr all
    set action accept
    set schedule always
    set service sip
    set traffic-shaper voip
    set reverse-traffic-shaper voip
end
```

Troubleshooting traffic shaping

This chapter outlines some troubleshooting tips and steps to diagnose the shapers and whether they are working correctly. These diagnose commands include:

- `diagnose system tos-based-priority`
- `diagnose firewall shaper traffic-shaper`
- `diagnose firewall per-ip-shaper`
- `diagnose debug flow`

Interface diagnosis

To optimize traffic shaping performance, first ensure that the network interface's Ethernet statistics are clean of errors, collisions, or buffer overruns. To check the interface, enter the following diagnose command to see the traffic statistics:

```
diagnose hardware deviceinfo nic <port_name>
```

Shaper diagnose commands

There are specific diagnose commands you can use to verify the configuration and flow of traffic, including packet loss due to the employed shaper.

All of these diagnose troubleshooting commands are supported in both IPv4 and IPv6.

TOS command

Use the following command to list command to view information of the TOS lists and traffic.

```
diagnose system tos-based-priority
```

This example displays the priority value currently correlated with each possible TOS bit value. Priority values are displayed in order of their corresponding TOS bit values, which can range between 0 and 15, from lowest TOS bit value to highest.

For example, if you have not configured TOS-based priorities, the following appears...

```
0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
```

...reflecting that all packets are currently using the same default priority, high (value 0).

If you have configured a TOS-based priority of `low` (value 2) for packets with a ToS bit value of 3, the following appears...

```
0 0 0 2 0 0 0 0 0 0 0 0 0 0 0 0
```

...reflecting that most packets are using the default priority value, except those with a ToS bit value of 3.

Shared shaper

To view information for the shared traffic shaper for security policies enter the command

```
diagnose firewall shaper traffic-shaper list
```

The resultant output displays the information on all available shapers. The more shapers available the longer the list. For example:

```
name Throughput
maximum-bandwidth 1200000 Kb/sec
guaranteed-bandwidth 50000 Kb/sec
current-bandwidth 0 B/sec
priority 1
packets dropped 0
```

Additional commands include:

`diagnose firewall shaper traffic-shaper state` - provides the total number of traffic shapers on the FortiGate unit.

`diagnose firewall shaper traffic-shaper stats` - provides summary statistics on the shapers. Sample output looks like the following:

```
shapers 9 ipv4 0 ipv6 0 drops 0
```

Per-IP shaper

To view information for the per-IP shaper for security policies enter the command

```
diagnose firewall shaper per-ip-shaper list
```

The resultant output displays the information on all available per-IP shapers. The more shapers available the longer the list. For example:

```
name accounting_group
maximum-bandwidth 200000 Kb/sec
maximum-concurrent-session 55
packet dropped 0
```

Additional commands include:

`diagnose firewall shaper per-ip-shaper state` - provides the total number of per-ip shapers on the FortiGate unit.

`diagnose firewall shaper per-ip-shaper stats` - provides summary statistics on the shapers. Sample output looks like the following:

```
memory allocated 3 packet dropped: 0
```

You can also clear the per-ip statistical data to begin a fresh diagnoses using:

```
diagnose firewall shaper per-ip-shaper clear
```

Packet loss with statistics on shapers

For each shaper there are counters that allow to verify if packets have been discarded. To view this information, in the CLI, enter the command diagnose firewall shaper. The results will look similar to the following output:

```
diagnose firewall shaper traffic-shaper list
name limit_GB_25_MB_50_LQ
maximum-bandwidth 50 Kb/sec
```

```
guaranteed-bandwidth 25 Kb/sec
current-bandwidth 51 Kb/sec
priority 3
dropped 1291985
```

The diagnose command output is different if the shapers are configured either per-policy or shared between policies.

For per-IP the output would be:

```
diagnose firewall shaper per-ip-shaper list

name accounting_group
maximum-bandwidth 200000 Kb/sec
maximum-concurrent-session 55
packet dropped 3264220
```

Packet lost with the debug flow

When using the debug flow diagnostic command, there is a specific message information that a packet has exceed the shaper limits and therefor discarded:

```
diagnose debug flow show console enable
diagnose debug flow filter addr 10.143.0.5
diagnose debug flow trace start 1000

id=20085 trace_id=11 msg="vd-root received a packet(proto=17,
     10.141.0.11:3735->10.143.0.5:5001) from port5."
id=20085 trace_id=11 msg="Find an existing session, id-0000eabc,
     original direction"
id=20085 trace_id=11 msg="exceeded shaper limit, drop"
```

Session list details with dual traffic shaper

When a Security Policy has a different traffic shaper for each direction, it is reflected in the session list output from the CLI:

```
diagnose system session list

session info: proto=6 proto_state=02 expire=115 timeout=3600
     flags=00000000 sock
flag=00000000 sockport=0 av_idx=0 use=4
origin-shaper=Limit_25Mbps prio=1 guarantee 25600/sec max 204800/sec
     traffic 48/sec
reply-shaper=Limit_100Mbps prio=1 guarantee 102400/sec max 204800/sec
     traffic 0/sec
ha_id=0 hakey=44020
policy_dir=0 tunnel=/
state=may_dirty rem os rs
statistic(bits/packets/allow_err): org=96/2/1 reply=0/0/0 tuples=2
orgin->sink: org pre->post, reply pre->post dev=2->3/3->2
     gwy=10.160.0.1/0.0.0.0
```

```
hook=pre dir=org act=dnat
     192.168.171.243:2538->192.168.182.110:80(10.160.0.1:80)
hook=post dir=reply act=snat
     10.160.0.1:80->192.168.171.243:2538(192.168.182.110:80)
pos/(before,after) 0/(0,0), 0/(0,0)
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0 serial=00011e81
     tos=ff/ff app=0 dd_type=0 dd_rule_id=0
```

Additional Information

- Packets discarded by the shaper impact flow-control mechanisms like TCP. For more accurate testing results prefer UDP protocol.
- Traffic shaping accuracy is optimum for security policies without a protection profile where no FortiGate content inspection is processed.
- Do not oversubscribe an outbandwith throughput. For example, sum[guaranteed BW] < outbandwith. For accuracy in bandwidth calculation, it is required to set the “outbandwidth” parameter on the interfaces. For more information see “Bandwidth guarantee, limit, and priority interactions” on page 2236.
- The FortiGate unit is not prioritizing traffic based on the DSCP marking configured in the security policy. However, TOS based prioritizing can be made at ingress. For more information see “Differentiated Services” on page 2251.

Chapter 18 Troubleshooting

This handbook chapter describes concepts of troubleshooting and solving issues that may occur with FortiGate units.

This FortiOS Handbook chapter contains the following chapters:

Life of a Packet explains the different layers and modules a packet goes through in FortiOS, including the order of operations.

Verifying FortiGate admin access security explains how to verify and configure administrative access.

Troubleshooting resources walks you through Fortinet's resources for troubleshooting.

Troubleshooting tools describes some of the basic commands and parts of FortiOS that can help you with troubleshooting.

Troubleshooting methodologies walks you through best practice concepts of FortiOS troubleshooting.

Technical Support Organization Overview describes how Fortinet Support operates, what they will need from you if you contact them, and what you can expect in general.

Life of a Packet

Directed by security policies, a FortiGate unit screens network traffic from the IP layer up through the application layer of the TCP/IP stack. This chapter provides a general, high-level description of what happens to a packet as it travels through a FortiGate security system.

The FortiGate unit performs three types of security inspection:

- stateful inspection, that provides individual packet-based security within a basic session state
- flow-based inspection, that buffers packets and uses pattern matching to identify security threats
- proxy-based inspection, that reconstructs content passing through the FortiGate unit and inspects the content for security threats.

Each inspection component plays a role in the processing of a packet as it traverses the FortiGate unit in route to its destination. To understand these inspections is the first step to understanding the flow of the packet.

This section contains the following topics:

Stateful inspection

With stateful inspection, the FortiGate unit looks at the first packet of a session to make a security decision. Common fields inspected include TCP SYN and FIN flags to identity the start and end of a session, the source/destination IP, source/destination port and protocol. Other checks are also performed on the packet payload and sequence numbers to verify it as a valid communication and that the data is not corrupted or poorly formed.

What makes it stateful is that one or both ends must save information about the session history in order to communicate. In stateless communication, only independent requests and responses are used, that do not depend on previous data. For example, UDP is stateless by nature because it has no provision for reliability, ordering, or data integrity.

The FortiGate unit makes the decision to drop, pass or log a session based on what is found in the first packet of the session. If the FortiGate unit decides to drop or block the first packet of a session, then all subsequent packets in the same session are also dropped or blocked without being inspected. If the FortiGate unit accepts the first packet of a session, then all subsequent packets in the same session are also accepted without being inspected.

Connections over connectionless

A connection is established when two end points use a protocol to establish connection through use of various methods such as segment numbering to ensure data delivery, and handshaking to establish the initial connection. Connections can be stateful because they record information about the state of the connection. Persistent connections reduce request latency because the end points do not need to re-negotiate the connection multiple times, but instead just send the information without the extra overhead. By contrast, connectionless communication does not keep any information about the data being sent or the state. It is based on an autonomous response/reply that is independent of other responses/replies that may have gone before. One example of connectionless communication is IP.

Benefits of connections over connectionless include being able to split data up over multiple packets, the data allows for a best-effort approach, and once the connection is established subsequent packets are not required to contain the full addressing information which saves on bandwidth. Connections are often reliable network services since acknowledgements can be sent when data is recieved.

What is a session?

A session is established on an existing connection, for a defined period of time, using a determined type of communication or protocol. Sessions can have specific bandwidth , and time to live (TTL) parameters.

You can compare a session to a conversation. A session is established when one end point initiates a request by establishing a TCP connection on a particular port, the receiving end is listening on that port, and replies. You could telnet to port 80 even though telnet normally uses port 23, because at this level, the application being used cannot be determined.

However, the strong points of sessions and stateful protocols can also be their weak points. Denial of service (DoS) attacks involve creating so many sessions that the connection state information tables are full and the unit will not accept additional sessions.

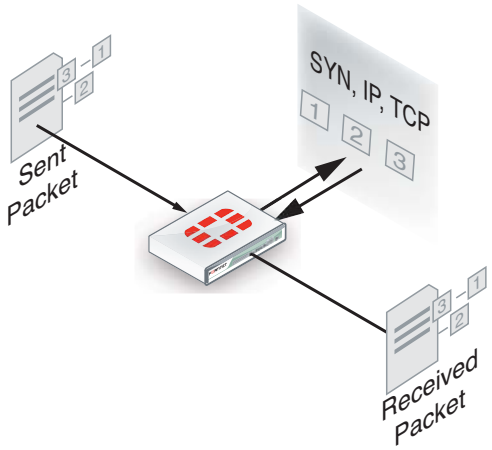
Differences between connections and sessions

In almost all cases, established sessions are stateful and all involve connections. However, some types of connections, such as UDP, are stateless, and are not sessions.

This means that not all traffic can be inspected by stateful inspection, because some of it is stateless. For example IP packets are stateless. Communications using HTTP are stateless, but HTTP often uses cookies to store persistent data in a way that approaches stateful.

Stateful inspection of sessions has the benefit of being able to apply the initial connection information to the packets that follow — the end points of the session will remain the same as will the protocol for example. That information can be examined for the first packet of the session and if it is malicious or not appropriate, the whole session can be dropped without committing significant resources.

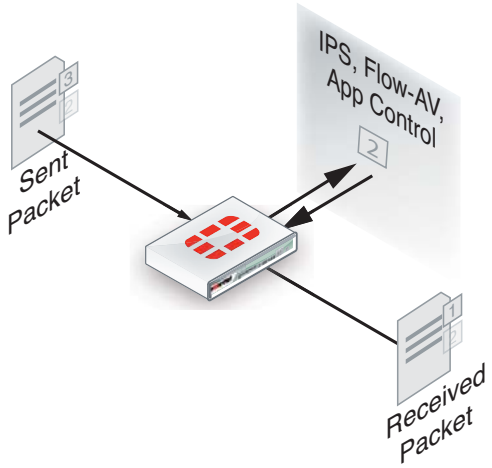
Figure 316: Stateful inspection of packets through the FortiGate unit



Flow inspection

With flow inspection (also called flow-based inspection), the FortiGate unit samples multiple packets in a session and multiple sessions, and uses a pattern matching engine to determine the kind of activity that the session is performing and to identify possible attacks or viruses. For example, if application control is operating, flow inspection can sample network traffic and identify the application that is generating the activity. Flow inspection using IPS samples network traffic and determines if the traffic constitutes an attack. Flow inspection can also be used for antivirus protection, web filtering, and data leak protection (DLP). Flow inspection occurs as the data is passing from its source to its destination. Flow inspection identifies and blocks security threats in real time as they are identified.

Figure 317: Flow inspection of packets through the FortiGate unit

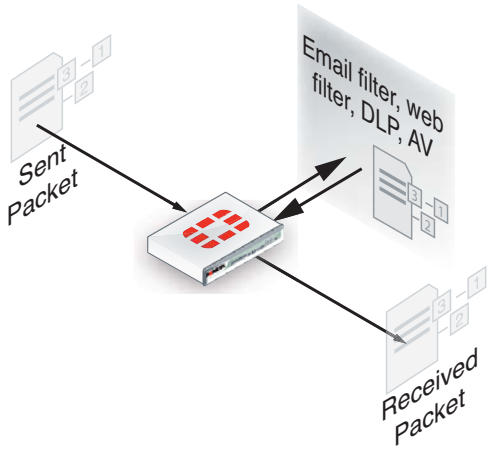


Flow inspection typically requires less processing than proxy inspection, and therefore flow antivirus, web filtering, and DLP inspection performance can be better than proxy inspection performance. However, some threats can only be detected when a complete copy of the payload (for example a complete email attachment) is obtained so, proxy inspection tends to be more accurate and complete than flow inspection.

Proxy inspection

Proxy inspection examines the content contained in content protocol sessions for security threats. Content protocols include HTTP, FTP, and email protocols. Security threats can be found in files and other content downloaded using these protocols. With proxy inspection, the FortiGate unit downloads the entire payload of a content protocol session and re-constructs it. For example, proxy inspection can reconstruct an email message and its attachments. After a satisfactory inspection the FortiGate unit passes the content on to the client. If the proxy inspection detects a security threat in the content, the content is removed from the communication stream before it reaches its destination. For example, if proxy inspection detects a virus in an email attachment, the attachment is removed from the email message before its sent to the client. Proxy inspection is the most thorough inspection of all, although it requires more processing power, and this may result in lower performance.

Figure 318: Proxy inspection of packets through the FortiGate unit



Comparison of inspection layers

The three inspection methods each have their own strengths and weaknesses. The following table looks at all three methods side-by-side.

Table 104: Inspection methods comparison

Feature	Stateful	Flow	Proxy
Inspection unit per session	first packet	selected packets	complete content
Memory, CPU required	low	medium	high
Level of threat protection	good	better	best
Authentication	yes		
IPsec and SSL VPN	yes		
Antivirus protection		yes	yes
Web Filtering		yes	yes
Data Leak Protection (DLP)		yes	yes

Table 104: Inspection methods comparison

Feature	Stateful	Flow	Proxy
Application control		yes	
IPS		yes	
Delay in traffic		no	small
Reconstruct entire content		no	yes

FortiOS functions and security layers

Within these security inspection types, FortiOS functions map to different inspections. The table below outlines when actions are taken as a packet progresses through its life within a FortiGate unit.

Table 105: FortiOS security functions and security layers

Security Function	Stateful	Flow	Proxy
Firewall	yes		
IPsec VPN	yes		
Traffic Shaping	yes		
User Authentication	yes		
Management Traffic	yes		
SSL VPN	yes		
Intrusion Prevention		yes	
Antivirus		yes	yes
Application Control		yes	
Web filtering		yes	yes
DLP			yes
Email Filtering		yes	yes
VoIP inspection			yes

Packet flow

After the FortiGate unit's external interface receives a packet, the packet proceeds through a number of steps on its way to the internal interface, traversing each of the inspection types, depending on the security policy and security profile configuration. The diagram in Figure 319 on page 2276 is a high level view of the packet's journey.

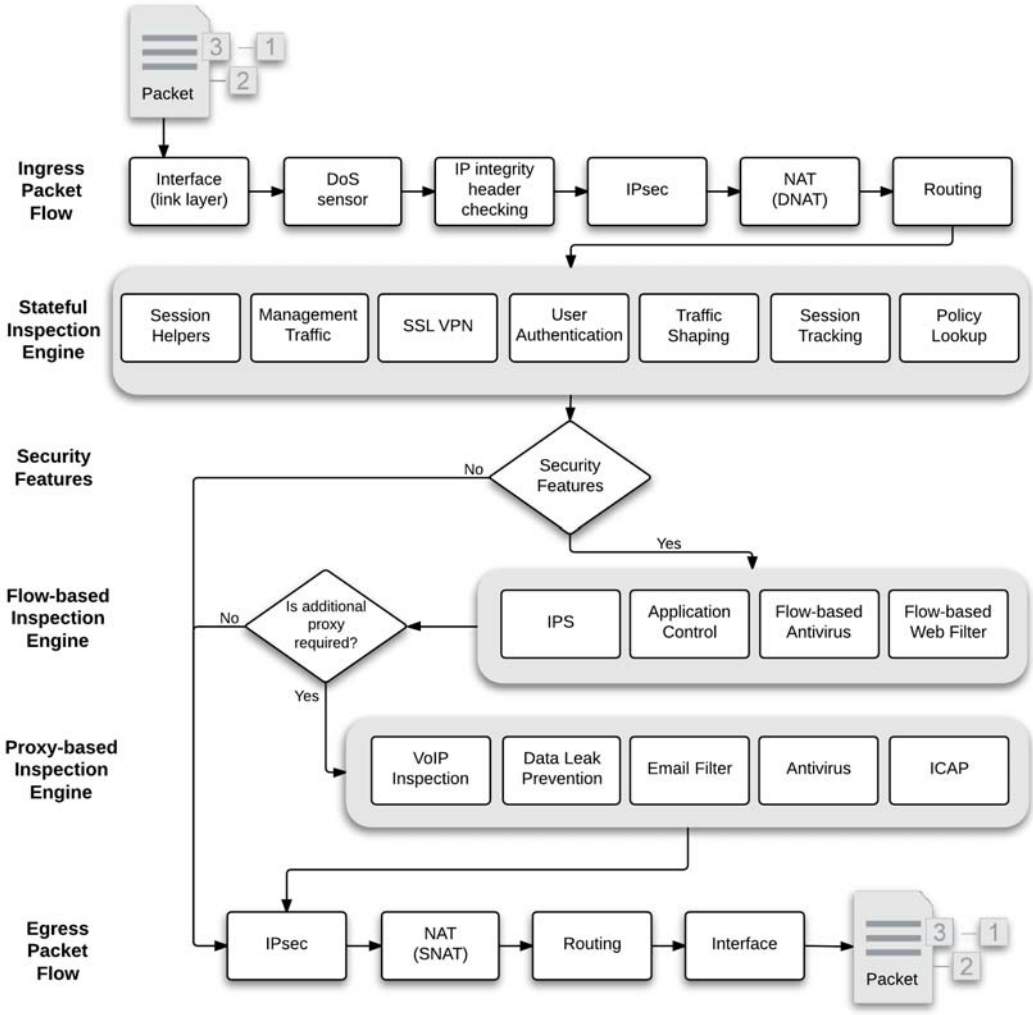
The description following is a high-level description of these steps as a packet enters the FortiGate unit towards its destination on the internal network. Similar steps occur for outbound traffic.

Packet inspection (Ingress)

In Figure 319 on page 2276, in the first set of steps (ingress), a number of header checks take place to ensure the packet is valid and contains the necessary information to reach its destination. This includes:

- Packet verification - during the IP integrity stage, verification is performed to ensure that the layer 4 protocol header is the correct length. If not, the packet is dropped.
- Session creation - the FortiGate unit attempts to create a session for the incoming data
- IP stack validation for routing - the firewall performs IP header length, version and checksum verifications in preparation for routing the packet.
- Verifications of IP options - the FortiGate unit validates the rouging information

Figure 319: Packet flow process



Interface

Ingress packets are received by a FortiGate interface.The packet enters the system, and the interface network device driver passes the packet to the Denial of Service (DoS) sensors, if enabled, to determine whether this is a valid information request or not.

DoS sensor

DoS scans are handled very early in the life of the packet to determine whether the traffic is valid or is part of a DoS attack. Unlike signature-based IPS which inspects all the packets within a certain traffic flow, the DoS module inspects all traffic flows but only tracks packets that can be used for DoS attacks (for example TCP SYN packets), to ensure they are within the permitted parameters. Suspected DoS attacks are blocked, other packets are allowed.

IP integrity header checking

The FortiGate unit reads the packet headers to verify if the packet is a valid TCP, UDP, ICMP, SCTP or GRE packet. The only verification that is done at this step to ensure that the protocol header is the correct length. If it is, the packet is allowed to carry on to the next step. If not, the packet is dropped.

IPsec

If the packet is an IPsec packet, the IPsec engine attempts to decrypt it. The IPsec engine applies the correct encryption keys to the IPsec packet and sends the unencrypted packet to the next step. IPsec is bypassed when for non-IPsec traffic and for IPsec traffic that cannot be decrypted by the FortiGate unit.

Destination NAT (DNAT)

The FortiGate unit checks the NAT table and determines the destination IP address for the traffic. This step determines whether a route to the destination address actually exists.

For example, if a user's browser on the internal network at IP address 192.168.1.1 visited the web site www.example.com using NAT, after passing through the FortiGate unit the source IP address becomes NATed to the FortiGate unit external interface IP address. The destination address of the reply back from www.example.com is the IP address of the FortiGate unit internal interface. For this reply packet to be returned to the user, the destination IP address must be destination NATed to 192.168.1.1.

DNAT must take place before routing so that the FortiGate unit can route packets to the correct destination.

Routing

The routing step determines the outgoing interface to be used by the packet as it leaves the FortiGate unit. In the previous step, the FortiGate unit determined the real destination address, so it can now refer to its routing table and decide where the packet must go next.

Routing also distinguishes between local traffic and forwarded traffic and selects the source and destination interfaces used by the security policy engine to accept or deny the packet.

Policy lookup

The policy look up is where the FortiGate unit reviews the list of security policies which govern the flow of network traffic, from the first entry to the last, to find a match for the source and

destination IP addresses and port numbers. The decision to accept or deny a packet, after being verified as a valid request within the stateful inspection, occurs here. A denied packet is discarded. An accepted packet will have further actions taken. If IPS is enabled, the packet will go to Flow-based inspection engine, otherwise it will go to the Proxy-based inspection engine.

If no other security options are enabled, then the session was only subject to stateful inspection. If the action is accept, the packet will go to Source NAT to be ready to leave the FortiGate unit.

Session tracking

Part of the stateful inspection engine, session tracking maintains session tables that maintain information about sessions that the stateful inspection module uses for maintaining sessions, NAT, and other session related functions.

User authentication

User authentication added to security policies is handled by the stateful inspection engine, which is why Firewall authentication is based on IP address. Authentication takes place after policy lookup selects a security policy that includes authentication. This is also known as identify-based policies. Authentication also takes place before security features are applied to the packet.

Management traffic

This local traffic is delivered to the FortiGate unit TCP/IP stack and includes communication with the web-based manager, the CLI, the FortiGuard network, log messages sent to FortiAnalyzer or a remote syslog server, and so on. Management traffic is processed by applications such as the web server which displays the FortiOS web-based manager, the SSH server for the CLI or the FortiGuard server to handle local FortiGuard database updates or FortiGuard Web Filtering URL lookups.

SSL VPN traffic

For local SSL VPN traffic, the internal packets are decrypted and are routed to a special interface. This interface is typically called ssl.root for decryption. Once decrypted, the packets go to policy lookup.

ICAP traffic

If you enable ICAP in a security policy, HTTP (and optionally HTTPS) traffic intercepted by the policy is transferred to ICAP servers in the ICAP profile added to the policy. The FortiGate unit is the surrogate, or “middle-man”, and carries the ICAP responses from the ICAP server to the ICAP client; the ICAP client then responds back, and the FortiGate unit determines the action that should be taken with these ICAP responses and requests.

Session helpers

Some protocols include information in the packet body (or payload) that must be analyzed to successfully process sessions for this protocol. For example, the SIP VoIP protocol uses TCP control packets with a standard destination port to set up SIP calls. To successfully process SIP VoIP calls, FortiOS must be able to extract information from the body of the SIP packet and use this information to allow the voice-carrying packets through the firewall.

FortiOS uses session helpers to analyze the data in the packet bodies of some protocols and adjust the firewall to allow those protocols to send packets through the firewall.

Flow-based inspection engine

Flow-based inspection is responsible for IPS, application control, flow-based antivirus scanning and VoIP inspection. Packets are sent to flow-based inspection if the security policy that accepts the packets includes one or more of these security features.

Flow-based antivirus scanning is only available on some FortiGate models.

Once the packet has passed the flow-based engine, it can be sent to the proxy inspection engine or egress.

Proxy-based inspection engine

The proxy inspection engine is responsible for carrying out antivirus protection, email filtering (antispam), web filtering and data leak prevention. The proxy engine will process multiple packets to generate content before it is able to make a decision for a specific packet.

IPsec

If the packet is transmitted through an IPsec tunnel, it is at this stage the encryption and required encapsulation is performed. For non-IPsec traffic (TCP/UDP) this step is bypassed.

Source NAT (SNAT)

When preparing the packet to leave the FortiGate unit, it needs to NAT the source address of the packet to the external interface IP address of the FortiGate unit. For example, a packet from a user at 192.168.1.1 accessing www.example.com is now using a valid external IP address as its source address.

Routing

The final routing step determines the outgoing interface to be used by the packet as it leaves the FortiGate unit.

Egress

Upon completion of the scanning at the IP level, the packet exits the FortiGate unit.

Example 1: client/server connection

The following example illustrates the flow of a packet of a client/web server connection with authentication and FortiGuard URL and antivirus filtering.

This example includes the following steps:

Initiating connection from client to web server

1. Client sends packet to web server.

2. Packet intercepted by FortiGate unit interface.

   2.1 Link level CRC and packet size checking. If the size is correct, the packet continues, otherwise it is dropped.
3. DoS sensor - checks are done to ensure the sender is valid and not attempting a denial of service attack.
4. IP integrity header checking, verifying the IP header length, version and checksums.
5. Next hop route
6. Policy lookup
7. User authentication
8. Proxy inspection

   8.1 Web Filtering

   8.2 FortiGuard Web Filtering URL lookup

   8.3 Antivirus scanning
9. Source NAT
10. Routing
11. Interface transmission to network
12. Packet forwarded to web server

Response from web server

1. Web Server sends response packet to client.
2. Packet intercepted by FortiGate unit interface

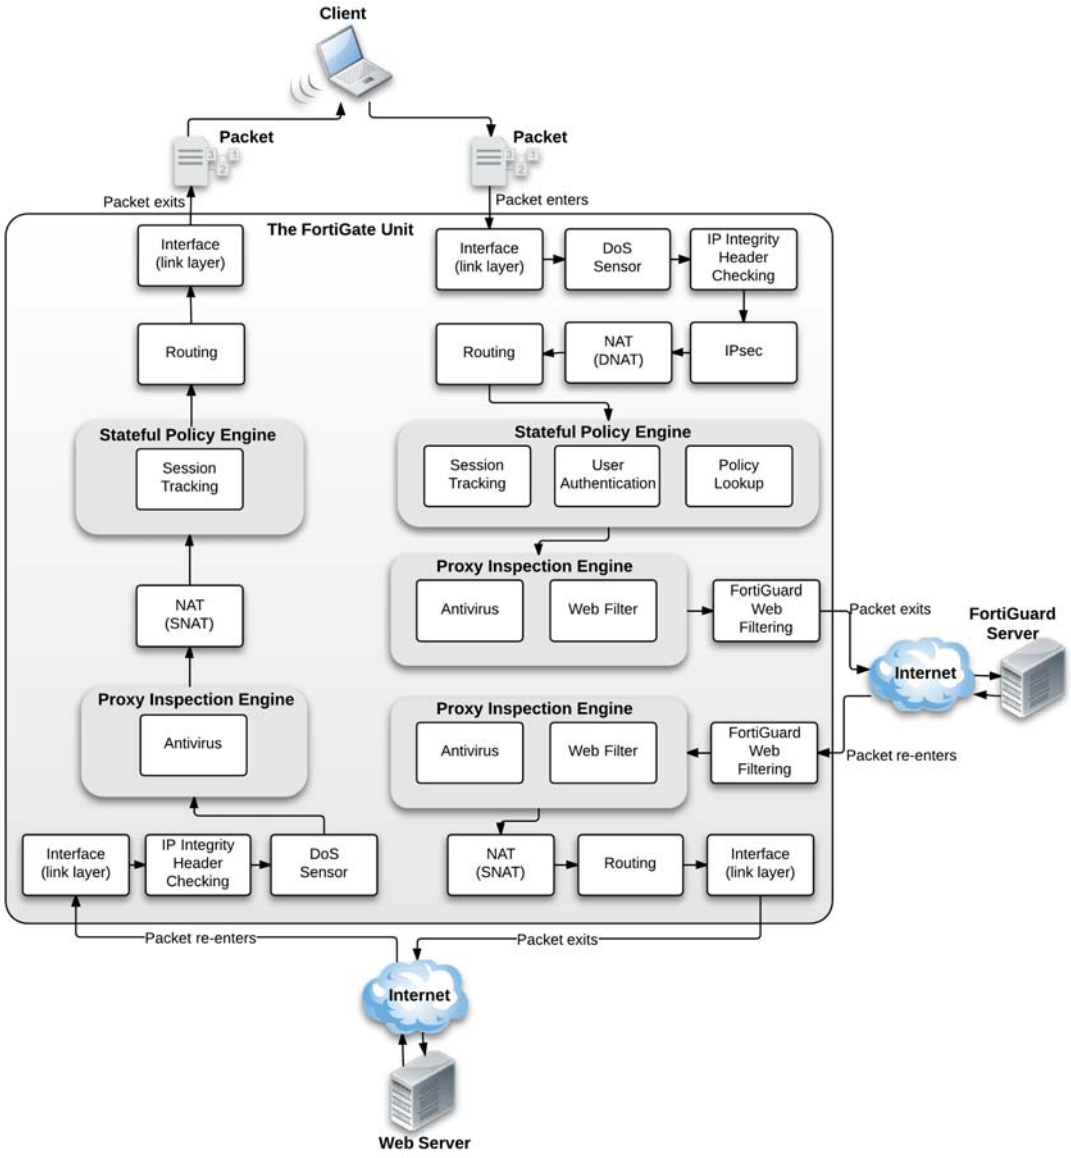
   2.1 Link level CRC and packet size checking.
3. IP integrity header checking.
4. DoS sensor.
5. Proxy inspection

   5.1 Antivirus scanning.
6. Source NAT.
7. Stateful Policy Engine

   7.1 Session Tracking
8. Next hop route
9. Interface transmission to network
10. Packet returns to client

This process is illustrated in Figure 320.

Figure 320: Client/server connection



Example 2: Routing table update

The following example illustrates the flow of a packet when there is a routing table update. As this is low level, there is no security involved. This example includes the following steps:

1. FortiGate unit receives routing update packet
2. Packet intercepted by FortiGate unit interface

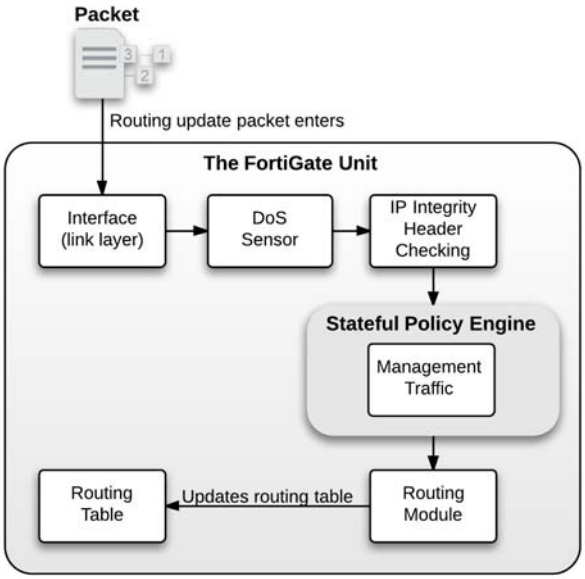
   2.1 Link level CRC and packet size checking. If the size is correct, the packet continues, otherwise it is dropped.
3. DoS sensor - checks are done to ensure the sender is valid and not attempting a denial of service attack.
4. IP integrity header checking, verifying the IP header length, version and checksums.
5. Stateful policy engine

   5.1 Management traffic (local traffic)

6. Routing module
   6.1 Update routing table

Figure 321 illustrates the process steps.

Figure 321: Routing table update



Example 3: Dialup IPsec VPN with application control

This example includes the following steps:

1. FortiGate unit receives IPsec packet from Internet
2. Packet intercepted by FortiGate unit interface
   2.1 Link level CRC and packet size checking. If the size is correct, the packet continues, otherwise it is dropped.
3. DoS sensor - checks are done to ensure the sender is valid and not attempting a denial of service attack.
4. IP integrity header checking, verifying the IP header length, version and checksums.
5. IPsec
   5.1 Determines that packet matched IPsec phase 1 configuration
   5.2 Unencrypted packet
6. Next hop route
7. Stateful policy engine
   7.1 Session tracking
8. Flow inspection engine
   8.1 IPS
   8.2 Application control
9. Source NAT
10. Routing

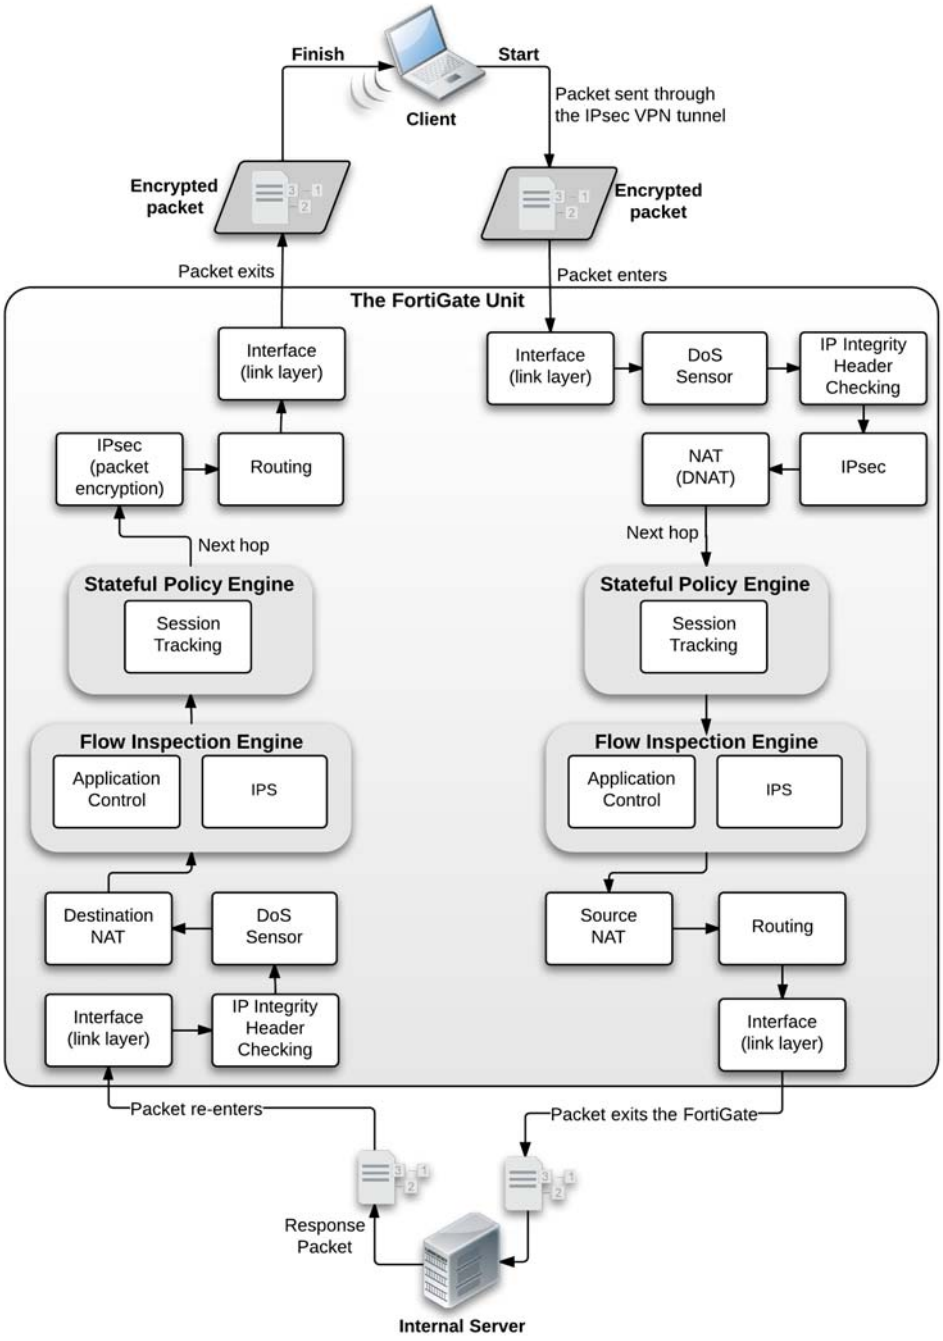
11. Interface transmission to network
12. Packet forwarded to internal server

Response from server

1. Server sends response packet
2. Packet intercepted by FortiGate unit interface
   - **2.1** Link level CRC and packet size checking
3. IP integrity header checking.
4. DoS sensor
5. Flow inspection engine
   - **5.1** IPS
   - **5.2** Application control
6. Stateful policy engine
   - **6.1** Session tracking
7. Next hop route
8. IPsec
   - **8.1** Encrypts packet
9. Routing
10. Interface transmission to network
11. Encrypted Packet returns to internet

Figure 322 illustrates the process.

Figure 322: Dialup IPsec with application control



Verifying FortiGate admin access security

FortiOS provides a number of methods that help to enhance FortiGate administrative access security. This section describes FortiGate administrative access security best practices.

- Install the FortiGate unit in a physically secure location
- Add new administrator accounts
- Change the admin account name and limit access to this account
- Only allow administrative access to the external interface when needed
- When enabling remote access, configure Trusted Hosts and Two-factor Authentication
- Change the default administrative port to a non-standard port
- Enable Password Policy
- Maintain short login timeouts
- Modify administrator account Lockout Duration and Threshold values
- Disable auto installation via USB
- Auditing and Logging

Install the FortiGate unit in a physically secure location

A good place to start with is physical security. Install the FortiGate unit in a secure location, such as a locked room or a room with restricted access. This way unauthorized users can't get physical access to the device.

If unauthorized users have physical access they can disrupt your entire network by disconnecting your FortiGate unit (either by accident or on purpose). They could also connect a console cable and attempt to log into the CLI. Also, when a FortiGate unit reboots, a person with physical access can interrupt the boot process and install different firmware.

Add new administrator accounts

Rather than allowing all administrators to access the FortiGate unit with the admin administrator account you should create administrator accounts for each person that requires administrative access. That way you can track who has made configuration changes and performed other administrative activities. Keep the number of administrative accounts to a minimum to keep better control on who can access the device.

To add administrators go to *System* > *Admin* > *Administrators* and select *Create New*.

If you want administrators to have access to all FortiGate configuration options, their accounts should have the *prof_admin* admin profile. Administrators with this profile can do anything except add new administrator accounts.

At least one account should always have the *super_admin* profile as this profile is required to add and remove administrators. To improve security only a very few administrators (usually one) should be able to add new administrators.

If you want some administrator accounts to have limited access to the FortiGate configuration you can create custom admin profiles that only allow access to selected parts of the configuration. To add custom admin profiles, go to *System* > *Admin* > *Admin Profiles* and select *Create New*.

For example, if you want to add an admin profile that does not allow changing firewall policies, when you configure the admin profile set *Firewall Configuration* to *None* or *Read Only*.

Change the admin account name and limit access to this account

The default super_admin administrator account, admin, is a well known administrator name so if this account is available it could be easier for attackers to access the FortiGate unit because they know they can log in with this name, only having to determine the password. You can improve security by changing this name to one more difficult for an attacker to guess.
To do this, create a new administrator account with the super_admin admin profile and log in as that administrator. Then go to System > Admin > Administrators and edit the admin administrator and change the Administrator name.
Once the account has been renamed you could delete the super_admin account that you just added. Consider also only using the super-admin account for adding or changing administrators. The less this account is used to less likely that it could be compromised.
You could also store the account name and password for this account in a secure location in case for some reason the account name or password is forgotten.

Only allow administrative access to the external interface when needed

When possible, don't allow administration access on the external interface and use internal access methods such as IPsec VPN or SSL VPN.

To disable administrative access on the external interface, go to *System* > *Network* > *Interfaces,* edit the external interface and disable HTTPS, PING, HTTP, SSH, and TELNET under *Administrative Access.*

This can also be done with CLI using following commands:

```
config system interface
  edit <external_interface_name>
  unset allowaccess
end
```

Please note that this will disable all services on the external interface including CAPWAP, FMG-Access, SNMP, and FCT-Access.
If you need some of these services enabled on your external interface, for example CAPWAP and FMG-Access to ensure connectivity between FortiGate unit and respectively FortiAP and FortiManager, then you need to use following CLI command:

```
config system interface
  edit <external_interface_name>
  set allowaccess capwap fgfm
end
```

When enabling remote access, configure Trusted Hosts and Two-factor Authentication

If you have to have remote access and can't use IPsec or SSL VPN then you should only allow HTTPS and SSH and use secure access methods such as trusted hosts and Two-facor authentication.

Configuring Trusted Hosts

Setting trusted hosts for administrators limits what computers an administrator can log in the FortiGate unit from. When you identify a trusted host, the FortiGate unit will only accept the administrator's login from the configured IP address or subnet. Any attempt to log in with the same credentials from any other IP address or any other subnet will be dropped. To ensure the administrator has access from different locations, you can enter up to ten IP addresses or subnets. Ideally, this should be kept to a minimum. For higher security, use an IP address with a net mask of 255.255.255.255, and enter an IP address (non-zero) in each of the three default trusted host fields.

Trusted hosts are configured when adding a new administrator by going to *System* > *Admin* > *Administrators* in the web-based manager and selecting *Restrict this Admin Login from Trusted Hosts Only*, or `config system admin` in the CLI.

The trusted hosts apply to the web-based manager, ping, snmp and the CLI when accessed through SSH. CLI access through the console port is not affected.

Also ensure all entries contain actual IP addresses, not the default 0.0.0.0.

Configuring Two-factor Authentication

FortiOS 5.0 provides support for FortiToken and FortiToken Mobile. FortiToken Mobile is a Fortinet application that enables you to generate One Time Passwords (OTPs) on a mobile device for FortiGate two-factor authentication. The user's mobile device and the FortiGate unit must be connected to the Internet to activate FortiToken mobile. Once activated, users can generate OTPs on their mobile device without having network access. FortiToken Mobile is available for iOS and Android devices from their respective Application stores. No cellular network is required for activation.

The latest FortiToken Mobile documentation is available from the FortiToken page of the

Fortinet Technical Documentation website.

Two free trial tokens are included with every registered FortiGate unit. Additional tokens can be purchased from your reseller or from Fortinet.

To assign a token to an administrator go to *System* > *Admin* > *Administrators* and either add a new or select an existing administrator to assign the token to. Configure the administrator as required, you need to enter your email address and phone number in order to receive the activation code for the FortiToken mobile. Select *Enable Two-factor Authentication*. Select the token to associate with the administrator. Select *OK* to assign the token to the administrator.

To configure your FortiGate unit to send email or SMS messages go to *System* > *Config* > *Messaging Servers*.

Change the default administrative port to a non-standard port

Administration Settings under *System* > *Admin* > *Settings* or `config system global` in the CLI, enable you to change the default port configurations for administrative connections to the FortiGate unit for added security. When connecting to the FortiGate unit when the port has changed, the port must be included. For example, if you are connecting to the FortiGate unit using HTTPS over port 8081, the url would be `https://192.168.1.99:8081`

If you make a change to the default port number for HTTP, HTTPS, Telnet, or SSH, ensure that the port number is not used for other services.

Enable Password Policy

Brute force password software can launch more than just dictionary attacks. It can discover common passwords where a letter is replaced by a number. For example, if “p4ssw0rd” is used as a password, it can be cracked.

Password policies, available by going to *System* > *Admin* > *Settings* > *Enable Password Policy*, enable you to create a password policy that any administrator who updates their passwords, must follow. Using the available options you can define the required length of the password, what it must contain (numbers, upper and lower case, and so on) and an expiry time frame. The FortiGate unit will warn of any password that is added and does not meet the criteria.

Maintain short login timeouts

To avoid the possibility of an administrator walking away from the management computer and leaving it exposed to unauthorized personnel, you can add an idle time-out. That is, if the web-based manager is not used for a specified amount of time, the FortiGate unit will automatically log the administrator out. To continue their work, they must log in again.

The time-out can be set as high as 480 minutes, or eight hours, although this is not recommend.

To set the idle time out, go to *System* > *Admin* > *Settings* and enter the amount of time for the Idle Timeout. A best practice is to keep the default of 5 min.

When logging into the console using SSH, the default time of inactivity to successfully log into the FortiGate unit is 120 seconds (2 minutes). You can configure the time to be shorter by using the CLI to change the length of time the command prompt remains idle before the FortiGate unit will log the administrator out. The range can be between 10 and 3600 seconds. To set the logout time enter the following CLI commands:

```
config system global
   set admin-ssh-grace-time <number_of_seconds>
end
```

Modify administrator account Lockout Duration and Threshold values

Account lockout policies control how and when accounts are locked out of the FortiGate unit. These policies are described and implemented as follows:

Administrator account Lockout Duration

If someone violates the lockout controls by entering an incorrect user name and/or password, account lockout duration sets the length of time the account is locked. the lockout duration can be set to a specific length of time using a value between 1 and 4294967295 seconds. The default value is 60 seconds.

When it's required use the CLI to modify the lockout duration as follow:

```
config system global
   set admin-lockout-duration <integer>
end
```

Administrator account Lockout Threshold

The lockout threshold sets the number of invalid logon attempts that are allowed before an account is locked out. You may set a value that balances the need to prevent account cracking against the needs of an administrator who may have difficulty accessing their account.

Its normal for an administrator to sometimes take a few attempts to logon with the right password.

The lockout threshold can be set to any value from 1 to 10. The Default value is 3, which is normally a good setting. However, to improve security you could reduce it to 1 or 2 as long as administrators know to take extra care when entering their passwords.

Use the following CLI command to modify the lockout threshold:

```
config system global
   set admin-lockout-threshold <integer>
end
```

Keep in mind that the higher the lockout value, the higher the risk that someone may be able to break into the FortiGate unit.

Disable auto installation via USB

An attacker with a physical access to the device could load a new configuration or firmware on the FortiGate using the USB port, reinitializing the device through a power cut. To avoid this, execute the following CLI commands:

```
config system auto-install
   set auto-install-config disable
   set auto-install-image disable
end
```

Auditing and Logging

Audit web facing administration interfaces. By default, FortiGate logs all deny action, you can check these actions by going to *Log & Report* > *Event Log* > *System*. This default behavior should not be changed. Also secure log files in a central location such as FortiCloud and configure alert email which provides an efficient and direct method of notifying an administrator of events. You can configure log settings by going to *Log & Report* > *Log Config*.

An auditing schedule should be established to routinely inspect logs for signs of intrusion and probing.

Troubleshooting resources

Before you begin troubleshooting, you need to know Fortinet's troubleshooting resources. Doing so will shorten the time to solve your issue. Indeed, an administrator can save time and effort during the troubleshooting process by first checking if the issue has been experienced before. Several self-help resources are available to provide valuable information about FortiOS technical issues, including:

Technical Documentation

Installation Guides, Administration Guides, Quick Start Guides, and other technical documents are available online at the following URL:

http://docs.fortinet.com

Fortinet Video Library

The Fortinet Video Library hosts a collection of video which provide valuable information about Fortinet products.

http://video.fortinet.com

Release Notes

Issues that are uncovered after the technical documentation has been published will often be listed in the Release Notes that accompany the device.

Knowledge Base

The Fortinet Knowledge Base provides access to a variety of articles, white papers, and other documentation providing technical insight into a range of Fortinet products. The Knowledge Base is available online at the following URL:

http://kb.fortinet.com

Fortinet Technical Discussion Forums

An online technical forums allow administrators to contribute to discussions about issues related to their Fortinet products. Searching the forum can help the administrator identify if an issue has been experienced by another user. The support forums can be accessed at the following URL:

http://support.fortinet.com/forum

Fortinet Training Services Online Campus

The Fortinet Training Services Online Campus hosts a collection of tutorials and training materials which can be used to increase knowledge of the Fortinet products.

http://campus.training.fortinet.com

Fortinet Customer Support

You have defined your problem, researched a solution, put together a plan to find the solution, and executed that plan. At this point if the problem has not been solved, its time to contact Fortinet Customer Support for assistance.

http://support.fortinet.com

Troubleshooting tools

FortiOS provides a number of tools that help with troubleshooting both hardware and software issues. These tools include diagnostics and ports; ports are used when you need to understand the traffic coming in or going out on a specific port, for example, UDP 53, which is used by the FortiGate unit for DNS lookup and RBL lookup.

This section also contains information about troubleshooting FortiGuard issues.

This section contains the following topics:

FortiOS diagnostics

A collection of diagnostic commands are available in FortiOS for troubleshooting and performance monitoring. Within the CLI commands, the two main groups of diagnostic commands are `get` and `diagnose` commands. Both commands display information about system resources, connections, and settings that enable you to locate and fix problems, or to monitor system performance.

This topic includes diagnostics commands to help with:

Additional diagnostic commands related to specific features are covered in the chapter for that specific feature. For example in-depth diagnostics for dynamic routing are covered in the dynamic routing chapter.

Check date and time

The system date and time are important for FortiGuard services, when logging events, and when sending alerts. The wrong time will make the log entries confusing and difficult to use.

Use Network Time Protocol (NTP) to set the date and time if possible. This is an automatic method that does not require manual intervention. However, you must ensure the port is allowed through the firewalls on your network. FortiToken synchronization requires NTP in many situations.

How to check the date and time - web-based manager

1. **Go to *System Information* > *System Time* on the dashboard.**

   Alternately, you can check the date and time using the CLI commands `execute date` and `execute time`.

2. **If required, select *Change* to adjust the date and time settings.**

   You can set the time zone, date and time, and select NTP usage. In the CLI, use the following commands to change the date and time:

```
config system global
   set timezone (use ? to get a list of IDs and descriptions of their
        timezone)
   set
config system ntp
   config ntpserver
   edit 1
      set server "ntp1.fortinet.net"
   next
   edit 2
      set server "ntp2.fortinet.net"
   next
end
set ntpsync enable
set syncinterval 60
end
```

Resource usage

Each program running on a computer has one or more processes associated with it. For example if you open a Telnet program, it will have an associated telnet process. The same is true in FortiOS. All the processes have to share the system resources in FortiOS including memory and CPU.

Use `get system performance status` command to show the FortiOS performance status.

Sample output:

```
FGT#get system performance status
CPU states: 0% user 0% system 0% nice 100% idle
CPU0 states: 0% user 0% system 0% nice 100% idle
CPU1 states: 0% user 0% system 0% nice 100% idle
CPU2 states: 0% user 0% system 0% nice 100% idle
CPU3 states: 0% user 0% system 0% nice 100% idle
Memory states: 25% used
Average network usage: 0 kbps in 1 minute, 0 kbps in 10 minutes, 0 kbps
     in 30 minutes
Average sessions: 5 sessions in 1 minute, 5 sessions in 10 minutes, 4
     sessions in 30 minutes
Average session setup rate: 0 sessions per second in last 1 minute, 0
     sessions per second in last 10 minutes, 0 sessions per second in
     last 30 minutes
Virus caught: 0 total in 1 minute
IPS attacks blocked: 0 total in 1 minute
Uptime: 0 days,  12 hours,  7 minutes
```

Monitor the CPU/memory usage of internal processes using the following command:

```
get system performance top <delay> <max_lines>
```

The data listed by the command includes the name of the daemon, the process ID, whether the process is sleeping or running, the CPU percentage being used, and the memory percentage being used.

Sample output:

```
FGT#get system performance top 10 100
Run Time:  0 days, 11 hours and 30 minutes
0U, 0S, 100I; 1977T, 1470F, 121KF
         pyfcgid      120      S       0.0     1.3

     proxyworker      111      S       0.0     1.0
          httpsd      125      S       0.0     0.8
          httpsd       52      S       0.0     0.8
          httpsd      124      S       0.0     0.8
          newcli      141      R       0.0     0.7
          newcli      128      S       0.0     0.7
           fgfmd      102      S       0.0     0.7
            iked       86      S       0.0     0.7
```

Proxy operation

Monitor proxy operations using the following command:

```
diag test application <application> <option>
```

The `<application>` value can include the following:

`acd`	Aggregate Controller.
`ddnscd`	DDNS client daemon.
`dhcp6c`	DHCP6 client daemon.
`dhcprelay`	DHCP relay daemon.
`dlpfingerprint`	DLP fingerprint daemon.
`dlpfpcache`	DLP fingerprint cache daemon.
`dnsproxy`	DNS proxy.
`dsd`	DLP Statistics daemon.
`forticldd`	FortiCloud daemon.
`forticron`	FortiCron daemon.
`fsd`	FortiExplorer daemon.
`ftpd`	FTP proxy.
`harelay`	HA relay daemon.
`http`	HTTP proxy.
`imap`	IMAP proxy.
`info-sslvpnd`	SSL-VPN info daemon.
`ipldbd`	IP load balancing daemon.
`ipsengine`	ips sensor
`ipsmonitor`	ips monitor
`ipsufd`	IPS urlfilter daemon.
`l2tpcd`	L2TP client daemon.
`lted`	USB LTE daemon.
`miglogd`	Miglog logging daemon.
`nat64d`	NAT 64 daemon.
`nntp`	NNTP proxy.
`pop3`	POP3 proxy.

pptpcd	PPTP client.
proxyacceptor	Proxy acceptor.
proxyworker	Proxy worker.
quarantined	Quarantine daemon.
radiusd	RADIUS daemon.
reportd	Report daemon.
reputation	Client reputation daemon.
scanunit	Scanning unit.
sflowd	sFlow daemon.
smtp	SMTP proxy.
snmpd	SNMP daemon.
sqldb	SQL database daemon.
ssh	SSH proxy.
sslacceptor	SSL proxy.
sslworker	SSL proxy.
swctrl_authd	Switch controller authentication daemon.
uploadd	Upload daemon.
urlfilter	URL filter daemon.
wa_cs	WAN optimization cs server.
wa_dbd	WAN optimization storage server.
wad	WAN optimization proxy.
wad_diskd	WAN optimization disk access daemon.
wccpd	WCCP daemon.
wpad	WPA daemon.

The <option> value depends from the application value used in the command. Here are some examples:

- If the application is http, the CLI command will be

```
diag test application http <option>
```

The <option> value can be one from the following:

2	Drop all connections
22	Drop max idle connections
222	Drop all idle connections
4	Display connection stat
44	Display info per connection
444	Display connections per state
4444	Display per-VDOM statistics
44444	Display information about idle connections
55	Display tcp info per connection
6	Display ICAP information
70	Disable ICAP 'Allow: 204' (default)
71	Enable ICAP 'Allow: 204'
72	Drop all ICAP server connections
11	Display the SSL session ID cache statistics
12	Clear the SSL session ID cache statistics
13	Display the SSL session ID cache
14	Clear the SSL session ID cache
80	Show Fortinet bar SSL-VPN bookmark info
81	Show Fortinet bar SSL-VPN bookmark cache
82	Show Fortinet bar SSL-VPN bookmark LRU list

- If the application is `ipsmonitor`, the CLI command will be

```
diag test application ipsmonitor <option>
```

The `<option>` value can be one from the following:

1	Display IPS engine information
2	Toggle IPS engine enable/disable status
3	Display restart log
4	Clear restart log
5	Toggle bypass status

6	Submit attack characteristics now
10	IPS queue length
11	Clear IPS queue length
12	IPS L7 socket statistics
13	IPS session list
14	IPS NTurbo statistics
15	IPSA statistics
97	Start all IPS engines
98	Stop all IPS engines
99	Restart all IPS engines and monitor

Hardware NIC

Monitor hardware network operations using the following command:

```
diag hardware deviceinfo nic <interface>
```

The information displayed by this command is important as errors at the interface are indicative of data link or physical layer issues which may impact the performance of the FortiGate unit.

The following is sample output when `<interface>` = `internal`:

```
System_Device_Name  port5
Current_HWaddr      00:09:0f:68:35:60
Permanent_HWaddr    00:09:0f:68:35:60
Link                up
Speed               100
Duplex              full
[……]
Rx_Packets=5685708
Tx_Packets=4107073
Rx_Bytes=617908014
Tx_Bytes=1269751248
Rx_Errors=0
Tx_Errors=0
Rx_Dropped=0
Tx_Dropped=0
[…..]
```

The `diag hardware deviceinfo nic` command displays a list of hardware related error names and values. The following table explains the items in the list and their meanings.

Table 106: Possible hardware errors and meanings

Field	Definition
Rx_Errors = rx error count	Bad frame was marked as error by PHY.
Rx_CRC_Errors + Rx_Length_Errors - Rx_Align_Errors	This error is only valid in 10/100M mode.
Rx_Dropped or Rx_No_Buffer_Count	Running out of buffer space.
Rx_Missed_Errors	Equals Rx_FIFO_Errors + CEXTERR (Carrier Extension Error Count). Only valid in 1000M mode, whichis marked by PHY.
Tx_Errors = Tx_Aborted_Errors	ECOL (Excessive Collisions Count). Only valid in half-duplex mode.
Tx_Window_Errors	LATECOL (Late Collisions Count). Late collisions are collisions that occur after 64-byte time into the transmission of the packet while working in 10 to100Mb/s data rate and 512-byte timeinto the transmission of the packet while working in the 1000Mb/s data rate. This register only increments if transmits are enabled and the device is in half-duplex mode.
Rx_Dropped	See Rx_Errors.
Tx_Dropped	Not defined.
Collisions	Total number of collisions experienced by the transmitter. Valid in half-duplex mode.
Rx_Length_Errors	Transmission length error.
Rx_Over_Errors	Not defined.
Rx_CRC_Errors	Frame CRC error.
Rx_Frame_Errors	Same as Rx_Align_Errors. This error is only valid in 10/100M mode.
Rx_FIFO_Errors	Same as Rx_Missed_Errors - a missed packet count.
Tx_Aborted_Errors	See Tx_Errors.
Tx_Carrier_Errors	The PHY should assert the internal carrier sense signal during every transmission. Failure to do so may indicate that the link has failed or the PHY has an incorrect link configuration. This register only increments if transmits are enabled. This register is not valid in internal SerDes 1 mode (TBI mode for the 82544GC/EI) and is only valid when the Ethernet controller is operating at full duplex.
Tx_FIFO_Errors	Not defined.
Tx_Heartbeat_Errors	Not defined.
Tx_Window_Errors	See LATECOL.
Tx_Single_Collision_Frames	Counts the number of times that a successfully transmitted packet encountered a single collision. The value only increments if transmits are enabled and the Ethernet controller is in half-duplex mode.
Tx_Multiple_Collision_Frames	A Multiple Collision Count which counts the number of times that a transmit encountered more than one collision but less than 16. The value only increments if transmits are enabled and the Ethernet controller is in half-duplex mode.

Table 106: Possible hardware errors and meanings

Field	Definition
Tx_Deferred	Counts defer events. A defer event occurs when the transmitter cannot immediately send a packet due to the medium being busy because another device is transmitting, the IPG timer has not expired, half-duplex deferral events are occurring, XOFF frames are being received, or the link is not up. This register only increments if transmits are enabled. This counter does not increment for streaming transmits that are deferred due to TX IPG.
Rx_Frame_Too_Longs	The Rx frame is over size.
Rx_Frame_Too_Shorts	The Rx frame is too short.
Rx_Align_Errors	This error is only valid in 10/100M mode.
Symbol Error Count	Counts the number of symbol errors between reads - SYMERRS. The count increases for every bad symbol received, whether or not a packet is currently being received and whether or not the link is up. This register only increments in internal SerDes mode.

Traffic trace

Traffic tracing allows a specific packet stream to be followed. This is useful to confirm packets are taking the route you expected on your network.

View the characteristics of a traffic session though specific security policies using:

```
diag sys session
```

Trace per-packet operations for flow tracing using:

```
diag debug flow
```

Trace per-Ethernet frame using:

```
diag sniffer packet
```

Session table

A session is a communication channel between two devices or applications across the network. Sessions enable FortiOS to inspect and act on a sequential group of packets in a session all together instead of inspecting each packet individually. Each of these sessions has an entry in the session table that includes important information about the session.

Use as a tool

Session tables are useful troubleshooting tools because they allow you to verify connections that you expect to see open. For example, if you have a web browser open to browse the Fortinet website, you would expect a session entry from your computer, on port 80, to the IP for the Fortinet website. Another troubleshooting method is if there are too many sessions for FortiOS to process, you can examine the session table for evidence why this is happening.

The FortiGate session table can be viewed from either the CLI or the web-based manager. The most useful troubleshooting data comes from the CLI. The session table in web-based manager also provides some useful summary information, particularly the current policy number that the session is using.

Web-based manager session information

In the web-based manager there are actually two places to view session information — the policy session monitor, and the dashboard Top Sources, Top Destinations and Top Applications

Top Sessions Dashboard

Top Sources Dashboard shows Top Sessions by source Address, Top Destinations shows Top sessions by Destination address, and Top Applications shows Top Sessions by applications. If there are not enough entries in the session table, try browsing to a different web site and re-examine the table. The *Policy ID* shows which security policy matches the session. The sessions that do not have a *Policy ID* entry originate from the FortiGate device

Session monitor

The session monitor is the session table. It lists the protocol used, source and destination addresses, source and destination ports, what policy ID was matched (if any), how long until the session expires, and how long it has been established.

If there is no policy ID listed in the session entry, the traffic originated from the FortiGate unit. Otherwise all sessions must match a security policy to pass through the FortiGate unit. You can specify a filter to show Forward Traffic only. To do this, click on the Edit icon (it looks like a pencil)

As there are potentially many sessions active at one time, there are different methods you can use to filter unimportant sessions out of your search. The easiest filter is to display only IPv4 or IPv6 sessions. By default both are displayed.

#	Src	Src Port	Dst	Dst Port	Policy ID	Expiry (sec)	Duration (sec)	
1	192.168.1.200:53659	53659	157.55.56.147	40004	1	26	153	
2	192.168.1.200:53659	53659	157.55.56.151	40020	1	124	55	
3	192.168.1.200:53659	53659	157.56.52.38	40045	1	88	91	
4	192.168.1.200:53659	53659	75.158.90.51	56715	1	83	150	
5	192.168.1.200:61730	61730	70.78.76.207	49149	1	3,584	28	
6	192.168.1.200:53659	53659	157.55.130.150	40020	1	11	168	
7	192.168.1.200:61638	61638	111.253.246.196	45660	1	3,594	398	
8	192.168.1.200:53659	53659	157.55.235.148	40004	1	66	113	
9	192.168.1.200:53659	53659	157.55.235.160	40044	1	128	52	
10	192.168.1.200:53875	53875	216.2.48.143	8888	1	56	123	
11	192.168.1.200:53659	53659	65.55.223.27	40012	1	105	74	
12	192.168.1.200:53659	53659	213.199.179.141	40021	1	127	52	
13	192.168.1.200:53659	53659	213.199.179.145	40037	1	10	169	
14	192.168.1.200:53659	53659	64.4.23.156	40032	1	54	125	
15	192.168.1.200:53659	53659	157.55.235.161	40013	1	88	91	
16	192.168.1.200:53659	53659	65.55.223.13	40021	1	124	55	
17	192.168.1.200:53659	53659	65.55.223.38	40029	1	103	76	
18	192.168.1.200:53876	53876	208.91.112.195	8888	1	56	123	
19	192.168.1.200:53876	53876	208.91.112.197	8888	1	56	123	

How to find which security policy a specific connection is using

Every program and device on your network must have a communication channel, or session, open to pass information. The FortiGate unit manages these sessions with its many features from traffic shaping, to antivirus scanning, and even blocking known bad web sites. Each session has an entry in the session table. In the web, you can use the Session Monitor or Top Session Dashboard to view session information.

You may want to find information for a specific session, say a secure web browser session, for troubleshooting. For example if that web browser session is not working properly, you can check the session table to ensure the session is still active, and that it is going to the proper

address. It can also tell you the security policy number it matches, so you can check what is happening in that policy.

1. **Know your connection information.**

   You need to be able to identify the session you want. For this you need the source IP address (usually your computer), the destination IP address if you have it, and the port number which is determined by the program being used. Some commons ports are:

   - port 80 (HTTP for web browsing),
   - port 22 (SSH used for secure login and file transfers)
   - port 23 (telnet for a text connection)
   - port 443 (HTTPS for secure web browsing

2. **Find your session and policy ID.**

   Follow *System* > *Dashboard*> *Top Sources* to the session table monitor. Find your session by finding your source IP address, destination IP address if you have it, and port number. The policy ID is listed after the destination information. If the list of sessions is very long, you can filter the list to make it easier to find your session.

3. **When there are many sessions, use a filter to help you find your session.**

   If there are multiple pages of sessions it is difficult to find a single session. To help you in your search you can use a filter to block out sessions that you don't want. Select the filter icon next to Src Address. In the window that pops up, enter your source IP address and select Apply. Now only sessions that originate from your IP address will be displayed in the session table. If the list is still too long, you can do the same for the Src port. That will make it easy to find your session and the security policy ID. When you are finished remember to clear the filters.

CLI session information

The session table output from the CLI (`diag sys session list`) is very verbose. Even on a system with a small amount of traffic, displaying the session table will generate a large amount of output. For this reason, filters are used to display only the session data of interest.

You can filter a column in the web-based manager by clicking the funnel icon on the column heading or from the CLI by creating a filter.

An entry is placed in the session table for each traffic session passing through a security policy. The following command will list the information for a session in the table:

```
diag sys session list
```

Sample Output:

```
FGT# diag sys session list
session info: proto=6 proto_state=05 expire=89 timeout=3600
     flags=00000000 av_idx=0 use=3
bandwidth=204800/sec    guaranteed_bandwidth=102400/sec
     traffic=332/sec prio=0  logtype=session ha_id=0 hakey=4450
tunnel=/
state=log shape may_dirty
statistic(bytes/packets/err): org=3408/38/0 reply=3888/31/0 tuples=2
orgin->sink: org pre->post, reply pre->post oif=3/5
     gwy=192.168.11.254/10.0.5.100
hook=post dir=org act=snat
     10.0.5.100:1251->192.168.11.254:22(192.168.11.105:1251)
hook=pre dir=reply act=dnat
     192.168.11.254:22->192.168.11.105:1251(10.0.5.100:1251)
pos/(before,after) 0/(0,0), 0/(0,0)
misc=0 domain_info=0 auth_info=0 ftgd_info=0 ids=0x0 vd=0
     serial=00007c33 tos=ff/ff
```

Since output can be verbose, the filter option allows specific information to be displayed, for example:

```
diag sys session filter <option>
```

The `<option>` values available include the following:

`clear`	Clear session filter.
`dintf`	Destination interface.
`dport`	Destination port.
`dst`	Destination IP address.
`duration`	duration
`expire`	expire
`negate`	Inverse filter.
`nport`	NAT'd source port
`nsrc`	NAT'd source ip address
`policy`	Policy ID.
`proto`	Protocol number.
`proto-state`	Protocol state.
`sintf`	Source interface.
`sport`	Source port.
`src`	Source IP address.
`vd`	Index of virtual domain. -1 matches all.

Even though UDP is a sessionless protocol, the FortiGate unit still keeps track of the following two different states:

- UDP reply not seen with a value of 0
- UDP reply seen with a value of 1

The following illustrates FW session states from the session table:

Table 107:

State	Meaning
log	Session is being logged.
local	Session is originated from or destined for local stack.
ext	Session is created by a firewall session helper.
may_dirty	Session is created by a policy. For example, the session for `ftp control channel` will have this state but `ftp data channel` will not. This is also seen when NAT is enabled.
ndr	Session will be checked by IPS signature.
nds	Session will be checked by IPS anomaly.
br	Session is being bridged (TP) mode.

Firewall session setup rate

The number of sessions that can be established in a set period of time is useful information. A session is an end-to-end TCP/IP connection for communication with a limited lifespan. If you record the setup rate during normal operation, when you experience problems you have that setup rate with the current number to see if its very different. While this will not solve your problems, it can be a useful step to help you define your problem.

A reduced firewall session setup rate could be the result of a number of things from a lack of system resources on the FortiGate unit, to reaching the limit of your session count for your VDOM.

To view your session setup rate - web-based manager

1. Got to *System* > *Dashboard*.
2. Maximize *Top Sources*
3. Read the *New Sessions per Second* value displayed at the bottom.

If the *Top Sessions* widget is not visible on your dashboard, go to the + *Widget* button at the top of the window. When a window pops up, select *Top Sessions* for it to be added to the dashboard.

To view your session setup rate method 1- CLI

```
FGT# get sys performance status
CPU states: 0% user 0% system 0% nice 100% idle
Memory states: 10% used
Average network usage: 0 kbps in 1 minute, 0 kbps in 10 minutes,
13 kbps in 30 minutes
Average sessions: 31 sessions in 1 minute, 30 sessions in 10
minutes, 31 sessions in 30 minutes
Average session setup rate: 0.5 sessions per second in last 1
minute, 0 sessions per second in last 10 minutes, 0 sessions per
second in last 30 minutes
Virus caught: 0 total in 1 minute
IPS attacks blocked: 0 total in 1 minute
Uptime: 44 days, 18 hours, 42 minutes
```

The information you are looking for is the Average sessions section, highlighted in the above output. In this example you can see there were 31 sessions in 1 minute, or an average of 0.5 sessions per second. The values for 10 minutes and 30 minutes allow you to take a longer average for a more reliable value if your FortiGate unit is working at maximum capacity. The smallest FortiGate unit can have 1 000 sessions established per second across the unit.

Remember that session setup rate is a global command. If you have multiple VDOMs configured with many sessions in each one, the session setup rate per VDOM will be slower than if there were no VDOMs configured.

Finding object dependencies

An administrator may not be permitted to delete a configuration object if there are other configuration objects that depend on it. This command identifies other objects which depend on or *make reference to* the configuration object in question. If an error is displayed that an object is in use and cannot be deleted, this command can help identify the source of the problem.

Another use is if you have a virtual interface with objects that depend on it, you need to find and remove those dependencies before you delete that interface.

CLI method

When running multiple VDOMs, this command is run in the Global configuration only and it searches for the named object both in the Global and VDOM configuration most recently used:

```
diag sys checkused <path.object.mkey>
```

For example, to verify which objects are referred to in a security policy with an ID of 1, enter the command as follows:

```
diag sys checkused firewall.policy.policyid 1
```

To check what is referred to by interface `port1`, enter the following command:

```
diag sys checkused system.interface.name port1
```

To show all the dependencies for an interface, enter the command as follows:

```
diag sys checkused system.interface.name <interface name>
```

Sample Output:

```
entry used by table firewall.address:name '10.98.23.23_host'
entry used by table firewall.address:name 'NAS'
entry used by table firewall.address:name 'all'
entry used by table firewall.address:name 'fortinet.com'
entry used by table firewall.vip:name 'TORRENT_10.0.0.70:6883'
entry used by table firewall.policy:policyid '21'
entry used by table firewall.policy:policyid '14'
entry used by table firewall.policy:policyid '19'
```

In this example, the interface has dependent objects, including four address objects, one VIP, and three security policies.

Web-based manager method

In the web-based manager, the object dependencies for an interface can be easily checked and removed.

To remove interface object dependencies - web-based manager

1. Go to *System* > *Interfaces*.

   The number in the *Ref.* column is the number of objects that refer to this interface.
2. Select the number in the *Ref.* column for the desired interface.

   A Window listing the dependencies will appear.
3. Use these detailed entries to locate and remove object references to this interface.

   The trash can icon will change from gray when all object dependencies have been removed.
4. Remove the interface by selecting the check box for the interface, and select *Delete*.

Flow trace

To trace the flow of packets through the FortiGate unit, use the following command:

```
diag debug flow trace start
```

Follow packet flow by setting a flow filter using this command:

```
diag debug flow filter <option>
```

Filtering options include the following:

`addr` IP address
`clear` clear filter
`daddr` destination IP address
`dport` destination port
`negate` inverse filter
`port` port
`proto` protocol number
`saddr` source IP address
`sport` source port
`vd` index of virtual domain, -1 matches all

Enable the output to be displayed to the CLI console using the following command:

```
diag debug flow show console
```

`diag debug flow` output is recorded as event log messages and are sent to a FortiAnalyzer unit if connected. ***Do not let this command run longer than necessary since it generates significant amounts of data***.

Start flow monitoring with a specific number of packets using this command:

```
diag debug flow trace start <N>
```

Stop flow tracing at any time using:

```
diag debug flow trace stop
```

The following is an example of the flow trace for the device at the following IP address: `203.160.224.97`

```
diag debug enable
diag debug flow filter addr 203.160.224.97
diag debug flow show console enable
diag debug flow show function-name enable
diag debug flow trace start 100
```

Flow trace output example - HTTP

Connect to the web site at the following address to observe the debug flow trace. The display may vary slightly:

```
http://www.fortinet.com
```

Comment: SYN packet received:

```
id=20085 trace_id=209 func=resolve_ip_tuple_fast
line=2700 msg="vd-root received a packet(proto=6,
192.168.3.221:1487->203.160.224.97:80) from port5."
```

SYN sent and a new session is allocated:

```
id=20085 trace_id=209 func=resolve_ip_tuple line=2799
msg="allocate a new session-00000e90"
```

Lookup for next-hop gateway address:

```

msg="find a route: gw-192.168.11.254 via port6"
```

Source NAT, lookup next available port:

```
id=20085 trace_id=209 func=get_new_addr line=1219
msg="find SNAT: IP-192.168.11.59, port-31925"
direction"
```

Matched security policy. Check to see which policy this session matches:

```
id=20085 trace_id=209 func=fw_forward_handler line=317
msg="Allowed by Policy-3: SNAT"
```

Apply source NAT:

```
id=20085 trace_id=209 func=__ip_session_run_tuple
line=1502 msg="SNAT 192.168.3.221->192.168.11.59:31925"
```

SYN ACK received:

```
id=20085 trace_id=210 func=resolve_ip_tuple_fast line=2700
msg="vd-root received a packet(proto=6, 203.160.224.97:80-
>192.168.11.59:31925) from port6."
```

Found existing session ID. Identified as the reply direction:

```
id=20085 trace_id=210 func=resolve_ip_tuple_fast line=2727
msg="Find an existing session, id-00000e90, reply
direction"
```

Apply destination NAT to inverse source NAT action:

```
id=20085 trace_id=210 func=__ip_session_run_tuple
line=1516 msg="DNAT 192.168.11.59:31925-
>192.168.3.221:1487"
```

Lookup for next-hop gateway address for reply traffic:

```
id=20085 trace_id=210 func=vf_ip4_route_input line=1543
msg="find a route: gw-192.168.3.221 via port5"
```

ACK received:

```
id=20085 trace_id=211 func=resolve_ip_tuple_fast line=2700
msg="vd-root received a packet(proto=6,
192.168.3.221:1487->203.160.224.97:80) from port5."
```

Match existing session in the original direction:

```
id=20085 trace_id=211 func=resolve_ip_tuple_fast line=2727
msg="Find an existing session, id-00000e90, original
direction"
```

Apply source NAT:

```
id=20085 trace_id=211 func=__ip_session_run_tuple
line=1502 msg="SNAT 192.168.3.221->192.168.11.59:31925"
```

Receive data from client:

```
id=20085 trace_id=212 func=resolve_ip_tuple_fast
line=2700 msg="vd-root received a packet(proto=6,
192.168.3.221:1487->203.160.224.97:80) from port5."
```

Match existing session in the original direction:

```
id=20085 trace_id=212 func=resolve_ip_tuple_fast
line=2727 msg="Find an existing session, id-00000e90,
original direction"
```

Apply source NAT:

```
id=20085 trace_id=212 func=__ip_session_run_tuple
line=1502 msg="SNAT 192.168.3.221->192.168.11.59:31925"
```

Receive data from server:

```
id=20085 trace_id=213 func=resolve_ip_tuple_fast
line=2700 msg="vd-root received a packet(proto=6,
203.160.224.97:80->192.168.11.59:31925) from port6."
```

Match existing session in reply direction:

```
id=20085 trace_id=213 func=resolve_ip_tuple_fast
line=2727 msg="Find an existing session, id-00000e90,
reply direction"
```

Apply destination NAT to inverse source NAT action:

```
id=20085 trace_id=213 func=__ip_session_run_tuple
line=1516 msg="DNAT 192.168.11.59:31925-
>192.168.3.221:1487"
```

Flow trace output example - IPsec (policy-based)

```
id=20085 trace_id=1 msg="vd-root received a packet(proto=1,
     10.72.55.240:1->10.71.55.10:8) from internal."
id=20085 trace_id=1 msg="allocate a new session-00001cd3"
id=20085 trace_id=1 msg="find a route: gw-66.236.56.230 via wan1"

     original direction"
id=20085 trace_id=2 msg="enter IPsec ="encrypted, and send to
     15.215.225.22 with source 66.236.56.226" tunnel-RemotePhase1"
id=20085 trace_id=2 msgid=20085 trace_id=2 msg="send to 66.236.56.230
     via intf-wan1"
```

Packet sniffing and packet capture

FortiOS devices can sniff packets using commands in the CLI or capture packets using the web-based manager. The differences between the two methods are not large.

Packet sniffing in the CLI is well suited for spot checking traffic from the CLI, but if you have complex filters to enter it can be a lot of work to enter them each time. You can also save the sniffing output; however, you must log to a file and then analyze the file later by hand.

Packet capture in the web-based manager makes it easy to set up multiple filters at once and just run one or two as you need them. You also have controls to start and stop capturing as you wish. Packet capture output is downloaded to your local computer as a *.pcap file which requires a third party application to read the file, such as Wireshark. This method is useful to send Fortinet support information to help resolve an issue.

Features	Packet sniffing	Packet capture
Command location	CLI	web-based manager
Third party software required	puTTY to log plaintext output	Wireshark to read *.pcap files
Read output in plain text file	yes	no
Read output as *.pcap file using Wireshark	no	yes
Easily configure single quick and simple filter	yes	no
Record packet interface	yes	no
Configure complex sniffer filters on multiple interface	no	yes
sniff IPv6	hard	easy
sniff non-IP packets	no	yes
Filter packets by protocol and/or port	easy	easy
Filter packets by source and/or destination address	easy	easy

Packet sniffing

Before you start sniffing packets on the CLI, you should be prepared to capture the output to a file — there can be huge amounts of data that you will not be able to see without saving it to a file. One method is to use a terminal program like puTTY to connect to the FortiGate unit's CLI. Then once the packet sniffing count is reached you can end the session and analyze the output in the file.

Details within packets passing through particular interfaces can be displayed using the packet sniffer with the following command:

```
diag sniffer packet <interface> <filter> <verbose> <count> <tsformat>
```

The `<interface>` value is required, with the rest being optional. If not included the default values will be `"none"`.

For example the simplest valid sniffer command would be:

```
diag sniffer packet any
```

The `<interface>` value can be any physical or virtual interface name. Use *any* to sniff packets on all interfaces.

The <filter> value limits the display of packets using filters, including Berkeley Packet Filtering (BPF) syntax. The <filter> value must be enclosed in quotes.

```
'[[src|dst] host <host_name_or_IP1>] [[src|dst] host
     <host_name_or_IP2>] [[arp|ip|ip6|gre|esp|udp|tcp] [port_no]]
     [[arp|ip|ip6|gre|esp|udp|tcp] [port_no]]‘
```

If a second host is specified in the filter, only the traffic between the two hosts will be displayed. Optionally, you can use logical OR to match only one of the hosts, or match one of multiple protocols or ports. When defining a port, there are up to two parts — protocol and port number.

For example, to display UDP 1812 traffic or TCP 8080 traffic, use the following:

```
'udp port 1812 or tcp port 8080’
```

To display all IP traffic that has a source of 192.168.1.2 and a destination of 192.168.2.3:

```
'ip src host 192.168.1.2 and dst host 192.168.2.3’
```

The <verbose> option allows different levels of information to be displayed. The verbose levels include:

1 Print header of packets

2 Print header and data from the IP header of the packets

3 Print header and data from the Ethernet header of the packets

4 Print header of packets with interface name

5 Print header and data from ip of packets with interface name

6 Print header and data from ethernet of packets with interface name

The <count> value indicates the number of packets to sniff before stopping. If this variable is not included, or is set to zero, the sniffer will run until you manually halt it with Ctrl-C.

The <tsformat> value define the format of timestamp. It can be:

a: absolute UTC time, yyyy-mm-dd hh:mm:ss.ms

l: absolute LOCAL time, yyyy-mm-dd hh:mm:ss.ms

otherwise: relative to the start of sniffing, ss.ms

Packet capture

FortiOS 5 includes packet capture to the web-based manager. To configure packet capture filters, go to *System* > *Network* > *Packet Capture*.

When you add a packet capture filter, enter the following information and select *OK*.

Interface	Select the interface to sniff from the dropdown menu. You must select one interface. You cannot change the interface without deleting the filter and creating a new one, unlike the other fields.
Max Packets to Capture	Enter the number of packets to capture before the filter stops. This number cannot be zero. You can halt the capturing before this number is reached.
Enable Filters	Select this option to specify your filter fields
Host(s)	Enter one or more hosts IP address Separate multiple hosts with commas. Enter a range using a dash without spaces, for example 172.16.1.5-172.16.1.15 or enter a subnet.
Port(s)	Enter one or more ports to capture on the selected interface. Separate multiple ports with commas. Enter a range using a dash without spaces, for example 88-90
VLAN(s)	Enter one or more vlans (if there is any). Separate multiple vlans with commas.
Protocol	Enter one or more protocol. Separate multiple protocol with commas. Enter a range using a dash without spaces, for example 1-6, 17, 21-25
Include IPv6 packets	Select this option if you are troubleshooting IPv6 networking, or if your network uses IPv6. Otherwise, leave it disabled.
Capture Non-IP packets	The protocols available in the list are all IP based except for ICMP (ping). To capture non-IP based packets select this feature. Some examples of non-IP packets include IPsec, IGMP, ARP, and as mentioned ICMP.

If you select a filter and go back to edit it, you have the added option of starting and stopping packet capture in the edit window, or downloading the captured packets. You can also see the filter status and the number of packets captured.

You can also select the filter and select *Start* to start capturing packets. While the filter is running, you will see the number of captured packets increasing until it reaches the max packet count or you select *Stop*. While the filter is running you cannot download the output file.

When the packet capture is complete, you can select *Download* to send the packet capture filter captured packets to your local computer as a *.pcap file. To read this file format, you will need to use Wireshark or a similar third party application. Using this tool you will have extensive analytics available to you and the full contents of the packets that were captured.

FA2 and NP2 based interfaces

Many Fortinet products contain network processors. Some of these products contain FortiAccel (FA2) network processors while others contain NP2 network processors. Network processor features, and therefore offloading requirements, vary by network processor model.

When using the FA2- and NP2-based interfaces, only the initial session setup will be seen through the `diag debug flow` command. If the session is correctly programmed into the ASIC (fastpath), the debug flow command will no longer see the packets arriving at the CPU. If the NP2 functionality is disabled, the CPU will see all the packets, however, this should only be used for troubleshooting purposes.

First, obtain the NP2 and port numbers with the following command:

```
diag npu np2 list
```

Sample output:

```
ID PORTS
-- -----
0 port1
0 port2
0 port3
0 port4
ID PORTS
-- -----
1 port5
1 port6
1 port7
1 port8
ID PORTS
-- -----
2 port9
2 port10
2 port11
2 port12
ID PORTS
-- -----
3 port13
3 port14
3 port15
3 port16
```

Run the following commands:

```
diag npu np2 fastpafth disable <dev_id>
```

(where `dev_id` is the NP2 number)

Then, run this command:

```
diag npu np2 fastpath-sniffer enable port1
```

Sample output:

```
NP2 Fast Path Sniffer on port1 enabled
```

This will cause all traffic on *port1* of NP2 to be sent to the CPU meaning a standard sniffer trace can be taken and other diag commands should work if it was a standard CPU driven port.

These commands are only for the newer NP2 interfaces. FA2 interfaces are more limited as the sniffer will only capture the initial packets before the session is offloaded into HW (FA2). The same holds true for the `diag debug flow` command as only the session setup will be shown, however, this is usually enough for this command to be useful.

Debug command

Debug output provides continuous, real-time event information. Debugging output continues until it is explicitly stopped or until the unit is rebooted. Debugging output can affect system performance and will be continually generated even though output might not be displayed in the CLI console.

Debug information displayed in the console will scroll in the console display and may prevent CLI commands from being entered, for example, the command to disable the debug display. To turn off debugging output as the display is scrolling by, press the ↑ key to recall the recent diag debug command, press backspace, and type "0", followed by *Enter*.

Debug output display is enabled using the following command:

```
diag debug enable
```

When finished examining the debug output, disable it using:

```
diag debug disable
```

Once enabled, indicate the debug information that is required using this command:

```
diag debug <option> <level>
```

Debug command options include the following:

`application`	application
`authd`	Authentication daemon.
`cli`	Debug CLI.
`cmdb-trace`	Trace CLI.
`config-error-log`	Configure error log info.
`console`	console
`crashlog`	Crash log info.
`disable`	Disable debug output.
`enable`	Enable debug output.
`flow`	Trace packet flow in kernel.
`fsso-polling`	FSSO active directory poll module.
`info`	Show active debug level settings.
`kernel`	kernel
`rating`	Display rating info.

report	Report for tech support.
reset	Reset all debug level to default.
rtmon	rtmon daemon
sql-log-error	SQL log database error info
urlfilter	urlfilter

The debug level can be set at the end of the command. Typical values are 2 and 3, for example:

```
diag debug application DHCPS 2
diag debug application spamfilter 2
```

Fortinet support will advise which debugging level to use.

Timestamps can be enabled to the debug output using the following command:

```
diag debug console timestamp enable
```

Debug output example

This example shows the IKE negotiation for a secure logging connection from a FortiGate unit to a FortiAnalyzer system.

```
diag debug reset
diag vpn ike log-filter src-addr4 192.168.11.2
diag debug enable
```

Sample Output:

```
FGh_FtiLog1: IPsec SA connect 0 192.168.11.2->192.168.10.201:500,
     natt_mode=0 rekey=0 phase2=FGh_FtiLog1
FGh_FtiLog1: using existing connection, dpd_fail=0
FGh_FtiLog1: found phase2 FGh_FtiLog1
FGh_FtiLog1: IPsec SA connect 0 192.168.11.2 -> 192.168.10.201:500
     negotiating
FGh_FtiLog1: overriding selector 225.30.5.8 with 192.168.11.2
FGh_FtiLog1: initiator quick-mode set pfs=1536...
FGh_FtiLog1: try to negotiate with 1800 life seconds.
FGh_FtiLog1: initiate an SA with selectors:
     192.168.11.2/0.0.0.0->192.168.10.201, ports=0/0, protocol=0/0
Send IKE Packet(quick_outI1):192.168.11.2:500(if0) ->
     192.168.10.201:500, len=348
Initiator: sent 192.168.10.201 quick mode message #1 (OK)
FGh_FtiLog1: set retransmit: st=168, timeout=6.
```

In this example:

192.168.11.2->192.168.10.201:500	Source and Destination gateway IP address

`dpd_fail=0`	Found existing Phase 1
`pfs=1536...`	Create new Phase 2 tunnel

The execute tac report command

`exec tac report` is an execute command that runs an exhaustive series of diagnostic commands. It runs commands that are only needed if you are using certain features like HA, VPN tunnels, or a modem. The report takes a few minutes to complete due to the amount of output generated. If you have your CLI output logged to a file, you can run this command to familiarize yourself with the CLI commands involved.

When you call Fortinet Customer Support, you will be asked to provide information about your unit and its current state using the output from this CLI command.

Other commands

ARP table

To view the ARP cache, use the following command:

```
get sys arp
```

To view the ARP cache in the system, use this command:

```
diag ip arp list
```

Sample output:

```
index=14 ifname=internal 224.0.0.5 01:00:5e:00:00:05 state=00000040
     use=72203 confirm=78203 update=72203 ref=1
index=13 ifname=dmz 192.168.3.100 state=00000020 use=1843
     confirm=650179 update=644179 ref=2      ? VIP
index=13 ifname=dmz 192.168.3.109 02:09:0f:78:69:ff state=00000004
     use=71743 confirm=75743 update=75743 ref=1
index=14 ifname=internal 192.168.11.56 00:1c:23:10:f8:20
     state=00000004 use=10532 confirm=10532 update=12658 ref=4
```

To remove the ARP cache, use this command:

```
execute clear system arp table
```

To remove a single ARP entry, use:

```
diag ip arp delete <interface name> <IP address>
```

To remove all entries associated with a particular interface, use this command:

```
diag ip arp flush <interface name>
```

To add static ARP entries, use the following command:

```
config system arp-table
```

Time and date settings

Check time and date settings for log message timestamp synchronization (the Fortinet support group may request this) and for certificates that have a time requirement to check for validity. Use the following commands:

```
execute time
current time is: 12:40:48
last ntp sync:Thu Mar 16 12:00:21 2006
execute date
current date is: 2006-03-16
```

To force synchronization with an NTP server, toggle the following command:

```
set ntpsync enable/disable
```

If all devices have the same time, it helps to correlate log entries from different devices.

IP address

There may be times when you want to verify the IP addresses assigned to the FortiGate unit interfaces are what you expect them to be. This is easily accomplished from the CLI using the following command.

```
diag ip address list
```

The output from this command lists the IP address and mask if available, the index of the interface (a sort of ID number) and the devname is the name of the interface. While physical interface names are set, virtual interface names can vary. Listing all the virtual interface names is a good use of this command. For vsys_ha and vsys_fgfm, the IP addresses are the local host — these are internally used virtual interfaces.

```
# diag ip address list
IP=10.31.101.100->10.31.101.100/255.255.255.0 index=3 devname=internal
IP=172.20.120.122->172.20.120.122/255.255.255.0 index=5 devname=wan1
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=8 devname=root
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=11 devname=vsys_ha
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=13 devname=vsys_fgfm
```

Other related commands include flushing the IP addresses (`diag ip address flush`), which will force a reload of the IP addresses. This can be useful if you think an IP address is wrong and don't want to reboot the unit. You can add or delete a single IP address (`diag ip address add <ipv4_addr>` or `diag ip address delete <ipv4_addr>`).

FortiOS ports

In the TCP and UDP stacks, there are 65 535 ports available for applications to use when communicating with each other. Many of these ports are commonly known to be associated with specific applications or protocols. These known ports can be useful when troubleshooting your network.

Use the following ports while troubleshooting the FortiGate device:

Table 108:

Port(s)	Functionality
UDP 53	DNS lookup, RBL lookup
UDP 53 or UDP 8888	FortiGuard Antispam or Web Filtering rating lookup
UDP 53 (default) or UDP 8888 and UDP 1027 or UDP 1031	FDN Server List - source and destination port numbers vary by originating or reply traffic. See the article “How do I troubleshoot performance issues when FortiGuard Web Filtering is enabled?” in the Knowledge Base.
UDP 123	NTP Synchronization
UDP 162	SNMP Traps
UDP 514	SYSLOG - All FortiOS versions can use syslog to send log messages to remote syslog servers. FortiOS v2.80 and v3.0 can also view logs stored remotely on a FortiAnalyzer unit.
TCP 22	Configuration backup to FortiManager unit or FortiGuard Analysis and Management Service.
TCP 25	SMTP alert email, encrypted virus sample auto-submit
TCP 389 or TCP 636	LDAP or PKI authentication
TCP 443	FortiGuard Antivirus or IPS update - When requesting updates from a FortiManager unit instead of directly from the FDN, this port must be reconfigured as TCP 8890.
TCP 443	FortiGuard Analysis and Management Service
TCP 514	FortiGuard Analysis and Management Service log transmission (OFTP)
TCP 541	SSL Management Tunnel to FortiGuard Analysis and Management Service (FortiOS v3.0 MR6 or later)
TCP 514	Quarantine, remote access to logs and reports on a FortiAnalyzer unit, device registration with FortiAnalyzer units (OFTP)
TCP 1812	RADIUS authentication
TCP 8000 and TCP 8002	FSSO
TCP 10151	FortiGuard Analysis and Management Service contract validation

FortiAnalyzer/FortiManager ports

If you have a FortiAnalyzer unit or FortiManager unit on your network you may need to use the following ports for troubleshooting network traffic.

Table 109:

Functionality	Port(s)
DNS lookup	UDP 53
NTP synchronization	UDP 123
Windows share	UDP 137-138
SNMP traps	UDP 162
Syslog, log forwarding	UDP 514
Log and report upload	TCP 21 or TCP 22
SMTP alert email	TCP 25
User name LDAP queries for reports	TCP 389 or TCP 636
RVS update	TCP 443
RADIUS authentication	TCP 1812
Log aggregation client	TCP 3000

FortiGuard troubleshooting

The FortiGuard service provides updates to Antivirus, IPsec, Webfiltering, and more. The FortiGuard Distribution System (FDS) involves a number of servers across the world that provide updates to your FortiGate unit. Problems can occur both with connection to FDS, and its configuration on your local FortiGate unit. Some of the more common troubleshooting methods are listed here including

- Troubleshooting process for FortiGuard updates
- FortiGuard server settings
- FortiGuard URL rating

Troubleshooting process for FortiGuard updates

The following process are the logical steps to take when troubleshooting FortiGuard update problems. This includes antivirus (AV), intrusion protection services (IPS), antispam (AS), and web filtering (WB).

1. Does the device have a valid licence that includes these services?

   Each device requires a valid FortiGuard license to access updates for some or all of these services. You can verify the support contract status for your devices at the Fortinet Support website — https://support.fortinet.com/.

2. If the device is part of an HA cluster, do all members of the cluster have the same level of support?

   As with the previous step, you can verify the support contract status for all the devices in your HA cluster at the Fortinet Support website.

3. Have services been enabled on the device?

   To see the FortiGuard information and status for a device, in the web-based manager go to *System* > *Config* > *FortiGuard*. On that page you can verify the status of each component, and if required enable each service. If there are problems, see the FortiGuard section of the FortiOS Handbook.

4. Is the device able to communicate with FortiGuard servers?

   At *System* > *Config* > *FortiGuard* you can also attempt to update AV and IPS, or test the availability of WF and AS default and alternate ports. If there are problems, see the FortiGuard section of the FortiOS Handbook.

5. Is there proper routing to reach the FortiGuard servers?

   Ensure there is a static or dynamic route that enables your ForitGate unit to reach the FortiGuard servers. Usually a generic default route to the internet is enough, but you may need to verify this if your network is complex.

6. Are there issues with DNS?

   An easy way to test this is to attempt a traceroute from behind the FortiGate unit to an external network using the FQDN for a location. If the traceroute FQDN name does not resolve, you have general DNS problems.

7. Is there anything upstream that might be blocking FortiGuard traffic, either on the network or ISP side?

   Many firewalls block all ports by default, and often ISPs block ports that are low. There may be a firewall between the FortiGate unit and the FortiGuard servers that is blocking the traffic. FortiGuard uses port 53 by default, so if it is being blocked you need to either open a hole for it, or change the port it is using.

8. Is there an issue with source ports?

   It is possible that ports used to contact FortiGuard are being changed before reaching FortiGuard or on the return trip before reaching your FortiGate unit. A possible solution for this is to use a fixed-port at NATd firewalls to ensure the port remains the same. Packet sniffing can be used to find more information on what is happening with ports.

9. Are there security policies that include antivirus?

   If no security policies include antivirus, the antivirus databse will not be updated. If antivirus is included, only the database type used will be updated.

FortiGuard server settings

Your local FortiGate unit connects to remote FortiGuard servers get updates to FortiGuard information such as new viruses that may have been found or other new threats. This section demonstrates ways to display information about FortiGuard server information on your FortiGate unit, and how to use that information and update it to fix potential problems. This includes

- Displaying the server list
- Sorting the server list
- Calculating weight

Displaying the server list

The `get webfilter status` command shows the list of FDS servers the FortiGate unit is using to send web filtering requests. Rating requests are only sent to the server on the top of

Troubleshooting methodologies

Before you begin troubleshooting anything but the most minor issues, you need to prepare. Doing so will shorten the time to solve your issue. This section helps to explain how you prepare before troubleshooting, as well as creating a troubleshooting plan and contacting support.

This section contains the following topics:

Establish a baseline

FortiGate units operate at all layers of the OSI model. For this reason troubleshooting problems can become complex. If you establish a normal operation parameters, or baseline, for your system before the problem occurs it will help reduce the complexity when you are troubleshooting.

Many of the guiding questions in the following sections are some form of comparing the current problem situation to normal operation on your FortiGate unit. For this reason it is a best practice that you know what your normal operating status is, and have a record of it you can refer to. This can easily be accomplished by monitoring the system performance with logs, SNMP tools, or regularly running information gathering commands and saving the output. This regular operation data will show trends, and enable you to see when changes happen and there may be a problem.

Back up your FortiOS configuration on a regular basis. This is a good practice for everyday as well as when troubleshooting. You can restore the backed up configuration when needed and save the time and effort of re-creating it from the factory default settings.

Some fundamental CLI commands you can use to obtain normal operating data for your system:

`get system status`	Displays versions of firmware and FortiGuard engines, and other system information.
`get system performance status`	Displays CPU and memory states, average network usage, average sessions and session setup rate, virus caught, IPS attacks blocked, and uptime.
`get hardware memory`	Displays informations about memory

`get system session status`	Displays total number of sessions
`get router info routing-table all`	Displays all the routes in the routing table including their type, source, and other useful data.
`get ips session`	Displays memory used and max available to IPS as well and counts.
`get webfilter ftgd-statistics`	Displays list of FortiGuard related counts of status, errors, and other data.
`diagnose firewall statistic show`	Displays the amount of network traffic broken down into categories such as email, VoIP, TCP, UDP, IM, Gaming, P2P, and Streaming.
`diag system session list`	Displays current detailed sessions list
`show system dns`	Displays configured DNS servers
`diag sys ntp status`	Displays informations about ntp servers

These commands are just a sample. Feel free to include any extra information gathering commands that apply to your system. For example if you have active VPN connections, record information about them using the `get vpn *` series of commands.

For an extensive snapshot of your system, run the CLI command used by TAC to gather extensive information about a system — `exec tac report`. It runs many diagnostic commands that are for specific configurations. This means no matter what features you are using, this command will record their current state. Then if you need to perform troubleshooting at a later date, you can run the same command again and compare the differences to quickly locate suspicious output you can investigate.

Define the problem

The following questions can help determine the scope of the problem and isolate it:

- What is the problem?

  Do not assume that the problem is being experienced is the actual problem. First determine that the problem does not lie elsewhere before starting to troubleshoot the FortiGate device.
- Has it ever worked before?

  If the device never worked from the first day, you may not want to spend time troubleshooting something that could well be defective. See “Troubleshooting bootup”
- Can the problem be reproduced at will or is it intermittent?

  If the problem is intermittent, it may be dependent on system load. Also an intermittent problem can be very difficult to troubleshoot due to the difficulty reproducing the issue.
- What has changed?

  Do not assume that nothing has changed in the network. Use the FortiGate event log to see if any configuration changes were made. The change could be in the operating environment, for example, a gradual increase in load as more sites are forwarded through the firewall.

  If something has changed, see what the affect is if the change is rolled back.
- Determine the scope of the problem - after you have isolated the problem what applications, users, devices, and operating systems does it effect?

Before you can solve a problem, you need to understand it. Often this step can be the longest in this process.

Ask questions such as:

- What is not working? Be specific.
- Is there more than one thing not working?
- Is it partly working? If so, what parts are working?
- Is it a connectivity issue for the whole device, or is there an application that isn't reaching the Internet?

Be as specific as possible with your answers, even if it takes awhile to find the answers.

These questions will help you define the problem. Once the problem is defined, you can search for a solution and then create a plan on how to solve it.

Gathering Facts

Fact gathering is an important part of defining the problem. Record the following information as it applies to the problem:

- Where did the problem occur?
- When did the problem occur and to whom?
- What components are involved?
- What is the affected application?
- Can the problem be traced using a packet sniffer?
- Can the problem be traced in the session table or using system debugging?
- Can log files be obtained that indicate a failure has occurred?

Answers to these questions will help you narrow down the problem, and what you have to check during your troubleshooting. The more things you can eliminate, the fewer things you need to check during troubleshooting. For this reason, be as specific and accurate as you can while gathering facts.

Create a troubleshooting plan

Once you have defined the problem, and searched for a solution you can create a plan to solve that problem. Even if your search didn't find a solution to your problem you may have found some additional things to check to further define your problem.

The plan should list all the possible causes of the problem that you can think of, and how to test for each possible cause.

Your troubleshooting plan will act as a checklist so that you know what you have tried and what is left to check. This is important to have if more than one person will be doing the troubleshooting. Without a written plan, people will become easily confused and steps will be skipped. Also if you have to hand over the problem to someone else, providing them with a detailed list of what data has been gathered and what solutions have been already tried demonstrates a good level of professionalism.

Be ready to add to your plan as needed. After you are part way through, you may discover that you forgot some tests or a test you performed discovered new information. This is normal.

Also if you contact support, they will require information about your problem as well as what you have already tried to fix the problem. This should all be part of your plan.

Providing Supporting Elements

If the Fortinet Technology Assistance Center (TAC) needs to be contacted to help you with your issue, be prepared to provide the following information:

- The firmware build version (use the `get system status` command)
- A network topology diagram
- A recent configuration file
- Optionally, a recent debug log
- Tell the support team what troubleshooting steps have already been performed and the results.

Do not provide the output from exec tac report unless Support requests it. The output from that command is very large and is not required in many cases.

For additional information about contacting Fortinet Customer Support, see “Technical Support Organization Overview” on page 2325.

All of this is your troubleshooting plan.

Obtain any required additional equipment

You may require additional networking equipment, computers, or other equipment to test your solution.

Normally network administrators have additional networking equipment available either to loan you, or a lab where you can bring the FortiGate unit to test.

If you do not have access to equipment, check for shareware applications that can perform the same task. Often there are software solutions when hardware is too expensive.

Ensure you have administrator level access to required equipment

Before troubleshooting your FortiGate unit, you will need administrator access to the equipment. If you are a client on a FortiGate unit with virtual domains enabled, often you can troubleshoot within your own VDOM. However, you should inform your FortiGate unit’s super admin that you will be doing troubleshooting.

Also, you may need access to other networking equipment such as switches, routers, and servers to help you test. If you do not normally have access to this equipment, contact your network administrator for assistance.

Contact Fortinet customer support for assistance

You have defined your problem, researched a solution, put together a plan to find the solution, and executed that plan. At this point if the problem has not been solved, its time to contact Fortinet Customer Support for assistance.

For more information, see “Technical Support Organization Overview” on page 2325.

Technical Support Organization Overview

This section explains how Fortinet's technical support works, as well as how you can easily create an account to get technical support for when issues arise that you cannot solve yourself.

This section contains the following topics:

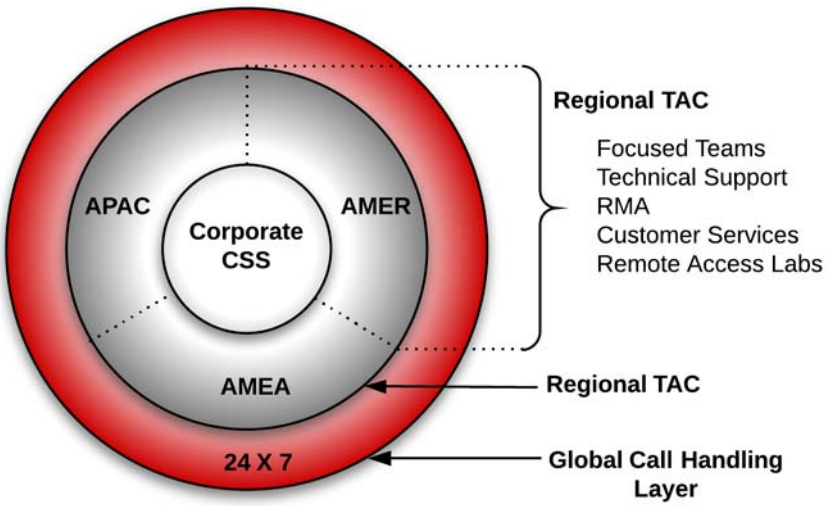
Fortinet Global Customer Services Organization

The Fortinet Global Customer Services Organization is composed of three regional *Technical Assistance Centers* (TAC):

- The Americas (AMER)
- Europe, Middle East, and Africa (EMEA)
- Asia Pacific (APAC)

The regional TACs are contacted through a global call center. Incoming service requests are then routed to the appropriate TAC. Each regional TAC delivers technical support to the customers in its regions during its hours of operation. These TACs also combine to provide seamless, around-the-clock support for all customers.

Figure 323: Fortinet regions and TAC



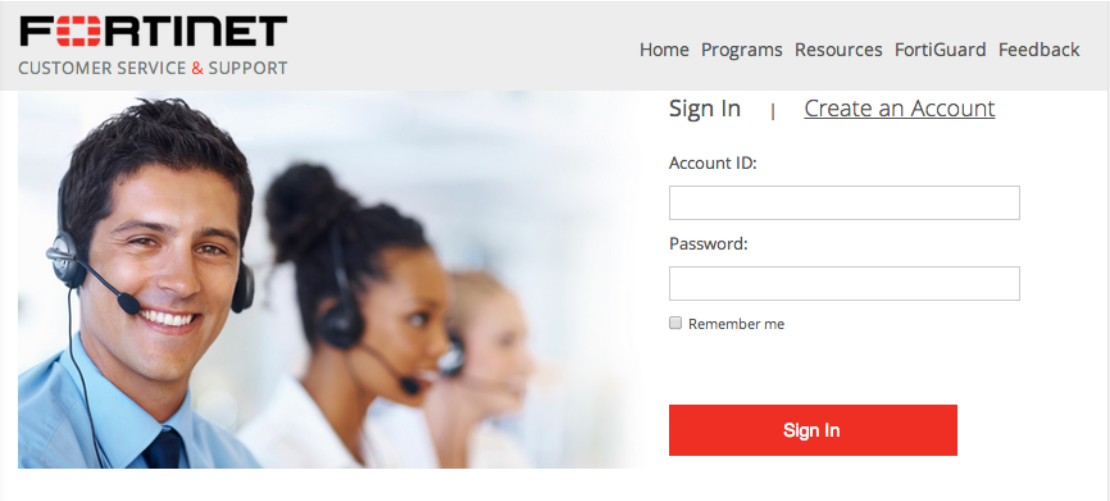
Creating an account

To receive technical support and service updates, Fortinet products in the organization must be registered. The **Product Registration Form** on the support website will allow the registration to be completed online. Creating an account on the support website is the first step in registering products.

Go to the Fortinet support site shown below:

https://support.fortinet.com/

Figure 324: Customer service and support home page



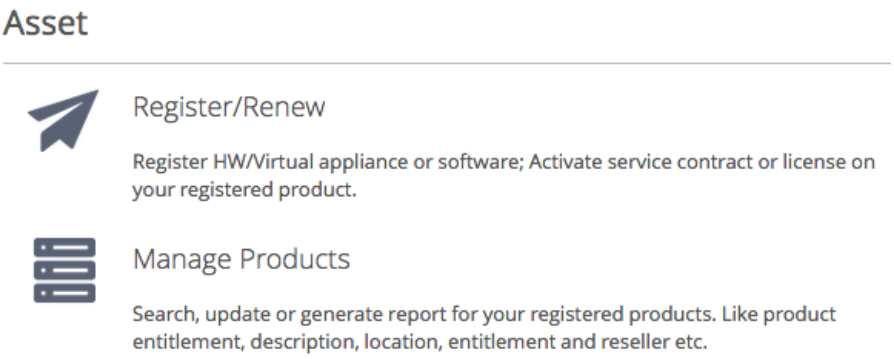
Once the support account has been created, product details can be provided by going to the *Product Register/Renew* and *Manage Product* buttons displayed on the home page. Alternately, the product registration can be completed at a later time.

Registering a device

Complete the following steps when registering a device for support purposes:

1. Log in using the *Username* and *Password* defined when the account was created
2. Under the Asset section, select *Register/Renew* to go to the Registration Wizard. Alternatively, use the Asset menu at the top of the page.

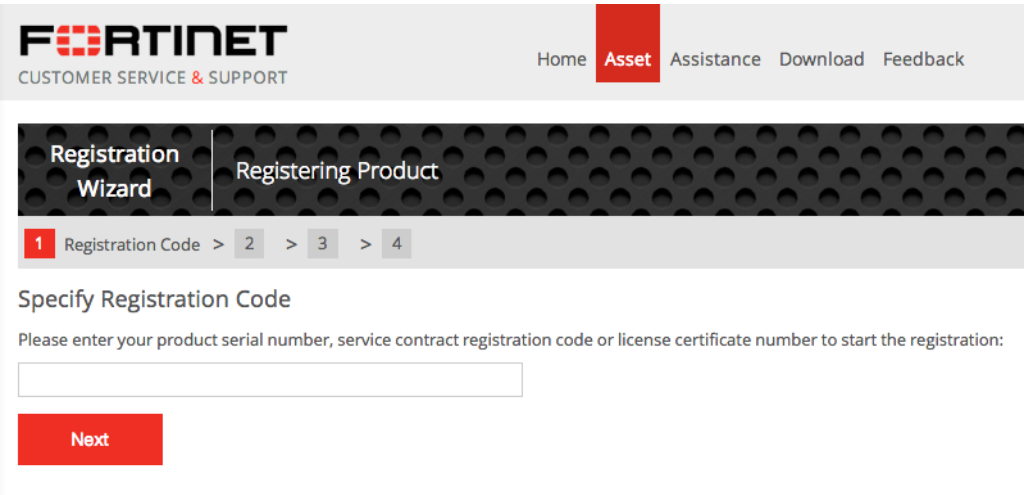
   Figure 325: Register/Renew and Manage Products menu



3. Get a serial number from the back of the FortiGate unit or from the exterior of the FortiGate shipping box.

4. Enter the serial number, service contract registration code or license certificate number to start the product registration.

Figure 326: Adding a product to a support account



5. Enter your registration information.
6. Read and accept the license agreement.
7. Complete the verification process.
8. Select *Finish* to complete the registration process.

Figure 327: Registration wizard

Reporting problems

Problems can be reported to a Fortinet Technical Assistance Center in the following ways:

- By logging an online ticket
- By phoning a technical support center

Logging online tickets

Problem reporting methods differ depending on the type of customer.

Fortinet partners

Fortinet Partners are entitled to priority web-based technical support. This service is designed for partners who provide initial support to their customers and who need to open a support ticket with Fortinet on their behalf. We strongly encourage submission and follow up of support tickets using this service.

The support ticket can be submitted after logging into the partner website using one of the following links using FortiPartner account details:

http://partners.fortinet.com

This link will redirect to the general *Fortinet Partner Portal* extranet website. Click *Support* > *Online Support Ticket*.

https://forticare.fortinet.com/customersupport/Login/CommonLogin.aspx

Fortinet customers

There are two methods to report a technical issue on the Fortinet Support website: creating a technical support ticket by product or creating any type of ticket with the Ticket Wizard for more options.

Fortinet customers should complete the following steps to create a support ticket by product:

1. Log in to the support website at the following address with the account credentials used when the account was created:
   https://support.fortinet.com
2. Navigate to the top menu, click *Asset* and select *Manage/View Products.*
3. In the product list, select the product that is causing the problem.
4. On the left side bar, go to the Assistance category, and select *Technical Request* to create a TA Ticket.
5. Complete the *Create TA Ticket* fields.
6. Click *View Products*.
7. In the *Products List*, select the product that is causing the problem.
8. Complete the *Create Support Ticket* fields.
9. Select *Finish* to complete the support ticket.

Fortinet customers who would like to submit a customer service ticket, DOA ticket, RMA ticket, or FortiGuard service ticket should use the Ticket Wizard and complete the following steps:

1. Log in to the support website at the following address with the account credentials used when the account was created:
   https://support.fortinet.com
2. Navigate to the top menu, click *Assistance* and select *Create a Ticket* from the drop down menu.
3. Select a ticket type and complete the remaining steps in the Ticket Wizard.
4. Select *Finish* to complete the ticket.

Following up on online tickets

Perform the following steps to follow up on an existing issue.

Partners should log into the following web site:

```
http://partners.fortinet.com
```

Customers should log into the following site:

```
http://support.fortinet.com.
```

1. Log in with the account credentials used when the account was created.
2. Navigate to the top menu, click *Assistance*, and select *Manage Tickets*.
3. Use the search field on the View Tickets page to locate the tickets assigned to the account.
4. Select the appropriate ticket number. Closed tickets cannot be updated. A new ticket must be submitted if it concerns the same problem.
5. Add a *New Comment* or *Attachment*.

6. Click *Submit* when complete.

Every web ticket update triggers a notification to the ticket owner, or ticket queue supervisor.

Telephoning a technical support center

The Fortinet Technical Assistance Centers can also be contacted by phone.

Call Fortinet Support Center at 1-408-486-7899 (international) or go to http://www.fortinet.com/support/contact_support.html and select your country from the drop-down list for local contact number.

Assisting technical support

The more information that can be provided to Fortinet technical support, the better they can assist in resolving the issue. Every new support request should contain the following information:

- A valid contact name, phone number, and email address.
- A clear and accurate problem description.
- A detailed network diagram with complete IP address schema.
- The configuration file, software version, and build number of the Fortinet device.
- Additional log files such as *Antivirus* log, *Attack* log, *Event* log, *Debug* log or similar information to include in the ticket as an attachment. If a third-party product is involved, for example, email server, FTP server, router, or switch, please provide the information on its software revision version, configuration, and brand name.

Support priority levels

Fortinet technical support assigns the following priority levels to support cases:

Priority 1

This **Critical** priority is assigned to support cases in which:

- The network or system is down causing customers to experience a total loss of service.
- There are continuous or frequent instabilities affecting traffic-handling capability on a significant portion of the network.
- There is a loss of connectivity or isolation to a significant portion of the network.
- This issue has created a hazard or an emergency.

Priority 2

This **Major** priority is assigned to support cases in which:

- The network or system event is causing intermittent impact to end customers.
- There is a loss of redundancy.
- There is a loss of routine administrative or diagnostic capability.

- There is an inability to deploy a key feature or function.
- There is a partial loss of service due to a failed hardware component.

Priority 3

This **Medium** priority is assigned to support cases in which:

- The network event is causing only limited impact to end customers.
- Issues seen in a test or pre-production environment exist that would normally cause adverse impact to a production network.
- The customer is making time sensitive information requests.
- There is a successful workaround in place for a higher priority issue.

Priority 4

This **Minor** priority is assigned to support cases in which:

- The customer is making information requests and asking standard questions about the configuration or functionality of equipment.

Customers must report Priority 1 and 2 issues by phone directly to the Fortinet EMEA Support Center.

For lower priority issues, you may submit an assistance request (ticket) via the web system.

The web ticket system also provides a global overview of all ongoing support requests.

Return material authorization process

In some cases hardware issues are experienced and a replacement unit must be sent. This is referred to as a Return Material Authorization (RMA). In these cases or RMAs, the support contract must be moved to the new device. Customers can move the support contract from the failing production unit to the new device through the support web site.

To move the support contract to a new device

1. Log in to the support web site with the credentials indicated when the account was created.
2. From *Manage Products*, locate the serial number of the defective unit from the list of devices displayed for the account. The *Product Info* for the selected device will be displayed.
3. In the left side bar under the *Assistance section*, select *RMA Transfer*.
4. Enter the *Original Serial Number* of the original device, enter the *New Serial Number,* and click *Replace* to complete the transfer.

This will transfer the support contract from the defective unit to the new unit with the serial number provided.

Chapter 19 Virtual Domains

This FortiOS Handbook chapter contains the following sections:

Virtual Domains provides an overview of the VDOM technologies, and the basic concepts and rules for using them. We recommend that you begin with this chapter before attempting to configure VDOMs on your FortiGate unit.

Virtual Domains in NAT/Route mode provides detailed explanations and examples for configuring VDOM features in your FortiGate unit using the NAT/Route mode.

Virtual Domains in Transparent mode provides detailed explanations, as well as basic and advanced examples for configuring these features in your FortiGate unit using Transparent mode.

Inter-VDOM routing describes inter-VDOM routing concepts and scenarios, and gives examples that illustrate them.

Troubleshooting Virtual Domains provides diagnostic and troubleshooting information for some potential VDOM issues.

Virtual Domains

Virtual domains (VDOMs) are a method of dividing a FortiGate unit into two or more virtual units that function as multiple independent units. VDOMs can provide separate firewall policies and, in NAT/Route mode, completely separate configurations for routing and VPN services for each connected network or organization.

This chapter will cover the basics of VDOMs, how they change your FortiGate unit, and how to work with VDOMs.

VDOMs let you split your physical FortiGate unit into multiple virtual units. The resulting benefits range from limiting Transparent mode ports to simplified administration, to reduced space and power requirements.

When VDOMs are disabled on any FortiGate unit, there is still one VDOM active: the root VDOM. It is always there in the background. When VDOMs are disabled, the root VDOM is not visible but it is still there.

The root VDOM must be there because the FortiGate unit needs a management VDOM for management traffic among other things. It is also why when you enable VDOMs, all your configuration is preserved in the root VDOM-because that is where you originally configured it.

This section includes:

Benefits of Virtual Domains

VDOMs provide the following benefits:

Improving Transparent mode configuration

When VDOMs are not enabled and you put your FortiGate unit into Transparent mode, all the interfaces on your unit become broadcast interfaces. The problem with this is that there are no interfaces free to do anything else.

With multiple VDOMs you can have one of them configured in Transparent mode, and the rest in NAT/Route mode. In this configuration, you have an available transparent mode FortiGate unit you can drop into your network for troubleshooting, and you also have the standard NAT for networking.

Easier administration

VDOMs provide separate security domains that allow separate zones, user authentication, firewall policies, routing, and VPN configurations. VDOMs separate security domains and

simplify administration of complex configurations—you do not have to manage as many settings at one time. For more information, see “Global and per-VDOM settings” on page 2338.

By default, each FortiGate unit has a VDOM named root. This VDOM includes all of the unit’s physical interfaces, modem, VLAN subinterfaces, zones, firewall policies, routing settings, and VPN settings.

Also, you can optionally assign an administrator account restricted to one VDOM. If the VDOM is created to serve an organization, this feature enables the organization to manage its own configuration. For more information, see “Administrators in Virtual Domains” on page 2357.

Each physical FortiGate unit requires a FortiGuard license to access security updates. VDOMs do not require any additional FortiGuard licenses, or updating — all the security updates for all the VDOMs are performed once per update at the global level. Combined this can be a potentially large money and time saving feature in your network.

Management systems such as SNMP, logging, alert email, FDN-based updates, and NTP-based time setting use addresses and routing in the management VDOM to communicate with the network. They can connect only to network resources that communicate with the management VDOM. Using a separate VDOM for management traffic enables easier management of the FortiGate unit global settings, and VDOM administrators can also manage their VDOMs more easily. For more information, see “Changing the management virtual domain” on page 2361.

Continued security

When a packet enters a VDOM, it is confined to that VDOM and is subject to any firewall policies for connections between VLAN subinterfaces or zones in that VDOM, just like those interfaces on a FortiGate unit without VDOMs enabled.

To travel between VDOMs, a packet must first pass through a firewall policy on a physical interface. The packet then arrives at another VDOM on that same FortiGate unit, but on a different interface, where it must pass through another firewall before entering. It doesn’t matter if the interface is physical or virtual — inter-VDOM packets still require the same security measures as when passing through physical interfaces.

VDOMs provide an additional level of security because regular administrator accounts are specific to one VDOM — an administrator restricted to one VDOM cannot change information on other VDOMs. Any configuration changes and potential errors will apply only to that VDOM and limit any potential down time. Using this concept, you can farther split settings so that the management domain is only accessible by the super_admin and does not share any settings with the other VDOMs.

Savings in physical space and power

To increase the number of physical FortiGate units, you need more rack space, cables, and power to install the new units. You also need to change your network configuration to accommodate the new physical units. In the future, if you need fewer physical units you are left with expensive hardware that is idle.

Increasing VDOMs involves no additional hardware, no additional cabling, and very few changes to existing networking configurations. VDOMs save physical space and power. You are limited only by the size of the VDOM license you buy and the physical resources on the FortiGate unit.

For example, if you are using one FortiGate 620B unit with 10 VDOMs instead of 10 physical units, over a year you will save an estimated 18,000 kWh. You could potentially save ten times that amount with a 100 VDOM license.

By default, FortiGate units support a maximum of 10 VDOMs in any combination of NAT/Route and Transparent modes. For FortiGate models numbered 3000 and higher, you can purchase a

license key to increase the maximum number of VDOMs beyond 10. For more information on VDOM licences, see “Virtual Domain Licensing” on page 2351.

More flexible MSSP configurations

If you are a managed security and service provider (MSSP), VDOMs are fundamental to your business. As a service provider you have multiple customers, each with their own needs and service plans. VDOMs allow you to have a separate configuration for each customer, or group of customers; with up to 500 VDOMs configured per FortiGate unit on high end models. See “Virtual Domain Licensing” on page 2351.

Not only does this provide the exact level of service needed by each customer, but administration of the FortiGate unit is easier as well - you can provide uninterrupted service generally with immediate changes as required. Most importantly, it allows you to only use the resources that each customer needs. Inter-VDOM links allow you to customize the level of interaction you need between each of your customers and your administrators. See “Inter-VDOM routing” on page 2400.

Enabling and accessing Virtual Domains

While Virtual Domains are essentially the same as your regular FortiGate unit for menu configuration, CLI command structure, and general task flow, there are some small differences.

After first enabling VDOMs on your FortiGate unit, you should take the time to familiarize yourself with the interface. This section will help walk you through virtual domains.

This section includes:

Enabling Virtual Domains

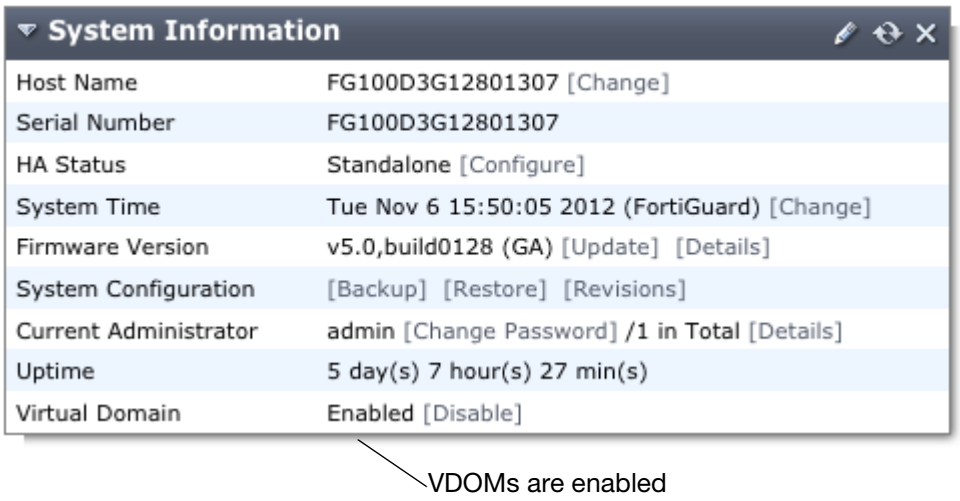
Using the default admin administration account, you can enable or disable VDOM operation on the FortiGate unit.

To enable VDOM configuration - web-based manager

1. Log in with a super_admin account.
2. Go to *System* > *Dashboard* > *Status*.
3. Under *System Information* > *Virtual Domain*, select *Enable* and confirm your selection.

The FortiGate unit logs off all sessions. You can now log in again as admin. For more information, see “Administrators in Virtual Domains” on page 2357.

Figure 328: System Information



To enable VDOM configuration - CLI

```
config system global
  set vdom-admin enable
end
```

Changes to the web-based manager and CLI

When Virtual Domains are enabled, your FortiGate unit will change. The changes will be visible in both the web-based manager and CLI, just the web-based manager, or just the CLI.

When enabling VDOMs, the web-based manager and the CLI are changed as follows:

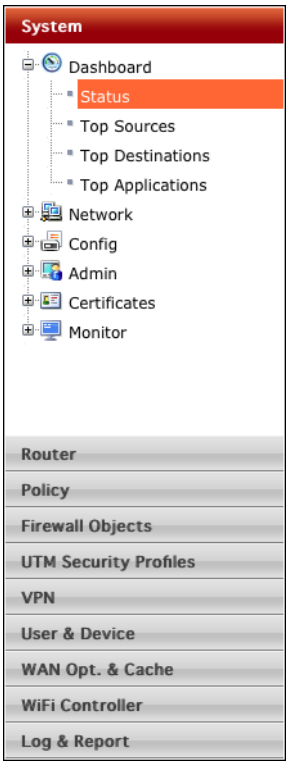
- Global and per-VDOM configurations are separated. This is indicated in the Online Help by Global and VDOM icons. See "Global and per-VDOM settings" on page 2338.
- Only admin accounts using the super_admin profiles can view or configure global options. See "Administrators in Virtual Domains" on page 2357.
- Admin accounts using the super_admin profile can configure all VDOM configurations.
- All other administrator accounts can configure only the VDOM to which they are assigned.

The following changes are specific to the web-based manager:

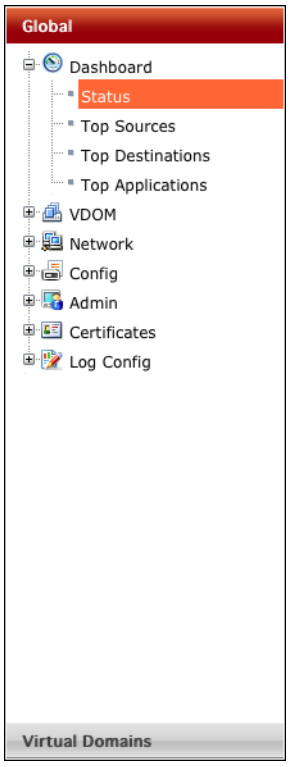
- In the Global view, the System section of the left-hand menu is renamed to Global, and includes a VDOM sub-menu.
- The Log Config menu is moved from Log & Report into the new Global section.
- For admin accounts using the super_admin profile, a new section called Virtual Domains is added at the bottom of the left-hand menu. It lists all the individual VDOMs as expandable menus, with all VDOM specific options in that menu, which allows you to easily select which VDOM to configure, including the root VDOM. See Figure 329 on page 2336.

Figure 329: Menu with VDOMs disabled, at the global level, and VDOM level

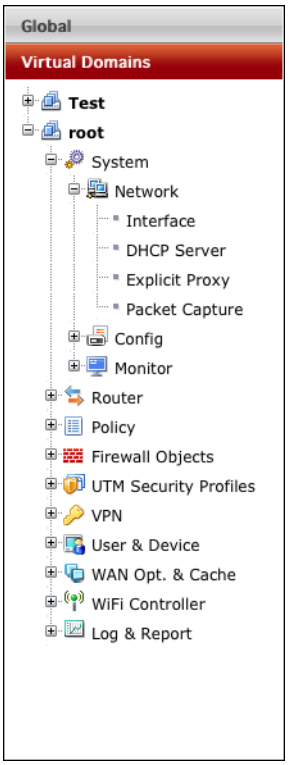
VDOMs disabled



VDOMs enabled (Global)



VDOMs enabled (per-vdom)



In the CLI, admin accounts using the super_admin profile must specify either the global or a VDOM-specific shell before entering commands:

- To change FortiGate unit system settings, from the top level you must first enter
  ```
  config global
  ```
  before entering commands.
- To change VDOM settings, from the top level you must first enter
  ```
  config vdom
    edit <vdom_name>
  ```
  before entering your commands for that VDOM. For information on which commands are global and which are per-VDOM, see “Global and per-VDOM settings” on page 2338.

Changes to FortiGate unit settings

Settings configured outside of a VDOM are called global settings. These settings affect the entire FortiGate unit and include areas such as interfaces, HA, maintenance, some antivirus settings, and some logging settings. In general, any unit settings that should only be changed by the top level administrator are global settings.

Settings configured within a VDOM are called VDOM settings. These settings affect only that specific VDOM and include areas such as operating mode, routing, firewall, VPN, some antivirus, some logging, and reporting.

For more information, see “Global and per-VDOM settings” on page 2338.

Viewing the VDOM list

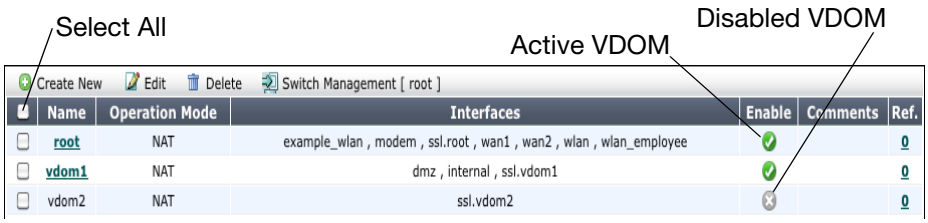
The VDOM list shows all virtual domains, their status, and which VDOM is the management VDOM. It is accessible if you are logged in on an administrator account with the super_admin profile such as the “admin” administrator account.

In the VDOM list you can create or delete VDOMs, edit VDOMs, change the management VDOM, and enable or disable VDOMs.

You can access the VDOM list in *Global* > *VDOM* > *VDOM*.

The root domain cannot be disabled, even if it is not the management VDOM.

Figure 330: List of VDOMs



Create New	Select to add a new VDOM. See "Creating a Virtual Domain" on page 2354.
Edit	Select to change an existing selected VDOM.
Delete	Select to delete the selected VDOM. See "Deleting a VDOM" on page 2356.
Switch Management	Select to switch the management VDOM. Also shows the current management VDOM. You must select an active non-management VDOM before this option becomes available. See "Changing the management virtual domain" on page 2361.
Selected	When checked, this checkbox indicates this VDOM has been selected. Nearly all operations such as Edit, Delete, and Switch Management require a VDOM to first be selected.
Name	The name of the VDOM. VDOMs are listed in alphabetical order. When the VDOM is active, you can select the VDOM name to enter that VDOM. See "Enabling and accessing Virtual Domains" on page 2334.
Operation Mode	Indicates the operation mode as either NAT (for NAT/Route mode) or TP (for Transparent mode).
Interfaces	The interfaces associated with this VDOM. Each VDOM also includes an interface that starts with "ssl." that is created by default.
Enable	A green checkmark indicates this VDOM is active. See "Disabling a Virtual Domain" on page 2355. A grey X indicated this VDOM is disabled. See "Disabling a Virtual Domain" on page 2355.
Comments	Comments entered when the VDOM was created are displayed here.
Ref.	The number of references to this VDOM in the configuration.

Global and per-VDOM settings

Settings configured outside of a VDOM are called global settings. These settings affect the entire FortiGate unit and include areas such as interfaces, HA, maintenance, some antivirus, and some logging. In general, any unit settings that should only be changed by the top level administrator are global settings.

Settings configured within a VDOM are called VDOM settings. These settings affect only that specific VDOM and include areas such as operating mode, routing, firewall, VPN, some antivirus, some logging settings, and reporting.

When Virtual Domains are not enabled, the entire FortiGate unit is effectively a single VDOM. Per-VDOM limits apply. For some resource types, the global limit cannot be reached with only one VDOM.

Some FortiGate unit documentation indicates which parts of the web-based manager, or the CLI are global and which are per-VDOM using the icons shown below. These icons are also present in the Online Help, available on your FortiGate unit.

Figure 331: Global and VDOM icons

For more information on CLI commands, see the FortiGate CLI Reference.

This section includes:

- Global settings - web-based manager
- Per-VDOM settings - web-based manager
- Global settings - CLI
- Per-VDOM settings - CLI

Global settings - web-based manager

The following table lists commands in the web-based manager that are considered global settings when VDOMs are enabled.

The following configuration settings affect all virtual domains. When virtual domains are enabled, only accounts with the default super_admin profile can access global settings.

Table 106: Global configuration settings

System	Dashboard > Status - Host name
	Dashboard > Status - HA Status
	Dashboard > Status - System Time
	Dashboard > Status - Firmware version
	Dashboard > Status - Configuration backup and restore
	VDOM > VDOM - list
	VDOM > VDOM - edit VDOM (mode and resources)
	VDOM > Global Resources
	Network > Interfaces
	Network > DNS - DNS and DDNS settings
	Config > HA
	Config > SNMP
	Config > Replacement Message - messages and images

Table 106: Global configuration settings (Continued)

	Config > FortiGuard - configuration Config > Advanced - scripts, USB Auto-install, debug log download Config > Messaging Servers Admin > Administrators Admin > Admin Profile Admin > Settings - web administration ports, password policy, display settings, timeouts, LCD panel Certificates - local, remote, and CA certificates, CRLs
Log&Report	Log Config - Log Setting

Per-VDOM settings - web-based manager

The following table lists commands in the web-based manager that are considered per-VDOM settings when VDOMs are enabled.

Table 107:VDOM configuration settings

System	Dashboard > Status - read-only except for administrator password Network > Interfaces (and zones) Network > DHCP Server Network > Explicit Proxy Network > Routing Table (Transparent mode only) Network > Packet Capture Config > Replacement Message (messages and images) Config > Advanced Monitor > DHCP Monitor
Router	All settings, including dead gateway detection
Policy	All settings
Firewall Objects	All settings
Security Profiles	All settings
VPN	All settings
User & Device	All settings
WiFi Controller	All settings

Table 107:VDOM configuration settings (Continued)

Log&Report	Traffic and Event Logs
	Reports
	FortiCloud
	Log Config > Log Setting and Alert E-mail
	Logging Monitor

Global settings - CLI

The following table lists commands in the web-based manager that are considered global settings when VDOMs are enabled.

From a super_admin profile account, use this command to configure features that apply to the complete FortiGate unit including all virtual domains. Virtual domain configuration (vdom-admin) must be enabled first.

This command syntax shows how you access the commands within config global. For information on these commands, refer to the relevant sections in this Reference. If there are

multiple versions of the same command with a “2” or “3” added, the additional commands are not listed but fall under the unnumbered command of the same name.

```
config global
   config antivirus heuristic
   config antivirus quarfilepattern
   config antivirus service
   config application name
   config dlp settings
   config endpoint-control app-detect

  get firewall vip ...
end
```

Per-VDOM settings - CLI

The following table lists commands in the web-based manager that are considered VDOM-specific settings when VDOMs are enabled.

From the super_admin account, you can use the commands below to add and configure virtual domains. The number of virtual domains you can add is dependent on the FortiGate model. Virtual domain configuration (vdom-admin) must be enabled.

Once you add a virtual domain you can configure it by adding zones, firewall policies, routing settings, and VPN settings. You can also move physical interfaces from the root virtual domain to other virtual domains and move VLAN subinterfaces from one virtual domain to another.

By default all physical interfaces are in the root virtual domain. You cannot remove an interface from a virtual domain if the interface is part of any of the following configurations:

- routing
- proxy arp
- DHCP server
- zone
- firewall policy
- redundant pair
- link aggregate (802.3ad) group

Delete these objects, or modify them, to be able to remove the interface.

This command syntax shows how you access the commands within a VDOM. Refer to the relevant sections in this Reference for information on these commands.

```
config vdom
  edit <vdom_name>
    config antivirus profile
    config antivirus quarantine
    config antivirus settings
    config application list
    config application rule-settings
    config dlp ... (except settings)
    config endpoint-control app-detect
    config endpoint-control profile
    config endpoint-control settings
    config firewall ... (except ssl)

    config ...
    execute ...
  end
end
```

For more information, see "Global and per-VDOM settings" on page 2338.

Resource settings

Your FortiGate unit has a limited amount of hardware resources such as memory, disk storage, CPU operations. When Virtual Domains are disabled, this limit is not a major concern because all sessions, users, and other processes share all the resources equally.

When using Virtual Domains, hardware resources can be divided differently between Virtual Domains as they are needed. Minimum levels of resources can be specified for each VDOM, so that no Virtual Domain will suffer a complete lack of resources.

For example, if one VDOM has only a web server and logging server connected, and a second VDOM has an internal network of 20 users, these two VDOMs will require different levels of resources. The first VDOM will require many sessions but no user accounts. This compares to the second VDOM where user accounts and management resources are required, but fewer sessions.

Using the global and per-VDOM resource settings, you can customize the resources allocated to each VDOM to ensure the proper level of service is maintained on each VDOM.

This section includes:

- Global resource settings
- Per-VDOM resource settings

Global resource settings

Global Resources apply to the whole FortiGate unit. They represent all of the hardware capabilities of your unit. By default the values are set to their maximum values. These values vary by your model due to each model having differing hardware capabilities.

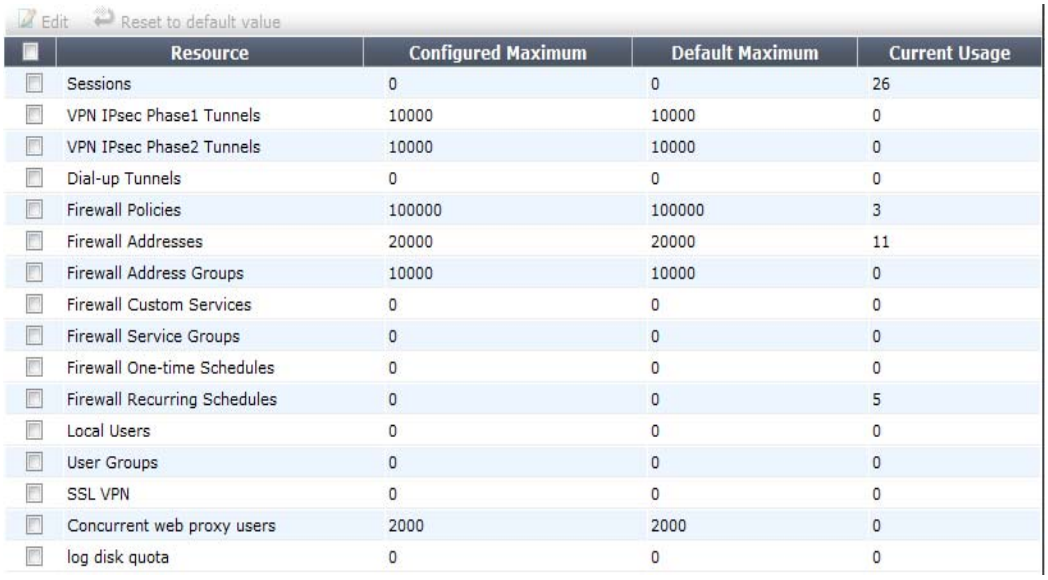
It can be useful to change the maximum values for some resources to ensure there is enough memory available for other resources that may be more important to your configuration.

To use the earlier example, if your FortiGate unit is protecting a number of web servers and other publicly accessible servers you would want to maximize the available sessions and proxies while minimizing other settings that are unused such as user settings, VPNs, and dial-up tunnels.

Global Resources are only configurable at the global level, and only the admin account has access to these settings.

Note that global resources, such as the log disk quote resource, will only be visible if your FortiGate unit hardware supports those resources, such as having a hard disk to support the log disk resource.

Figure 332: Global Resources- web-based manager



To view global resource settings - web-based manager

Select *Global* > *VDOM* > *Global Resources*.

The following information is displayed:

Edit	Select to edit the *Configured Maximum* value for a single selected *Resource*. If multiple *Resources* are selected, *Edit* is not available.
Reset to default value	Select to return one or more selected *Resources* to factory default settings.
Checkbox	Select a *Resource* for editing or resetting to default values.
Resource	The name of the available global resources.
Configured Maximum	The currently configured maximum for this resource. This value can be changed by selecting the *Resource* and editing it.
Default Maximum	The factory configured maximum value for this resource. You cannot set the *Configured Maximum* higher than the *Default Maximum*.
Current Usage	The amount of this resource that is currently being used. This value is useful for determining when and if you may need to adjust *Configured Maximum* values for some resources on your FortiGate unit.

To view global resource settings - CLI

```
config global
  config system resource-limits
  get
```

When viewing the global resource limits in the CLI, the output appears similar to:

```
FGT1000A (global) # config system resource-limits
FGT1000A (resource-limits) # get

session              : 0
ipsec-phase1         : 10000
ipsec-phase2         : 10000
dialup-tunnel        : 0
firewall-policy      : 100000
firewall-address     : 20000
firewall-addrgrp     : 10000
custom-service       : 0
service-group        : 0
onetime-schedule     : 0
recurring-schedule   : 0
user                 : 0
user-group           : 0
sslvpn               : 0
proxy              : 2000
```

For explicit proxies, when configuring limits on the number of concurrent users, you need to allow for the number of users based on their authentication method. Otherwise you may run out of user resources prematurely.

- Each session-based authenticated user is counted as a single user using their authentication membership (RADIUS, LDAP, FSAE, local database etc.) to match users in other sessions. So one authenticated user in multiple sessions is still one user.
- For all other situations, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.

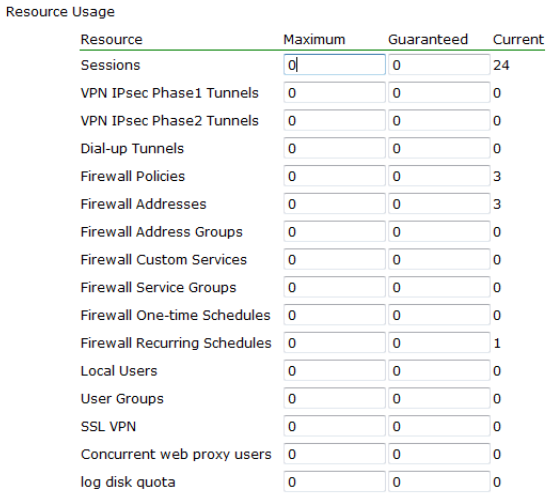
Per-VDOM resource settings

While Global resources apply to resources shared by the whole FortiGate unit, per-VDOM resources are specific to only one Virtual Domain.

By default all the per-VDOM resource settings are set to no limits. This means that any single VDOM can use up all the resources of the entire FortiGate unit if it needs to do so. This would starve the other VDOMs for resources to the point where they would be unable to function. For this reason, it is recommended that you set some maximums on resources that are most vital to your customers.

Each Virtual Domain has its own resource settings. These settings include both maximum, and minimum levels. The maximum level is the highest amount of that resource that this VDOM can use if it is available on the FortiGate unit. Minimum levels are a guaranteed level that this minimum level of the resource will always be available no matter what the other VDOMs may be using.

Figure 333:per-VDOM resources - web-based manager



For example, consider a FortiGate unit that has ten VDOMs configured. vdom1 has a maximum of 5000 sessions and a minimum of 1000 sessions. If the FortiGate unit has a global maximum of 20,000 sessions, it is possible that vdom1 will not be able to reach its 5000 session upper limit. However, at all times vdom1 is guaranteed to have 1000 sessions available that it can use. On the other hand, if the remaining nine VDOMs use only 1000 sessions each, vdom1 will be able to reach its maximum of 5000.

To view per-VDOM resource settings - web-based manager

1. Select *Global* > *VDOM* > *VDOM*.
2. Select the `root` VDOM, and select *Edit*.
3. Adjust the settings in the *Resource Usage* section of the page.

Resource	Name of the resource. Includes dynamic and static resources.
Maximum	Override the global limit to reduce the amount of each resource available for this VDOM. The maximum must the same as or lower than the global limit. The default value is 0, which means the maximum is the same as the global limit. **Note:** If you set the maximum resource usage for a VDOM you cannot reduce the default maximum global limit for all VDOMs below this maximum.
Guaranteed	Enter the minimum amount of the resource available to this VDOM regardless of usage by other VDOMs. The default value is 0, which means that an amount of this resource is not guaranteed for this VDOM.
Current	The amount of the resource that this VDOM currently uses.

4. Select *OK*.

To view per-VDOM resource settings - CLI

```
config global
  config system vdom-property
    edit root
  get
```

When viewing the per-VDOM resource limits in the CLI, the output appears similar to the following. Note that the first two lines are not part of the resource limits. In the CLI, the first number is the maximum value, and the second number is the guaranteed minimum.

```
FGT1KA3607500810 (vdom-property) # edit root
FGT1KA3607500810 (root) # get

name                 : root
description          : property limits for vdom root
session              : 0 0
ipsec-phase1         : 0 0
ipsec-phase2         : 0 0
dialup-tunnel        : 0 0
firewall-policy      : 0 0
firewall-address     : 0 0
firewall-addrgrp     : 0 0
custom-service       : 0 0
service-group        : 0 0
onetime-schedule     : 0 0
recurring-schedule   : 0 0
user                 : 0 0
user-group           : 0 0
sslvpn               : 0 0
proxy             : 0 0
```

Virtual Domain Licensing

For FortiGate models in the 1U category and higher, you can purchase a license key to increase the maximum number of VDOMs. Most Enterprise and Large Enterprise (2U) models can support up to 500 VDOMs. Chassis-based models can support over 500 VDOMs. For specific information, see the product data sheet.

Configuring 500 or more VDOMs will result in reduced system performance. See “FortiGate unit running very slowly” on page 2440.

Your FortiGate unit has limited resources that are divided among all configured VDOMs. These resources include system memory and CPU. Running security features on many VDOMs at once can limit resources available for basic processing. If you require many VDOMs, all with active security features, it is recommended to upgrade to a more powerful FortiGate unit.

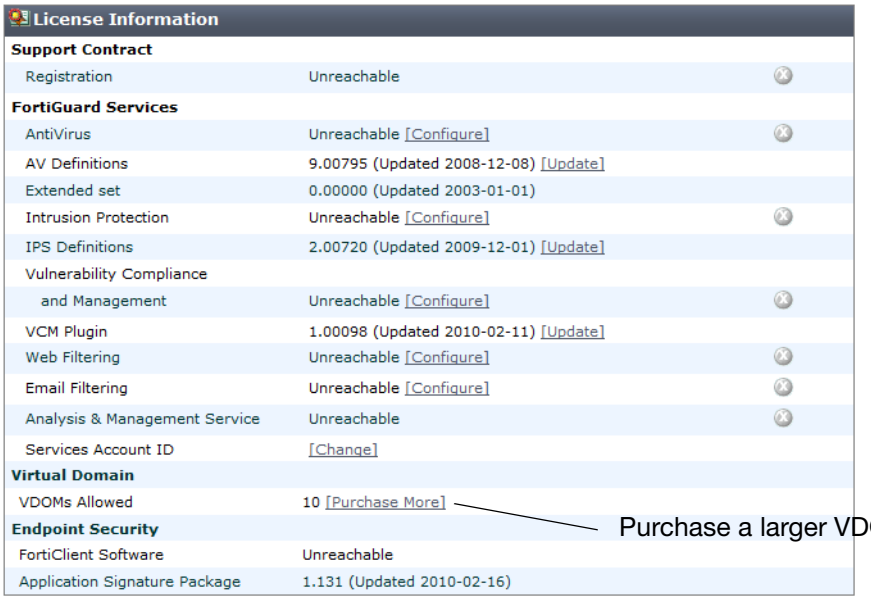
It is important to backup your configuration before upgrading the VDOM license on your FortiGate unit or units, especially with FortiGate units in HA mode.

To obtain a VDOM license key

1. Log in with a super_admin account.
2. Go to *System* > *Dashboard* > *Status*.
3. Record your FortiGate unit serial number as shown in "System Information" on page 2335.
4. Under *License Information* > *Virtual Domain*, select *Purchase More*.

If you do not see the *Purchase More* option on the System Dashboard, your FortiGate model does not support more than 10 VDOMs.

Figure 334:VDOM License Information



5. You will be taken to the Fortinet customer support web site where you can log in and purchase a license key for 25, 50, 100, 250, 500, or more VDOMs.
6. When you receive your license key, go to the Dashboard and select *Upload License* under *License Information*, *Virtual Domains*.
7. In the *Input License Key* field, enter the 32-character license key you received from Fortinet customer support.
8. Select *Apply*.

To verify the new VDOM license, in global configuration go to *System* > *Dashboard*. Under *License Information*, *Virtual Domains* the maximum number of VDOMs allowed is shown.

VDOMs created on a registered FortiGate unit are recognized as real devices by any connected FortiAnalyzer unit. The FortiAnalyzer unit includes VDOMs in its total number of registered devices. For example, if three FortiGate units are registered on the FortiAnalyzer unit and they contain a total of four VDOMs, the total number of registered FortiGate units on the FortiAnalyzer unit is seven. For more information, see the FortiAnalyzer Administration Guide.

Logging in to VDOMs

Only super_admin administrator accounts can access all global settings on the FortiGate unit and all of the VDOMs as well. Other administrator accounts can access and configure only their

single VDOM and they must connect to an interface that is part of that VDOM. For example, administratorB is the admin for vdomB. If he tries to log into vdomA, or an interface that is part of vdomA he will not be able to log on. For more information on administrators in VDOMs, see "Administrators in Virtual Domains" on page 2357.

Management services communicate using the management VDOM, which is the root VDOM by default. For more information, see "Changing the management virtual domain" on page 2361.

Management traffic requires an interface that has access to the Internet. If there is no interface assigned to the VDOM containing the management traffic, services including updates will not function. For more information, see "Changing the management virtual domain" on page 2361.

To access a VDOM with a super_admin account - web-based manager

1. Log in with a super_admin account.
2. In the *Virtual Domains* menu on the left-hand side, select the VDOM to configure.

   The menu will expand to show the various pages and settings for that VDOM.
3. When you have finished configuring the VDOM, you can
   - open the *Global* menu to return to global configuration
   - log out.

To access a VDOM with a super_admin account - CLI

With the super_admin, logging into the CLI involves also logging into the specific VDOM. If you need a reminder, use `edit ?` to see a list of existing VDOMs before you editing a VDOM.

If you misspell a VDOM you are trying to switch to, you will create a new VDOM by that name. Any changes you make will be part of the new VDOM, and not the intended VDOM. If you are having problems where your changes aren't visible, back up to the top level and use `edit ?` to see a list of VDOMs to ensure this has not happened. If it has happened, see "Deleting a VDOM" on page 2356.

```
config vdom
   edit ?
   edit <chosen_vdom>
      ..
      <enter vdom related commands>
      ..
   end
exit
```

To access a VDOM with a non super_admin account - web-based manager

1. Connect to the FortiGate unit using an interface that belongs to the VDOM to be configured.
2. Log in using an administrator account that has access to the VDOM.

   The main web-based manager page opens. The interface is largely the same as if the device has VDOMs disabled. From here you can access VDOM-specific settings.

To access a VDOM with a non-super_admin account - CLI

A non-super_admin account has access to only one VDOM and must log in through an interface that belongs to the same VDOM, but the process is the same as logging into a non-VDOM unit.

```
Login: regular_admin
Password: <password>
..
<enter vdom related commands>
..
exit
```

Configuring Virtual Domains

Only a super_admin administrator account such as the default “admin” account can create, disable, or delete VDOMs. That account can create additional administrators for each VDOM.

This section includes:

Creating a Virtual Domain

Once you have enabled Virtual Domains on your FortiGate unit, you can create additional Virtual Domains beyond the default root Virtual Domain.

By default new Virtual Domains are set to NAT/Route operation mode. If you want a Virtual Domain to be in Transparent operation mode, you must manually change it. See “Virtual Domains in Transparent mode” on page 2380.

You can name new Virtual Domains as you like with the following restrictions:

- only letters, numbers, “-”, and “_” are allowed
- no more than 11 characters are allowed
- no spaces are allowed
- VDOMs cannot have the same names as interfaces, zones, switch interfaces, or other VDOMs.

When creating large numbers of VDOMs you should not enable advanced features such as proxies, web filtering, and antivirus due to limited FortiGate unit resources. Also when creating large numbers of VDOMs, you may experience reduced performance for the same reason.

To create a VDOM - web-based manager

1. Log in with a super_admin account.
2. Go to *System* > *Dashboard* > *Status* and ensure that Virtual Domains are enabled. If not, see “Enabling and accessing Virtual Domains” on page 2334.
3. Select *System* > *VDOM* > *VDOM*.
4. Select *Create New*.
5. Enter a unique name for your new VDOM.

6. Enter a short and descriptive comment to identify this VDOM.
7. Select *OK*.

   Repeat Steps 4 through 7 to add additional VDOMs.

To create a VDOM - CLI

```
config vdom
  edit <new_vdom_name>
end
```

If you want to edit an existing Virtual Domain in the CLI, and mistype the name a new Virtual Domain will be created with this new misspelled name. If you notice expected configuration changes are not visible, this may be the reason. You should periodically check your VDOM list to ensure there are none of these misspelled VDOMs present.

Disabling a Virtual Domain

The status of a VDOM can be Enabled, or Disabled.

Active status VDOMs can be configured. Active is the default status when a VDOM is created. The management VDOM must be an Active VDOM. For more information on the management VDOM, see "Changing the management virtual domain" on page 2361.

Disabled status VDOMs are considered "offline". The configuration remains, but you cannot use the VDOM, and only the super_admin administrator can view it. You cannot delete a disabled VDOM without first enabling it, and removing references to it like usual—there is no *Delete* icon for disabled status VDOMs. You can assign interfaces to a disabled VDOM. See "Deleting a VDOM" on page 2356.

The following procedures show how to disable a VDOM called "test-vdom".

To disable a VDOM - web-based manager

1. Go to *Global* > *VDOM* > *VDOM*.
2. Open the VDOM for editing.
3. Ensure *Enable* is not selected and then select *OK*.

   The VDOM's Enable icon in the VDOM list is a grey X.

To disable a VDOM - CLI

```
config vdom
  edit test-vdom
    config system settings
      set status disable
    end
end
```

To enable a VDOM - web-based manager

1. Go to *Global* > *VDOM* > *VDOM*.
2. Open the VDOM for editing.
3. Ensure *Enable* is selected and then select *OK*.

   The VDOM's Enable icon in the VDOM list is a green checkmark.

To enable a VDOM - CLI

```
config vdom
  edit test-vdom
    config system settings
      set status enable
    end
end
```

Deleting a VDOM

Deleting a VDOM removes it from the FortiGate unit configuration.

Before you can delete a VDOM, all references to it must be removed. This includes any objects listed in "Per-VDOM settings - web-based manager" on page 2340. If there are any references to the VDOM remaining, you will see an error message and not be able to delete the VDOM.

The VDOM must also be enabled. A disabled VDOM cannot be deleted. You cannot delete the root VDOM or the management VDOM.

Before deleting a VDOM, a good practice is to reset any interface referencing that VDOM to its default configuration, with "root" selected as the Virtual Domain.

The following procedures show how to delete the `test-vdom` VDOM.

To delete a VDOM - web-based manager

1. Go to *Global* > *VDOM* > *VDOM*.
2. Select the check box for the VDOM and then select the *Delete* icon.

   If the *Delete* icon is not active, there are still references to the VDOM that must first be removed. The *Delete* icon is available when all the references to this VDOM are removed.
3. Confirm the deletion.

To delete a VDOM - CLI

```
config vdom
  delete test-vdom
end
```

Removing references to a VDOM

When you are doing to delete a VDOM, all references to that VDOM must first be removed. It can be difficult to find all the references to the VDOM. This section provides a list of common objects that must be removed before a VDOM can be deleted, and a CLI command to help list the dependencies.

Interfaces are an important part of VDOMs. If you can move all the interfaces out of a VDOM, generally you will be able to delete that VDOM.

Common objects that refer to VDOMs

When you are getting ready to delete a VDOM check for, and remove the following objects that refer to that VDOM or its components:

- Routing - both static and dynamic routes
- Firewall addresses, policies, groups, or other settings
- Security Features/Profiles
- VPN configuration
- Users or user groups
- Logging
- DHCP servers
- Network interfaces, zones, custom DNS servers
- VDOM Administrators

Administrators in Virtual Domains

When Virtual Domains are enabled, permissions change for administrators. Administrators are now divided into per-VDOM administrators, and `super_admin` administrators. Only `super_admin` administrator accounts can create other administrator accounts and assign them to a VDOM.

This section includes:

Administrator VDOM permissions

Different types of administrator accounts have different permissions within VDOMs. For example, if your are using a super_admin profile account, you can perform all tasks. However, if you are using a regular admin account, the tasks available to you depend on whether you have read only or read/write permissions. The following table shows what tasks can performed by which administrators.

Table 108: Administrator VDOM permissions

Tasks	Regular administrator account		Super_admin profile administrator account
	Read only permission	Read/write permission	
View global settings	yes	yes	yes
Configure global settings	no	no	yes
Create or delete VDOMs	no	no	yes
Configure multiple VDOMs	no	no	yes
Assign interfaces to a VDOM	no	no	yes
Revision Control Backup and Restore	no	no	yes

Table 108: Administrator VDOM permissions

Create VLANs	no	yes - for 1 VDOM	yes - for all VDOMs
Assign an administrator to a VDOM	no	no	yes
Create additional admin accounts	no	yes - for 1 VDOM	yes - for all VDOMs
Create and edit protection profiles	no	yes - for 1 VDOM	yes - for all VDOMs

The only difference in admin accounts when VDOMs are enabled is selecting which VDOM the admin account belongs to. Otherwise, by default the administration accounts are the same as when VDOMs are disabled and closely resemble the `super_admin` account in their privileges.

Creating administrators for Virtual Domains

Using the admin administrator account, you can create additional administrator accounts and assign them to VDOMs.

The newly-created administrator can access the FortiGate unit only through network interfaces that belong to their assigned VDOM or through the console interface. The network interface must be configured to allow management access, such as HTTPS and SSH. Without these in place, the new administrator will not be able to access the FortiGate unit and will have to contact the super_admin administrator for access.

The following procedure creates a new Local administrator account called `admin_sales` with a password of `fortinet` in the `sales` VDOM using the `admin_prof` default profile.

To create an administrator for a VDOM - web-based manager

1. Log in with a super_admin account.
2. Go to *System* > *Admin* > *Administrators*.
3. Select *Create New*.
4. Select *Regular* for Type, as you are creating a Local administrator account.
5. Enter the necessary information about the administrator: email, password, etc.
6. If this admin will be accessing the VDOM from a particular IP address or subnet, enable *Restrict this Admin Login from Trusted Hosts Only* and enter the IP in *Trusted Host #1*. See "Using trusted hosts" on page 2359.
7. Select `prof_admin` for the *Admin Profile*.
8. Select `sales` from the list of *Virtual Domains*.
9. Select *OK*.

To create administrators for VDOMs - CLI

```
config global
  config system admin
    edit <new_admin_name>
      set vdom <vdom_for_this_account>
      set password <pwd>
      set accprofile <an_admin_profile>
      ...
    end
```

Using trusted hosts

Setting trusted hosts for all of your administrators increases the security of your network by further restricting administrative access. In addition to knowing the password, an administrator must connect only through the subnet or subnets you specify. You can even restrict an administrator to a single IP address if you define only one trusted host IP address with a netmask of 255.255.255.255.

When you set trusted hosts for all administrators, the FortiGate unit does not respond to administrative access attempts from any other hosts. This provides the highest security. If you leave even one administrator unrestricted, the unit accepts administrative access attempts on any interface that has administrative access enabled, potentially exposing the unit to attempts to gain unauthorized access.

The trusted hosts you define apply both to the web-based manager and to the CLI when accessed through Telnet or SSH. CLI access through the console is not affected.

The trusted host addresses all default to 0.0.0.0/0.0.0.0 for IPv4, or ::/0 for IPv6. If you set one of the zero addresses to a non-zero address, the other zero addresses will be ignored. The only way to use a wildcard entry is to leave the trusted hosts at 0.0.0.0/0.0.0.0 or ::0. However, this configuration is less secure.

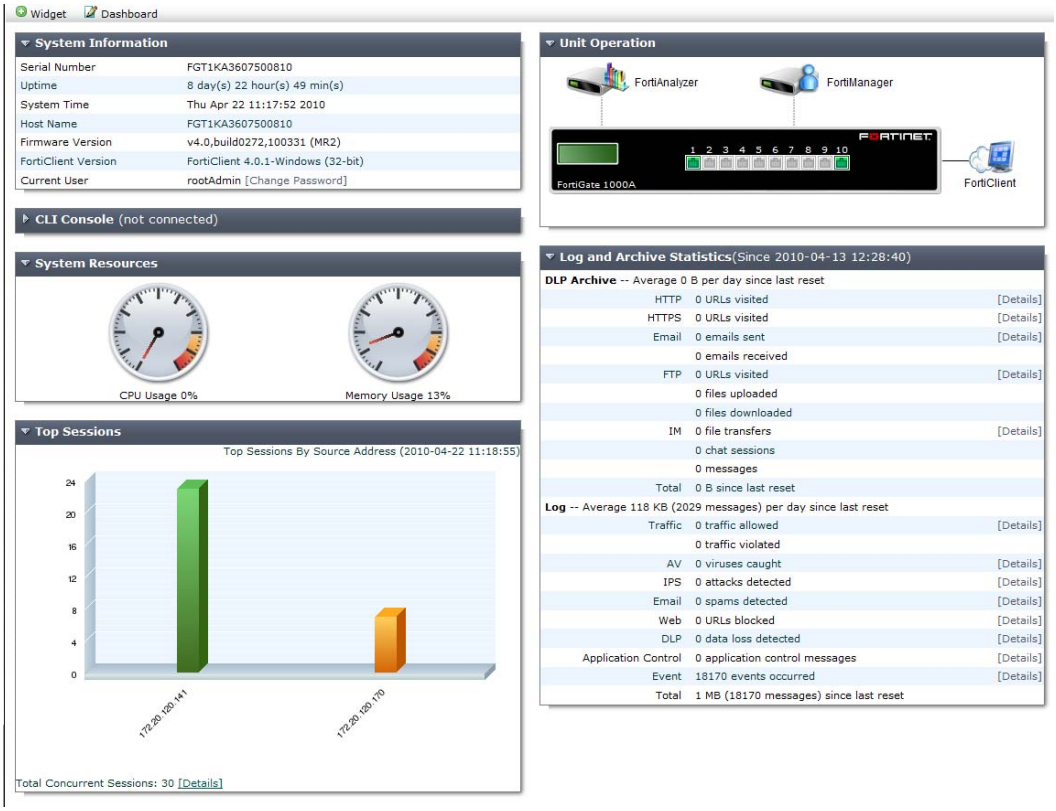
Virtual Domain administrator dashboard display

When administrators logs into their virtual domain, they see a different dashboard than the global administrator will see. The VDOM dashboard displays information only relevant to that VDOM — no global or other VDOM information is displayed.

Table 109:

Information	per-VDOM	Global
System Information	read-only	yes
License Information	no	yes
CLI console	yes	yes
Unit Operation	read-only	yes
Alert Message Console	no	yes
Top Sessions	limited to VDOM sessions	yes
Traffic	limited to VDOM interfaces	yes
Statistics	yes	yes

Figure 335:VDOM administrator dashboard



Virtual Domains in NAT/Route mode

Virtual domains (VDOMs) are a method of dividing a FortiGate unit into two or more virtual units that each function as independent units. Each virtual domain has separate routing and security policies. A single FortiGate unit with virtual domains is flexible enough to serve multiple departments of an organization, separate organizations, or be the basis for a service provider's managed security service.

The examples in this chapter are intended to be followed in order as procedures build on previous procedures. If you do not complete the previous procedures, the procedure you are working on may not work properly. If this happens, consult previous procedures or FortiGate documentation.

This chapter contains the following sections:

Virtual domains in NAT/Route mode

Once you have enabled virtual domains and created one or more VDOMs, you need to configure them. Configuring VDOMs on your FortiGate unit includes tasks such as the ones listed here; while you may not require all for your network topology, it is recommended that you perform them in the order given:

Changing the management virtual domain

The management virtual domain is the virtual domain where all the management traffic for the FortiGate unit originates. This management traffic needs access to remote servers, such as FortiGuard services and NTP, to perform its duties. It needs access to the Internet to send and receive this traffic.

Management traffic includes, but is not limited to:

- DNS lookups
- logging to FortiAnalyzer or syslog
- FortiGuard service
- sending alert emails
- Network time protocol traffic (NTP)
- Sending SNMP traps
- Quarantining suspicious files and email.

By default the management VDOM is the root domain. When other VDOMs are configured on your FortiGate unit, management traffic can be moved to one of these other VDOMs.

Reasons to move the management VDOM include selecting a non-root VDOM to be your administration VDOM, or the root VDOM not having an interface with a connection to the Internet.

You cannot change the management VDOM if any administrators are using RADIUS authentication.

The following procedure will change the management VDOM from the default `root` to a VDOM named `mgmt_vdom`. It is assumed that `mgmt_vdom` has already been created and has an interface that can access the Internet.

To change the management VDOM - web-based manager

1. Select *Global* > *VDOM* > *VDOM.*
2. Select the checkbox next to the required VDOM.
3. Select *Switch Management.*

   The current management VDOM is shown in square brackets, “[root]” for example.

To change the management VDOM - CLI

```
config global
  config system global
    set management-vdom mgmt_vdom
  end
```

Management traffic will now originate from `mgmt_vdom`..

Configuring interfaces in a NAT/Route VDOM

A VDOM must contain at least two interfaces to be useful. These can be physical interfaces or VLAN interfaces. By default, all physical interfaces are in the root VDOM. When you create a new VLAN, it is in the root VDOM by default.

When there are VDOMs on the FortiGate unit in both NAT and Transparent operation modes, some interface fields will be displayed as “-” on *System* > *Network* > *Interfaces*. Only someone with a super_admin account can view all the VDOMs.

When moving an interface to a different VDOM, firewall IP pools and virtual IPs for this interface are deleted. You should manually delete any routes that refer to this interface. Once the interface has been moved to the new VDOM, you can add these services to the interface again.

When configuring VDOMs on FortiGate units with accelerated interfaces you must assign both interfaces in the pair to the same VDOM for those interfaces to retain their acceleration. Otherwise they will become normal interfaces.

This section includes the following topics:

Adding a VLAN to a NAT/Route VDOM

The following example shows one way that multiple companies can maintain their security when they are using one FortiGate unit with VLANs that share interfaces on the unit.

This procedure will add a VLAN interface called `client1-v100` with a VLAN ID of 100 to an existing VDOM called `client1` using the physical interface called `port2`.

The physical interface does not need to belong to the VDOM that the VLAN belongs to.

To add a VLAN subinterface to a VDOM - web-based manager

1. Go to *Global* > *Network* > *Interfaces*.
2. Select *Create New*.
3. Enter the following information and select *OK*:

Name	client1-v100
Interface	port2
VLAN ID	100
Virtual Domain	Client1
Addressing mode	Manual
IP/Netmask	172.20.120.110/255.255.255.0
Administrative Access	HTTPS, SSH

You will see an expand arrow added to the port2 interface. When the arrow is expanded, the interface shows the `client1-v100` VLAN subinterface.

To add a VLAN subinterface to a VDOM - CLI

```
config global
  config system interface
    edit client1-v100
      set type vlan
      set vlanid 100
      set vdom Client1
      set interface port2
      set ip 172.20.120.110 255.255.255.0
      set allowaccess https ssh
    end
```

Moving an interface to a VDOM

Interfaces belong to the root VDOM by default. Moving an interface is the same procedure no matter if its moving from the root VDOM or a any other VDOM.

If you have an accelerated pair of physical interfaces both interfaces must be in the same VDOM or you will lose their acceleration.

The following procedure will move the port3 interface to the Client2 VDOM. This is a common action when configuring a VDOM. It is assumed that the Client2 VDOM has already been created. It is also assumed that your FortiGate unit has a port3 interface. If you are using a different model, your physical interfaces may not be named `port2`, `external` or `port3`.

To move an existing interface to a different VDOM - web-based manager

1. Go to *Global* > *Network* > *Interfaces*.
2. Select *Edit* for the port3 interface.
3. Select `Client2` as the new *Virtual Domain*.
4. Select *OK*.

To move an existing interface to a different VDOM - CLI

```
config global
  config system interface
    edit port3
      set vdom Client2
    end
```

Deleting an interface

Before you can delete a virtual interface, or move an interface from one VDOM to another, all references to that interface must be removed. For a list of objects that can refer to an interface see "Per-VDOM settings - web-based manager" on page 2340.

The easiest way to be sure an interface can be deleted is when the Delete icon is no longer greyed out. If it remains greyed out when an interface is selected, that interface still has objects referring to it, or it is a physical interface that cannot be deleted.

To delete a virtual interface - web-based manager

1. Ensure all objects referring to this interface have been removed.
2. Select *Global* > *Network* > *Interfaces*.
3. Select the interface to delete.
4. Select the delete icon.

Adding a zone to a VDOM

Grouping interfaces and VLAN subinterfaces into zones simplifies policy creation. You can configure policies for connections to and from a zone, but not between interfaces in a zone.

Zones are VDOM-specific. A zone cannot be moved to a different VDOM. Any interfaces in a zone cannot be used in another zone. To move a zone to a new VDOM requires deleting the current zone and re-creating a zone in the new VDOM.

The following procedure will create a zone called `accounting` in the `client2` VDOM. It will not allow intra-zone traffic, and both `port3` and `port2` interfaces belong to this zone. This is a method of grouping and isolating traffic over particular interfaces—it is useful for added security and control within a larger network.

To add a zone to a VDOM - web-based manager

1. In *Virtual Domains*, select the client2 VDOM.
2. Go to *System* > *Network* > *Interfaces*.
3. Select *Create New* > *Zone*.
4. Enter the following information and select *OK*:

Zone Name	accounting
Block intra-zone traffic	Select
Interface Members	port3, port2

To add a zone to a VDOM - CLI

```
config vdom
  edit client2
    config system zone
      edit accounting
        set interface port3 port2
        set intrazone deny
      end
  end
```

Configuring VDOM routing

Routing is VDOM-specific. Each VDOM should have a default static route configured as a minimum. Within a VDOM, routing is the same as routing on your FortiGate unit without VDOMs enabled.

When configuring dynamic routing on a VDOM, other VDOMs on the FortiGate unit can be neighbors. The following topics give a brief introduction to the routing protocols, and show specific examples of how to configure dynamic routing for VDOMs. Figures are included to show the FortiGate unit configuration after the successful completion of the routing example.

This section includes:

Default static route for a VDOM

The routing you define applies only to network traffic entering non-ssl interfaces belonging to this VDOM. Set the administrative distance high enough, typically 20, so that automatically configured routes will be preferred to the default.

In the following procedure, it is assumed that a VDOM called “Client2” exists. The procedure will create a default static route for this VDOM. The route has a destination IP of 0.0.0.0, on the port3 interface. It has a gateway of 10.10.10.1, and an administrative distance of 20.

The values used in this procedure are very standard, and this procedure should be part of configuring all VDOMs.

To add a default static route for a VDOM - web-based manager

1. In *Virtual Domains*, select the client2 VDOM.
2. Go to *Router* > *Static* > *Static Routes*.
3. Select *Create New*.

4. Enter the following information and select *OK*:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2
Gateway	10.10.10.1
Distance	20

To add a default static route for a VDOM - CLI

```
config vdom
  edit client2
    config router static
      edit 4
        set device port2
        set dst 0.0.0.0 0.0.0.0
        set gateway 10.10.10.1
        set distance 20
      end
  end
```

Dynamic Routing in VDOMs

Dynamic routing is VDOM-specific, like all other routing. Dynamic routing configuration is the same with VDOMs as with your FortiGate unit without VDOMs enabled, once you are at the routing menu. If you have multiple VDOMs configured, the dynamic routing configuration between them can become quite complex.

VDOMs provide some interesting changes to dynamic routing. Each VDOM can be a neighbor to the other VDOMs. This is useful in simulating a dynamic routing area or AS or network using only your FortiGate unit.

You can separate different types of routing to different VDOMs if required. This allows for easier troubleshooting. This is very useful if your FortiGate unit is on the border of a number of different routing domains.

For more information on dynamic routing in FortiOS, see “Dynamic Routing Overview” on page 304.

Inter-VDOM links must have IP addresses assigned to them if they are part of a dynamic routing configuration. Inter-VDOM links may or may not have IP addresses assigned to them. Without IP addresses, you need to be careful how you configure routing. While the default static route can be assigned an address of 0.0.0.0 and rely instead on the interface, dynamic routing almost always requires an IP address.

RIP

The RIP dynamic routing protocol uses hop count to determine the best route, with a hop count of 1 being directly attached to the interface and a hop count of 16 being unreachable. For example if two VDOMs on the same FortiGate unit are RIP neighbors, they have a hop count of 1.

OSPF

OSPF communicates the status of its network links to adjacent neighbor routers instead of the complete routing table. When compared to RIP, OSPF is more suitable for large networks, it is

not limited by hop count, and is more complex to configure. For smaller OSPF configurations its easiest to just use the backbone area, instead of multiple areas.

BGP

BGP is an Internet gateway protocol (IGP) used to connect autonomous systems (ASes) and is used by Internet service providers (ISPs). BGP stores the full path, or path vector, to a destination and its attributes which aid in proper routing.

Configuring security policies for NAT/Route VDOMs

Security policies are VDOM-specific. This means that all firewall settings for a VDOM, such as firewall addresses and security policies, are configured within the VDOM.

In VDOMs, all firewall related objects are configured per-VDOM including addresses, service groups, security profiles, schedules, traffic shaping, and so on. If you want firewall addresses, you will have to create them on each VDOM separately. If you have many addresses, and VDOMs this can be tedious and time consuming. Consider using a FortiManager unit to manage your VDOM configuration — it can get firewall objects from a configured VDOM or FortiGate unit, and push those objects to many other VDOMs or FortiGate units. See the FortiManager Administration Guide.

You can customize the *Policy* display by including some or all columns, and customize the column order onscreen. Due to this feature, security policy screenshots may not appear the same as on your screen.

Configuring a security policy for a VDOM

Your security policies can involve only the interfaces, zones, and firewall addresses that are part of the current VDOM, and they are only visible when you are viewing the current VDOM. The security policies of this VDOM filter the network traffic on the interfaces and VLAN subinterfaces in this VDOM.

A firewall service group can be configured to group multiple services into one service group. When a descriptive name is used, service groups make it easier for an administrator to quickly determine what services are allowed by a security policy.

In the following procedure, it is assumed that a VDOM called `Client2` exists. The procedure will configure an outgoing security policy. The security policy will allow all HTTPS and SSH traffic for the `SalesLocal` address group on VLAN_200 going to all addresses on port3. This traffic will be scanned and logged.

To configure a security policy for a VDOM - web-based manager

1. In *Virtual Domains*, select the client2 VDOM.
2. Go to *Policy* > *Policy*.
3. Select *Create New*.
4. Enter the following information and select *OK*:

Source Interface/Zone	VLAN_200
Source Address	SalesLocal
Destination Interface/Zone	port3

Destination Address	any
Schedule	always
Service	Multiple - HTTPS, SSH
Action	ACCEPT
Log Allowed Traffic	enable

To configure a security policy for a VDOM - CLI

```
config vdom
  edit Client2
    config firewall policy
      edit 12
        set srcintf VLAN_200
        set srcaddr SalesLocal
        set dstintf port3(dmz)
        set dstaddr any
        set schedule always
        set service HTTPS SSH
        set action accept
        set status enable
        set logtraffic enable
      end
  end
```

Configuring security profiles for NAT/Route VDOMs

In NAT/Route VDOMs, security profiles are exactly like regular FortiGate unit operation with one exception. In VDOMs, there are no default security profiles.

If you want security profiles in VDOMs, you must create them yourself. If you have many security profiles to create in each VDOM, you should consider using a FortiManager unit. It can get existing profiles from a VDOM or FortiGate unit, and push those profiles down to multiple other VDOMs or FortiGate units. See FortiManager Administration Guide.

When VDOMs are enabled, you only need one FortiGuard license for the physical unit, and download FortiGuard updates once for the physical unit. This can result in a large time and money savings over multiple physical units if you have many VDOMs.

Configuring VPNs for a VDOM

Virtual Private Networking (VPN) settings are VDOM-specific, and must be configured within each VDOM. Configurations for IPsec Tunnel, IPsec Interface, PPTP and SSL are VDOM-specific. However, certificates are shared by all VDOMs and are added and configured globally to the FortiGate unit.

Example NAT/Route VDOM configuration

Company A and Company B each have their own internal networks and their own ISPs. They share a FortiGate unit that is configured with two separate VDOMs, with each VDOM running in

NAT/Route mode enabling separate configuration of network protection profiles. Each ISP is connected to a different interface on the FortiGate unit.

This network example was chosen to illustrate one of the most typical VDOM configurations.

This example has the following sections:

Network topology and assumptions

Both companies have their own ISPs and their own internal interface, external interface, and VDOM on the FortiGate unit.

For easier configuration, the following IP addressing is used:

- all IP addresses on the FortiGate unit end in ".2" such as 10.11.101.2.
- all IP addresses for ISPs end in ".7", such as 172.20.201.7.
- all internal networks are 10.*.*.* networks, and sample internal addresses end in ".55".

The IP address matrix for this example is as follows.

Address	Company A	Company B
ISP	`172.20.201.7`	`192.168.201.7`
Internal network	`10.11.101.0`	`10.012.101.0`
FortiGate / VDOM	`172.20.201.2 (port1)` `10.11.101.2 (port4)`	`192.168.201.2 (port3)` `10.012.101.2 (port2)`

The Company A internal network is on the 10.11.101.0/255.255.255.0 subnet. The Company B internal network is on the 10.12.101.0/255.255.255.0 subnet.

There are no switches or routers required for this configuration.

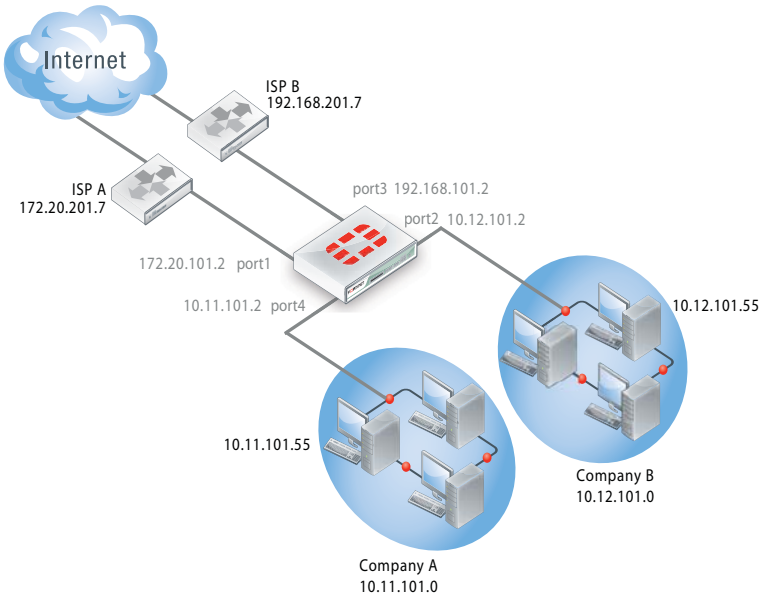
There are no VLANs in this network topology.

The interfaces used in this example are port1 through port4. Different FortiGate models may have different interface labels. port1 and port3 are used as external interfaces. port2 and port4 are internal interfaces.

The administrator is a super_admin account. If you are a using a non-super_admin account, refer to "Global and per-VDOM settings" on page 2338 to see which parts a non-super_admin account can also configure.

When configuring security policies in the CLI always choose a policy number that is higher than any existing policy numbers, select `services` before `profile-status`, and `profile-status` before `profile`. If these commands are not entered in that order, they may not be available to enter.

Figure 336: Example VDOM configuration



General configuration steps

For best results in this configuration, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Creating the VDOMs
2. Configuring the FortiGate interfaces
3. Configuring the vdomA VDOM, and Configuring the vdomB VDOM
4. Testing the configuration

Creating the VDOMs

In this example, two new VDOMs are created — vdomA for Company A and vdomB for Company B. These VDOMs will keep the traffic for these two companies separate while enabling each company to access its own ISP.

To create two VDOMs - web-based manager

1. Log in with a super_admin account.
2. Go to *Global* > *VDOM* > *VDOM*, and select *Create New*.
3. Enter `vdomA` and select *OK*.
4. Select *OK* again to return to the VDOM list.
5. Select *Create New*.
6. Enter `vdomB` and select *OK*.

To create two VDOMs - CLI

```
config vdom
  edit vdomA
  next
  edit vdomB
  end
```

Configuring the FortiGate interfaces

This section configures the interfaces that connect to the companies' internal networks, and to the companies' ISPs.

All interfaces on the FortiGate unit will be configured with an IP address ending in ".2" such as 10.11.101.2. This will simplify network administration both for the companies, and for the FortiGate unit global administrator. Also the internal addresses for each company differ in the second octet of their IP address - Company A is 10.11.*, and Company B is 10.12.*.

This section includes the following topics:

If you cannot change the VDOM of an network interface it is because something is referring to that interface that needs to be deleted. Once all the references are deleted the interface will be available to switch to a different VDOM. For example a common reference to the external interface is the default static route entry. See "Configuring interfaces in a NAT/Route VDOM" on page 2362.

Configuring the vdomA interfaces

The `vdomA` VDOM includes two FortiGate unit interfaces: port1 and external.

The port4 interface connects the Company A internal network to the FortiGate unit, and shares the internal network subnet of 10.11.101.0/255.255.255.0.

The external interface connects the FortiGate unit to ISP A and the Internet. It shares the ISP A subnet of 172.20.201.0/255.255.255.0.

To configure the vdomA interfaces - web-based manager

1. Go to *Global* > *Network* > *Interfaces*.
2. Select *Edit* on the port1 interface.
3. Enter the following information and select *OK*:

Virtual Domain	vdomA
Addressing mode	Manual
IP/Netmask	172.20.201.2/255.255.255.0

4. Select *Edit* on the port4 interface.
5. Enter the following information and select *OK*:

Virtual Domain	vdomA
Addressing mode	Manual
IP/Netmask	10.11.101.2/255.255.255.0

To configure the vdomA interfaces - CLI

```
config global
  config system interface
    edit port1
      set vdom vdomA
      set mode static
      set ip 172.20.201.2 255.255.255.0
    next
    edit port4
      set vdom ABCdomain
      set mode static
      set ip 10.11.101.2 255.255.255.0
    end
  end
```

Configuring the vdomB interfaces

The `vdomB` VDOM uses two FortiGate unit interfaces: port2 and port3.

The port2 interface connects the Company B internal network to the FortiGate unit, and shares the internal network subnet of 10.12.101.0/255.255.255.0.

The port3 interface connects the FortiGate unit to ISP B and the Internet. It shares the ISP B subnet of 192.168.201.0/255.255.255.0.

To configure the vdomB interfaces - web-based manager

1. Go to *Global* > *Network* > *Interfaces*.
2. Select *Edit* on the port3 interface.
3. Enter the following information and select *OK*:

Virtual domain	vdomB
Addressing mode	Manual
IP/Netmask	192.168.201.2/255.255.255.0

4. Select *Edit* on the port2 interface.
5. Enter the following information and select *OK*:

Virtual domain	vdomB
Addressing mode	Manual
IP/Netmask	10.12.101.2/255.255.255.0

To configure the vdomB interfaces - CLI

```
config global
  config system interface
    edit port3
      set vdom vdomB
      set mode static
      set ip 192.168.201.2 255.255.255.0
    next
    edit port2
      set vdom vdomB
      set mode static
      set ip 10.12.101.2 255.255.255.0
    end
```

Configuring the vdomA VDOM

With the VDOMs created and the ISPs connected, the next step is to configure the vdomA VDOM.

Configuring the vdomA includes the following:

- Adding vdomA firewall addresses
- Adding the vdomA security policy
- Adding the vdomA default route

Adding vdomA firewall addresses

You need to define the addresses used by Company A's internal network for use in security policies. This internal network is the 10.11.101.0/255.255.255.0 subnet.

The FortiGate unit provides one default address, "all", that you can use when a security policy applies to all addresses as the source or destination of a packet.

To add the vdomA firewall addresses - web-based manager

1. In *Virtual Domains*, select *vdomA*.
2. Go to *Firewall Objects* > *Address* > *Address*.
3. Select *Create New*.
4. Enter the following information and select *OK*:

Address Name	Ainternal
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0/255.255.255.0
Interface	port4

To add the ABCdomain VDOM firewall addresses - CLI

```
config vdom
  edit vdomA
    config firewall address
      edit Ainternal
        set type ipmask
        set subnet 10.11.101.0 255.255.255.0
      end
  end
```

Adding the vdomA security policy

You need to add the `vdomA` security policy to allow traffic from the internal network to reach the external network, and from the external network to internal as well. You need two policies for this domain.

To add the vdomA security policy - web-based manager

1. In *Virtual Domains*, select *vdomA*.
2. Go to *Policy* > *Policy*.
3. Select *Create New*.
4. Enter the following information and select *OK*:

Source Interface/Zone	port4
Source Address	Ainternal
Destination Interface/Zone	port1
Destination Address	all
Schedule	Always
Service	ANY
Action	ACCEPT

5. Select *Create New*.
6. Enter the following information and select *OK*:

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	port4
Destination Address	Ainternal
Schedule	Always
Service	ANY
Action	ACCEPT

To add the vdomA security policy - CLI

```
config vdom
  edit vdomA
    config firewall policy
      edit 1
        set srcintf port4
        set srcaddr Ainternal
        set dstintf port1
        set dstaddr all
        set schedule always
        set service ANY
        set action accept
        set status enable
      next
      edit 2
        set srcintf port1
        set srcaddr all
        set dstintf port4
        set dstaddr Ainternal
        set schedule always
        set service ANY
        set action accept
        set status enable
      end
```

Adding the vdomA default route

You also need to define a default route to direct packets from the Company A internal network to ISP A. Every VDOM needs a default static route, as a minimum, to handle traffic addressed to external networks such as the Internet.

The administrative distance should be set slightly higher than other routes. Lower admin distances will get checked first, and this default route will only be used as a last resort.

To add a default route to the vdomA - web-based manager

1. For *Virtual Domains*, select *vdomA*
2. Goo to *Router* > *Static* > *Static Routes*.
3. Select *Create New*.
4. Enter the following information and select *OK*:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port1
Gateway	172.20.201.7
Distance	20

To add a default route to the vdomA - CLI

```
config vdom
  edit vdomA
    config router static
      edit 1
        set device port1
        set gateway 172.20.201.7
      end
```

Configuring the vdomB VDOM

In this example, the vdomB VDOM is used for Company B. Firewall and routing settings are specific to a single VDOM.

vdomB includes the FortiGate port2 interface to connect to the Company B internal network, and the FortiGate port3 interface to connect to ISP B. Security policies are needed to allow traffic from port2 to external and from external to port2 interfaces.

This section includes the following topics:

Adding the vdomB firewall address

You need to define addresses for use in security policies. In this example, the vdomB VDOM needs an address for the port2 interface and the “all” address.

To add the vdomB firewall address - web-based manager

1. In *Virtual Domains*, select *vdomB*.
2. Go to *Firewall Objects* > *Address* > *Address*.
3. Select *Create New*.
4. Enter the following information and select *OK*:

Address Name	Binternal
Type	Subnet / IP Range
Subnet / IP Range	10.12.101.0/255.255.255.0
Interface	port2

To add the vdomB firewall address - CLI

```
config vdom
  edit vdomB
    config firewall address
      edit Binternal
        set type ipmask
        set subnet 10.12.101.0 255.255.255.0
      end
  end
```

Adding the vdomB security policy

You also need a security policy for the Company B domain. In this example, the security policy allows all traffic.

To add the vdomB security policy - web-based manager

1. Log in with a super_admin account.
2. In *Virtual Domains*, select vdomB.
3. Go to *Policy* > *Policy*.
4. Select *Create New*.
5. Enter the following information and select *OK*:

Source Interface/Zone	port2
Source Address	Binternal
Destination Interface/Zone	port3
Destination Address	all
Schedule	Always
Service	ANY
Action	ACCEPT

6. Select *Create New*.
7. Enter the following information and select *OK*:

Source Interface/Zone	port3
Source Address	all
Destination Interface/Zone	port2
Destination Address	Binternal
Schedule	Always
Service	ANY
Action	ACCEPT

To add the vdomB security policy - CLI

```
config vdom
  edit vdomB
    config firewall policy
      edit 1
        set srcintf port2
        set dstintf port3
        set srcaddr Binternal
        set dstaddr all
        set schedule always
        set service ANY
        set action accept
        set status enable
      edit 1
        set srcintf port3
        set dstintf port2
        set srcaddr all
        set dstaddr Binternal
        set schedule always
        set service ANY
        set action accept
        set status enable
      end
  end
```

Adding a default route to the vdomB VDOM

You need to define a default route to direct packets to ISP B.

To add a default route to the vdomB VDOM - web-based manager

1. Log in as the super_admin administrator.
2. In *Virtual Domains*, select vdomB.
3. Go to *Router* > *Static* > *Static Routes*.
4. Select *Create New*.
5. Enter the following information and select *OK*:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3
Gateway	192.168.201.7
Distance	20

To add a default route to the vdomB VDOM - CLI

```
config vdom
  edit vdomB
    config router static
      edit 1
        set dst 0.0.0.0/0
        set device external
        set gateway 192.168.201.7
      end
  end
```

Testing the configuration

Once you have completed configuration for both company VDOMs, you can use diagnostic commands, such as `tracert` in Windows, to test traffic routed through the FortiGate unit. Alternately, you can use the `traceroute` command on a Linux system with similar output.

Possible errors during the traceroute test are:

- "`***Request timed out`" - the trace was not able to make the next connection towards the destination fast enough
- "`Destination host unreachable`" - after a number of timed-out responses the trace will give up

Possible reasons for these errors are bad connections or configuration errors.

For additional troubleshooting, see "Troubleshooting Virtual Domains" on page 2440.

Testing traffic from the internal network to the ISP

In this example, a route is traced from the Company A internal network to ISP A. The test was run on a Windows PC with an IP address of 10.11.101.55.

The output here indicates three hops between the source and destination, the IP address of each hop, and that the trace was successful.

From the Company A internal network, access a command prompt and enter this command:

```
C:\>tracert 172.20.201.7
Tracing route to 172.20.201.7 over a maximum of 30 hops:
  1    <10 ms    <10 ms    <10 ms  10.11.101.2
  2    <10 ms    <10 ms    <10 ms  172.20.201.2
  3    <10 ms    <10 ms    <10 ms  172.20.201.7

Trace complete.
```

Virtual Domains in Transparent mode

In Transparent mode, the FortiGate unit behaves like a layer-2 bridge but can still provide services such as antivirus scanning, web filtering, spam filtering and intrusion protection to traffic. There are some limitations in Transparent mode in that you cannot use SSL VPN, PPTP/L2TP VPN, DHCP server, or easily perform NAT on traffic. The limits in Transparent mode apply to IEEE 802.1Q VLAN trunks passing through the unit.

VDOMs can each be configured to operate either in Transparent or NAT/Route operation mode, with each VDOM behaving like a separate FortiGate unit operating in the respective mode. VLANs configured on a VDOM in Transparent mode are the same as VLANs configured on the FortiGate unit when VDOMs are disabled.

This chapter includes the following sections:

Transparent operation mode

In transparent mode, the FortiGate unit becomes a layer-2 IP forwarding bridge. This means that Ethernet frames are forwarded based on destination MAC address, and no other routing is performed. All incoming traffic that is accepted by the firewall, is broadcast out on all interfaces.

In transparent mode the FortiGate unit is a forwarding bridge, not a switch. A switch can develop a port table and associated MAC addresses, so that it can bridge two ports to deliver the traffic instead of broadcasting to all ports. In transparent mode, the FortiGate unit does not following this switch behavior, but instead is the forwarding bridge that broadcasts all packets out over all interfaces, subject to security policies.

Features such as broadcast domains, forwarding domains, and STP apply to both FortiGate units and VDOMs in Transparent mode.

Broadcast domains

A broadcast domain is a network segment in which any network equipment can transmit data directly to another device without going through a routing device. All the devices share the same subnet. The subnets are separated by layer-3 devices, such as routers, that can forward traffic from one broadcast domain to the next.

Broadcast domains are important to transparent mode FortiGate units because the broadcast domain is the limit of where the FortiGate unit can forward packets when it is in transparent mode.

Forwarding domains

Address Resolution Protocol (ARP) packets are vital to communication on a network, and ARP support is enabled on FortiGate unit interfaces by default. Normally you want ARP packets to pass through the FortiGate unit. However, in Transparent mode ARP packets arriving on one interface are sent to all other interfaces including VLANs giving the appearance of duplicates of the same MAC address on different interfaces. Some layer-2 switches become unstable when

they detect these duplicate MAC addresses. Unstable switches may become unreliable or reset and cause network traffic to slow down considerably.

When you are using VLANs in Transparent mode, the solution to the duplicate MAC address issue is to use the `forward-domain` CLI command. This command tags VLAN traffic as belonging to a particular collision group, and only VLANs tagged as part of that collision group receive that traffic—it is like an additional set of VLANs. By default, all interfaces and VLANs are part of forward-domain collision group 0.

To assign VLAN 200 to collision group 2, VLAN 300 to collision group 3, and all other interfaces to stay in the default collision group 0 enter the following CLI commands:

```
config system interface
  edit vlan200
    set vlanid 200
    set forward_domain 2
  next
  edit vlan300
    set vlanid 300
    set forward_domain 3
  next
end
```

When using forwarding domains, you may experience connection issues with layer-2 traffic, such as ping, if your network configuration has

- packets going through the FortiGate unit in Transparent mode multiple times,
- more than one forwarding domain (such as incoming on one forwarding domain and outgoing on another)
- IPS and AV enabled.

Spanning Tree Protocol

VDOMs and FortiGate units do not participate in the Spanning Tree Protocol (STP). STP is an IEEE 802.1 protocol that ensures there are no layer-2 loops on the network. Loops are created when there is more than one route for traffic to take and that traffic is broadcast back to the original switch. This loop floods the network with traffic, quickly reducing available bandwidth to zero.

If you use your VDOM or FortiGate unit in a network topology that relies on STP for network loop protection, you need to make changes to your FortiGate configuration. Otherwise, STP recognizes your FortiGate unit as a blocked link and forwards the data to another path. By default, your FortiGate unit blocks STP as well as other non-IP protocol traffic. Using the CLI, you can enable forwarding of STP and other layer-2 protocols through the interface. In this example, layer-2 forwarding is enabled on the port2 interface:

```
config global
  config system interface
    edit port2
      set l2forward enable
      set stpforward enable
    next
  end
```

There are different CLI commands to allow other common layer-2 protocols such as IPX, PPTP or L2TP on the network. For more information, see the FortiOS CLI Reference.

Differences between NAT/Route and Transparent mode

The differences between NAT/Route mode and Transparent mode include:

Table 110: Differences between NAT/Route and Transparent modes

Features	NAT/Route mode	Transparent mode
Specific Management IP address required	No	Yes
Perform Network Address Translation (NAT)	Yes	Yes
Stateful packet inspection	Yes	Yes
Layer-2 forwarding	Yes	Yes
Layer-3 routing	Yes	No
Unicast Routing / Policy Based routing	Yes	No
DHCP server	Yes	No
IPsec VPN	Yes	Yes
PPTP/L2TP VPN	Yes	No
SSL VPN	Yes	No
Security features	Yes	Yes
VLAN support	Yes	Yes - limited to VLAN trunks.
Ping servers (dead gateway detection)	Yes	No

To provide administrative access to a FortiGate unit or VDOM in Transparent mode, you must define a management IP address and a gateway. This step is not required in NAT/Route mode where you can access the FortiGate unit through the assigned IP address of any interface where administrative access is permitted.

If you incorrectly set the Transparent mode management IP address for your FortiGate unit, you will be unable to access your unit through the web-based manager. In this situation, you will need to connect to the FortiGate unit using the console cable and change the settings so you can access the unit. Alternately, if your unit has an LCD panel, you can change the operation mode and interface information through the LCD panel.

Operation mode differences in VDOMs

A VDOM, such as root, can have a maximum of 255 interfaces in Network Address Translation (NAT) mode or Transparent mode. This includes VLANs, other virtual interfaces, and physical interfaces. To have more than a total of 255 interfaces configured, you need multiple VDOMs with multiple interfaces on each.

In Transparent mode without VDOMs enabled, all interfaces on the FortiGate unit act as a bridge — all traffic coming in on one interface is sent back out on all the other interfaces. This effectively turns the FortiGate unit into a two interface unit no matter how many physical interfaces it has. When VDOMs are enabled, this allows you to determine how many interfaces to assign to a VDOM running in Transparent mode. If there are reasons for assigning more than

two interfaces based on your network topology, you are able to. However, the benefit of VDOMs in this case is that you have the functionality of Transparent mode, but you can use interfaces for NAT/Route traffic as well.

You can add more VDOMs to separate groups of VLAN subinterfaces. When using a FortiGate unit to serve multiple organizations, this configuration simplifies administration because you see only the security policies and settings for the VDOM you are configuring. For information on adding and configuring virtual domains, see "Benefits of Virtual Domains" on page 2332.

One essential application of VDOMs is to prevent problems caused when a FortiGate unit is connected to a layer-2 switch that has a global MAC table. FortiGate units normally forward ARP requests to all interfaces, including VLAN subinterfaces. It is then possible for the switch to receive duplicate ARP packets on different VLANs. Some layer-2 switches reset when this happens. As ARP requests are only forwarded to interfaces in the same VDOM, you can solve this problem by creating a VDOM for each VLAN. For a configuration example, see "Example of VDOMs in Transparent mode" on page 2384.

Configuring VDOMs in Transparent mode

In Transparent mode, your FortiGate unit becomes a layer-2 bridge — any traffic coming in on one port is broadcast out on all the other ports. If your FortiGate unit has many interfaces, this is not the best use of those interfaces. VDOMs can limit Transparent mode to only a few interfaces while allowing the rest of the FortiGate unit to remain in NAT/Route mode.

The essential steps to configure your FortiGate unit to work with VLANs in Transparent mode are:

- Switching to Transparent mode
- Adding VLAN subinterfaces
- Creating security policies.

You can also configure the security profiles that manage antivirus scanning, web filtering and spam filtering.

In Transparent mode, you can access the FortiGate web-based manager by connecting to an interface configured for administrative access and using HTTPS to access the management IP address. On the FortiGateunit used for examples in this guide, administrative access is enabled by default on the internal interface and the default management IP address is `10.11.0.1`.

Switching to Transparent mode

A VDOM is in NAT/Route mode by default when it is created. You must switch it to Transparent mode, and add a management IP address so you can access the VDOM from your management computer.

Before applying the change to Transparent mode, ensure the VDOM has administrative access on the selected interface, and that the selected management IP address is reachable on your network.

To switch the `tpVDOM` VDOM to Transparent mode - web-based manager

1. Go to *Global* > *VDOM* > *VDOM*.
2. Edit the *tpVDOM*.
3. Select `Transparent` for *Operation mode*.

4. Enter the management IP/Netmask.

   The IP address must be accessible to the subnet where the management computer is located. For example 10.11.0.99/255.255.255.0 will be able to access the 10.11.0.0 subnet.

5. Select *Apply*.

When you select *Apply*, the FortiGate unit will log you out. When you log back in, the VDOM will be in Transparent mode.

To switch the `tpVDOM` VDOM to Transparent mode - CLI

```
config vdom
  edit tpVDOM
    config system settings
      set opmode transparent
      set mangeip 10.11.0.99 255.255.255.0
    end
  end
```

Adding VLAN subinterfaces

There are a few differences when adding VLANs in Transparent mode compared to NAT/Route mode.

In Transparent mode, VLAN traffic is trunked across the VDOM. That means VLAN traffic cannot be routed, changed, or inspected. For this reason when you assign a VLAN to a Transparent mode VDOM, you will see the *Addressing Mode* section of the interface configuration disappear in from the web-based manager. It is because with no routing, inspection, or any activities able to be performed on VLAN traffic the VDOM simply re-broadcasts the VLAN traffic. This requires no addressing.

Also any routing related features such as dynamic routing or Virtual Router Redundancy Protocol (VRRP) are not available in Transparent mode for any interfaces.

Creating security policies

Security policies permit communication between the FortiGate unit's network interfaces based on source and destination IP addresses. Typically you will also limit communication to desired times and services for additional security.

In Transparent mode, the FortiGate unit performs antivirus and antispam scanning on each packet as it passes through the unit. You need security policies to permit packets to pass from the VLAN interface where they enter the unit to the VLAN interface where they exit the unit. If there are no security policies configured, no packets will be allowed to pass from one interface to another. For more information, see the FortiGate Administration Guide, or FortiGate Fundamentals Guide.

Example of VDOMs in Transparent mode

In this example, the FortiGate unit provides network protection to two organizations — Company A and Company B. Each company has different policies for incoming and outgoing traffic, requiring three different security policies and protection profiles.

VDOMs are not required for this configuration, but by using VDOMs the profiles and policies can be more easily managed on a per-VDOM basis either by one central administrator or separate administrators for each company. Also future expansion is simply a matter of adding additional VDOMs, whilst not disrupt the existing VDOMs.

For this example, firewalls are only included to deal with web traffic. This is to provide an example without making configuration unnecessarily complicated.

This example includes the following sections:

- Network topology and assumptions
- General configuration steps
- Configuring common items
- Creating virtual domains
- Configuring the Company_A VDOM
- Configuring the Company_B VDOM
- Configuring the VLAN switch and router
- Testing the configuration

Network topology and assumptions

Each organization's internal network consists of a different range of IP addresses:

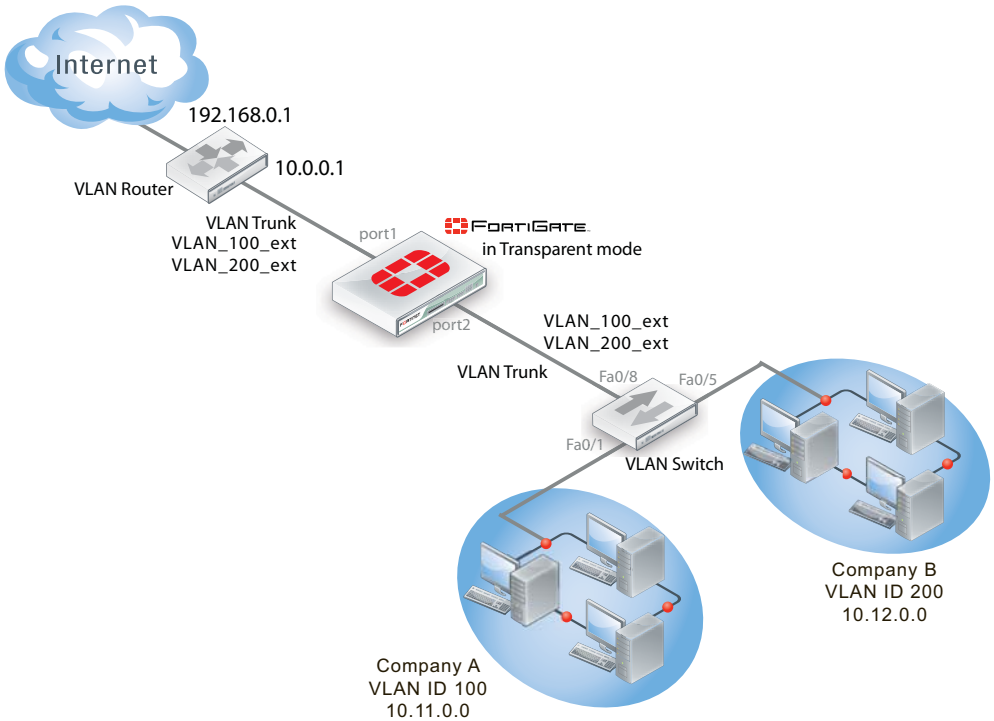
- 10.11.0.0/255.255.0.0 for Company A.
- 10.12.0.0/255.255.0.0 for Company B.

For the procedures in this section, it is assumed that you have enabled VDOM configuration on your FortiGate unit. For more information, see "Enabling and accessing Virtual Domains" on page 2334.

The VDOM names are similar to the company names for easy recognition. The root VDOM cannot be renamed and is not used in this example.

Interfaces used in this example are port1 and port2. Some FortiGate models may not have interfaces with these names. port1 is an external interface. port2 is an internal interface.

Figure 337:VLAN and VDOM Transparent example network topology



General configuration steps

The following steps summarize the configuration for this example. For best results, follow the procedures in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Configuring common items
2. Creating virtual domains
3. Configuring the Company_A VDOM
4. Configuring the Company_B VDOM
5. Configuring the VLAN switch and router
6. Testing the configuration

Configuring common items

Both VDOMs require you configure security profiles. These will be configured the same way, but need to be configured in both VDOMs.

The relaxed profile allows users to surf websites they are not allowed to visit during normal business hours. Also a quota is in place to restrict users to one hour of access to these websites to ensure employees do not take long and unproductive lunches.

To create a strict web filtering profile - web-based manager

1. Go to the proper VDOM, and select *Security Profiles* > *Web Filter* > *Profile*.
2. Select *Create New*.
3. Enter `strict` for the *Name*.
4. Expand FortiGuard Web Filtering, and select block for all Categories except Business Oriented, and Other.
5. Block all Classifications except Cached Content, and Image Search.
6. Ensure *FortiGuard Quota* for all Categories and Classifications is Disabled.
7. Select *OK*.

To create a strict web filtering profile - CLI

```
config vdom
  edit <vdom_name>
    config webfilter profile
      edit strict
        config ftgd-wf
          set allow g07 g08 g21 g22 c01 c03
          set deny g01 g02 g03 g04 g05 g06 c02 c04 c05 c06 c07
        end
        set web-ftgd-err-log enable
      end
```

To create a relaxed web filtering profile - web-based manager

1. Go to the proper VDOM, and select *Security Profiles* > *Web Filter* > *Profile*.
2. Select *Create New*.
3. Enter `relaxed` for the *Name*.
4. Expand FortiGuard Web Filtering, and select block for Potentially Security Violating Category, and Spam URL Classification.

5. Enable FortiGuard Quotas to allow 1 hour for all allowed Categories and Classifications.

Creating virtual domains

The FortiGate unit supports 10 virtual domains. Root is the default VDOM. It cannot be deleted or renamed. The root VDOM is not used in this example. New VDOMs are created for Company A and Company B

To create the virtual domains - web-based manager

1. With VDOMs enabled, select *System* > *VDOM* > *VDOM*.
2. Select *Create New*.
3. Enter `Company_A` for Name, and select *OK*.
4. Select *Create New*.
5. Enter `Company_B` for Name, and select *OK*.

To create the virtual domains - CLI

```
config system vdom
  edit Company_A
  next
  edit Company_B
  end
```

Configuring the Company_A VDOM

This section describes how to add VLAN subinterfaces and configure security policies for the Company_A VDOM.

This section includes the following topics:

Adding VLAN subinterfaces

You need to create a VLAN subinterface on the port2 interface and another one on the port1 interface, both with the same VLAN ID.

To add VLAN subinterfaces - web-based manager

1. Go to *System* > *Network* > *Interfaces*.
2. Select *Create New*.
3. Enter the following information and select *OK*:

Name	VLAN_100_int
Interface	port2
VLAN ID	100
Virtual Domain	Company_A

4. Select *Create New*.

5. Enter the following information and select *OK*:

Name	VLAN_100_ext
Interface	port1
VLAN ID	100
Virtual Domain	Company_A

To add the VLAN subinterfaces - CLI

```
config system interface
  edit VLAN_100_int
    set interface port2
    set vlanid 100
    set vdom Company_A
  next
  edit VLAN_100_ext
    set interface port1
    set vlanid 100
    set vdom Company_A
  end
```

Creating the Lunch schedule

Both organizations have the same lunch schedule, but only Company A has relaxed its security policy to allow employees more freedom in accessing the Internet during lunch. Lunch schedule will be Monday to Friday from 11:45am to 2:00pm (14:00).

To create a recurring schedule for lunchtime - web-based manager

1. In Company_A VDOM, go to *Firewall Objects* > *Schedule* > *Recurring*.
2. Select *Create New*.
3. Enter `Lunch` as the name for the schedule.
4. Select *Mon*, *Tues*, *Wed*, *Thu*, and *Fri*.
5. Set the *Start* time as `11:45` and set the *Stop* time as `14:00`.
6. Select *OK*.

To create a recurring schedule for lunchtime - CLI

```
config vdom
  edit Company_A
    config firewall schedule recurring
      edit Lunch
        set day monday tuesday wednesday thursday friday
        set start 11:45
        set end 14:00
      end
```

Configuring Company_A firewall addresses

For Company A, its networks are all on the 10.11.0.0 network, so restricting addresses to that domain provides added security.

To configure Company_A firewall addresses - web-based manager

1. In the Company_A VDOM, go to *Firewall Objects* > *Address* > *Address*.
2. Select *Create New*.
3. Enter `CompanyA` in the *Address Name* field.
4. Type 10.11.0.0/255.255.0.0 in the *Subnet* / *IP Range* field.
5. Select *OK*.

To configure vdomA firewall addresses - CLI

```
config firewall address
  edit CompanyA
    set type ipmask
    set subnet 10.11.0.0 255.255.0.0
  end
```

Creating Company_A security policies

A security policy can include varying levels of security feature protection. This example only deals with web filtering. The following security policies use the custom security `strict` and `relaxed` profiles configured earlier. See "Configuring common items" on page 2386.

For these security policies, we assume that all protocols will be on their standard ports, such as port 80 for http traffic. If the ports are changed, such as using port 8080 for http traffic, you will have to create custom services for protocols with non-standard ports, and assign them different names.

The firewalls configured in this section are:

- internal to external — always deny all
- external to internal — always deny all
- internal to external — always allow all, security features - web filtering: strict
- internal to external — Lunch allow all, security features - web filtering:relaxed

Security policies allow packets to travel between the internal VLAN_100 interface to the external interface subject to the restrictions of the protection profile. Entering the policies in this order means the last one configured is at the top of the policy list, and will be checked first. This is important because the policies are arranged so if one does not apply the next is checked until the end of the list.

To configure Company_A security policies - web-based manager

1. Go to *Policy* > *Policy*.
2. Select *Create New*.

3. Enter the following information and select *OK*:

Source Interface/Zone	VLAN_100_int
Source Address	CompanyA
Destination Interface/Zone	VLAN_100_ext
Destination Address	all
Schedule	always
Service	all
Action	DENY

This policy is a catch all for outgoing traffic to ensure that if it doesn't match any of the other policies, it will not be allowed. This is standard procedure.

4. Select *Create New*.
5. Enter the following information and select *OK*:

Source Interface/Zone	VLAN_100_ext
Source Address	all
Destination Interface/Zone	VLAN_100_int
Destination Address	CompanyA
Schedule	always
Service	all
Action	DENY

This policy is a catch all for incoming traffic to ensure that if it doesn't match any of the other policies, it will not be allowed. This is standard procedure.

6. Select *Create New*.

7. Enter the following information and select *OK*:

Source Interface/Zone	VLAN_100_int
Source Address	CompanyA
Destination Interface/Zone	VLAN_100_ext
Destination Address	all
Schedule	always
Service	all
Action	ACCEPT
Security Features	Enable
Web Filtering	strict

   This policy enforces strict scanning at all times, while allowing all traffic. It ensures company policies are met for network security.

8. Select *Create New*.
9. Enter the following information and select *OK*:

Source Interface/Zone	VLAN_100_int
Source Address	CompanyA
Destination Interface/Zone	VLAN_100_ext
Destination Address	all
Schedule	Lunch
Service	all
Action	ACCEPT
Security Features	enable
Web Filtering	relaxed

   This policy provides relaxed protection during lunch hours — going from strict down to scan for protocol options and web filtering. AntiVirus and Email Filtering remain at strict for security — relaxing them would not provide employees additional access to the Internet and it would make the company vulnerable.

10. Verify that the policies entered appear in the list with the last policy (lunch) at the top, and the first policy (deny all) at the bottom. Otherwise traffic will not flow as expected.

To configure Company_A security policies - CLI

```
config vdom
  edit Company_A
    config firewall policy
      edit 1
        set srcintf VLAN_100_int
        set dstintf VLAN_100_ext
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule Lunch
        set webfiltering relaxed
      next
      edit 3
        set srcintf VLAN_100_int
        set dstintf VLAN_100_ext
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule BusinessDay
        set service HTTP
        set profile_status enable
        set profile BusinessOnly
      end
```

Configuring the Company_B VDOM

This section describes how to add VLAN subinterfaces and configure security policies for the Company B VDOM.

This section includes the following topics:

Adding VLAN subinterfaces

You need to create a VLAN subinterface on the internal interface and another one on the external interface, both with the same VLAN ID.

To add VLAN subinterfaces - web-based manager

1. Go to *System* > *Network* > *Interfaces*.
2. Select *Create New*.
3. Enter the following information and select *OK*:

Name	VLAN_200_int
Interface	port2

VLAN ID	200
Virtual Domain	Company_B

4. Select *Create New*.
5. Enter the following information and select *OK*:

Name	VLAN_200_ext
Interface	port1
VLAN ID	200
Virtual Domain	Company_B

To add the VLAN subinterfaces - CLI

```
config system interface
  edit VLAN_200_int
    set interface internal
    set vlanid 200
    set vdom Company_B
  next
  edit VLAN_200_ext
    set interface external
    set vlanid 200
    set vdom Company_B
  end
```

Creating Company_B service groups

Company_B does not want its employees to use any online chat software except NetMeeting, which the company uses for net conferencing. To simplify the creation of a security policy for this purpose, you create a service group that contains all of the services you want to restrict. A security policy can manage only one service or one group.

To create a chat service group - web-based manager

1. Go to *Firewall Objects* > *Service* > *Groups*.
2. Select *Create New*.
3. Enter `Chat` in the *Group Name* field.
4. For each of IRC, AOL, SIP-MSNmessenger and TALK, select the service in the *Available Services* list and select the right arrow to add it to the *Members* list.

If a particular service does not appear in the *Available Services* list, see the list in *Firewall Objects* > *Service* > *Services*. Some services do not appear by default unless edited.

5. Select *OK*.

To create a games and chat service group - CLI

```
config firewall service group
  edit Chat
    set member IRC SIP-MSNmessenger AOL TALK
  end
```

Configuring Company_B firewall addresses

Company B's network is all in the 10.12.0.0 network. Security can be improved by only allowing traffic from IP addresses on that network.

To configure Company_B firewall address - web-based manager

1. In the Company_B VDOM, go to *Firewall Objects* > *Address* > *Address.*
2. Select *Create New*.
3. Enter `new` in the *Address Name* field.
4. Type 10.12.0.0/255.255.0.0 in the *Subnet / IP Range* field.
5. Select *OK*.

To configure Company_B firewall addresses - CLI

```
config vdom
  edit Company_B
    config firewall address
      edit all
        set type ipmask
        set subnet 10.12.0.0 255.255.0.0
      end
```

Configuring Company_B security policies

Security policies allow packets to travel between the internal and external VLAN_200 interfaces subject to the restrictions of the protection profile.

To configure Company_B security policies - web-based manager

1. Go to *Policy* > *Policy*.
2. Select *Create New*.
3. Enter the following information and select *OK*:

Source Interface/Zone	VLAN_200_int
Source Address	all
Destination Interface/Zone	VLAN_200_ext
Destination Address	all
Schedule	BusinessDay
Service	games-chat
Action	DENY

This policy prevents the use of network games or chat programs (except NetMeeting) during business hours.

4. Enter the following information and select *OK*:

Source Interface/Zone	VLAN_200_int
Source Address	all
Destination Interface/Zone	VLAN_200_ext
Destination Address	all
Schedule	Lunch
Service	HTTP
Action	ACCEPT
Protection Profile	Relaxed

   This policy relaxes the web category filtering during lunch hour.

5. Select *Create New*.
6. Enter the following information and select *OK*:

Source Interface/Zone	VLAN_200_int
Source Address	all
Destination Interface/Zone	VLAN_200_ext
Destination Address	all
Schedule	BusinessDay
Service	HTTP
Action	ACCEPT
Protection Profile	BusinessOnly

   This policy provides rather strict web category filtering during business hours.

7. Select *Create New*.

8. Enter the following information and select *OK*:

Source Interface/Zone	VLAN_200_int
Source Address	all
Destination Interface/Zone	VLAN_200_ext
Destination Address	all
Schedule	always
Service	ANY
Action	ACCEPT
Protection Profile	Relaxed

Because it is last in the list, this policy applies to the times and services not covered in preceding policies. This means that outside of regular business hours, the Relaxed protection profile applies to email and web browsing, and online chat and games are permitted. Company B needs this policy because its employees sometimes work overtime. The other companies in this example maintain fixed hours and do not want any after-hours Internet access.

To configure Company_B security policies - CLI

```
config firewall policy
  edit 1
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set schedule BusinessDay
    set service Games
    set action deny
  next
  edit 2
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set action accept
    set schedule Lunch
    set service HTTP
    set profile_status enable
    set profile Relaxed
  next
  edit 3
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set action accept
    set schedule BusinessDay
    set service HTTP
    set profile_status enable
    set profile BusinessOnly
  next
  edit 4
    set srcintf VLAN_200_int
    set srcaddr all
    set dstintf VLAN_200_ext
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set profile_status enable
    set profile Relaxed
  end
```

Configuring the VLAN switch and router

The Cisco switch is the first VLAN device internal passes through, and the Cisco router is the last device before the Internet or ISP.

This section includes the following topics:

Configuring the Cisco switch

On the Cisco Catalyst 2900 ethernet switch, you need to define the VLANs 100, 200 and 300 in the VLAN database, and then add configuration files to define the VLAN subinterfaces and the 802.1Q trunk interface.

Add this file to Cisco VLAN switch:

```
!
interface FastEthernet0/1
 switchport access vlan 100
!
interface FastEthernet0/5
 switchport access vlan 300
!
interface FastEthernet0/6
 switchport trunk encapsulation dot1q
 switchport mode trunk
!
```

Switch 1 has the following configuration:

Port 0/1	VLAN ID 100
Port 0/3	VLAN ID 200
Port 0/6	802.1Q trunk

Configuring the Cisco router

The configuration for the Cisco router in this example is the same as in the basic example, except we add VLAN_300. Each of the three companies has its own subnet assigned to it.

The IP addressees assigned to each VLAN on the router are the gateway addresses for the VLANs. For example, devices on VLAN_100 would have their gateway set to 10.11.0.1/255.255.0.0.

```
!
interface FastEthernet0/0
switchport trunk encapsulation dot1q
 switchport mode trunk
!
interface FastEthernet0/0.1
 encapsulation dot1Q 100
 ip address 10.11.0.1 255.255.0.0
!
interface FastEthernet0/0.3
 encapsulation dot1Q 200
 ip address 10.12.0.1 255.255.0.0
!
```

The router has the following configuration:

Port 0/0.1	VLAN ID 100
Port 0/0.3	VLAN ID 200
Port 0/0	802.1Q trunk

Testing the configuration

Use diagnostic commands, such as tracert, to test traffic routed through the network.

You should test traffic between the internal VLANs as well as from the internal VLANs to the Internet to ensure connectivity.

For additional troubleshooting, see "Troubleshooting Virtual Domains" on page 2440.

This section includes the following topics:

Testing traffic from VLAN_100 to the Internet

In this example, a route is traced from VLANs to a host on the Internet. The route target is www.example.com.

From a host on VLAN_100, access a command prompt and enter this command:

```
C:\>tracert www.example.com
Tracing route to www.example.com [208.77.188.166]
over a maximum of 30 hops:
 1    <10 ms    <10 ms    <10 ms   10.100.0.1
...
14    172 ms    141 ms    140 ms   208.77.188.166
Trace complete.
```

The number of steps between the first and the last hop, as well as their IP addresses, will vary depending on your location and ISP. However, all successful tracerts to www.example.com will start and end with these lines.

Repeat the tracert for VLAN_200.

The tracert for each VLAN will include the gateway for that VLAN as the first step. Otherwise, the tracert should be the same for each VLAN.

Testing traffic from VLAN_100 to VLAN_200

In this example, a route is traced between two internal networks. The route target is a host on VLAN_200. The Windows traceroute command `tracert` is used.

From VLAN_100, access a Windows command prompt and enter this command:

```
C:\>tracert 10.12.0.2
Tracing route to 10.12.0.2 over a maximum of 30 hops:
  1    <10 ms    <10 ms    <10 ms   10.100.0.1
  2    <10 ms    <10 ms    <10 ms 10.12.0.2
Trace complete.
```

You can repeat this for different routes in the topology. In each case the IP addresses will be the gateway for the starting VLAN, and the end point at the ending VLAN.

Inter-VDOM routing

Inter-VDOM routing and Inter-VDOM links allow communication between VDOMs. VDOM links are virtual interfaces that connect VDOMs. A VDOM link contains a pair of interfaces with each one connected to a VDOM, and forming either end of the inter-VDOM connection.

This chapter contains the following sections:

Benefits of inter-VDOM routing

Inter-VDOM routing has a number of advantages over independent VDOM routing. These benefits include:

Continued support for secure firewall policies

VDOMs help to separate traffic based on your needs. This is an important step in satisfying regulations that require proof of secure data handling. This is especially important to health, law, accounting, and other businesses that handle sensitive data every day.

By keeping things separate, traffic has to leave the FortiGate unit and re-enter to change VDOMs. This forces traffic to go through the firewall when leaving and enter through another firewall, keeping traffic secure.

With inter-VDOM routing, the need for the physical interfaces is greatly reduced. However, firewall policies still need to be in place for traffic to pass through any interface, physical or virtual, and thus provide the same level of security both internally and externally. Configuration of firewall policies is the same for inter-VDOM links as for any other interface, and your data will continue to have the high level of security.

Configuration flexibility

A typical VDOM uses at least two interfaces, typically physical interfaces, one for internal and one for external traffic. Depending on the configuration, more interfaces may be required. This means that the maximum number of VDOMs configurable on a FortiGate unit using physical interfaces is the number of interfaces available divided by two. VLANs can increase the number by providing multiple virtual interfaces over a single physical interface, but VLANs have some limitations. Using physical interfaces for inter-VDOM communication therefore limits the number of possible configurations on your FortiGate unit.

To overcome this limitation, inter-VDOM links can be created within the FortiGate unit. Using virtual interfaces, inter-VDOM links free up the physical interfaces for external traffic. Using VDOM links on a FortiGate unit with 8 physical interfaces, you can have 4 VDOMs communicating with each other (meshed configuration) and continue to have 2 physical interfaces each for internal and external connections. This configuration would have required 20 physical interfaces without inter-VDOM routing. With inter-VDOM routing it only requires 8 physical interfaces, with the other 12 interfaces being internal VDOM links.

Inter-VDOM routing allows you to make use of Standalone VDOM configuration, Management VDOM configuration and Meshed VDOM configuration without being limited by the number of physical interfaces on your FortiGate unit.

Getting started with VDOM links

Once VDOMs are configured on your FortiGate unit, configuring inter-VDOM routing and VDOM-links is very much like creating a VLAN interface. VDOM-links are managed through the web-based manager or CLI. In the web-based manager, VDOM link interfaces are managed in the network interface list.

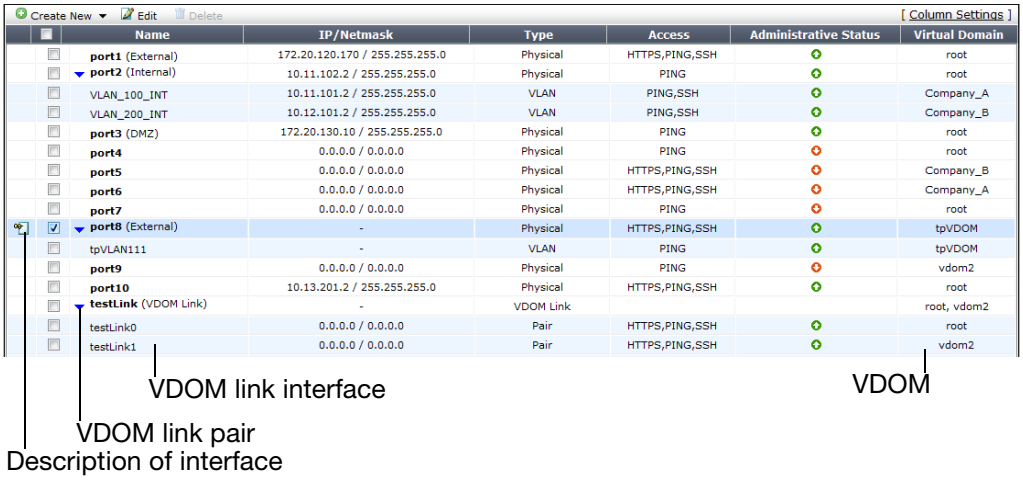
This section includes the following topics:

Viewing VDOM links

VDOM links are displayed on the network interface list in the web-based manager. You can view VDOM links only if you are using a super_admin account and in global configuration.

To view the network interface list, in the Global menu go to *System* > *Network* > *Interfaces.*

Figure 338: Interface list displaying interface names and information



Create New	Select the arrow to create a new interface or VDOM link. Interface options include VLAN, Aggregate, Redundant, or loopback interfaces. For more information, see “Creating VDOM links” on page 2403.
Edit	Select to change interface configuration for the selected interface. This option not available if no interfaces or multiple interfaces are selected.
Delete	Select to remove an interface from the list. One or more interfaces must be selected for this option to be available. You cannot delete permanent physical interfaces, or any interfaces that have configuration referring to them. See “Deleting VDOM links” on page 2405 or “Deleting an interface” on page 2364.
Column Settings	Select to change which information is displayed about the interfaces, and in which order the columns appear. Use to display VDOM, VLAN, and other information.
Checkbox	Select the checkbox for an interface to edit or delete that interface. Select multiple interfaces to delete those interfaces. Optionally select the check box at the top of the column to select or unselect all checkboxes.
Name	The name of the interface. The name of the VDOM link (`vlink1`) has an expand arrow to display or hide the pair of VDOM link interfaces. For more information, see “Viewing VDOM links” on page 2401.
IP/Netmask	The IP address and netmask assigned to this interface.
Type	The type of interface such as physical, VLAN, or VDOM link pair.
Access	The protocols allowed for administrators to connect to the FortiGate unit.

Administrative Status	The status of this interface, either set to up (active) or down (disabled).
Virtual Domain	The virtual domain this interface belongs to. For more information on VDOMs, see “Virtual Domains in NAT/Route mode” on page 2361.

Creating VDOM links

VDOM links connect VDOMs together to allow traffic to pass between VDOMs as per firewall policies. Inter-VDOM links are virtual interfaces that are very similar to VPN tunnel interfaces except inter-VDOM links do not require IP addresses. See “IP addresses and inter-VDOM links” on page 2404.

To create a VDOM link, you first create the point-to-point interface, and then bind the two interface objects associated with it to the virtual domains.

In creating the point-to-point interface, you also create two additional interface objects by default. They are called `vlink10` and `vlink11` - the interface name you chose with a 1 or a 0 to designate the two ends of the link.

Once the interface objects are bound, they are treated like normal FortiGate interfaces and need to be configured just like regular interfaces.

The assumptions for this example are as follows:

- Your FortiGate unit has VDOMs enabled and you have 2 VDOMs called `customer1` and `customer2` already configured. For more information on configuring VDOMs see “Only a super_admin administrator account such as the default “admin” account can create, disable, or delete VDOMs. That account can create additional administrators for each VDOM.” on page 2354.
- You are using a super_admin account

To configure an inter-VDOM link - web-based manager

1. Go to *Global* > *Network* > *Interfaces*.
2. Select *Create New* > *VDOM link*, enter the following information, and select *OK*.

Name		vlink1 (The name can be up to 11 characters long. Valid characters are letters, numbers, “-”, and “_”. No spaces are allowed.)
Interface #0		
	Virtual Domain	customer1
	IP/Netmask	10.11.12.13/255.255.255.0
	Administrative Access	HTTPS, SSL

Interface #1		
	Virtual Domain	customer2
	IP/Netmask	172.120.100.13/255.255.255.0
	Administrative Access	HTTPS, SSL

To configure an inter-VDOM link - CLI

```
config global
  config system vdom-link
    edit vlink1
    end
  config system interface
    edit vlink10
      set vdom customer1
    next
    edit vlink11
      set vdom customer2
    end
```

Once you have created and bound the interface ends to VDOMs, configure the appropriate firewall policies and other settings that you require. To confirm the inter-VDOM link was created, find the VDOM link pair and use the expand arrow to view the two VDOM link interfaces. You can select edit to change any information.

IP addresses and inter-VDOM links

Besides being virtual interfaces, here is one main difference between inter-VDOM links and regular interfaces— default inter-VDOM links do not require IP addresses. IP addresses are not required by default because an inter-VDOM link is an internal connection that can be referred to by the interface name in firewall policies, and other system references. This introduces three possible situations with inter-VDOM links that are:

- **unnumbered** - an inter-VDOM link with no IP addresses for either end of the tunnel
- **half numbered** - an inter-VDOM link with one IP address for one end and none for the other end
- **full numbered** - an inter-VDOM link with two IP addresses, one for each end.

Not using an IP address in the configuration can speed up and simplify configuration for you Also you will not use up all the IP addresses in your subnets if you have many inter-VDOM links.

Half or full numbered interfaces are required if you are doing NAT, either SNAT or DNAT as you need an IP number on both ends to translate between.

You can use unnumbered interfaces in static routing, by naming the interface and using `0.0.0.0` for the gateway. Running traceroute will not show the interface in the list of hops. However you can see the interface when you are sniffing packets, which is useful for troubleshooting.

Deleting VDOM links

When you delete the VDOM link, the two link objects associated with it will also be deleted. You cannot delete the objects by themselves. The example uses a VDOM routing connection called “vlink1”. Removing vlink1 will also remove its two link objects vlink10 and vlink11.

Before deleting the VDOM link, ensure all policies, firewalls, and other configurations that include the VDOM link are deleted, removed, or changed to no longer include the VDOM link.

To remove a VDOM link - web-based manager

1. Go to *Global* > *Network* > *Interfaces*.
2. Select *Delete* for the VDOM link *vlink1*.

To remove a VDOM link - CLI

```
config global
  config system vdom-link
    delete vlink1
  end
```

For more information, see the FortiGate CLI Reference.

NAT to Transparent VDOM links

Inter-VDOM links can be created between VDOMs in NAT mode and VDOMs in Transparent mode, but it must be done through the CLI, as the VDOM link type must be changed from the default PPP to Ethernet for the two VDOMs to communicate. The below example assumes one vdom is in NAT mode and one is Transparent.

An IP address must be assigned to the NAT VDOM’s interface, but no IP address should be assigned to the Transparent VDOM’s interface.

To configure a NAT to Transparent VDOM link - CLI

```
config global
  config system vdom-link
    edit vlink1
    set type ethernet
    end
  config system interface
    edit vlink10
      set vdom (interface 1 name)
      set ip (interface 1 ip)
    next
    edit vlink11
      set vdom (interface 2 name)
    end
```

Ethernet-type is not recommended for standard NAT to NAT inter-VDOM links, as the default PPP-type link does not require the VDOM links to have addresses, while Ethernet-type does. VDOM link addresses are explained in “IP addresses and inter-VDOM links” on page 2404.

Inter-VDOM configurations

By using fewer physical interfaces to inter-connect VDOMs, inter-VDOM links provide you with more configuration options.

None of these configurations use VLANs to reduce the number of physical interfaces. It is generally assumed that an internal or client network will have its own internal interface and an external interface to connect to its ISP and the Internet.

These inter-VDOM configurations can use any FortiGate model with possible limitations based on the number of physical interfaces. VLANs can be used to work around these limitations.

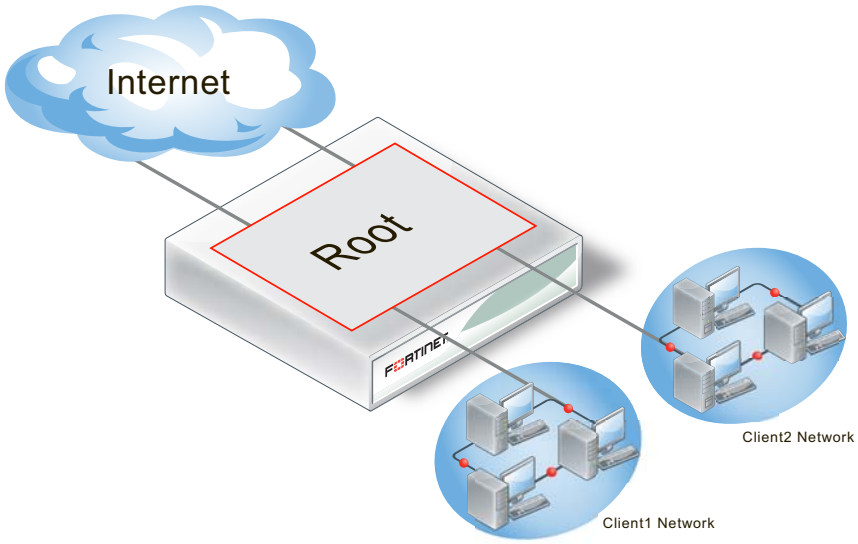
In the following inter-VDOM diagrams, red indicates the physical FortiGate unit, grey indicate network connections external to the FortiGate unit, and black is used for inter-VDOM links and VDOMs.

This section includes the following topics:

Standalone VDOM configuration

The standalone VDOM configuration uses a single VDOM on your FortiGate unit — the root VDOM that all FortiGate units have by default. This is the VDOM configuration you are likely familiar with. It is the default configuration for FortiGate units before you create additional VDOMs.

Figure 339: Standalone VDOM



The configuration shown in Figure 339 has no VDOM inter-connections and requires no special configurations or settings.

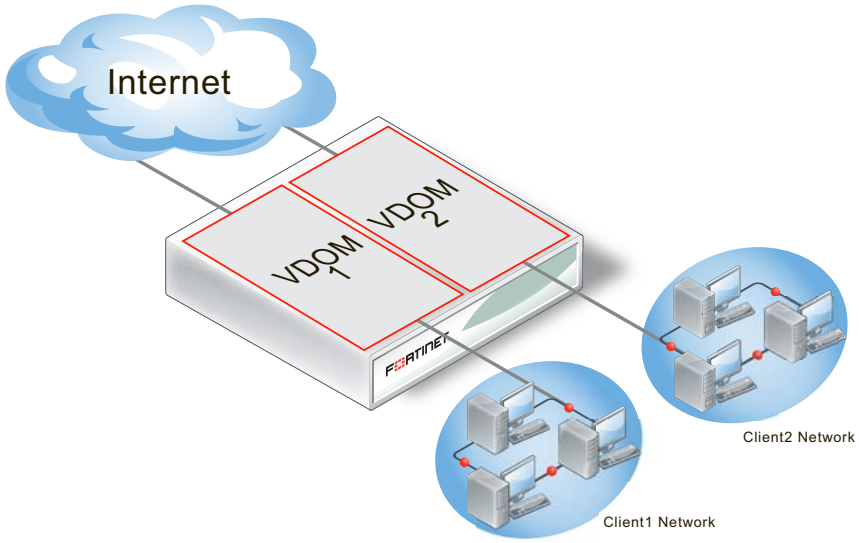
The standalone VDOM configuration can be used for simple network configurations that only have one department or one company administering the connections, firewalls and other VDOM-dependent settings.

However, with this configuration, keeping client networks separate requires many interfaces, considerable firewall design and maintenance, and can quickly become time consuming and complex. Also, configuration errors for one client network can easily affect other client networks, causing unnecessary network downtime.

Independent VDOMs configuration

The independent VDOMs configuration uses multiple VDOMs that are completely separate from each other. This is another common VDOM configuration.

Figure 340: Independent VDOMs



This configuration has no communication between VDOMs and apart from initially setting up each VDOM, it requires no special configurations or settings. Any communication between VDOMs is treated as if communication is between separate physical devices.

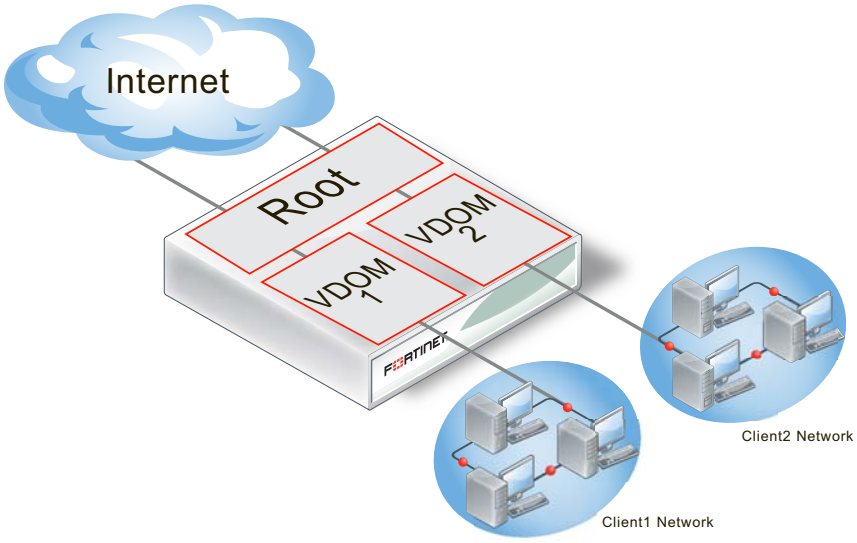
The independent inter-VDOM configuration can be used where more than one department or one company is sharing the FortiGate unit. Each can administer the connections, firewalls and other VDOM-dependent settings for only its own VDOM. To each company or department, it appears as if it has its own FortiGate unit. This configuration reduces the amount of firewall configuration and maintenance required by dividing up the work.

However, this configuration lacks a management VDOM for VDOMs 1, 2, and 3. This is illustrated in Figure 50. This management VDOM would enable an extra level of control for the FortiGate unit administrator, while still allowing each company or department to administer its own VDOM.

Management VDOM configuration

In the management VDOM configuration, the root VDOM is the management VDOM. The other VDOMs are connected to the management VDOM with inter-VDOM links. There are no other inter-VDOM connections.

Figure 341: Management VDOM configuration



The inter-VDOM links connect the management VDOM to the other VDOMs. This does not require any physical interfaces, and the bandwidth of inter-VDOM links can be faster than physical interfaces, depending on the CPU workload.

Only the management VDOM is connected to the Internet. The other VDOMs are connected to internal networks. All external traffic is routed through the management VDOM using inter-VDOM links and firewall policies between the management VDOM and each VDOM. This ensures the management VDOM has full control over access to the Internet, including what types of traffic are allowed in both directions. There is no communication directly between the non-root VDOMs. Security is greatly increased with only one point of entry and exit. Only the management VDOM needs to be fully managed to ensure network security in this case. Each client network can manage its own configuration without compromising security or bringing down another client network.

The management VDOM configuration is ideally suited for a service provider business. The service provider administers the management VDOM with the other VDOMs as customers. These customers do not require a dedicated IT person to manage their network. The service provider controls the traffic and can prevent the customers from using banned services and prevent Internet connections from initiating those same banned services. One example of a banned service might be Instant Messaging (IM) at a company concerned about intellectual property. Another example could be to limit bandwidth used by file-sharing applications without banning that application completely. Firewall policies control the traffic between the customer VDOM and the management VDOM and can be customized for each customer.

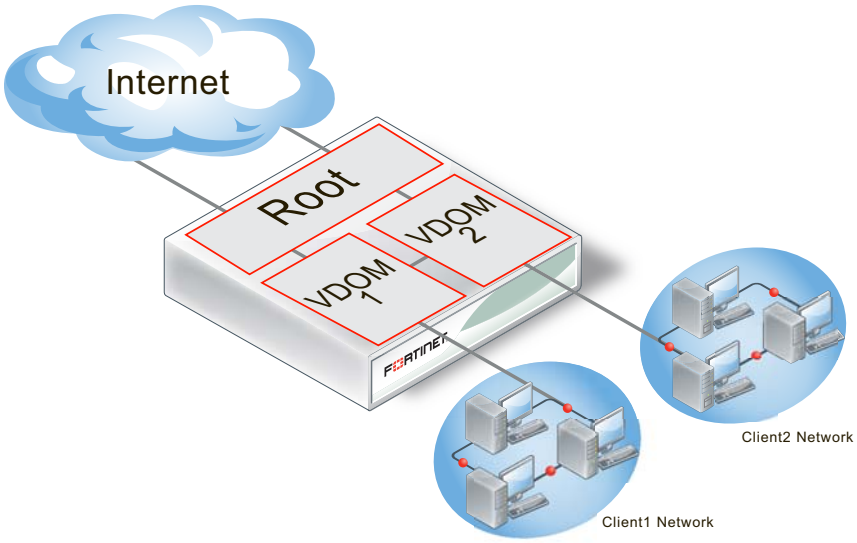
The management VDOM configuration is limited in that the customer VDOMs have no inter-connections. In many situations this limitation is ideal because it maintains proper security. However, some configurations may require customers to communicate with each other, which would be easier if the customer VDOMs were inter-connected.

Meshed VDOM configuration

The meshed VDOMs configuration, including partial and full mesh, has VDOMs inter-connected with other VDOMs. There is no special feature to accomplish this—they are just complex VDOM configurations.

Partial mesh means only some VDOMs are inter-connected. In a full mesh configuration, all VDOMs are inter-connected to all other VDOMs. This can be useful when you want to provide full access between VDOMs but handle traffic differently depending on which VDOM it originates from or is going to.

Figure 342: Meshed VDOMs



With full access between all VDOMs being possible, it is extra important to ensure proper security. You can achieve this level of security by establishing extensive firewall policies and ensuring secure account access for all administrators and users.

Meshed VDOM configurations can become complex very quickly, with full mesh VDOMs being the most complex. Ensure this is the proper solution for your situation before using this configuration. Generally, these configurations are seen as theoretical and are rarely deployed in the field.

Dynamic routing over inter-VDOM links

BGP is supported over inter-VDOM links. Unless otherwise indicated, routing works as expected over inter-VDOM links.

If an inter-VDOM link has no assigned IP addresses to it, it may be difficult to use that interface in dynamic routing configurations. For example BGP requires an IP address to define any BGP router added to the network.

In OSPF, you can configure a router using a router ID and not its IP address. In fact, having no IP address avoids possible confusing between which value is the router ID and which is the IP address. However for that router to become adjacent with another OSPF router it will have to share the same subnet, which is technically impossible without an IP address. For this reason, while you can configure an OSPF router using an IP-less inter-VDOM link, it will likely be of limited value to you.

In RIP the metric used is hop count. If the inter-VDOM link can reach other nodes on the network, such as through a default route, then it may be possible to configure a RIP router on an inter-VDOM link. However, once again it may be of limited value due to limitations.

As stated earlier, BGP requires an IP address to define a router — an IP-less inter-VDOM link will not work with BGP.

In Multicast, you can configure an interface without using an IP address. However that interface will be unable to become an RP candidate. This limits the roles available to such an interface.

HA virtual clusters and VDOM links

FortiGate HA is implemented by configuring two or more FortiGate units to operate as an HA cluster. To the network, the HA cluster appears to function as a single FortiGate unit, processing network traffic and providing normal security services such as firewall, VPN, IPS, virus scanning, web filtering, and spam filtering.

Virtual clustering extends HA features to provide failover protection and load balancing for a FortiGate unit operating with virtual domains. A virtual cluster consists of a cluster of two FortiGate units operating with virtual domains. Traffic on different virtual domains can be load balanced between the cluster units.

With virtual clusters (vclusters) configured, inter-VDOM links must be entirely within one vcluster. You cannot create links between vclusters, and you cannot move a VDOM that is linked into another virtual cluster. If your FortiGate units are operating in HA mode, with multiple vclusters when you create the vdom-link, the CLI command `config system vdom-link` includes an option to set which vcluster the link will be in.

What is virtual clustering?

Virtual clustering is an extension of the FGCP for FortiGate units operating with multiple VDOMS enabled. Virtual clustering operates in active-passive mode to provide failover protection between two instances of a VDOM operating on two different cluster units. You can also operate virtual clustering in active-active mode to use HA load balancing to load balance sessions between cluster units. Alternatively, by distributing VDOM processing between the two cluster units you can also configure virtual clustering to provide load balancing by distributing sessions for different VDOMs to each cluster unit.

Virtual clustering and failover protection

Virtual clustering operates on a cluster of two (and only two) FortiGate units with VDOMs enabled. Each VDOM creates a cluster between instances of the VDOMs on the two FortiGate units in the virtual cluster. All traffic to and from the VDOM stays within the VDOM and is processed by the VDOM. One cluster unit is the primary unit for each VDOM and one cluster unit is the subordinate unit for each VDOM. The primary unit processes all traffic for the VDOM. The subordinate unit does not process traffic for the VDOM. If a cluster unit fails, all traffic fails over to the cluster unit that is still operating.

Virtual clustering and heartbeat interfaces

The HA heartbeat provides the same HA services in a virtual clustering configuration as in a standard HA configuration. One set of HA heartbeat interfaces provides HA heartbeat services for all of the VDOMs in the cluster. You do not have to add a heartbeat interface for each VDOM.

Virtual clustering and HA override

For a virtual cluster configuration, override is enabled by default for both virtual clusters when you:

- Enable VDOM portioning from the web-based manager by moving virtual domains to virtual cluster 2
- Enter set vcluster2 enable from the CLI config system ha command to enable virtual cluster 2.

Usually you would enable virtual cluster 2 and expect one cluster unit to be the primary unit for virtual cluster 1 and the other cluster unit to be the primary unit for virtual cluster 2. For this distribution to occur override must be enabled for both virtual clusters. Otherwise you will need to restart the cluster to force it to renegotiate.

Virtual clustering and load balancing or VDOM partitioning

There are two ways to configure load balancing for virtual clustering. The first is to set the HA mode to active-active. The second is to configure VDOM partitioning. For virtual clustering, setting the HA Mode to active-active has the same result as active-active HA for a cluster without virtual domains. The primary unit receives all sessions and load balances them among the cluster units according to the load balancing schedule. All cluster units process traffic for all virtual domains.

Note: If override is enabled the cluster may renegotiate too often. You can choose to disable override at any time. If you decide to disable override, for best results, you should disable it for both cluster units.

In a VDOM partitioning virtual clustering configuration, the HA mode is set to active-passive. Even though virtual clustering operates in active-passive mode you can configure a form of load balancing by using VDOM partitioning to distribute traffic between both cluster units. To configure VDOM partitioning you set one cluster unit as the primary unit for some virtual domains and you set the other cluster unit as the primary unit for other virtual domains. All traffic for a virtual domain is processed by the primary unit for that virtual domain. You can control the distribution of traffic between the cluster units by adjusting which cluster unit is the primary unit for each virtual domain.

For example, you could have 4 VDOMs, two of which have a high traffic volume and two of which have a low traffic volume. You can configure each cluster unit to be the primary unit for one of the high volume VDOMs and one of the low volume VDOMs. As a result each cluster unit will be processing traffic for a high volume VDOM and a low volume VDOM, resulting in an even distribution of traffic between the cluster units. You can adjust the distribution at any time. For example, if a low volume VDOM becomes a high volume VDOM you can move it from one cluster unit to another until the best balance is achieved. From the web-based manager you configure VDOM partitioning by setting the HA mode to active-passive and distributing virtual domains between Virtual Cluster 1 and Virtual Cluster 2. You can also configure different device priorities, port monitoring, and remote link failover, for Virtual Cluster 1 and Virtual Cluster 2.

From the CLI you configure VDOM partitioning by setting the HA mode to a-p. Then you configure device priority, port monitoring, and remote link failover and specify the VDOMs to include in virtual cluster 1. You do the same for virtual cluster 2 by entering the config secondary-vcluster command.

Failover protection does not change. If one cluster unit fails, all sessions are processed by the remaining cluster unit. No traffic interruption occurs for the virtual domains for which the still functioning cluster unit was the primary unit. Traffic may be interrupted temporarily for virtual domains for which the failed unit was the primary unit while processing fails over to the still functioning cluster unit. If the failed cluster unit restarts and rejoins the virtual cluster, VDOM partitioning load balancing is restored.

Example of inter-VDOM routing

This example shows how to configure a FortiGate unit to use inter-VDOM routing.

This section contains the follow topics:

Network topology and assumptions

Two departments of a company, Accounting and Sales, are connected to one FortiGate-800 unit. To do its work, the Sales department receives a lot of email from advertising companies that would appear to be spam if the Accounting department received it. For this reason, each department has its own VDOM to keep firewall policies and other configurations separate. A management VDOM makes sense to ensure company policies are followed for traffic content.

The traffic between Accounting and Sales will be email and HTTPS only. It could use a VDOM link for a meshed configuration, but we will keep from getting too complex. With the configuration, inter-VDOM traffic will have a slightly longer path to follow than normal—from one department VDOM, through the management VDOM, and back to the other department VDOM. Since inter-VDOM links are faster than physical interfaces, this longer path should not be noticed.

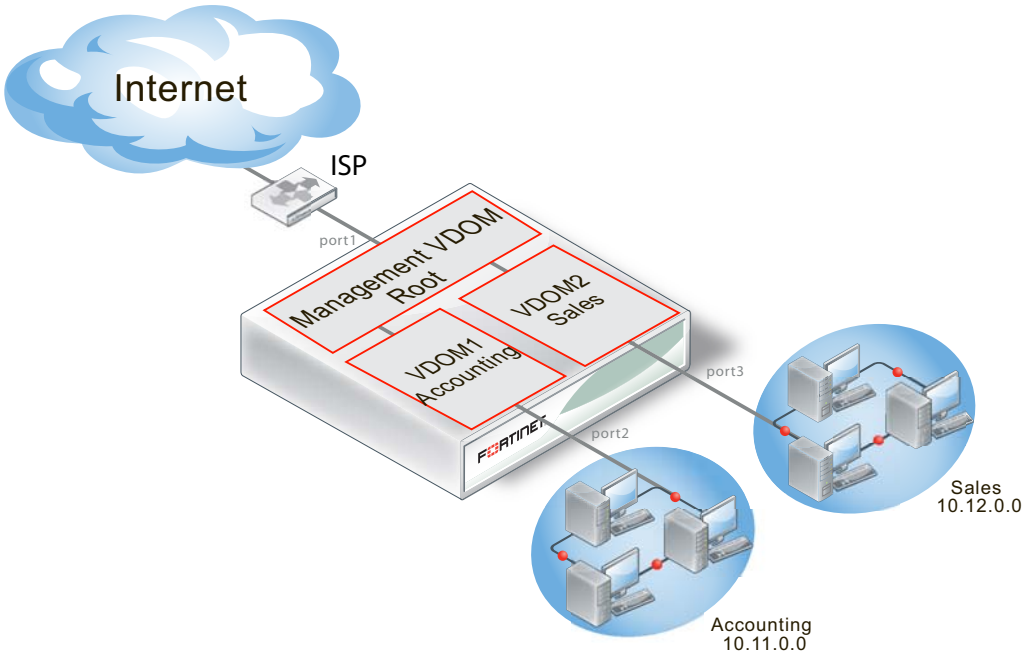
Firewall policies will be in place. For added security, firewall policies will allow only valid office services such as email, web browsing, and FTP between either department and the Internet. Any additional services that are required can be added in the future.

The company uses a single ISP to connect to the Internet. The ISP uses DHCP to provide an IP address to the FortiGate unit. Both departments use the same ISP to reach the Internet.

Other assumptions for this example are as follows:

- Your FortiGate unit has interfaces labelled port1 through port4 and VDOMs are not enabled.
- You are using the super_admin account.
- You have the FortiClient application installed.
- You are familiar with configuring interfaces, firewalls, and other common features on your FortiGate unit.

Figure 343: Management VDOM for two departments



General configuration steps

This example includes the following general steps. For best results, follow the steps in the order given. Also, note that if you perform any additional actions between procedures, your configuration may have different results.

1. Creating the VDOMs
2. Configuring the physical interfaces
3. Configuring the VDOM links
4. Configuring the firewall and Security Profile settings
5. Testing the configuration

Creating the VDOMs

This procedure enables VDOMs and creates the Sales and Accounting VDOMs.

To create the VDOMs - web-based manager

1. Log in as the super_admin administrator.
2. Go to *System* > *Dashboard* > *Status* > *System Information* > *Virtual Domain*, and select *Enable*.
3. Log in again.
4. Go to *System* > *VDOM* > *VDOM*.
5. Select *Create New*, enter `Accounting` for the VDOM Name, and select *OK*.
6. Select *Create New*, enter `Sales` for the VDOM Name, and select *OK*.

To create the VDOMs - CLI

```
config system global
  set vdom enable
end

config system vdom
  edit Accounting
  next
  edit Sales
  next
end
```

Configuring the physical interfaces

Next, the physical interfaces must be configured. This example uses three interfaces on the FortiGate unit - port2 (internal), port3(dmz), and port1(external). port2 and port3 interfaces each have a department's network connected. port1 is for all traffic to or from the Internet and will use DHCP to configure its IP address, which is common with many ISPs.

To configure the physical interfaces - web-based manager

1. Go to *Global* > *Network* > Interfaces.
2. Select *Edit* for the port2 interface, enter the following information, and select *OK*.

Alias	AccountingLocal
Virtual Domain	Accounting
Addressing mode	Manual
IP/Netmask	172.100.1.1/255.255.0.0
Administrative Access	HTTPS, PING, SSH
Description	This is the accounting department internal interface.

3. Select *Edit* for the port3 interface, enter the following information, and select *OK*.

Alias	SalesLocal
Virtual Domain	Sales
Addressing mode	Manual
IP/Netmask	192.168.1.1/255.255.0.0
Administrative Access	HTTPS, PING, SSH
Description	This is the sales department internal interface.

4. Select *Edit* for the port1 interface, enter the following information, and select *OK*.

Alias	ManagementExternal
Virtual Domain	root

Addressing Mode	DHCP
Distance	5
Retrieve default gateway from server	Enable
Override internal DNS	Enable
Administrative Access	HTTPS, SSH, SNMP
Description	This is the accounting department internal interface.

When the mode is set to DHCP or PPoE on an interface you can set the distance field. This is the administrative distance for any routes learned through the gateway for this interface. The gateway is added to the static route table with these values. A lower distance indicates a preferred route.

To configure the physical interfaces - CLI

```
config global
  config system interface
    edit port2
      set alias AccountingLocal
      set vdom Accounting
      set mode static
      set ip 172.100.1.1 255.255.0.0
      set allowaccess https ping ssh
      set description "The accounting dept internal interface"
    next
    edit port3
      set alias SalesLocal
      set vdom Sales
      set mode static
      set ip 192.168.1.1 255.255.0.0
      set allowaccess https ping ssh
      set description "The sales dept. internal interface"
    next
    edit port1
      set alias ManagementExternal
      set vdom root
      set mode DHCP
      set distance 5
      set gwdetect enable
      set dns-server-override enable
      set allowaccess https ssh snmp
      set description “The systemwide management interface.”
    end
```

Configuring the VDOM links

To complete the connection between each VDOM and the management VDOM, you need to add the two VDOM links; one pair is the Accounting - management link and the other is for Sales - management link.

When configuring inter-VDOM links, you do not have to assign IP addresses to the links unless you are using advanced features such as dynamic routing that require them. Not assigning IP addresses results in faster configuration, and more available IP addresses on your networks.

If you require them, or if you simply want to assign IP addresses for clarity can do so.

To configure the Accounting and management VDOM link - web-based manager

1. Go to *Global* > *Network* > *Interfaces*.
2. Select the expand arrow to select *Create New* > *VDOM link*.
3. Enter the following information, and select *OK*.

Name	AccountVlnk
Interface #0	
Virtual Domain	Accounting
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Accounting VDOM side of the link.
Interface #1	
Virtual Domain	root
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Management VDOM side of the link.

To configure the Accounting and management VDOM link - CLI

```
config global
  config system vdom-link
    edit AccountVlnk
    next
  end
  config system interface
    edit AccountVlnk0
      set vdom Accounting
      set ip 0.0.0.0 0.0.0.0
      set allowaccess https ping ssh
      set description "Accounting side of the VDOM link"
    next
    edit AccountVlnk1
      set vdom root
      set ip 0.0.0.0 0.0.0.0
      set allowaccess https ping ssh
      set description "Management side of the VDOM link"
    end
```

To configure the Sales and management VDOM link - web-based manager

1. Go to *Global* > *Network* > Interfaces.
2. Select the expand arrow and select *Create New* > *VDOM link*.
3. Enter the following information, and select *OK*.

Name	SalesVlnk
Interface #0	
Virtual Domain	Sales
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Sales VDOM side of the link.
Interface #1	
Virtual Domain	root
IP/Netmask	0.0.0.0/0.0.0.0
Administrative Access	HTTPS, PING, SSH
Description	The Management VDOM side of the link.

To configure the Sales and management VDOM link - CLI

```
config global
  config system vdom-link
    edit SalesVlnk
  end
  config system interface
    edit SalesVlnk0
      set vdom Accounting
      set ip 0.0.0.0 0.0.0.0
      set allowaccess https ping ssh
      set description "Sales side of the VDOM link"
    next
    edit SalesVlnk1
      set vdom root
      set ip 0.0.0.0 0.0.0.0
      set allowaccess https ping ssh
      set description "Management side of the VDOM link"
    end
  end
```

Configuring the firewall and Security Profile settings

With the VDOMs, physical interfaces, and VDOM links configured the firewall must now be configured to allow the proper traffic. Firewalls are configured per-VDOM, and firewall objects must be created for each VDOM separately.

For this example, the firewall group of services allowed between the internal networks and the Internet are the basic services for web browsing, file transfer, and email. These include: HTTP, HTTPS, SSL, FTP, DNS, NTP, POP3, and SMTP.

The only services allowed between Sales and Accounting are secure web browsing (HTTPS) and email (POP3 and SMTP)

The limited number of services ensures security between departments. The list of services can be expanded in the future if needed.

Security profile settings will block all non-essential business websites while logging all web traffic, scan and file filter all web and email protocols, and block game and peer-to-peer applications using application control.

For added security, FortiClient is required on internal computers with AntiVirus scanning configured. This is enforced by *Endpoint NAC* in firewall policies.

Using firewall addresses makes the firewall policies easier to read. Also if any changes need to be made in the future, you can simply update the addresses without changing the firewall policies. The addresses required are:

- `AccountingLocal` - all traffic from the internal accounting network
- `AccountingVlnk` - all traffic from the VDOM link between accounting and management VDOMs
- `SalesLocal` - all traffic from the internal sales network
- `SalesVlnk` - all traffic from the VDOM link between sales and management VDOM.

The Accounting VDOM requires `AccountingLocal`, `AccountingVlnk`, and `SalesLocal`. The Sales VDOM requires `SalesLocal`, `SalesVlnk`, and `AccountingLocal`.

The firewall policies required on the Accounting VDOM are:

- AccountingLocal to Internet
- Internet to AccountingLocal
- SalesLocal to AccountingLocal
- AccountingLocal to SalesLocal

The firewall policies required on the Sales VDOM are:

- SalesLocal to Internet
- Internet to SalesLocal
- SalesLocal to AccountingLocal
- AccountingLocal to SalesLocal

This section includes the following topics:

Configuring firewall service groups

Service groups are an easy way to manage multiple services, especially if the same services are used on different networks.

The two service groups used here are intended for normal office traffic to the Internet, and for restricted traffic between departments. In both cases network traffic will be limited to the services listed to prevent any potential security risks or bandwidth-robbing applications.

These service groups can be changed as needed to either include additional valid services that are being used on the network, or to exclude services that are not required. Also, custom services can be created as needed for applications that are not listed.

To configure two firewall service groups - web-based manager

1. Open the *Accounting* VDOM.
2. Go to *Firewall Objects* > *Service* > *Group.*
3. Select *Create New*, enter the following information, and select *OK.*

Group Name	OfficeServices
Members	HTTP, HTTPS, SSL, FTP, DNS, NTP, POP3, PING, SMTP

4. Select *Create New*, enter the following information, and select *OK*.

Group Name	AccountingSalesServices
Members	HTTPS, POP3, PING, SMTP

To configure two firewall service groups - CLI

```
config vdom
  edit Accounting
    config firewall service group
      edit OfficeServices
        set member HTTP HTTPS SSL FTP DNS NTP POP3 PING SMTP
      next
      edit AccountingSalesServices
        set member HTTPS POP3 PING SMTP
      end
  end
```

Configuring Security Profile settings for the Accounting VDOM

Security Profile settings include web filtering, antivirus, application control, and other features. This example just uses those three features to ensure that

- the business environment is free from viruses
- employees do not surf grossly inappropriate websites, and
- employees do not use games or peer-to-peer applications at work.

To configure web filtering for the Accounting VDOM - web-based manager

1. Open the *Accounting* VDOM.
2. Go to *Security Profiles* > *Web Filter* > *Profile*.
3. Select *Create New*.
4. Enter `webStrict` for the *Name*.
5. Select the arrow to expand the *FortiGuard Web Filtering* section.
6. Block all *Categories* except Business Oriented, Other, and Unrated.
7. Block all *Classifications* except Image Search..
8. Log all *Categories* and *Classifications*.
9. Select *OK*.

To configure web filtering for the Accounting VDOM - CLI

```
config vdom
  edit Accounting
    config webfilter profile
      edit webStrict
        config ftgd-wf
          set allow g07 g08 g21 g22 c01 c03
          set deny g01 g02 g03 g04 g05 g06 c02 c04 c05 c06 c07
        end
      set web-ftgd-err-log enable
      end
  end
```

To configure AntiVirus for the Accounting VDOM - web-based manager

1. Open the *Accounting* VDOM.
2. Go to *Security Profiles* > *AntiVirus* > *Profile*.
3. Select *Create New*.

4. Enter `avStrict` for the *Name*.
5. Enable *Scan* for all protocols.
6. Enable *File filter* for all protocols, and select `built-in-patterns` for *Option*.
7. Enable logging for both *Scan* and *File Filter*.
8. Select *OK*.

To configure AntiVirus for the Accounting VDOM - CLI

```
config vdom
  edit Accounting
    config antivirus profile
      edit avStrict
        config http
          set options scan file-filter
        end
        config ftp
          set options scan file-filter
        end
        config imap
          set options scan file-filter
        end
        config pop3
          set options scan file-filter
        end
        config smtp
          set options scan file-filter
        end
        config nntp
          set options scan file-filter
        end
        config im
          set options scan file-filter
        end
        set filepattable 1
        set av-virus-log enable
        set av-block-log enable
      end
end
```

To configure application control for the Accounting VDOM - web-based manager

1. Open the *Accounting* VDOM.
2. Go to *Security Profiles* > *Application Control* > *Application Sensor.*
3. Select *Create New* (+ button at top right of page).
4. Enter `appStrict` for *Name* and select OK.
5. Select *Create New*.
6. In *Filters*, set *Category* to *game*.

7. In *Applications*/*Settings*, enter the following, and select *OK*.

Action	Block
Packet Logging	Enable

8. Select *Create New*.
9. In *Filters*, set *Category* to *p2p*.
10. In *Applications*/*Settings*, enter the following, and select *OK*.

Action	Block
Packet Logging	Enable

11. Select *Apply*.

To configure application control for the Accounting VDOM - CLI

```
config vdom
  edit Accounting
    config application list
      edit appStrict
        config entries
          edit 1
            set category 2
          next
          edit 2
            set category 8
          end
      end
end
```

Configuring firewall settings for the Accounting VDOM

This configuration includes two firewall addresses and two firewall policies for the Accounting VDOM - one for the internal network, and one for the VDOM link with the management VDOM (root).

For added security, all traffic allowed will be scanned. Only valid office traffic will be allowed using the service group `OfficeServices`. The FortiClient application must be used to ensure additional protection for the sensitive accounting information.

All sales and accounting computers have the FortiClient application installed, so the firewall policies check that FortiClient is installed and that antivirus scanning is enabled.

Note the spelling of `AccountVlnk` which is due to the eleven character limit on VDOM link names.

To configure firewall addresses - web-based manager

1. Open the *Accounting* VDOM.
2. Select *Firewall Objects* > *Address* > *Address*

3. Select *Create New*, enter the following information, and select *OK*.

Address Name	AccountingLocal
Type	Subnet/ IP Range
Subnet / IP Range	172.100.0.0
Interface	port1

4. Select *Create New*, enter the following information, and select *OK*.

Address Name	AccountManagement
Type	Subnet/ IP Range
Subnet / IP Range	10.0.1.0
Interface	AccountVlnk

To configure firewall addresses - CLI

```
config vdom
  edit Accounting
    config firewall address
      edit AccountingLocal
        set type iprange
        set subnet 172.100.0.0
        set associated-interface port1
      next
      edit AccountManagement
        set type iprange
        set subnet 10.0.1.0
        set associated-interface AccountVlnk
      end
    end
```

To configure protocol options for Accounting VDOM - web-based manager

1. Open the *Accounting* VDOM.
2. Select *Policy* > *Policy* > *Protocol Options.*
3. Select *Create New*.
4. Enter `default` for the *Name*.
5. Select *OK*.

To configure the firewall policies from AccountingLocal to the Internet - web-based manager

1. Open the *Accounting* VDOM.
2. Go to *Policy* > *Policy*.
3. Select *Create New*, enter the following information, and then select *OK*.

Source Interface/Zone	port2
Source Address	AccountingLocal

Destination Interface/Zone	AccountVlnk
Destination Address	AccountManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
Security Features	enabled
Protocol Option	default
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict
Enable Endpoint NAC	Enforce_FortiClient_AV

4. Open the *root* VDOM.
5. Go to *Policy* > *Policy.*
6. Select *Create New*, enter the following information, and then select *OK*.

Source Interface/Zone	AccountVlnk
Source Address	AccountManagement
Destination Interface/Zone	port2
Destination Address	all
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
Security Features	enable
Protocol Option	default
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict
Enable Endpoint NAC	disabled

To configure the firewall policies from AccountingLocal to Internet - CLI

```
config vdom
  edit Accounting
    config firewall policy
      edit 1
        set srcintf "port2"
        set dstintf "AccountVlnk"
        set srcaddr "AccountingLocal"
        set dstaddr "AccountManagement"
        set action accept
        set schedule "always"
        set service "OfficeServices"
        set nat enable
        set av-profile avStrict
        set webfilter-profile webStrict
        set application-list appStrict
        set profile-protocol-options default
        set endpoint-check enable
        set endpoint-profile "FortiClient_installed"
      end
  end

config vdom
  edit root
    config firewall policy
      edit 2
        set srcintf AccountVlnk
        set dstintf port1
        set srcaddr AccountManagement
        set dstaddr all
        set action accept
        set schedule always
        set service OfficeServices
        set nat enable
        set av-profile "scan"
        set webfilter-profile "scan"
        set application-list "AppControlList"
        set profile-protocol-options default
        set endpoint-check disable
      end
  end
```

To configure the firewall policies from Internet to AccountingLocal - web-based manager

1. Open the *root* VDOM.
2. Go to *Policy* > *Policy*.

3. Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	port1
Source Address	all
Destination Interface/Zone	AccountVlnk
Destination Address	AccountManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
Security Features	enable
Protocol Option	default
Web Filtering	webStrict
AntiVirus Filtering	avStrict
Application Control	appStrict
Enable Endpoint NAC	disabled

4. Open the *Accounting* VDOM.
5. Go to *Policy* > *Policy.*
6. Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	AccountVlnk
Source Address	AccountManagement
Destination Interface/Zone	port2
Destination Address	AccountingLocal
Schedule	always
Service	OfficeServices
Action	ACCEPT
Enable NAT	enable
Security Features	enable
Protocol Option	default
Web Filtering	webStrict
AntiVirus Filtering	avStrict

Application Control	appStrict
Enable Endpoint NAC	disabled

To configure the firewall policies from Internet to AccountingLocal - CLI

```
config vdom
  edit root
    config firewall policy
      edit 3
        set srcintf port1
        set dstintf AccountVlnk
        set srcaddr all
        set dstaddr AccountManagement
        set action accept
        set schedule always
        set service OfficeServices
        set nat enable
        set av-profile avStrict
        set webfilter-profile webStrict
        set application-list appstrict
        set profile-protocol-options default
        set endpoint-check disable
      end
  end
config vdom
  edit Accounting
    config firewall policy
      edit 4
        set srcintf AccountVlnk
        set dstintf port2
        set srcaddr AccountManagement
        set dstaddr AccountingLocal
        set action accept
        set schedule always
        set service OfficeServices
        set nat enable
        set av-profile avStrict
        set webfilter-profile webStrict
        set application-list appstrict
        set profile-protocol-options default
        set endpoint-check disable
      end
  end
```

Configuring Security Profile settings for the Sales VDOM

Security profile settings include web filtering, antivirus, application control, and other features. This example just uses those three features to ensure that

- the business environment is free from viruses
- employees do not surf grossly inappropriate websites, and
- employees do not use games or peer-to-peer applications at work.

Note that Sales web traffic is different from Accounting, and web filtering is different to account for this.

To configure web filtering for the Sales VDOM - web-based manager

1. Open the *Sales* VDOM.
2. Go to *Security Profiles* > *Web Filter* > *Profile*.
3. Select *Create New*.
4. Enter `webStrict` for the *Name*.
5. In *FortiGuard Categories*, select all of the categories except *Bandwidth Consuming*, *General Interest - Business* and *Unrated*.
6. In *Change Action for Selected Categories* select *Block*.
7. Select *Apply*.

To configure web filtering for the Sales VDOM - CLI

```
config vdom
  edit Sales
    config webfilter profile
      edit webStrict
        config ftgd-wf
          set allow g07 g08 g21 g22 c01 c03
          set deny g01 g02 g03 g04 g05 g06 c02 c04 c05 c06 c07
        end
        set web-ftgd-err-log enable
      end
  end
```

To configure AntiVirus for the Sales VDOM - web-based manager

1. Open the *Sales* VDOM.
2. Go to *Security Profiles* > *AntiVirus* > *Profile*.
3. Select *Create New*.
4. Enter `avStrict` for the *Name*.
5. Enable virus scan for all protocols.
6. Select *Apply*.

To configure AntiVirus for the Sales VDOM - CLI

```
config vdom
  edit Sales
    config antivirus profile
      edit "avStrict"
        config http
          set options scan file-filter
        end
        config ftp
          set options scan file-filter
        end
        config imap
          set options scan file-filter
        end
        config pop3
          set options scan file-filter
        end
        config smtp
          set options scan file-filter
        end
        config nntp
          set options scan file-filter
        end
        config im
          set options scan file-filter
        end
        set filepattable 1
        set av-virus-log enable
        set av-block-log enable
      end
  end
```

To configure application control for the Sales VDOM - web-based manager

1. Open the *Accounting* VDOM.
2. Go to *Security Profiles* > *Application Control* > *Application Sensor.*
3. Select *Create New* (+ button at top right of page).
4. Enter `appStrict` for *Name* and select OK.
5. Select *Create New*.
6. In *Filters*, set *Category* to *game*.
7. In *Applications*/*Settings*, enter the following, and select *OK*.

Action	Block
Packet Logging	Enable

8. Select *Create New*.
9. In *Filters*, set *Category* to *p2p*.

10. In *Applications/Settings*, enter the following, and select *OK*.

Action	Block
Packet Logging	Enable

11. Select *Apply*.

To configure application control for the Sales VDOM - CLI

```
config vdom
  edit Sales
    config application list
      edit "appStrict"
        config entries
          edit 1
            set category 2
          next
          edit 2
            set category 8
          end
      end
  end
```

Configuring firewall settings for the Sales VDOM

Like the Accounting firewall settings, this configuration includes two firewall addresses and two firewall policies for the sales VDOM: one for the internal network, and one for the VDOM link with the management VDOM.

When entering the CLI commands, the number of the firewall policies must be high enough to be a new policy. Depending on the number of firewall policies on your FortiGate unit, this may require starting at a higher number than the 6 required for the default configuration. This number is added automatically when you configure firewall policies using the web manager interface.

The FortiClient application must be used on Sales network computers to ensure additional protection for the sensitive information and for protection against spam.

To configure firewall addresses - web-based manager

1. Open the *Sales* VDOM.
2. Go to *Firewall Objects* > *Address* > *Address.*
3. Select *Create New,* enter the following information, and select *OK*.

Address Name	SalesLocal
Type	Subnet / IP Range
Subnet / IP Range	172.100.0.0
Interface	port3

4. Go to *Firewall Objects* > *Addresses.*

5. Select *Create New*, enter the following information, and select OK.

Address Name	SalesManagement
Type	Subnet / IP Range
Subnet / IP Range	10.0.1.0
Interface	SalesVlnk

To configure the firewall addresses - CLI

```
config vdom
  edit Sales
    config fireall address
      edit SalesLocal
        set type iprange
        set subnet 172.100.0.0
        set associated-interface port2
      next
      edit SalesManagement
        set type iprange
        set subnet 10.0.1.0
        set associated-interface SalesVlnk
      end
  end
```

To configure the firewall policies from SalesLocal to the Internet - web-based manager

1. Open the *Sales* VDOM.
2. Go to *Policy* > *Policy.*
3. Select *Create New*, enter the following information, and select OK.

Source Interface/Zone	port3
Source Address	SalesLocal
Destination Interface/Zone	SalesVlnk
Destination Address	SalesManagement
Schedule	always
Service	OfficeServices
Action	ACCEPT
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled
Redirect Non-conforming Clients to Download Portal	enabled

4. Open the *root* VDOM.
5. Go to *Policy* > *Policy.*

6. Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	SalesVlnk
Source Address	SalesManagement
Destination Interface/Zone	external
Destination Address	all
Schedule	always
Service	OfficeServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled

To configure the firewall policies from SalesLocal to the Internet - CLI

```
config vdom
  edit root
    config firewall policy
      edit 6
        set srcintf port2
        set srcaddr SalesLocal
        set dstintf SalesVlnk
        set dstaddr SalesManagement
        set schedule always
        set service OfficeServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
        set endpoint-redir-portal enable
      end
  end

config vdom
  edit Sales
    config firewall policy
      edit 7
        set srcintf SalesVlnk
        set srcaddr SalesManagement
        set dstintf external
        set dstaddr all
        set schedule always
        set service OfficeServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
      end
  end
```

To configure the firewall policies from the Internet to SalesLocal - web-based manager

1. Open the *root* VDOM.
2. Go to *Policy* > *Policy.*
3. Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	external
Source Address	all
Destination Interface/Zone	SalesVlnk
Destination Address	SalesManagement

Schedule	always
Service	OfficeServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled

4. Open the *Sales* VDOM.
5. Go to *Policy* > *Policy.*
6. Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	SalesVlnk
Source Address	SalesManagement
Destination Interface/Zone	port2
Destination Address	SalesLocal
Schedule	always
Service	OfficeServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled
Redirect Non-conforming Clients to Download Portal	enabled

To configure the firewall policies from the Internet to SalesLocal - CLI

```
config vdom
  edit root
    config firewall policy
      edit 8
        set srcintf external
        set srcaddr all
        set dstintf SalesVlnk
        set dstaddr SalesManagement
        set schedule always
        set service OfficeServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
        set endpoint-redir-portal enable
      end
  end

config vdom
  edit Sales
    config firewall policy
      edit 9
        set srcintf SalesVlnk
        set srcaddr SalesManagement
        set dstintf port2
        set dstaddr SalesLocal
        set schedule always
        set service OfficeServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
        set endpoint-redir-portal enable
      end
  end
```

Configuring firewall settings between the Accounting and Sales VDOMs

Firewall policies are required for any communication between each internal network and the Internet. Policies are also required for the two internal networks to communicate with each other through the management VDOM.

The more limited AccountingSalesServices group of services will be used between Sales and Accounting to ensure the traffic is necessary business traffic only. These policies will result in a partially meshed VDOM configuration. The FortiClient application must be used to ensure additional protection for the sensitive accounting information.

Two firewall policies are required to allow traffic in both directions between Sales and Accounting.

To configure the firewall policy between Sales and Accounting on the management VDOM - web-based manager

1. Open the *root* VDOM.
2. Go to *Policy* > *Policy.*
3. Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	SalesVlnk
Source Address	SalesManagement
Destination Interface/Zone	AccountVlnk
Destination Address	AccountingManagement
Schedule	always
Service	AccountingSalesServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled
Redirect Non-conforming Clients to Download Portal	enabled

4. Go to *Policy* > *Policy.*
5. Select *Create New*, enter the following information, and select *OK*.

Source Interface/Zone	AccountVlnk
Source Address	AccountingManagement
Destination Interface/Zone	SalesVlnk
Destination Address	SalesManagement
Schedule	always
Service	AccountingSalesServices
Action	ACCEPT
Protection Profile	scan
Log Allowed Traffic	enabled
Enable Endpoint Control Check	disabled
Redirect Non-conforming Clients to Download Portal	enabled

To configure the firewall policy between Sales and Accounting on the management VDOM - CLI

```
config vdom
  edit root
    config system firewall policy
      edit 9
        set srcintf SalesVlnk
        set srcaddr SalesManagement
        set dstintf AccountVlnk
        set dstaddr AccountManagement
        set schedule always
        set service AccountingSalesServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
        set endpoint-redir-portal enable
      next
      edit 10
        set srcintf AccountVlnk
        set srcaddr AccountManagement
        set dstintf SalesVlnk
        set dstaddr SalesManagement
        set schedule always
        set service AccountingSalesServices
        set action accept
        set profile-status enable
        set profile scan
        set logtraffic enable
        set endpoint-check enable
        set endpoint-redir-portal enable
      end
  end
```

Testing the configuration

Once the inter-VDOM routing has been configured, tests must be conducted to confirm proper operation. If there are any problems, use the troubleshooting tips to resolve them.

This section includes the following topics:

- Testing connectivity
- Troubleshooting Tips

Testing connectivity

Testing connectivity ensures that physical networking connections as well as FortiGate unit interface configurations, including firewall policies, are properly configured.

The easiest way to test connectivity is to use the `ping` and `traceroute` commands to confirm the connectivity of different routes on the network. Include testing:

- from AccountingLocal to Internet
- from Internet to AccountingLocal
- from SalesLocal to Internet
- from Internet to SalesLocal
- from AccountingLocal to SalesLocal.

When using the commands on a Windows computer, go to a command line prompt and enter either `ping <IP address>` or `tracert <IP address>`.

When using the commands on a FortiGate unit, go to the CLI and enter either `exec ping <IP address>` or `exec traceroute <IP address>`.

Troubleshooting Tips

When there are problems with connectivity, the following troubleshooting tips will help resolve the issues.

- If a multiple hop test, such as traceroute, is not successful then reduce it to a single hop to simplify the test. Test each link of the path to see which hop is down. If all hops are up, check the FortiGate unit policies to ensure they allow basic traffic to flow as expected.
- If ping does not work, confirm that the FortiGate unit interfaces have Ping enabled and also ensure Ping is enabled in the firewall policies. Otherwise the Ping traffic will be blocked.
- If one protocol does not work but others do work, check the FortiGate unit firewall policies for that one protocol to ensure it is allowed.
- If there are unexplained connectivity problems, check the local computer to ensure it does not have a software firewall running that may be blocking traffic. MS Windows computers have a firewall running by default that can cause problems.

For additional troubleshooting, see “Troubleshooting Virtual Domains” on page 2440.

Troubleshooting Virtual Domains

When you are configuring VDOMs you may run into some issues, with your VDOM configuration, your network configuration, or your device setup. This section addresses common problems and specific concerns that an administrator of a VDOM network may have.

This section includes:

VDOM admin having problems gaining access

With VDOMs configured, administrators have an extra layer of permissions and may have problems accessing their information.

Confirm the admin's VDOM

Each administrator account, other than the super_admin account, is tied to one specific VDOM. That administrator is not able to access any other VDOM. It may be possible they are trying to access the wrong VDOM.

Confirm the VDOM's interfaces

An administrator can only access their VDOM through interfaces that are assigned to that VDOM. If interfaces on that VDOM are disabled or unavailable there will be no method of accessing that VDOM by its local administrator. The super_admin will be required to either bring up the interfaces, fix the interfaces, or move another interface to that VDOM to restore access.

Confirm the VDOMs admin access

As with all FortiGate units, administration access on the VDOM's interfaces must be enabled for that VDOM's administrators to gain access. For example if SSH is not enabled, that is not available to administrators.

To enable admin access, the super_admin will go to the *Global* > *Network* > *Interfaces* page, and for the interface in question enable the admin access.

FortiGate unit running very slowly

You may experience a number of problems resulting from your FortiGate unit being overloaded. These problems may appear as:

- CPU and memory threshold limits exceeded on a continual basis
- AV failopen happening on a regular basis
- dropped traffic or sessions due to lack of resources

These problems are caused by a lack of system resources. There are a number of possible reasons for this.

Too many VDOMs

If you have configured many VDOMs on your system, past the default ten VDOMs, this could easily be your problem.

Each VDOM you create on your FortiGate unit requires system resources to function - CPU cycles, memory, and disk space. When there are too many VDOMs configured there are not enough resources for operation. This may be a lack of memory in the session table, or no CPU cycles for processing incoming IPS traffic, or even a full disk drive.

Go to *System* > *VDOM* and see the number of configured VDOMs on your system. If you are running 500 or more VDOMs, you must have a FortiGate 5000 chassis. Otherwise you need to reduce the number of VDOMs on your system to fix the problem. Even if you have the proper hardware, you may encounter noticeably slow throughput if you are using advanced features such as security profiles or deep content inspection with many configured VDOMs.

One or more VDOMs are consuming all the resources

If you have sufficient hardware to support the number of VDOMs you are running, check the global resources on your FortiGate unit. At a glance it will tell you if you are running out of a particular resource such as sessions, or users. If this is the case, you can then check your VDOMs to see if one particular VDOM is using more than its share of resources. If that is the case you can change the resource settings to allow that VDOM (or those VDOMs) fewer resources and in turn allow the other VDOMs access to those resources.

Too many Security Features in use

It is likely that reducing the Security Features in use regardless of number of VDOMs will greatly improve overall system performance and should be considered as an option.

Finally it is possible that your FortiGate unit configuration is incorrect in some other area, which is using up all your resources. For example, forgetting that you are running a network sniffer on an interface will create significant amounts of traffic that may prevent normal operation.

General VDOM tips and troubleshooting

Besides ping and traceroute, there are additional tools for troubleshooting your VDOM configurations. These include packet sniffing and debugging the packet flow.

Perform a sniffer trace

When troubleshooting networks, it helps to look inside the headers of packets to determine if they are traveling along the route you expect that they are. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your FortiGate unit has NP interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP interfaces, you should disable offloading on those interfaces.

What sniffing packets can tell you

If you are running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the FortiGate unit, if the ARP resolution is correct, and if the traffic is being sent back to the source as expected.

Sniffing packets can also tell you if the Fortigate unit is silently dropping packets for reasons such as RPF (Reverse Path Forwarding), also called Anti Spoofing, which prevents an IP packet from being forwarded if its Source IP does not either belong to a locally attached subnet (local interface), or be part of the routing between the FortiGate and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymmetric enable`), however this will disable stateful inspection on the FortiGate unit and cause many features to be turned off.

Note If you configure virtual IP addresses on your Fortigate unit, it will use those addresses in preference to the physical IP addresses. You will notice this when you are sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

How to sniff packets

When you are using VDOMs, you must be in a VDOM to access the `diag sniffer` command. At the global level, the command is not available. This is limit the packets only to the ones on your VDOM, and protects the privacy of other VDOM clients.

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose> <count>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as “port1” or “internal”. This can also be “any” to sniff all interfaces.
<‘filter’>	What to look for in the information the sniffer reads. “none” indicates no filtering, and all packets will be displayed as the other arguments indicate. The filter must be inside single quotes (‘).
<verbose>	The level of verbosity as one of: **1 -** print header of packets **2 -** print header and data from IP of packets **3 -** print header and data from Ethernet of packets
<count>	The number of packets the sniffer reads before stopping. If you don’t put a number here, the sniffer will run forever unit you stop it with <CTRL C>.

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next 3 packets on the port1 interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]
0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955
     ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757
     ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614
     ack 3314279933
```

For a more advanced example of packet sniffing, the following commands will report packets on any interface travelling between a computer with the host name of `PC1` and the computer with the host name of `PC2`. With verbosity 4 and above, the sniffer trace will display the interface names where traffic enters or leaves the FortiGate unit. Remember to stop the sniffer, type `CTRL+C`. Note that `PC1` and `PC2` may be VDOMs.

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2>" 4
```

or

```
FGT# diagnose sniffer packet any "(host <PC1> or host <PC2>) and
     icmp" 4
```

The following sniffer CLI command includes the ARP protocol in the filter which may be useful to troubleshoot a failure in the ARP resolution (for instance PC2 may be down and not responding to the FortiGate ARP requests).

```
FGT# diagnose sniffer packet any "host <PC1> or host <PC2> or arp" 4
```

Debugging the packet flow

Traffic should come in and leave the VDOM. If you have determined that network traffic is not entering and leaving the VDOM as expected, debug the packet flow.

Debugging can only be performed using CLI commands. Debugging the packet flow requires a number of debug commands to be entered as each one configures part of the debug action, with the final command starting the debug.

If your FortiGate unit has NP interfaces that are offloading traffic, this will change the packet flow. Before performing the debug on any NP interfaces, you should disable offloading on those interfaces.

The following configuration assumes that `PC1` is connected to the internal interface of the FortiGate unit and has an IP address of `10.11.101.200`. `PC1` is the host name of the computer.

To debug the packet flow in the CLI, enter the following commands:

```
FGT# diag debug enable
FGT# diag debug flow filter add <PC1>
FGT# diag debug flow show console enable
FGT# diag debug flow trace start 100
FGT# diag debug enable
```

The `start 100` argument in the above list of commands will limit the output to 100 packets from the flow. This is useful for looking at the flow without flooding your log or your display with too much information.

To stop all other debug activities, enter the command:

```
FGT# diag debug flow trace stop
```

The following is an example of debug flow output for traffic that has no matching Firewall Policy, and is in turn blocked by the FortiGate unit. The denied message indicates the traffic was blocked. Note that even with VDOMs not enabled, vd-root is still shown.

```
id=20085 trace_id=319 func=resolve_ip_tuple_fast line=2825
     msg="vd-root received a packet(proto=6,
     192.168.129.136:2854->192.168.96.153:1863) from port3."

id=20085 trace_id=319 func=resolve_ip_tuple line=2924 msg="allocate
     a new session-013004ac"

id=20085 trace_id=319 func=vf_ip4_route_input line=1597 msg="find a
     route: gw-192.168.150.129 via port1"

id=20085 trace_id=319 func=fw_forward_handler line=248 msg=" Denied
     by forward policy check"
```

Chapter 20 Virtual FortiGate Units for FortiOS 5.0

This document describes how to deploy a FortiGate virtual appliance in several virtualization server environments. This includes how to configure the virtual hardware settings of the virtual appliance.

This document assumes:

- you have already successfully installed the virtualization server on the physical machine,
- you have installed appropriate VM management software on either the physical server or a computer to be used for VM management.

This document does not cover configuration and operation of the virtual appliance after it has been successfully installed and started. For these issues, see the *FortiGate 5.0 Handbook*.

This document includes the following sections:

FortiGate VM Overview

The following topics are included in this section:

FortiGate VM models and licensing

Fortinet offers the FortiGate VM in five virtual appliance models determined by license. When configuring your FortiGate VM, be sure to configure hardware settings within the ranges outlined in Table 111. Contact your Fortinet Authorized Reseller for more information.

Table 111: FortiGate VM model information

Technical Specification	FG-VM00	FG-VM01	FG-VM02	FG-VM04	FG-VM08
Virtual CPUs (min/max)	1/1	1/1	1/2	1/4	1/8
Virtual Network Interfaces (min/max)	2 / 10				
Virtual Memory (min/max)	1 GB / 1 GB	1 GB / 2 GB	1 GB / 4 GB	1 GB / 6 GB	1 GB / 12 GB
Virtual Storage (min/max)	30 GB / 2 TB				
Managed Wireless Access Points (tunnel mode / global)	32 / 32	32 / 64	256 / 512	256 / 512	1024 / 4096
Virtual Domains (default / max)	1 / 1	10 / 10	10 / 25	10 / 50	10 / 250

After placing an order for FortiGate VM, a license registration code is sent to the email address used on the order form. Use the registration number provided to register the FortiGate VM with Customer Service & Support and then download the license file. Once the license file is uploaded to the FortiGate VM and validated, your FortiGate VM appliance is fully functional.

FortiGate VM evaluation license

FortiGate VM includes a limited embedded 15-day trial license that supports:

- 1 CPU maximum
- 1024 MB memory maximum
- low encryption only (no HTTPS administrative access)
- all features except FortiGuard updates

You cannot upgrade the firmware, doing so will lock the Web-based Manager until a license is uploaded. Technical support is not included. The trial period begins the first time you start

FortiGate VM. After the trial license expires, functionality is disabled until you upload a license file.

Registering FortiGate VM with Customer Service & Support

To obtain the FortiGate VM license file you must first register your FortiGate VM with Customer Service & Support.

To register your FortiGate VM:

1. Log in to the Customer Service & Support portal using an existing support account or select *Sign Up* to create a new account.
2. In the main page, under *Asset*, select *Register/Renew*.

   The *Registration* page opens.
3. Enter the registration code that was emailed to you and select *Register*. A registration form will display.
4. After completing the form, a registration acknowledgement page will appear.
5. Select the *License File Download* link.
6. You will be prompted to save the license file (`.lic`) to your local computer. See "Upload the FortiGate VM license file" on page 2484 for instructions on uploading the license file to your FortiGate VM via the Web-based Manager.

Downloading the FortiGate VM deployment package

FortiGate VM deployment packages are included with FortiGate firmware images on the Customer Service & Support site. First, see Table 112 to determine the appropriate VM deployment package for your VM platform.

Table 112: Selecting the correct FortiGate VM deployment package for your VM platform

VM Platform	FortiGate VM Deployment File
Citrix XenServer v5.6sp2, 6.0 and later	FGT_VM64-v500-buildnnnn-FORTINET.out.CitrixXen.zip
OpenXen v3.4.3, 4.1	FGT_VM64-v500-buildnnnn-FORTINET.out.OpenXen.zip
Microsoft Hyper-V Server 2008R2 and 2012	FGT_VM64-v500-buildnnnn-FORTINET.out.hyperv.zip
KVM (qemu 0.12.1)	FGT_VM64-v500-buildnnnn-FORTINET.out.kvm.zip
VMware ESX 4.0, 4.1 ESXi 4.0/4.1/5.0/5.1/5.5	FGT_VM32-v500-buildnnnn-FORTINET.out.ovf.zip (32-bit) FGT_VM64-v500-buildnnnn-FORTINET.out.ovf.zip

For more information see the FortiGate product datasheet available on the Fortinet web site, http://www.fortinet.com/products/fortigate/virtualappliances.html.

The firmware images FTP directory is organized by firmware version, major release, and patch release. The firmware images in the directories follow a specific naming convention and each firmware image is specific to the device model. For example, the FGT_VM32-v500-build0151-FORTINET.out.ovf.zip image found in the v5.0 Patch Release 2 directory is specific to the FortiGate VM 32-bit environment.

You can also download the *FortiOS Release Notes*, FORTINET-FORTIGATE MIB file, FSSO images, and SSL VPN client in this directory. The Fortinet Core MIB file is located in the main FortiGate v5.00 directory.

To download the FortiGate VM deployment package:

1. In the main page of the Customer Service & Support site, select *Download* > *Firmware Images*.

   The *Firmware Images* page opens.
2. In the *Firmware Images* page, select *FortiGate*.
3. Browse to the appropriate directory on the FTP site for the version that you would like to download.
4. Download the appropriate `.zip` file for your VM server platform.

   You can also download the *FortiGate Release Notes*.
5. Extract the contents of the deployment package to a new file folder.

Deployment package contents

Citrix XenServer

The FORTINET.out.CitrixXen.zip file contains:

- fortios.vhd: the FortiGate VM system hard disk in VHD format
- fortios.xva: binary file containing virtual hardware configuration settings
- in the ovf folder:
  - FortiGate-VM64.ovf: Open Virtualization Format (OVF) template file, containing virtual hardware settings for Xen
  - fortios.vmdk: the FortiGate VM system hard disk in VMDK format
  - datadrive.vmdk: the FortiGate VM log disk in VMDK format

The ovf folder and its contents is an alternative method of installation to the .xva and VHD disk image.

OpenXEN

The FORTINET.out.OpenXen.zip file contains only fortios.qcow2, the FortiGate VM system hard disk in qcow2 format. You will need to manually:

- create a 30GB log disk
- specify the virtual hardware settings

Microsoft Hyper-V

The FORTINET.out.hyperv.zip file contains:

- in the Virtual Hard Disks folder:
  - fortios.vhd: the FortiGate VM system hard disk in VHD format
  - DATADRIVE.vhd: the FortiGate VM log disk in VHD format
- In the Virtual Machines folder:
  - fortios.xml: XML file containing virtual hardware configuration settings for Hyper-V. This is compatible with Windows Server 2012.
- Snapshots folder: optionally, Hyper-V stores snapshots of the FortiGate VM state here

KVM

The FORTINET.out.kvm.zip contains only fortios.qcow2, the FortiGate VM system hard disk in qcow2 format. You will need to manually:

- create a 30GB log disk
- specify the virtual hardware settings

VMware ESX/ESXi

The FORTINET.out.ovf.zip file contains:

- fortios.vmdk: the FortiGate VM system hard disk in VMDK format
- datadrive.vmdk: the FortiGate VM log disk in VMDK format
- Open Virtualization Format (OVF) template files:
  - FortiGate-VM64.ovf: OVF template based on Intel e1000 NIC driver
  - FortiGate-VM64.hw04.ovf: OVF template file for older (v3.5) VMware ESX server
  - FortiGate-VMxx.hw07_vmxnet2.ovf: OVF template file for VMware vmxnet2 driver
  - FortiGate-VMxx.hw07_vmxnet3.ovf: OVF template file for VMware vmxnet3 driver

Deploying the FortiGate VM appliance

Prior to deploying the FortiGate VM appliance, the VM platform must be installed and configured so that it is ready to create virtual machines. The installation instructions for FortiGate VM assume that

- You are familiar with the management software and terminology of your VM platform.
- An Internet connection is available for FortiGate VM to contact FortiGuard to validate its license or, for closed environments, a FortiManager can be contacted to validate the FortiGate VM license. See “Validate the FortiGate VM license with FortiManager” on page 2485.

For assistance in deploying FortiGate VM, refer to the deployment chapter in this guide that corresponds to your VMware environment. You might also need to refer to the documentation provided with your VM server. The deployment chapters are presented as examples because for any particular VM server there are multiple ways to create a virtual machine. There are command line tools, APIs, and even alternative graphical user interface tools.

Before you start your FortiGate VM appliance for the first time, you might need to adjust virtual disk sizes and networking settings. The first time you start FortiGate VM, you will have access only through the console window of your VM server environment. After you configure one

FortiGate network interface with an IP address and administrative access, you can access the FortiGate VM web-based manager.

After deployment and license validation, you can upgrade your FortiGate VM appliance's firmware by downloading either FGT_VM32-v500-buildnnnn-FORTINET.out (32-bit) or FGT_VM64-v500-buildnnnn-FORTINET.out (64-bit) firmware. Firmware upgrading on a VM is very similar to upgrading firmware on a hardware FortiGate unit.

Deployment example: VMware

Once you have downloaded the FGT_VMxx-v500-build0xxx-FORTINET.out.ovf.zip file and extracted the package contents to a folder on your local computer, you can use the vSphere client to create the virtual machine from the deployment package OVF template.

The following topics are included in this section:

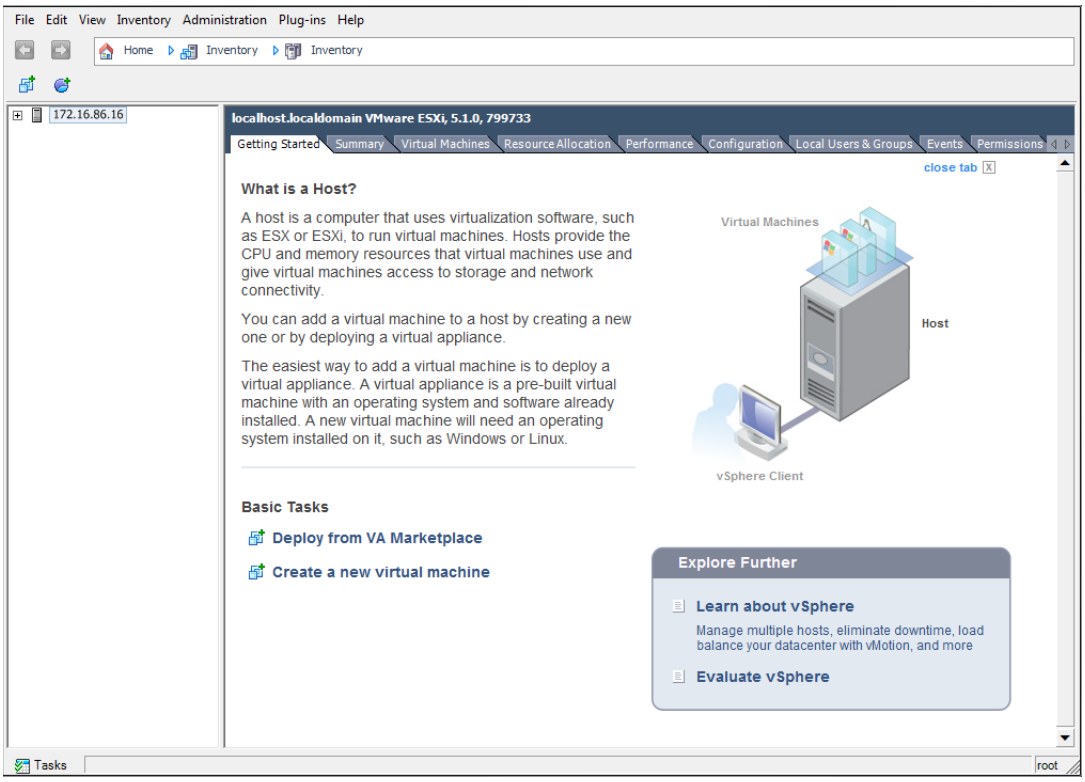
- Open the FortiGate VM OVF file with the vSphere client
- Configure FortiGate VM hardware settings
- Power on your FortiGate VM

Open the FortiGate VM OVF file with the vSphere client

To deploy the FortiGate VM OVF template:

1. Launch the VMware vSphere client, enter the IP address or host name of your server, enter your user name and password and select *Login*.

   The vSphere client home page opens.

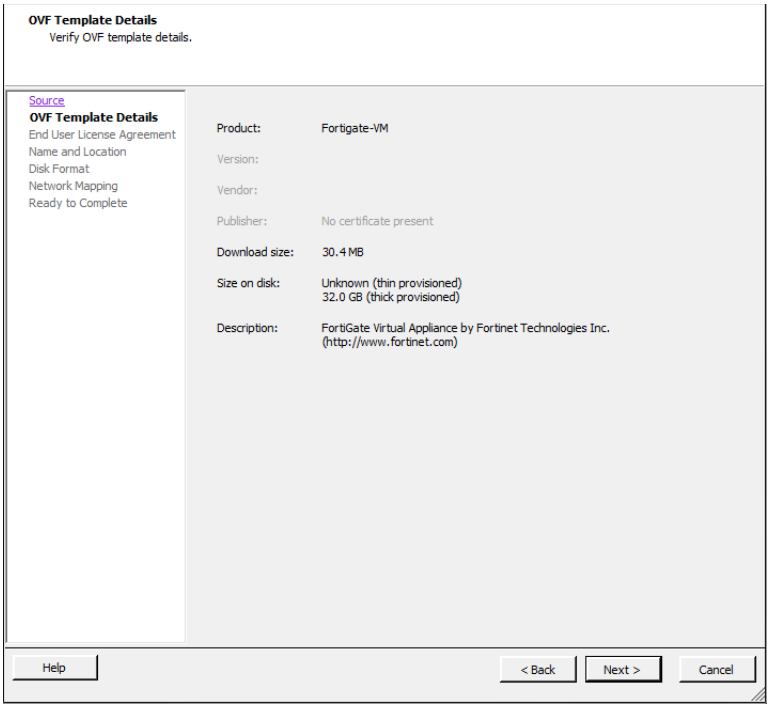


2. Select *File* > *Deploy OVF Template* to launch the OVF Template wizard.

   The OVF Template *Source* page opens.

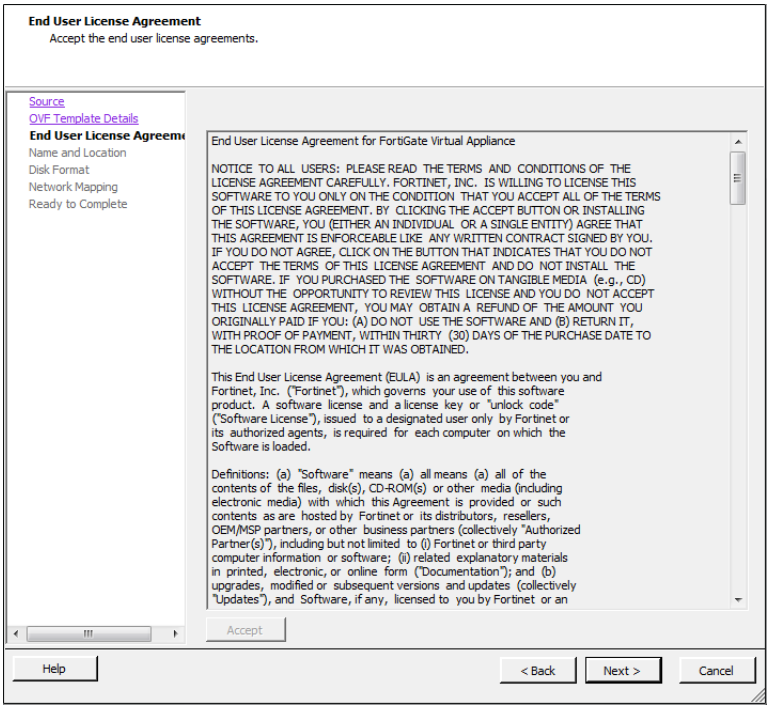
3. Select the source location of the OVF file. Select *Browse* and locate the OVF file on your computer. Select *Next* to continue.

   The OVF Template *Details* page opens.



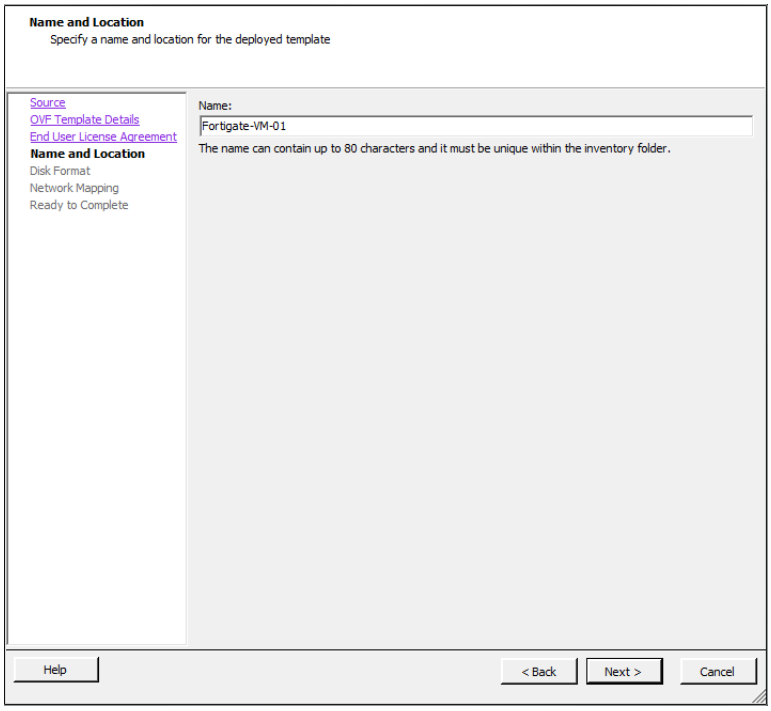
4. Verify the OVF template details. This page details the product name, download size, size on disk, and description. Select *Next* to continue.

   The OVF Template *End User License Agreement* page opens.



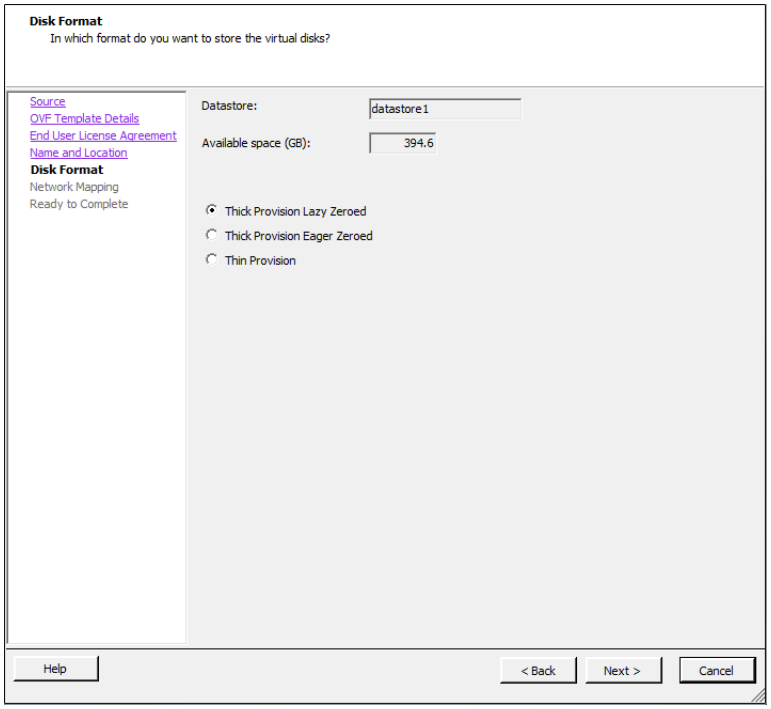
5. Read the end user license agreement for FortiGate VM. Select *Accept* and then select *Next* to continue.

The OVF Template *Name and Location* page opens.



6. Enter a name for this OVF template. The name can contain up to 80 characters and it must be unique within the inventory folder. Select *Next* to continue.

   The OVF Template *Disk Format* page opens.



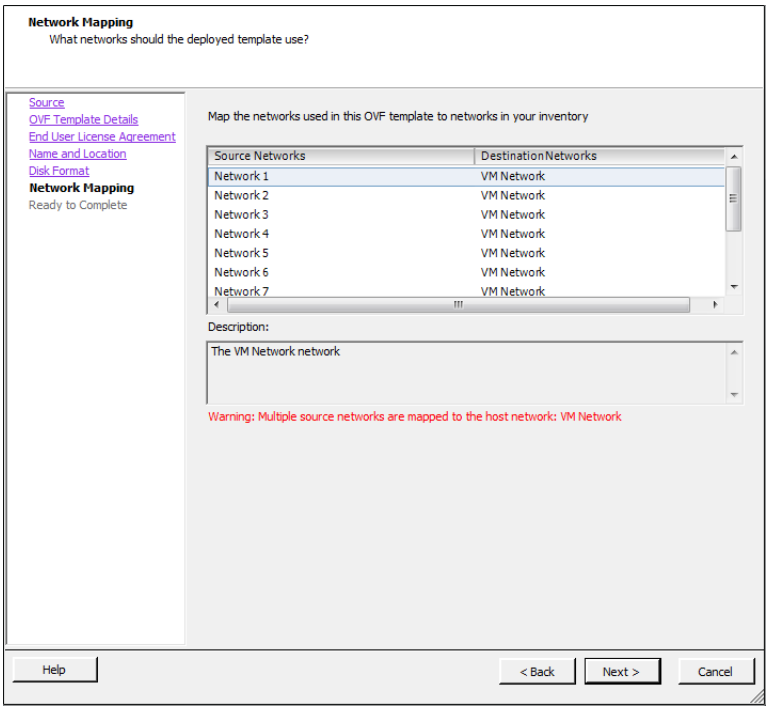
7. Select one of the following:

   - *Thick Provision Lazy Zeroed*: Allocates the disk space statically (no other volumes can take the space), but does not write zeros to the blocks until the first write takes place to that block during runtime (which includes a full disk format).

- *Thick Provision Eager Zeroed*: Allocates the disk space statically (no other volumes can take the space), and writes zeros to all the blocks.
- *Thin Provision*: Allocates the disk space only when a write occurs to a block, but the total volume size is reported by VMFS to the OS. Other volumes can take the remaining space. This allows you to float space between your servers, and expand your storage when your size monitoring indicates there is a problem. Note that once a Thin Provisioned block is allocated, it remains on the volume regardless if you have deleted data, etc.

8. Select *Next* to continue.

   The OVF Template *Network Mapping* page opens.



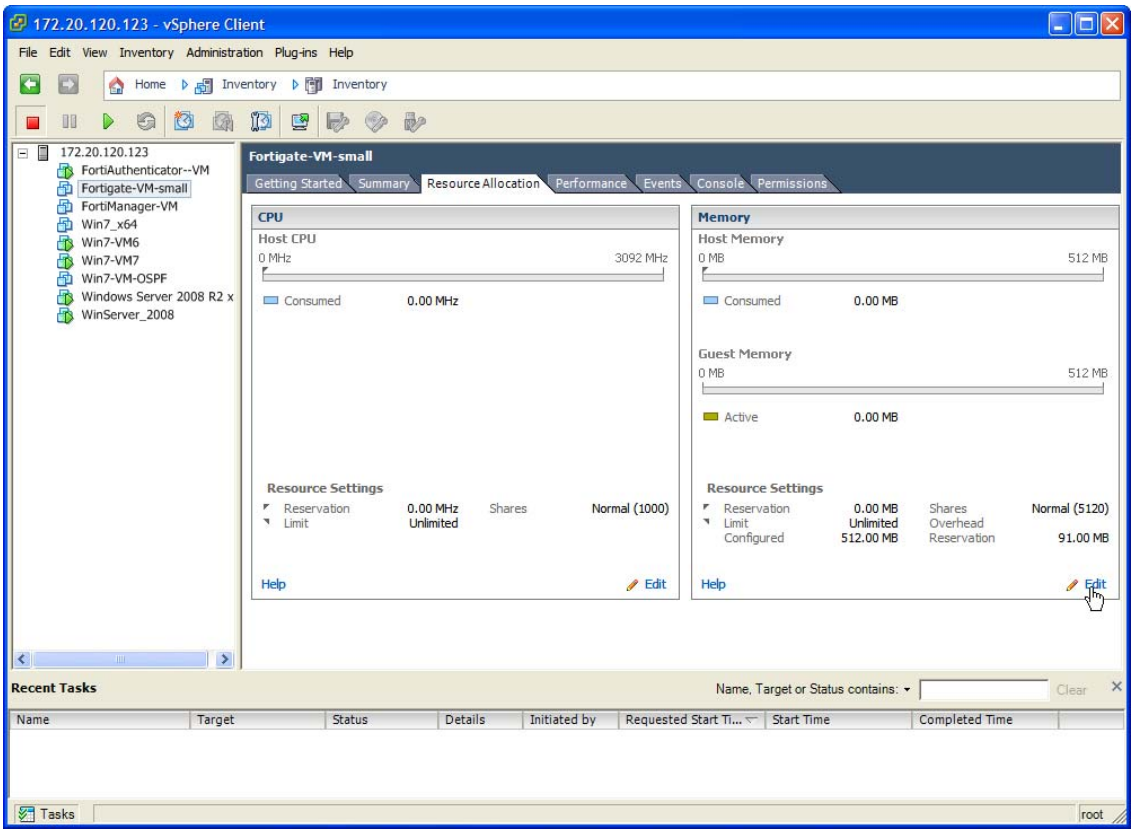
9. Map the networks used in this OVF template to networks in your inventory. Network 1 maps to port1 of the FortiGate VM. You must set the destination network for this entry to access the device console. Select *Next* to continue.

   The OVF Template *Ready to Complete* page opens.

10. Review the template configuration. Make sure that *Power on after deployment* is not enabled. You might need to configure the FortiGate VM hardware settings prior to powering on the FortiGate VM.
11. Select *Finish* to deploy the OVF template. You will receive a *Deployment Completed Successfully* dialog box once the FortiGate VM OVF template wizard has finished.

Configure FortiGate VM hardware settings

Before powering on your FortiGate VM you must configure the virtual memory, virtual CPU, and virtual disk configuration to match your FortiGate VM license. See Table 111 on page 2446 for FortiGate VM model information.



Transparent mode configuration

If you want to use your FortiGate-VM in transparent mode, your VMware server's virtual switches must operate in promiscuous mode. This permits these interfaces to receive traffic that will pass through the FortiGate unit but was not addressed to the FortiGate unit.

In VMware, promiscuous mode must be explicitly enabled:

1. In the vSphere client, select your VMware server in the left pane and then select the *Configuration* tab in the right pane.
2. In *Hardware*, select *Networking*.
3. Select *Properties* of vSwitch0.
4. In the *Properties* window left pane, select *vSwitch* and then select *Edit*.
5. Select the *Security* tab, set *Promiscuous Mode* to *Accept*, then select *OK*.
6. Select *Close*.
7. Repeat steps 3 through 6 for other vSwitches that your transparent mode FortiGate-VM uses.

Power on your FortiGate VM

You can now proceed to power on your FortiGate VM. There are several ways to do this:

- Select the name of the FortiGate VM you deployed in the inventory list and select *Power on the virtual machine* in the *Getting Started* tab.
- In the inventory list, right-click the name of the FortiGate VM you deployed, and select *Power* > *Power On*.
- Select the name of the FortiGate VM you deployed in the inventory list. Click the *Power On* button on the toolbar.

Select the Console tab to view the console. To enter text, you must click in the console pane. The mouse is then captured and cannot leave the console screen. As the FortiGate console is text-only, no mouse pointer is visible. To release the mouse, press Ctrl-Alt.

Deployment example: MS Hyper-V

Once you have downloaded the `.hyperv.zip` file and extracted the package contents to a folder on your Microsoft server, you can deploy the VHD package to your Microsoft Hyper-V environment.

The following topics are included in this section:

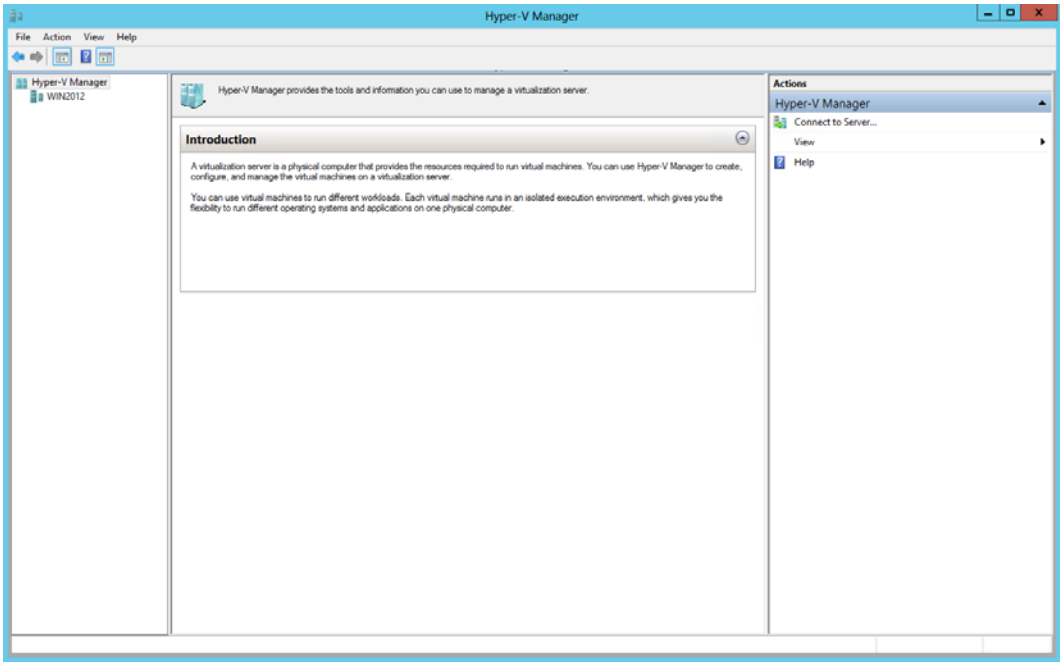
- Create the FortiGate VM virtual machine
- Configure FortiGate VM hardware settings
- Start the FortiGate VM

Create the FortiGate VM virtual machine

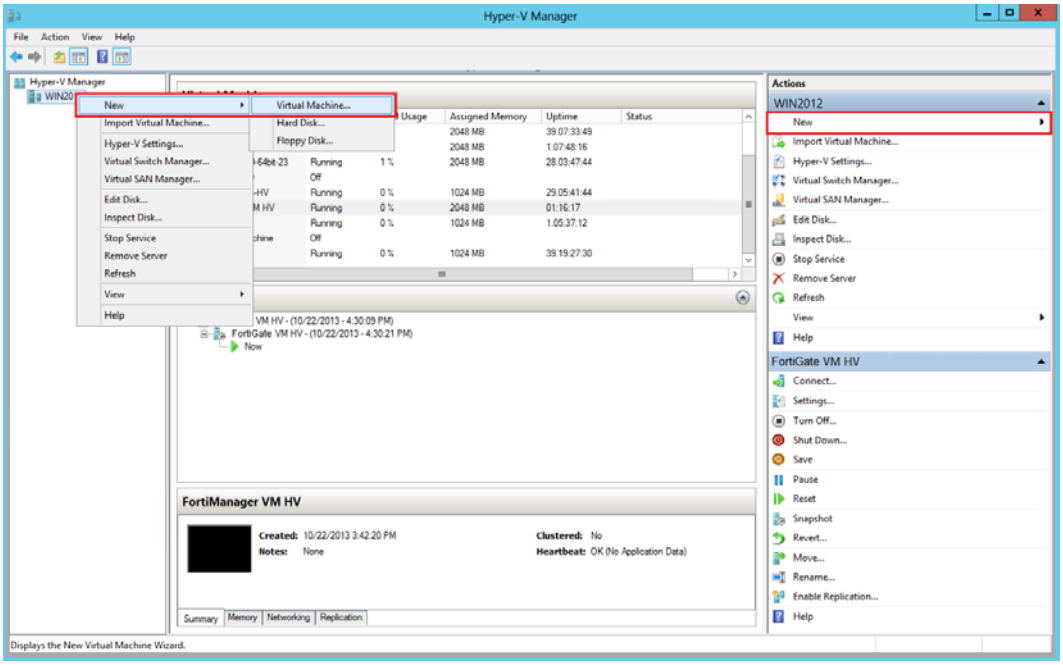
To create the FortiGate VM virtual machine:

1. Launch the Hyper-V Manager in your Microsoft server.

   The *Hyper-V Manager* home page opens.

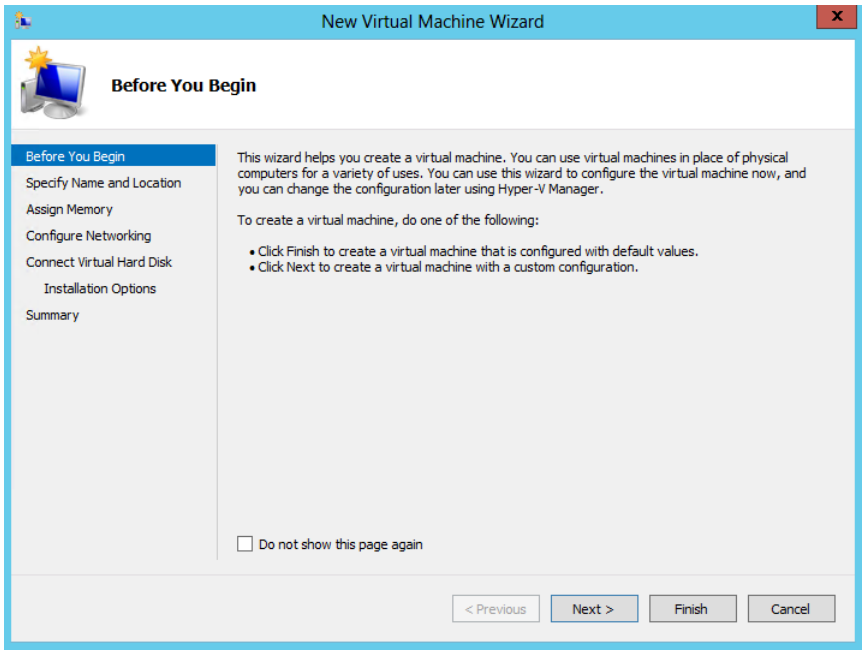


2. Select the server in the right-tree menu. The server details page is displayed.



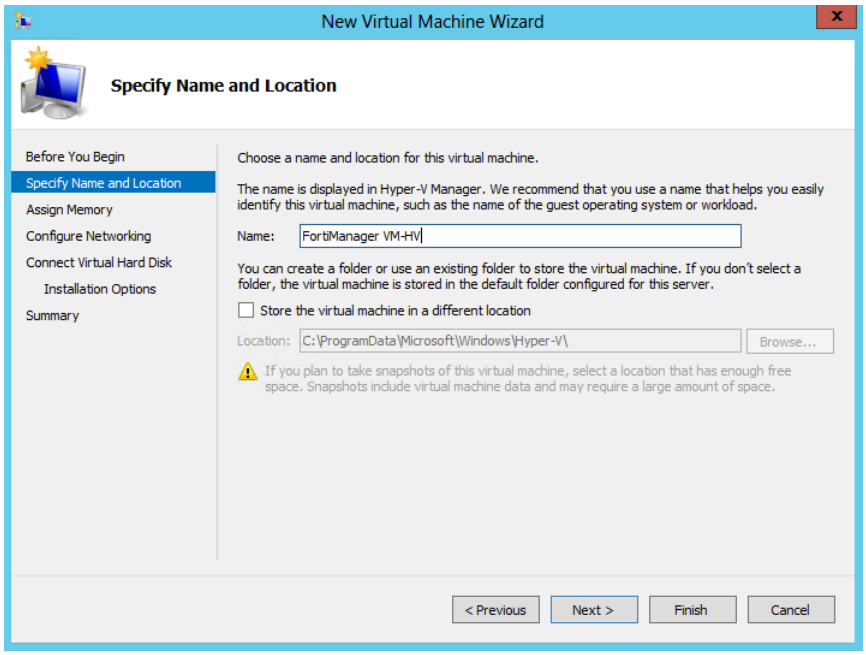
3. Right-click the server and select *New* and select *Virtual Machine* from the menu. Optionally, in the *Actions* menu, select *New* and select *Virtual Machine* from the menu.

The *New Virtual Machine Wizard* opens.



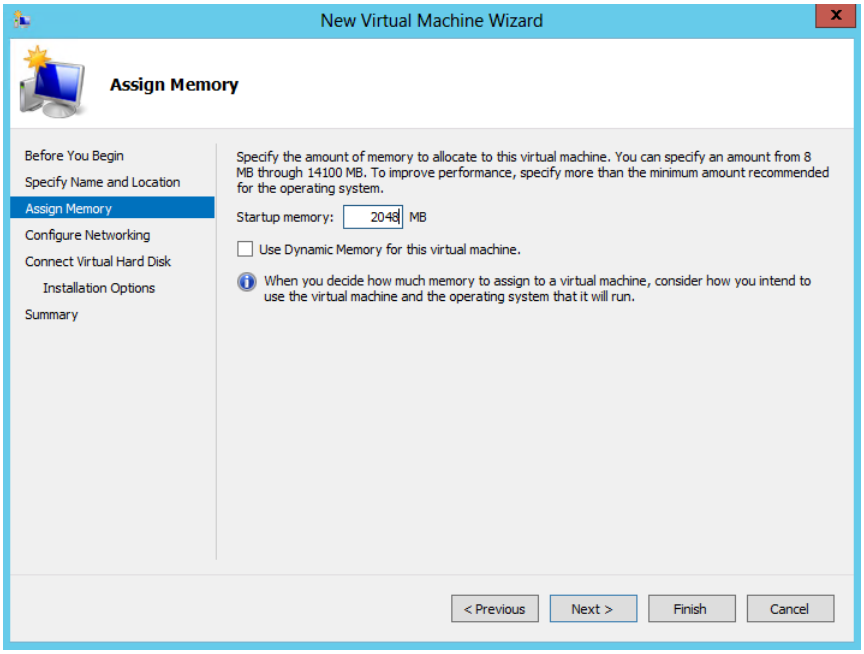
4. Select *Next* to create a virtual machine with a custom configuration.

   The *Specify Name and Location* page is displayed.



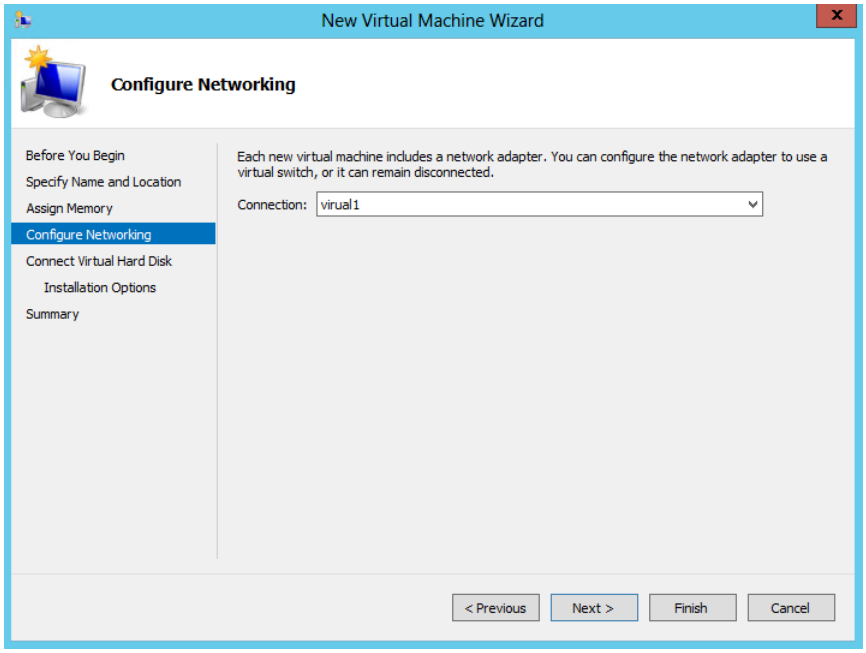
5. Enter a name for this virtual machine. The name is displayed in the Hyper-V Manager.

   Select *Next* to continue. The *Assign Memory* page is displayed.



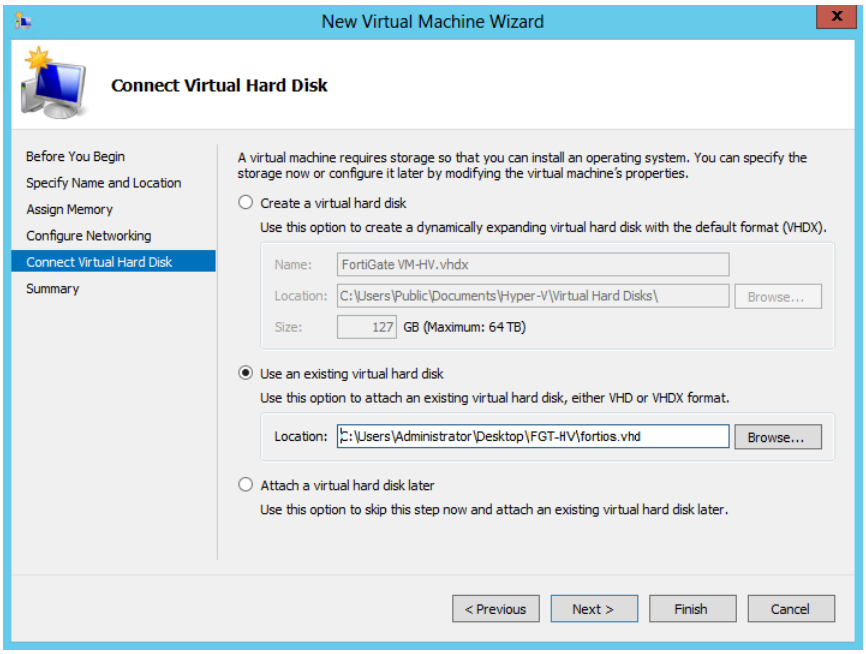
6. Specify the amount of memory to allocate to this virtual machine. The default memory for FortiGate VM is 1GB (1024MB).

   Select *Next* to continue. The *Configure Networking* page is displayed.



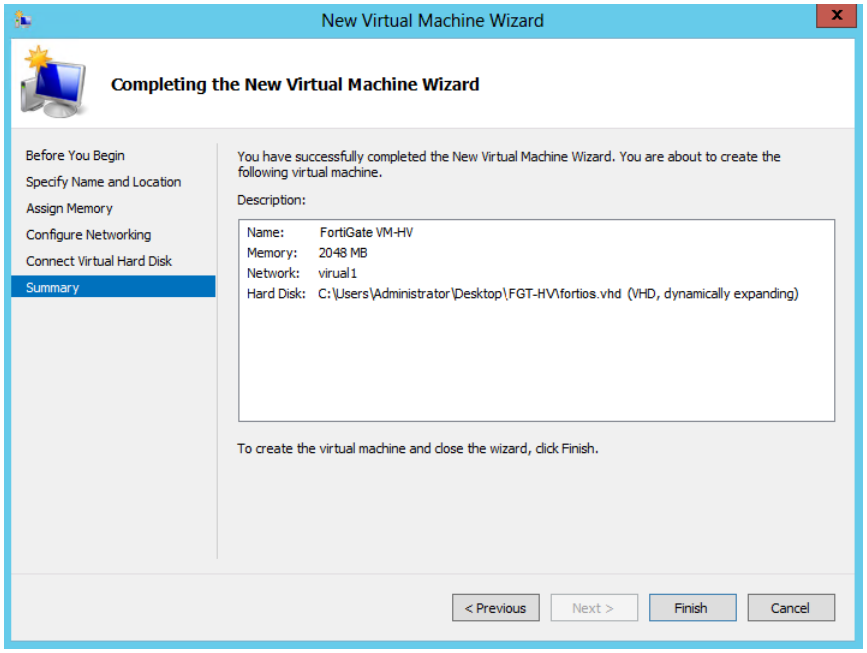
7. Each new virtual machine includes a network adapter. You can configure the network adapter to use a virtual switch, or it can remain disconnected. FortiGate VM requires four network adapters. You must configure network adapters in the *Settings* page.

   Select *Next* to continue. The *Connect Virtual Hard Disk* page is displayed.



8. Select to use an existing virtual hard disk and browse for the `fmg.vhd` file that you downloaded from the Fortinet Customer Service & Support portal.

   Select *Next* to continue. The *Summary* page is displayed.



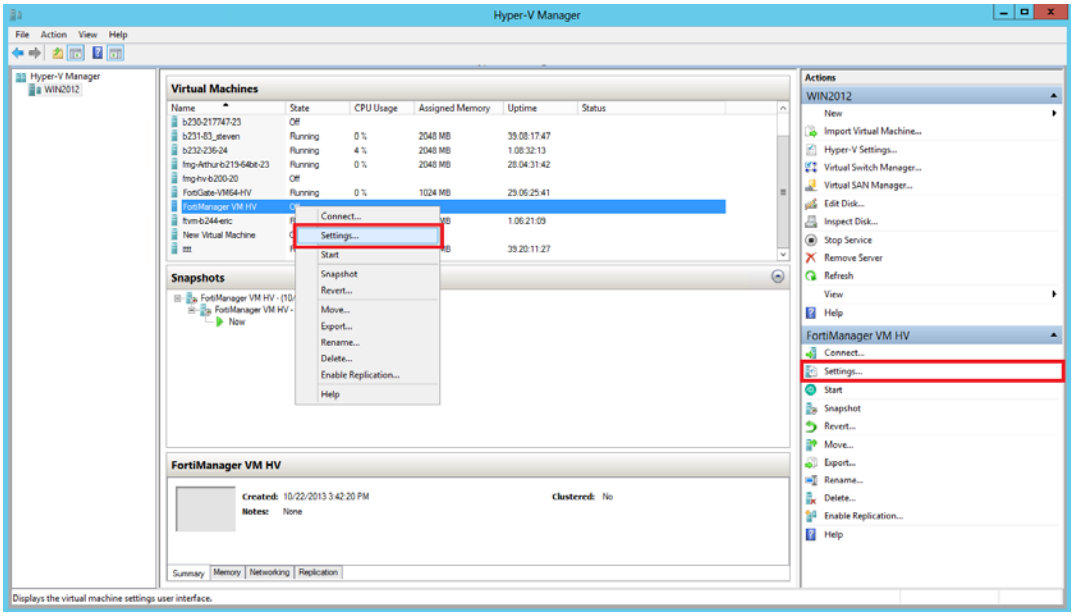
9. To create the virtual machine and close the wizard, select *Finish*.

Configure FortiGate VM hardware settings

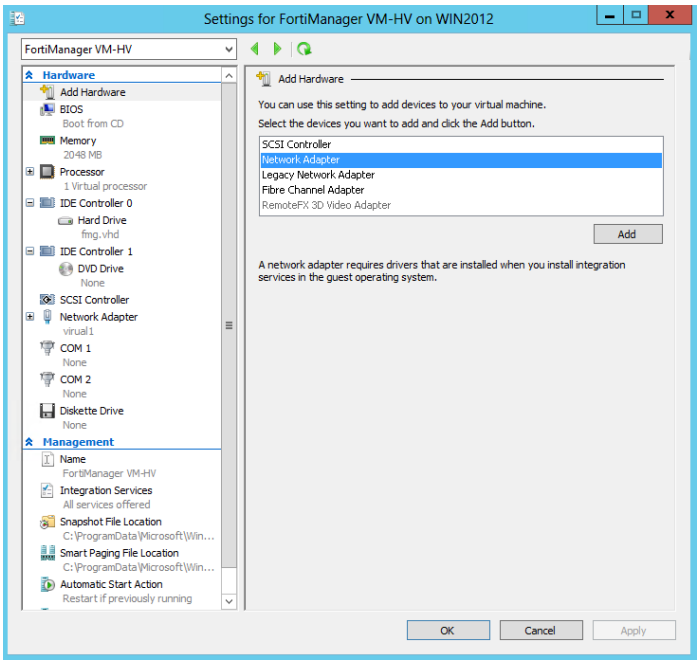
Before powering on your FortiGate VM you must configure the virtual memory, virtual CPU, and virtual disk configuration to match your FortiGate VM license. See Table 111 on page 2446 for FortiGate VM model information.

To configure settings for FortiGate VM on the server:

1. In the Hyper-V Manager, locate the name of the virtual machine, right-click the entry, and select *Settings* from the menu. Optionally, you can select the virtual machine and select *Settings* in the *Actions* menu.



The *Settings* page is displayed.



2. Configure virtual processors, network adapters, and virtual hard drive settings.
3. Select *Apply* to save the settings and then select *OK* to close the settings page.

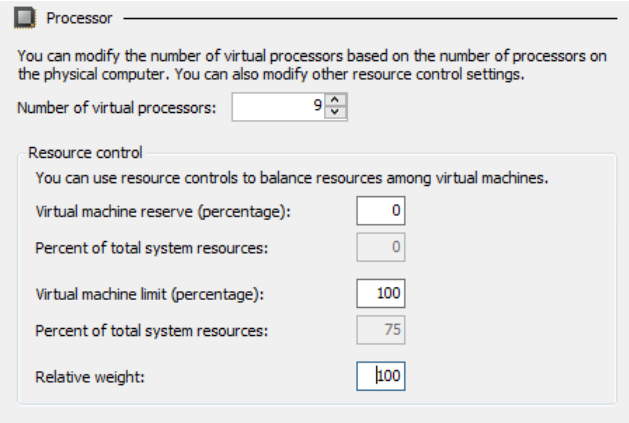
FortiGate VM virtual processors

You must configure FortiGate VM virtual processors in the server settings page. The number of processors is dependent on your server environment.

Configure FortiGate VM virtual processors:

1. In the *Settings* page, select *Processor* from the *Hardware* menu.

   The *Processor* page is displayed.



2. Configure the number of virtual processors for the FortiGate VM virtual machine. Optionally, you can use resource controls to balance resources among virtual machines.
3. Select *Apply* to save the settings.

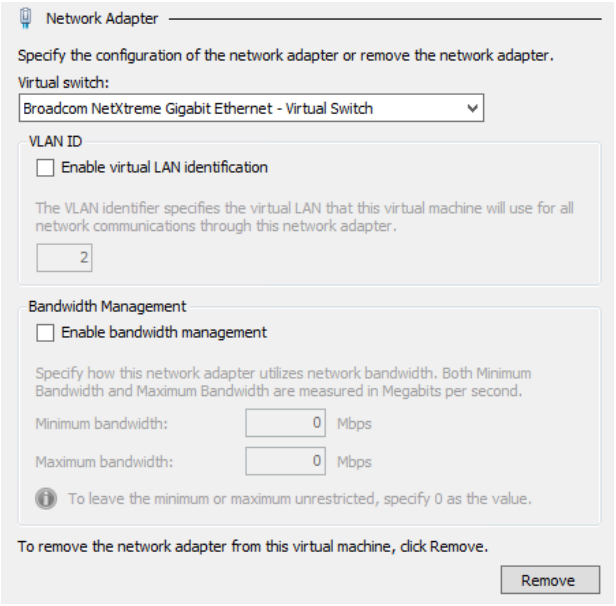
FortiGate VM network adapters

You must configure FortiGate VM network adapters in the server settings page. FortiGate VM supports four network adapters.

Configure FortiGate VM network adapters:

1. In the *Settings* page, select *Add Hardware* from the *Hardware* menu, select *Network Adapter* in the device list, and select the *Add* button.

   The *Network Adapter* page is displayed.



2. You must manually configure four network adapters for FortiGate VM in the settings page. For each network adapter, select the virtual switch from the drop-down list.
3. Select *Apply* to save the settings.

FortiGate VM virtual hard disk

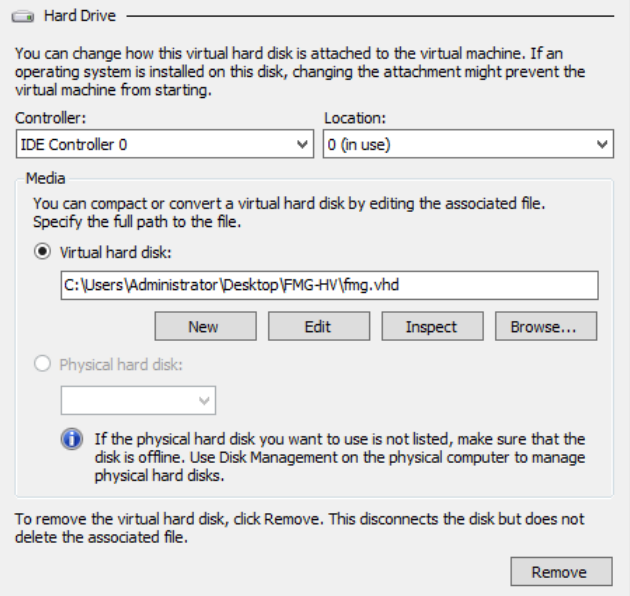
You must configure the FortiGate VM virtual hard disk in the server settings page.

If you know your environment will expand in the future, it is recommended to increase the hard disk size beyond 30GB. The VM license limit is 2TB.

Configure a FortiGate VM virtual hard drive:

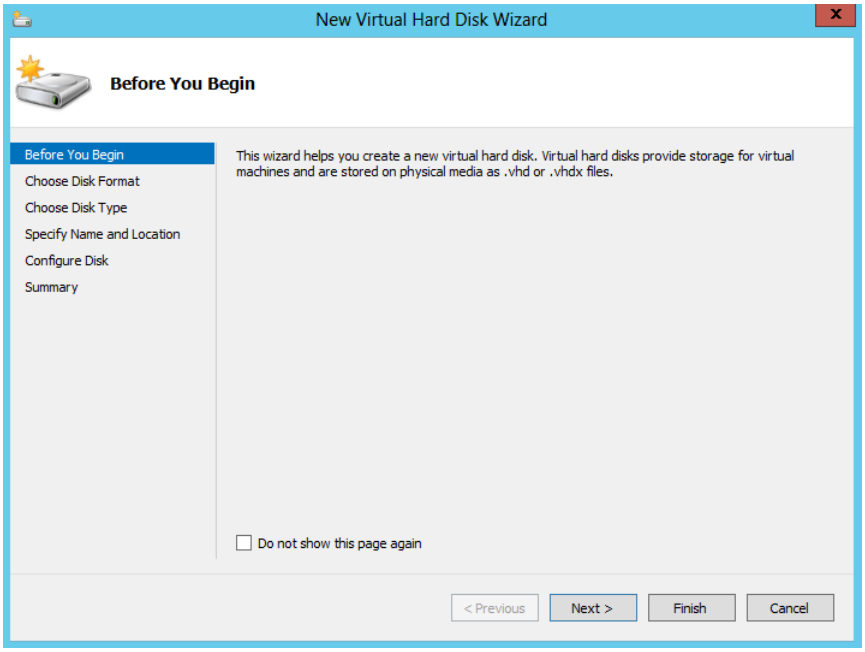
1. In the *Settings* page, select *IDE Controller 0* > *Hard Drive* from the *Hardware* menu.

   The *Hard Drive* page is displayed.



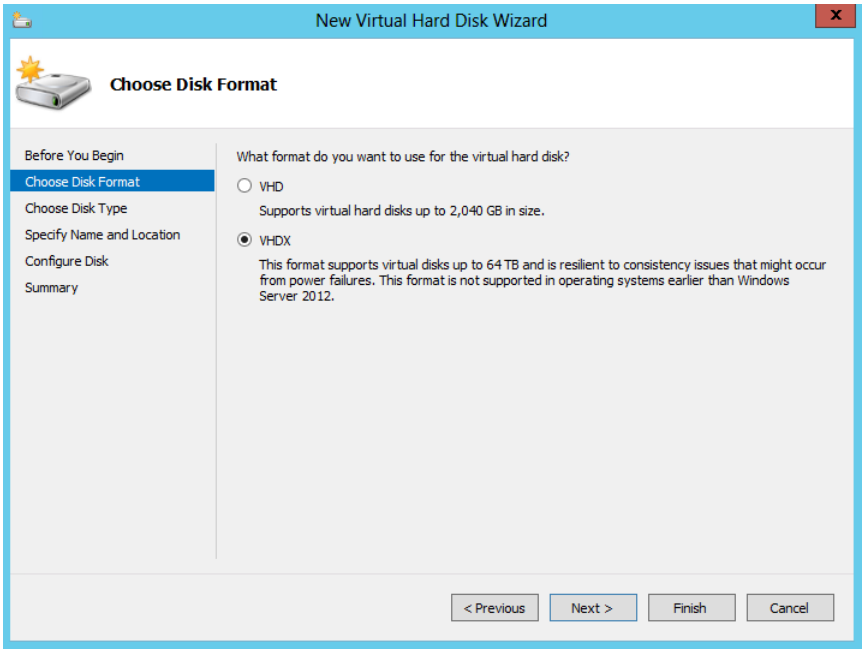
2. Select *New* to create a new virtual hard disk.

   The *New Virtual Hard Disk Wizard* opens.



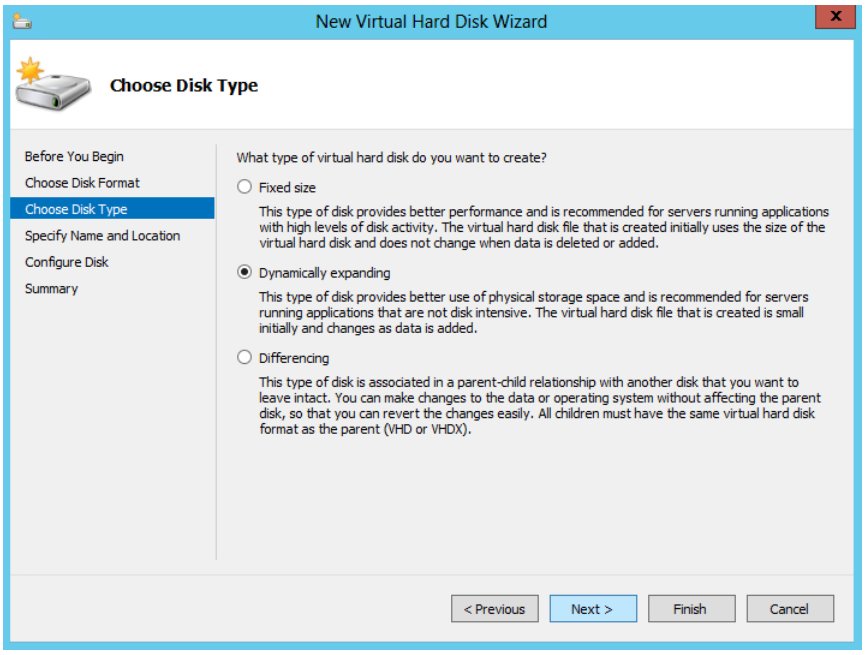
3. This wizard helps you to create a new virtual hard disk.

   Select *Next* to continue. The *Choose Disk Format* page opens.



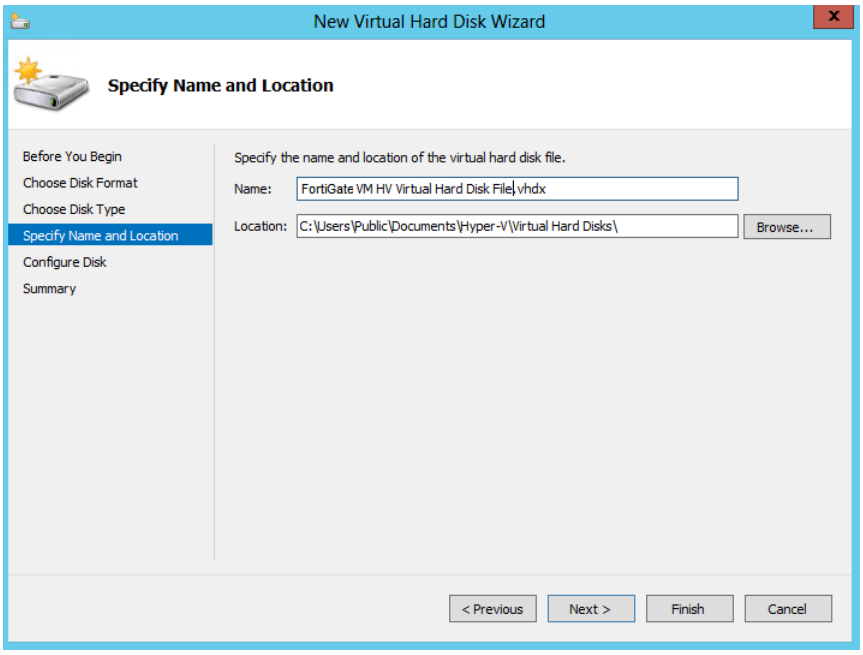
4. Select to use VHDX format virtual hard disks. This format supports virtual disks up to 64TB and is resilient to consistency issues that might occur from power failures. This format is not supported in operating systems earlier than Windows Server 2012. Note that FortiGate-VM does not support hard disks larger than 2TB.

Select *Next* to continue. The *Choose Disk Type* page opens.



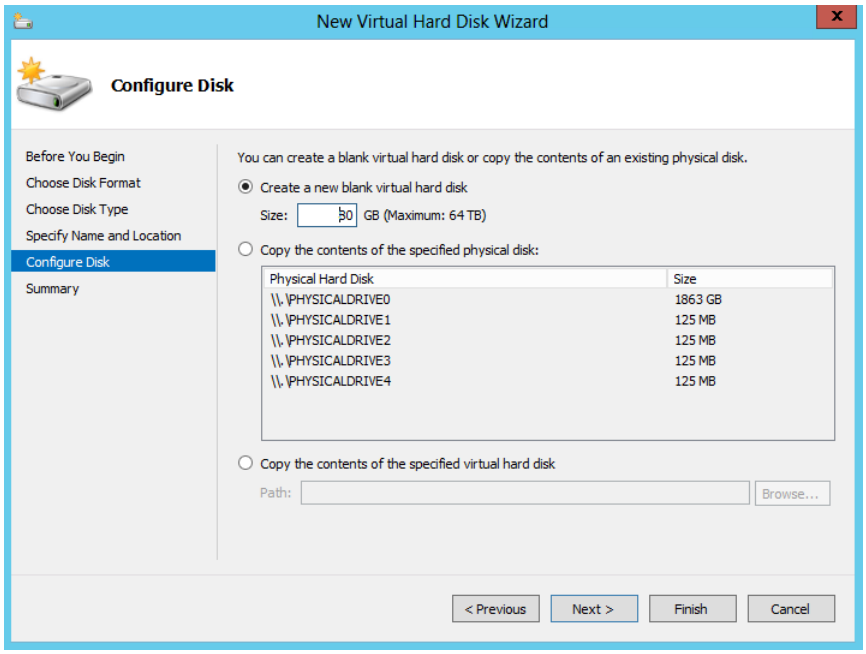
5. Select the type of virtual disk you want to use. Select one of the following disk types:
   - Fixed size: This type of disk provides better performance and is recommended for servers running applications with high levels of disk activity. The virtual hard disk file that is created initially uses the size of the virtual hard disk and does not change when data is deleted or added.
   - Dynamic expanding: This type of disk provides better use of physical storage space and is recommended for servers running applications that are not disk intensive. The virtual disk file that is created is small initially and changes as data is added.
   - Differencing: This type of disk is associated in a parent-child relationship with another disk that you want to leave intact. You can make changes to the data or operating system without affecting the parent disk, so that you can revert the changes easily. All children must have the same virtual hard disk format as the parent (VHD or VHDX).

Select *Next* to continue. The *Specify Name and Location* page opens.



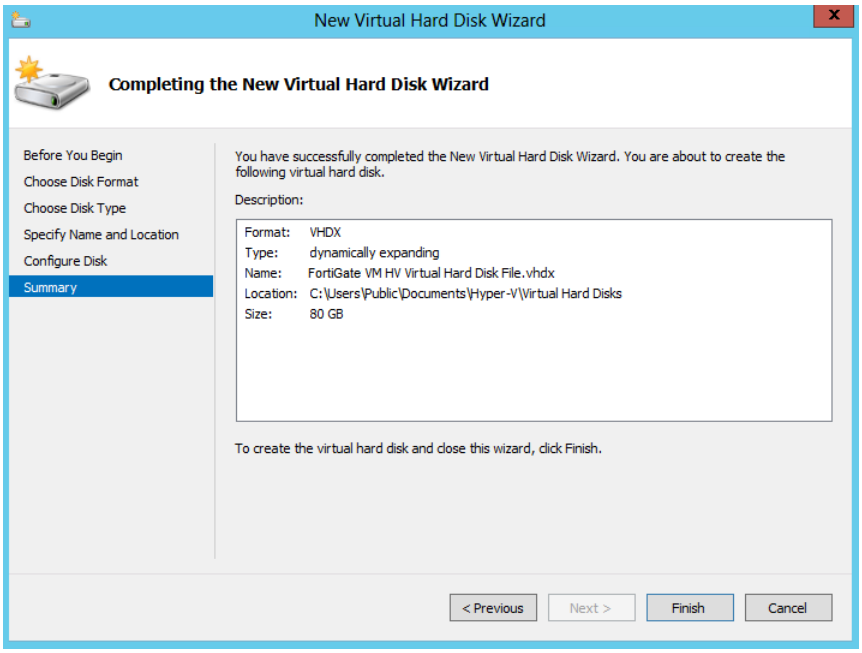
6. Specify the name and location of the virtual hard disk file. Use the *Browse* button to select a specific file folder on your server.

   Select *Next* to continue. The *Configure Disk* page opens.



7. Select to *Create a new blank virtual hard disk* and enter the size of the disk in GB. The maximum size is dependent on your server environment.

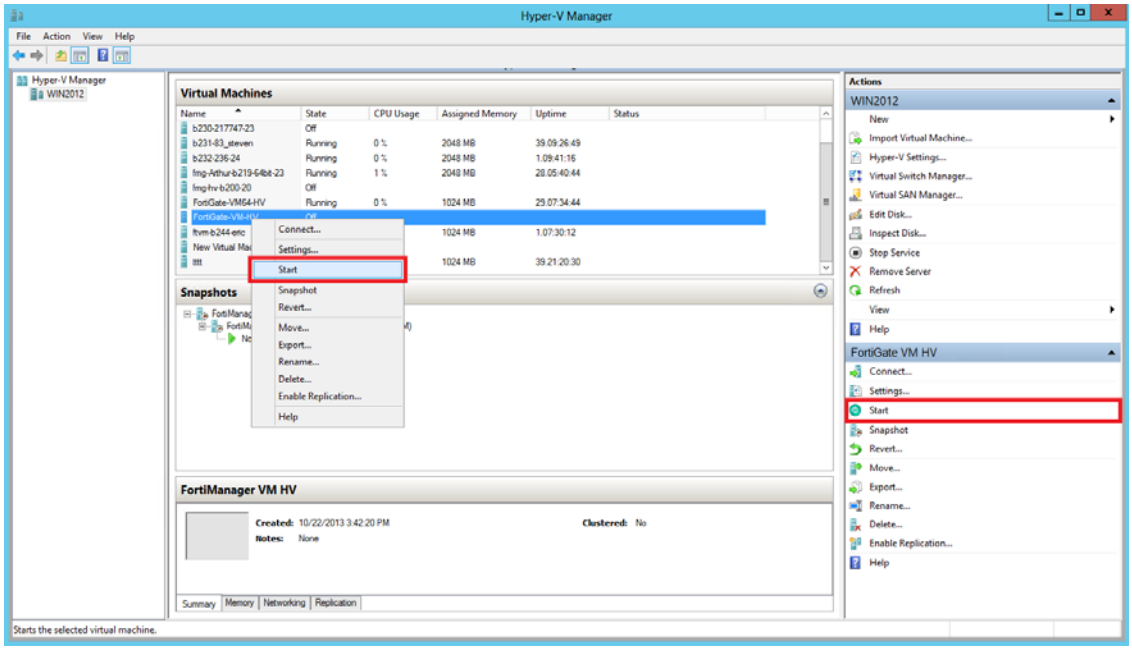
   Select *Next* to continue. The *Summary* page opens.



8. The summary page provides details of the virtual hard disk. Select *Finish* to create the virtual hard disk.
9. Select *Apply* to save the settings and select *OK* to exit the settings page.

Start the FortiGate VM

You can now proceed to power on your FortiGate VM. Select the name of the FortiGate VM in the list of virtual machines, right-click, and select *Start* in the menu. Optionally, you can select the name of the FortiGate VM in the list of virtual machines and select *Start* in the *Actions* menu.



Deployment example: KVM

Once you have downloaded the FORTINET.out.kvm.zip file and extracted virtual hard drive image file fortios.qcow2, you can create the virtual machine in your KVM environment.

The following topics are included in this section:

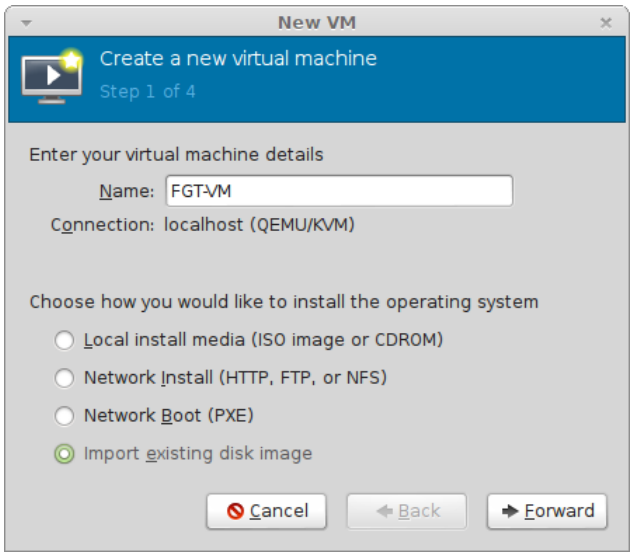
- Create the FortiGate VM virtual machine
- Configure FortiGate VM hardware settings
- Start the FortiGate VM

Create the FortiGate VM virtual machine

To create the FortiGate VM virtual machine:

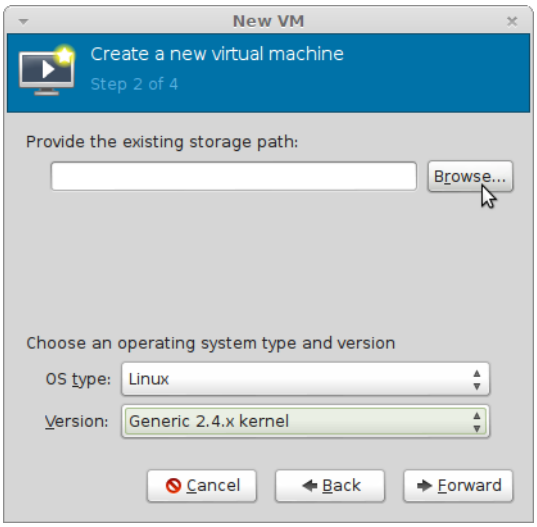
1. Launch Virtual Machine Manager (virt-manager) on your KVM host server.

   The *Virtual Machine Manager* home page opens.
2. In the toolbar, select *Create a new virtual machine*.

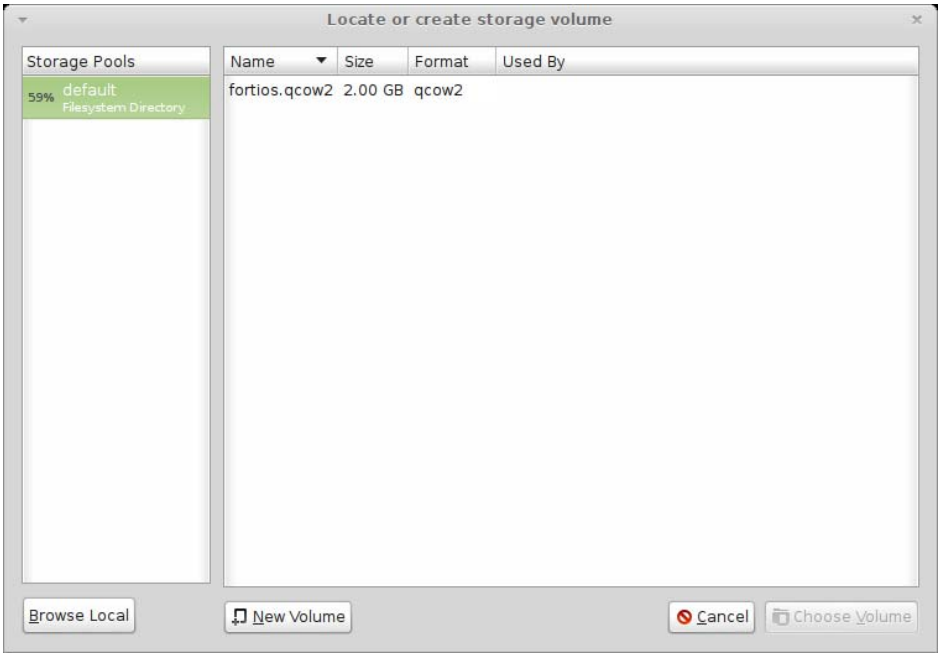


3. Enter a *Name* for the VM, FGT-VM for example.
4. Ensure that *Connection* is localhost. (This is the default.)
5. Select *Import existing disk image*.

6. Select *Forward*.



7. In *OS Type* select *Linux*.
8. In *Version*, select *Generic 2.4.x.kernel*.
9. Select *Browse*.



10. If you copied the fortios.qcow2 file to `/var/lib/libvirt/images`, it will be visible on the right. If you saved it somewhere else on your server, select Browse Local and find it.
11. Choose *Choose Volume*.
12. Select *Forward*.
13. Specify the amount of memory and number of CPUs to allocate to this virtual machine. The amounts must not exceed your license limits. See "FortiGate VM models and licensing" on page 2446.
14. Select *Forward*.
15. Expand *Advanced options*. A new virtual machine includes one network adapter by default. Select a network adapter on the host computer. Optionally, set a specific MAC address for the virtual network interface. Set *Virt Type* to *virtio* and *Architecture* to *qcow2*.
16. Select *Finish*.

Configure FortiGate VM hardware settings

Before powering on your FortiGate VM you must add the log disk and configure the virtual hardware of your FortiGate VM.

To configure settings for FortiGate VM on the server:

1. In the Virtual Machine Manager, locate the name of the virtual machine and then select Open from the toolbar.
2. Select *Add Hardware*. In the *Add Hardware* window select *Storage*.
3. Select *Create a disk image on the computer's harddrive* and set the size to 30GB.

If you know your environment will expand in the future, it is recommended to increase the hard disk size beyond 30GB. The VM license limit is 2TB.

4. Enter:

Device type	Virtio disk
Cache mode	Default
Storage format	raw

5. Select *Network* to configure add more the network interfaces. The *Device type* must be *Virtio*.

   A new virtual machine includes one network adapter by default. You can add more through the Add Hardware window. FortiGate VM requires four network adapters. You can configure network adapters to connect to a virtual switch or to network adapters on the host computer.
6. Select *Finish*.

Start the FortiGate VM

You can now proceed to power on your FortiGate VM. Select the name of the FortiGate VM in the list of virtual machines. In the toolbar, select *Console* and then select *Start*.

Deployment example: OpenXen

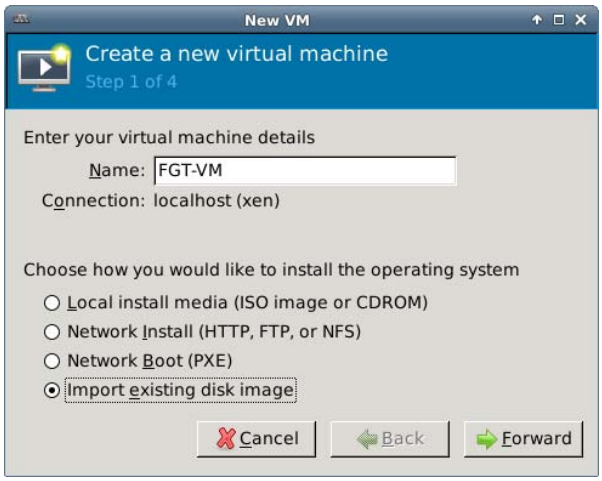
Once you have downloaded the FORTINET.out.OpenXen.zip file and extracted virtual hard drive image file fortios.qcow2, you can create the virtual machine in your OpenXen environment.

The following topics are included in this section:

Create the FortiGate VM virtual machine (VMM)

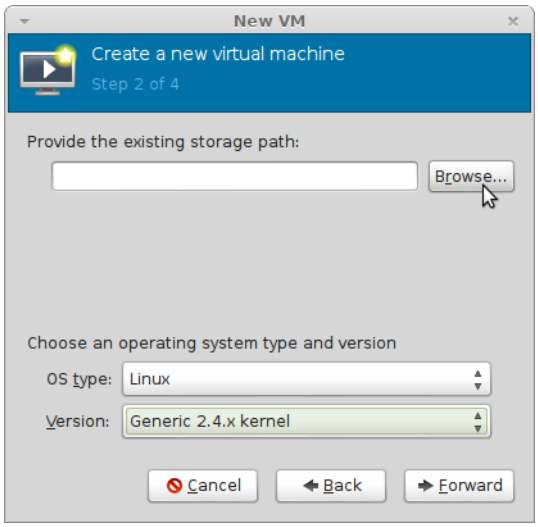
To create the FortiGate VM virtual machine:

1. Launch Virtual Machine Manager (virt-manager) on your OpenXen host server.
   The *Virtual Machine Manager* home page opens.
2. In the toolbar, select *Create a new virtual machine*.



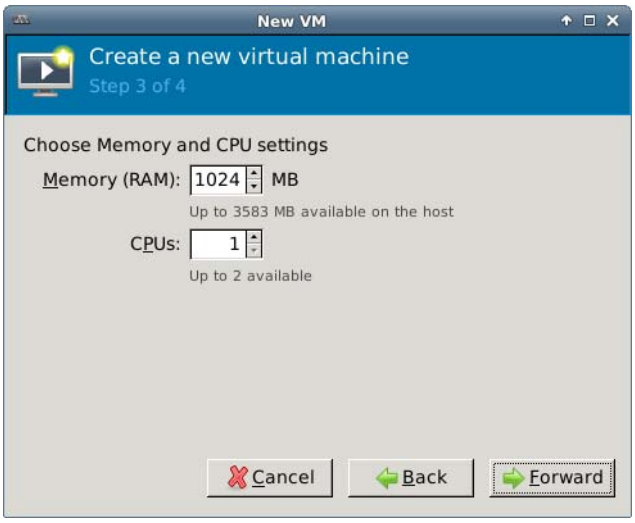
3. Enter a *Name* for the VM, FGT-VM for example.
4. Ensure that *Connection* is localhost. (This is the default.)
5. Select *Import existing disk image*.

6. Select *Forward*.



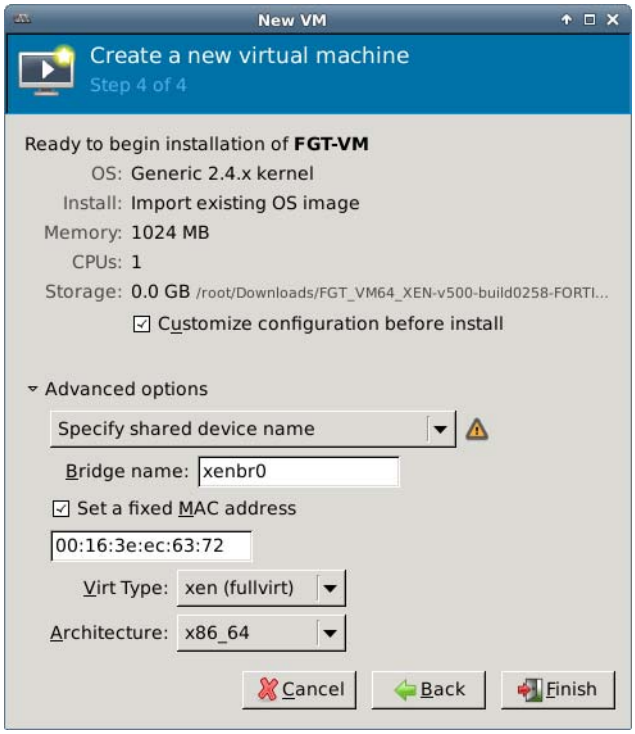
7. In *OS Type* select *Linux*.
8. In *Version*, select *Generic 2.4.x.kernel*.
9. Select *Browse*.

   The *Locate or create storage volume* window opens.
10. Select *Browse Local,* find the fortios.qcow2 disk image file.
11. Select fortios.qcow2 and select *Choose Volume*.
12. Select *Forward*.



13. Specify the amount of memory and number of CPUs to allocate to this virtual machine. The amounts must not exceed your license limits. See “FortiGate VM models and licensing” on page 2446.

14. Select *Forward*.



15. Select *Customize configuration before install*. This enables you to make some hardware configuration changes before VM creation is started.
16. Expand *Advanced options*. A new virtual machine includes one network adapter by default. Select *Specify shared device name* and enter the name of the bridge interface on the OpenXen host. Optionally, set a specific MAC address for the virtual network interface. *Virt Type* and *Architecture* are set by default and should be correct.

17. Select *Finish*.

    The virtual machine hardware configuration window opens.

    You can use this window to add hardware such as network interfaces and disk drives.

18. Select *Add Hardware*. In the *Add Hardware* window select *Storage*.
19. Select *Create a disk image on the computer's harddrive* and set the size to 30GB.

If you know your environment will expand in the future, it is recommended to increase the hard disk size beyond 30GB. The VM license limit is 2TB.

20. Enter:

Device type	Virtio disk
Cache mode	Default
Storage format	raw

21. Select *Network* to configure add more the network interfaces. The *Device type* must be *Virtio*.

    A new virtual machine includes one network adapter by default. You can add more through the Add Hardware window. FortiGate VM requires four network adapters. You can configure network adapters to connect to a virtual switch or to network adapters on the host computer.
22. Select *Finish*.
23. Select Begin Installation. After the installation completes successfully, the VM starts and the console window opens.

Deployment example: Citrix XenServer

Once you have downloaded the FORTINET.out.CitrixXen.zip file and extracted the files, you can create the virtual machine in your Citrix Xen environment.

The following topics are included in this section:

- Create the FortiGate VM virtual machine (XenCenter)

Create the FortiGate VM virtual machine (XenCenter)

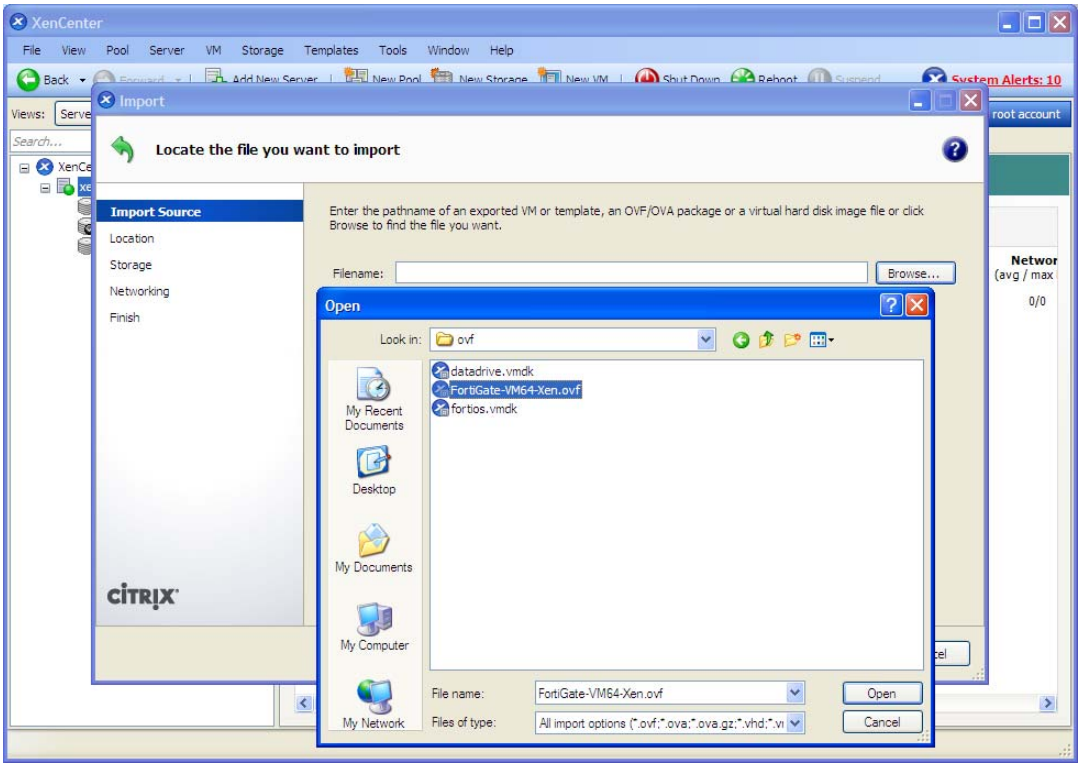
To create the FortiGate VM virtual machine from the OVF file

1. Launch XenCenter on your management computer.

   The management computer can be any computer that can run Citrix XenCenter, a Windows application.
2. If you have not already done so, select *ADD a server*. Enter your Citrix XenServer IP address and the root logon credentials required to manage that server.

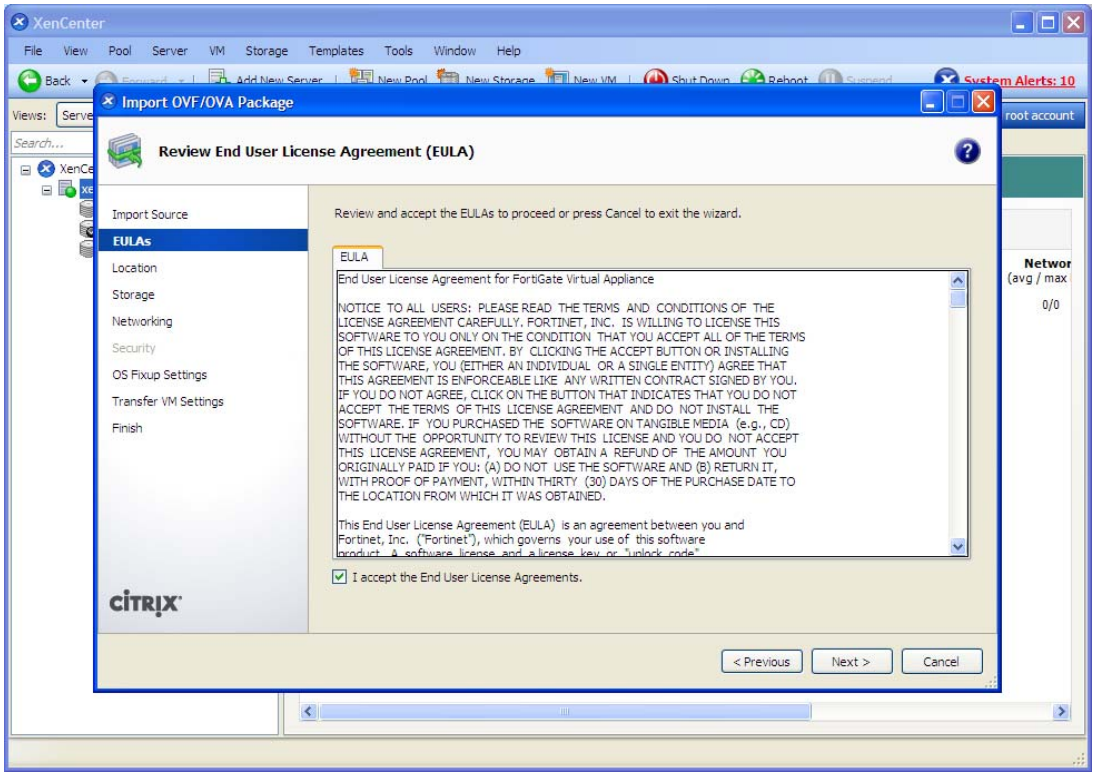
   Your Citrix XenServer is added to the list in the left pane.

   The *Virtual Machine Manager* home page opens.
3. Go to *File* > *Import*. An import dialog will appear.
4. Click the *Browse* button, find the FortiGate-VM64-Xen.ovf template file, then click *Open*.

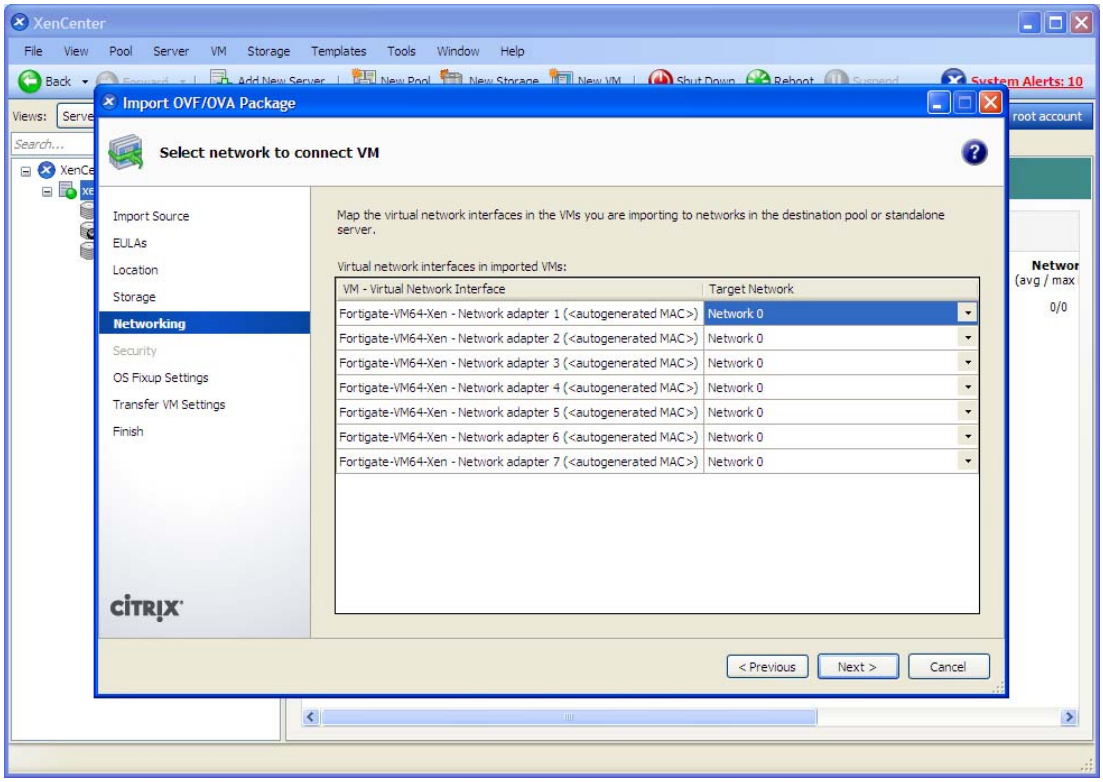


5. Select *Next*.

6. Accept the FortiGate Virtual Appliance EULA, then select *Next*.



7. Choose the pool or standalone server that will host the VM, then select *Next*.
8. Select the storage location for FortiGate VM disk drives or accept the default. Select *Next*.
9. Configure how each vNIC (virtual network adapter) in FortiGate VM will be mapped to each vNetwork on the Citrix XenServer, then click *Next*.



10. Click *Next* to skip OS fixup.
11. Select *Next* to use the default network settings for transferring the VM to the host.
12. select *Finish*.

The Citrix XenServer imports the FortiGate VM files and configures the VM as specified in the OVF template. Depending on your computer's hardware speed and resource load, and also on the file size and speed of the network connection, this might take several minutes to complete.

When VM import is complete, the XenCenter left pane includes the FortiGate VM in the list of deployed VMs for your Citrix XenServer.

Configure virtual hardware

Before you start your FortiGate-VM for the first time, you need to adjust your virtual machine's virtual hardware settings to meet your network requirements.

Configuring number of CPUs and memory size

Your FortiGate-VM license limits the number CPUs and amount of memory that you can use. The amounts you allocate must not exceed your license limits. See "FortiGate VM models and licensing" on page 2446.

To access virtual machine settings

1. Open XenCenter.
2. Select your FortiGate VM in the left pane.

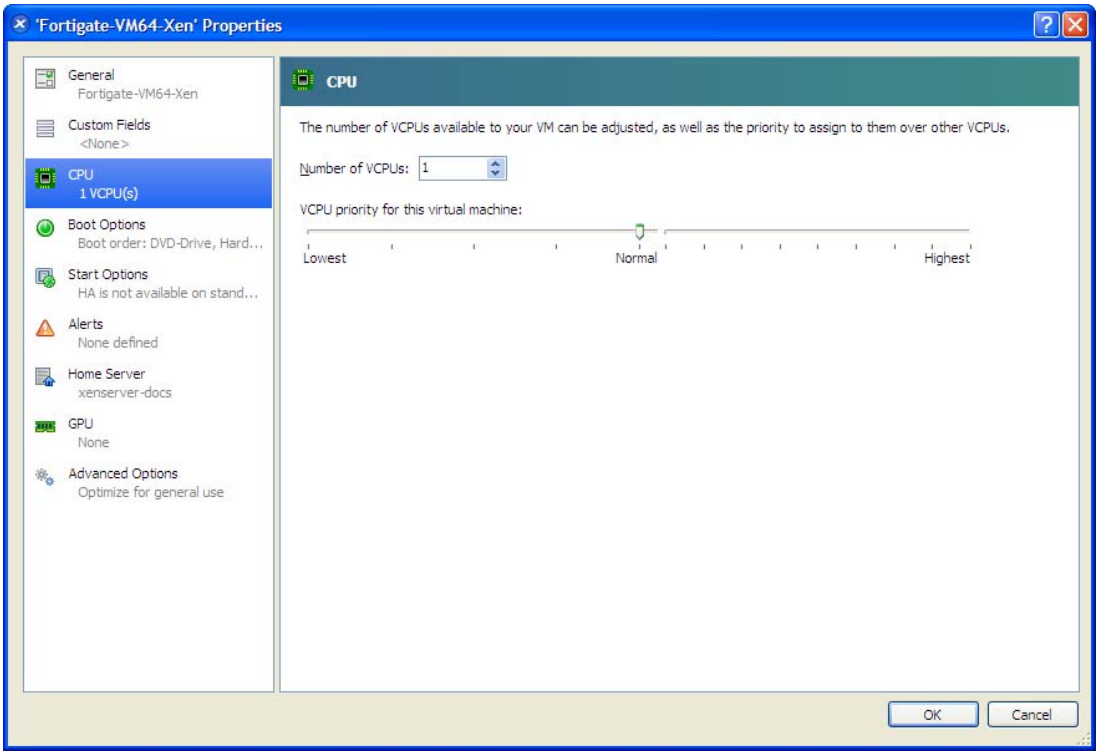
   The tabs in the right pane provide access to the virtual hardware configuration. The Console tab provides access to the FortiGate console.

To set the number of CPUs

1. In the XenCenter left pane, right-click the FortiGate VM and select Properties.

   The Properties window opens.

2. In the left pane, select CPU.

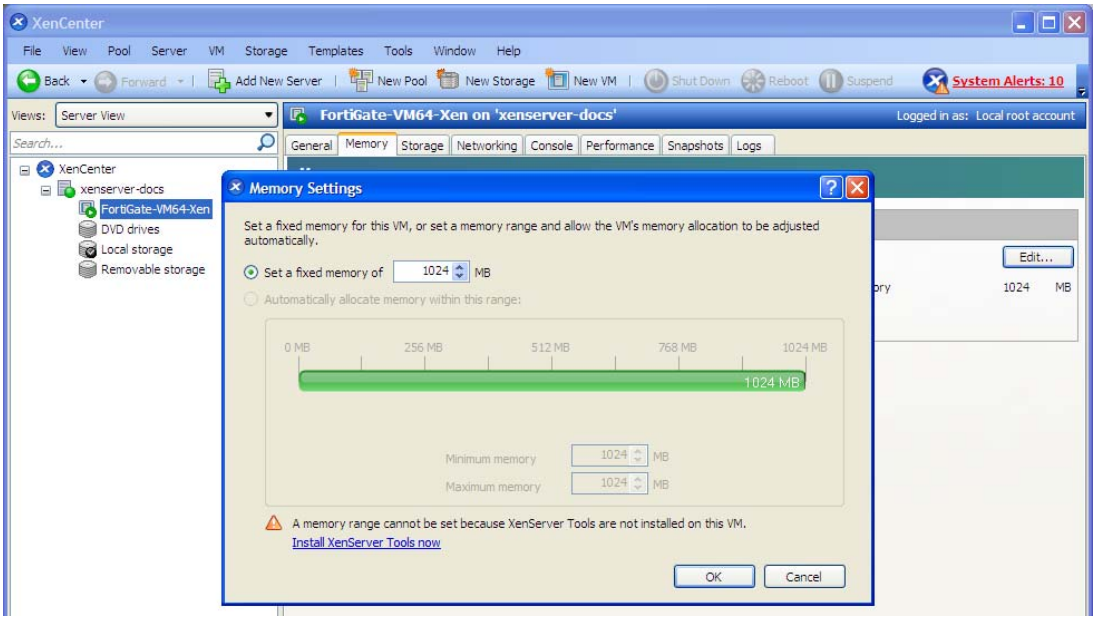


3. Adjust *Number of CPUs* and then select *OK*.

   XenCenter will warn if you select more CPUs than the Xen host computer contains. Such a configuration might reduce performance.

To set memory size

1. In the XenCenter left pane, select the FortiGate VM.
2. In the right pane, select the *Memory* tab.
3. Select *Edit*, modify the value in the *Set a fixed memory of* field and select *OK*.

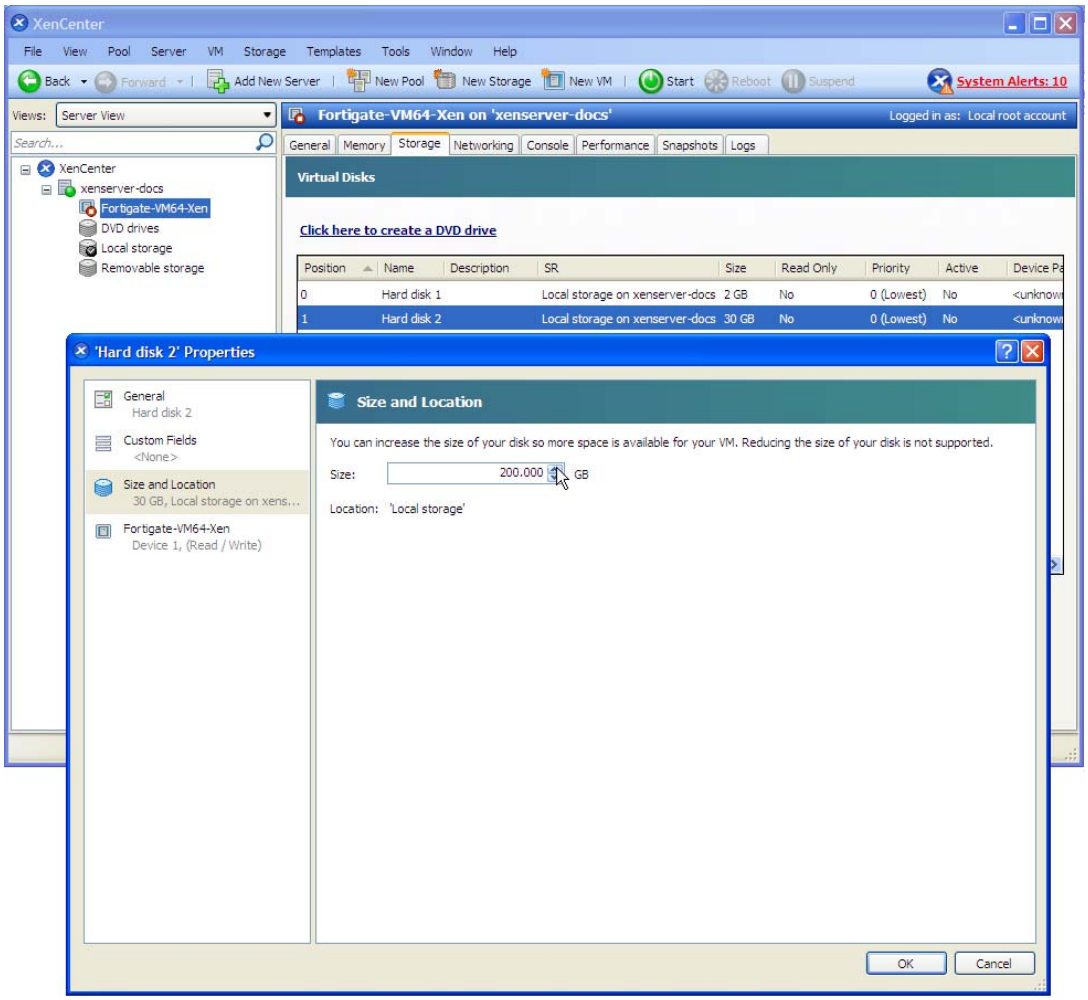


Configuring disk storage

By default the FortiGate VM data disk 30GB. You will probably want to increase this. Disk resizing must be done before you start the VM for the first time.

To resize the FortiGate data disk

1. In the XenCenter left pane, select the FortiGate VM.
2. Select the *Storage* tab. Select *Hard disk 2* (the 30GB drive), then select *Properties*.
   The *'Hard disk 2' Properties* window opens.
3. Select *Size and Location*. Adjust *Size* and select *OK*.



FortiGate VM Initial Configuration

Before you can connect to the FortiGate VM web-based manager you must configure a network interface in the FortiGate VM console. Once an interface with administrative access is configured, you can connect to the FortiGate VM web-based Manager and upload the FortiGate VM license file that you downloaded from the Customer Service & Support website.

The following topics are included in this section:

- Set FortiGate VM port1 IP address
- Connect to the FortiGate VM Web-based Manager
- Upload the FortiGate VM license file
- Configure your FortiGate VM

Set FortiGate VM port1 IP address

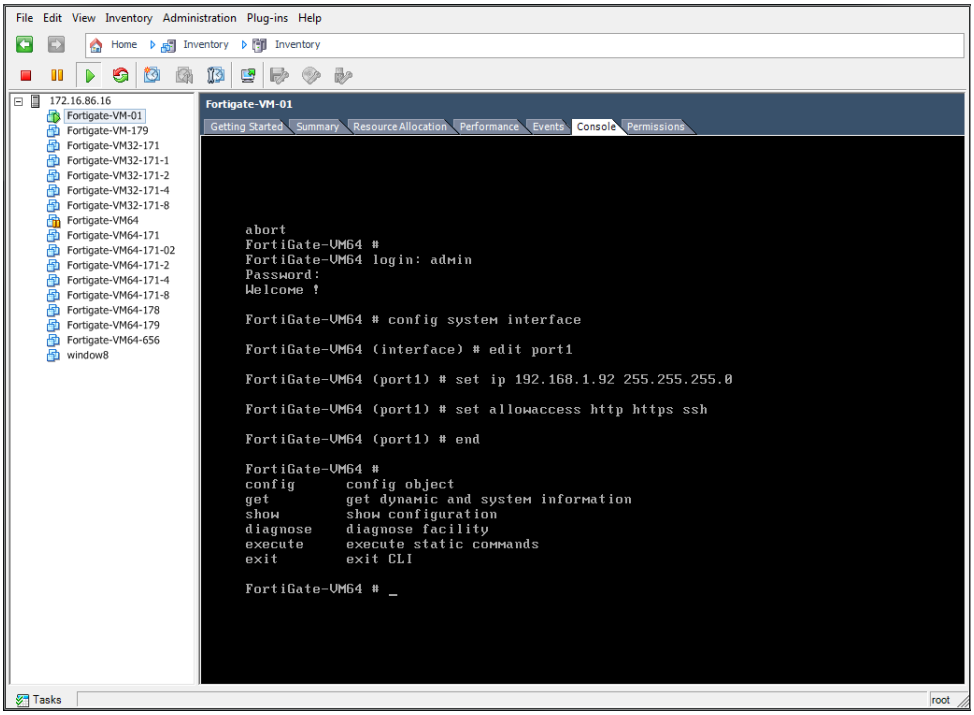
Hypervisor management environments include a guest console window. On the FortiGate VM, this provides access to the FortiGate console, equivalent to the console port on a hardware FortiGate unit. Before you can access the Web-based manager, you must configure FortiGate VM port1 with an IP address and administrative access.

To configure the port1 IP address:

1. In your hypervisor manager, start the FortiGate VM and access the console window.

   You might need to press Return to see a login prompt.

   Figure 344: Example of FortiGate VM console access



2. At the FortiGate VM login prompt enter the username `admin`. By default there is no password. Just press Return.
3. Using CLI commands, configure the port1 IP address and netmask. Also, HTTP access must be enabled because until it is licensed the FortiGate VM supports only low-strength encryption. HTTPS access will not work.

   For example:

```
config system interface
  edit port1
    set ip 192.168.0.100 255.255.255.0
    append allowaccess http
  end
```

You can also use the `append allowaccess` CLI command to enable other access protocols, such as `auto-ipsec`, `http`, `probe-response`, `radius-acct`, `snmp`, and `telnet`. The `ping`, `https`, `ssh`, and `fgfm` protocols are enabled on the `port1` interface by default.

4. To configure the default gateway, enter the following CLI commands:

```
config router static
  edit 1
    set device port1
    set gateway <class_ip>
end
```

You must configure the default gateway with an IPv4 address. FortiGate VM needs to access the Internet to contact the FortiGuard Distribution Network (FDN) to validate its license.

5. To configure your DNS servers, enter the following CLI commands:

```
config system dns
  set primary <Primary DNS server>
  set secondary <Secondary DNS server>
end
```

The default DNS servers are `208.91.112.53` and `208.91.112.52`.

6. To upload the FortiGate VM license from an FTP or TFTP server, use the following CLI command:

```
execute restore vmlicense {ftp | tftp} <VM license file name>
    <Server IP or FQDN>[:server port]
```

You can also upload the license in the FortiGate VM Web-based Manager. See “Upload the FortiGate VM license file” on page 2484.

Connect to the FortiGate VM Web-based Manager

When you have configured the port1 IP address and netmask, launch a web browser and enter the IP address that you configured for port1. At the login page, enter the username `admin` and password field and select *Login*. The default password is no password. The Web-based Manager will appear with an *Evaluation License* dialog box, see Figure 345.

Figure 345: Web-based Manager and Evaluation License dialog box

Upload the FortiGate VM license file

Every Fortinet VM includes a 15-day trial license. During this time the FortiGate VM operates in evaluation mode. Before using the FortiGate VM you must enter the license file that you downloaded from the Customer Service & Support website upon registration.

To upload the FortiGate VM licence file:

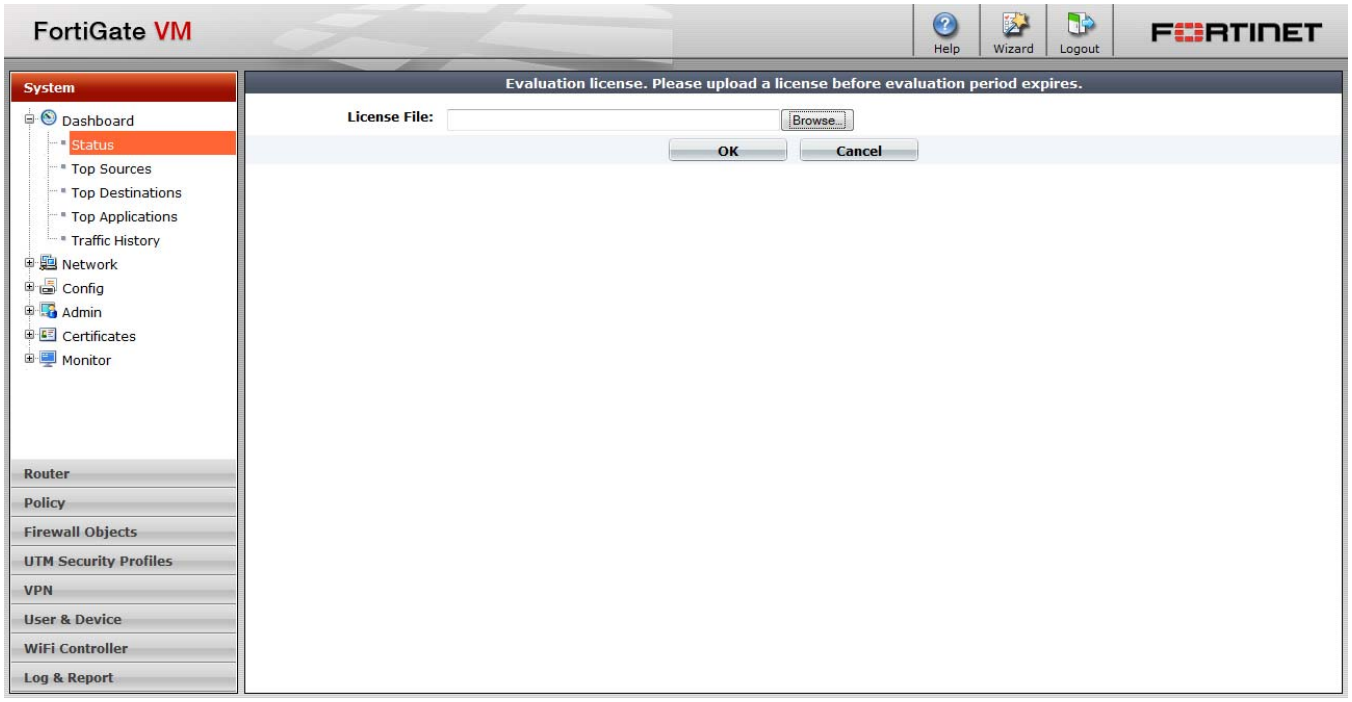
1. In the *Evaluation License* dialog box, select *Enter License*.

You can also upload the license file via the CLI using the following CLI command:

```
execute restore vmlicense [ftp | tftp] <filenmame string> <ftp
    server>[:ftp port]
```

The license upload page opens.

Figure 346: License upload page



2. Select *Browse* and locate the license file (`.lic`) on your computer. Select *OK* to upload the license file.
3. Refresh the browser to login.
4. Enter `admin` in the Name field and select *Login*. The VM registration status appears as valid in the License Information widget once the license has been validated by the FortiGuard Distribution Network (FDN) or FortiManager for closed networks.

Validate the FortiGate VM license with FortiManager

You can validate your FortiGate VM license with some models of FortiManager. To determine whether your FortiManager unit has the VM Activation feature, see Features section of the *FortiManager Product Data sheet*.

To validate your FortiGate VM with your FortiManager:

1. To configure your FortiManager as a closed network, enter the following CLI command on your FortiManager:

```
config fmupdate publicnetwork
  set status disable
end
```

2. To configure FortiGate VM to use FortiManager as its override server, enter the following CLI commands on your FortiGate VM:

```
config system central-management
  set mode normal
  set type fortimanager
  set fmg <IPv4 address of the FortiManager device>
```

```
    set fmg-source-ip <Source IPv4 address when connecting to the
        FortiManager device>
    set fortimanager-fds-override enable
    set vdom <Enter the name of the VDOM to use when communicating
        with the FortiManager device>
end
```

3. Load the FortiGate VM license file in the Web-based Manager. Go to *System* > *Dashboard* > *Status*. In the *License Information* widget, in the *Registration Status* field, select *Update*. Browse for the `.lic` license file and select *OK*.
4. To activate the FortiGate VM license, enter the following CLI command on your FortiGate VM:

   ```
   execute update-now
   ```

5. To check the FortiGate VM license status, enter the following CLI commands on your FortiGate VM:

   ```
   get system status
   ```

   The following output is displayed:

   ```
   Version: Fortigate-VM v5.0,build0099,120910 (Interim)
   Virus-DB: 15.00361(2011-08-24 17:17)
   Extended DB: 15.00000(2011-08-24 17:09)
   Extreme DB: 14.00000(2011-08-24 17:10)
   IPS-DB: 3.00224(2011-10-28 16:39)
   FortiClient application signature package: 1.456(2012-01-17 18:27)
   Serial-Number: FGVM02Q105060000
   License Status: Valid
   BIOS version: 04000002
   Log hard disk: Available
   Hostname: Fortigate-VM
   Operation Mode: NAT
   Current virtual domain: root
   Max number of virtual domains: 10
   Virtual domains status: 1 in NAT mode, 0 in TP mode
   Virtual domain configuration: disable
   FIPS-CC mode: disable
   Current HA mode: standalone
   Distribution: International
   Branch point: 511
   Release Version Information: MR3 Patch 4
   System time: Wed Jan 18 11:24:34 2012

   diagnose hardware sysinfo vm full
   ```

   The following output is displayed:

   ```
   UUID: 564db33a29519f6b1025bf8539a41e92
   valid:    1
   status:   1
   code:     200 (If the license is a duplicate, code 401 will be
       displayed)
   warn:     0
   copy:     0
   received: 45438
   ```

```
warning:  0
recv:     201201201918
dup:
```

Configure your FortiGate VM

Once the FortiGate VM license has been validated you can begin to configure your device. You can use the *Wizard* located in the top toolbar for basic configuration including enabling central management, setting the admin password, setting the time zone, and port configuration.

For more information on configuring your FortiGate VM see the FortiOS Handbook at http://docs.fortinet.com.

Chapter 21 VoIP Solutions: SIP for FortiOS 5.0

This FortiOS Handbook chapter contains the following sections:

FortiGate VoIP solutions: SIP

This chapter includes the following sections:

SIP overview

The Session Initiation Protocol (SIP) is an IETF application layer signaling protocol used for establishing, conducting, and terminating multiuser multimedia sessions over TCP/IP networks using any media. SIP is often used for Voice over IP (VoIP) calls but can be used for establishing streaming communication between end points.

SIP employs a request and response transaction model similar to HTTP for communicating between endpoints. SIP sessions being with a SIP client sending a SIP request message to another client to initiate a multimedia session. The other client responds with a SIP response message. Using these request and response messages, the clients engage in a SIP dialog to negotiate how to communicate and then start, maintain, and end the communication session.

SIP commonly uses TCP or UDP port 5060 and/or 5061. Port 5060 is used for non-encrypted SIP signaling sessions and port 5061 is typically used for SIP sessions encrypted with SSL or TLS.

Devices involved in SIP communications are called SIP User Agents (UAs) (also sometimes called a User Element (UE)). UAs include User Agent Clients (UACs) that communicate with each other and User Agent Servers (UASs) that facilitate communication between UACs. For a VoIP application, an example of a UAC would be a SIP phone and an example of a UAS would be a SIP proxy server.

A SIP message contain headers that include client and server names and addresses required for the communication sessions. The body of a SIP message contains Session Description Protocol (SDP) statements that establish the media communication (port numbers, protocols and codecs) that the SIP UAs use. SIP VoIP most commonly uses the Real Time Protocol (RTP) and the Real Time Control Protocol (RTCP) for voice communication. Once the SIP dialog establishes the SIP call the VoIP stream can run independently, although SIP messages can affect the VoIP stream by changing port numbers or addresses and by ending it.

Once SIP communication and media settings are established, the UAs communicate with each using the established media settings. When the communication session is completed, one of the UAs ends the session by sending a final SIP request message and the other UA sends a SIP response message and both UAs end the SIP call and stop the media stream.

FortiGate units provide security for SIP communications using the SIP session helper and the SIP ALG:

- The SIP session-helper provides basic high-performance support for SIP calls passing through the FortiGate unit by opening SIP and RTP pinholes and performing source and destination IP address and port translation for SIP and RTP packets and for the IP addresses and port numbers in the SIP headers and the SDP body of the SIP messages. For more about the SIP session helper, see "The SIP session helper" on page 2505.
- The SIP Application Layer Gateway (ALG) provides the same features as the session helper plus additional advanced features such as deep SIP message inspection, SIP logging, SIP IPv6 support, SIP message checking, HA failover of SIP sessions, and SIP rate limiting. For more about the SIP ALG, see "The SIP ALG" on page 2512.

There are a large number of SIP-related Internet Engineering Task Force (IETF) documents (Request for Comments) that define behavior of SIP and related applications. FortiGate units provide complete support of RFC 3261 for SIP, RFC 4566 for SDP and RFC 3262 for Provisional Response Acknowledgement (PRACK). FortiGate units also provide support for other SIP and SIP-related RFCs and performs "Deep SIP message inspection" on page 2558 for SIP statements defined in other SIP RFCs.

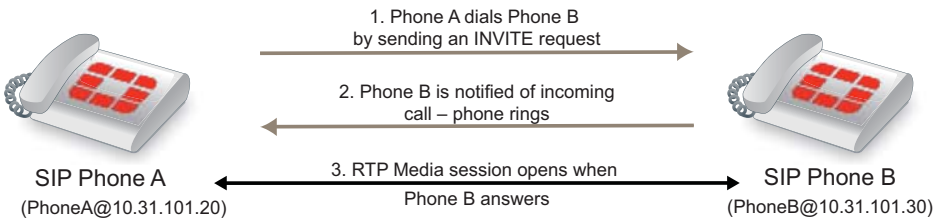
Common SIP VoIP configurations

This section describes some common SIP VoIP configurations and simplified SIP dialogs for these configurations. This section also shows some examples of how adding a FortiGate unit affects SIP processing.

Peer to peer configuration

In the peer to peer configuration shown in Figure 347, two SIP phones (in the example, FortiFones) communicate directly with each other. The phones send SIP request and response messages back and forth between each other to establish the SIP session.

Figure 347:SIP peer to peer configuration

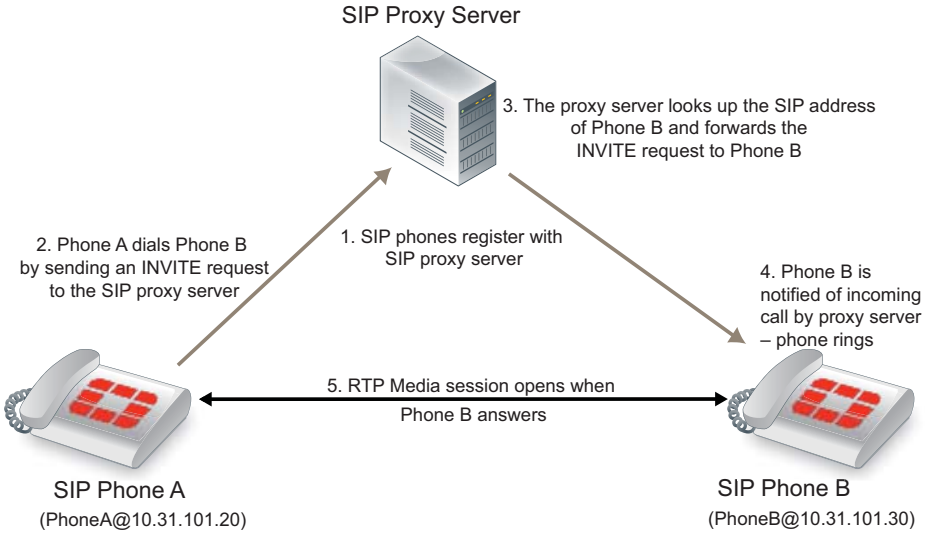


Peer to peer configurations are not very common because they require the SIP phones to keep track of the names and addresses of all of the other SIP phones that they can communicate with. In most cases a SIP proxy or re-direct server maintains addresses of a large number of SIP phones and a SIP phone starts a call by contacting the SIP proxy server.

SIP proxy server configuration

A SIP proxy server act as intermediary between SIP phones and between SIP phones (for example, two FortiFones) and other SIP servers. As shown in Figure 348, SIP phones send request and response messages the SIP proxy server. The proxy server forwards the messages to other clients or to other SIP proxy servers. Proxy servers can hide SIP phones by proxying the signaling messages. To the other users on the VoIP network, the signaling invitations look as if they come from the SIP proxy server.

Figure 348:SIP in proxy mode

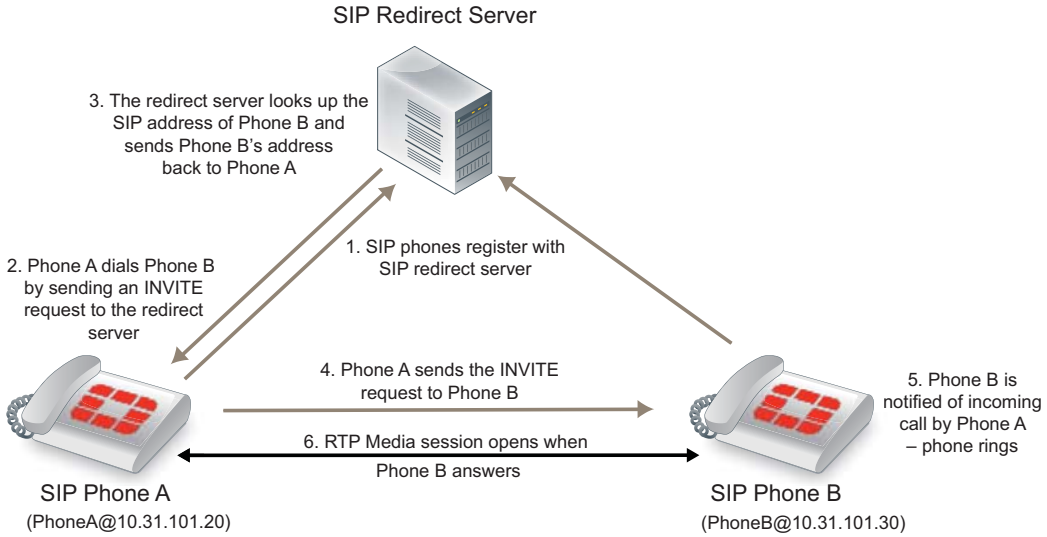


A common SIP configuration would include multiple networks of SIP phones. Each of the networks would have its own SIP server. Each SIP server would proxy the communication between phones on its own network and between phones in different networks.

SIP redirect server configuration

A SIP redirect server accepts SIP requests, maps the addresses in the request into zero or more new addresses and returns those addresses to the client. The redirect server does not initiate SIP requests or accept calls. As shown in Figure 349, SIP clients send INVITE requests to the redirect server, which then looks up the destination address. The redirect server returns the destination address to the client. The client uses this address to send the INVITE request directly to the destination SIP client.

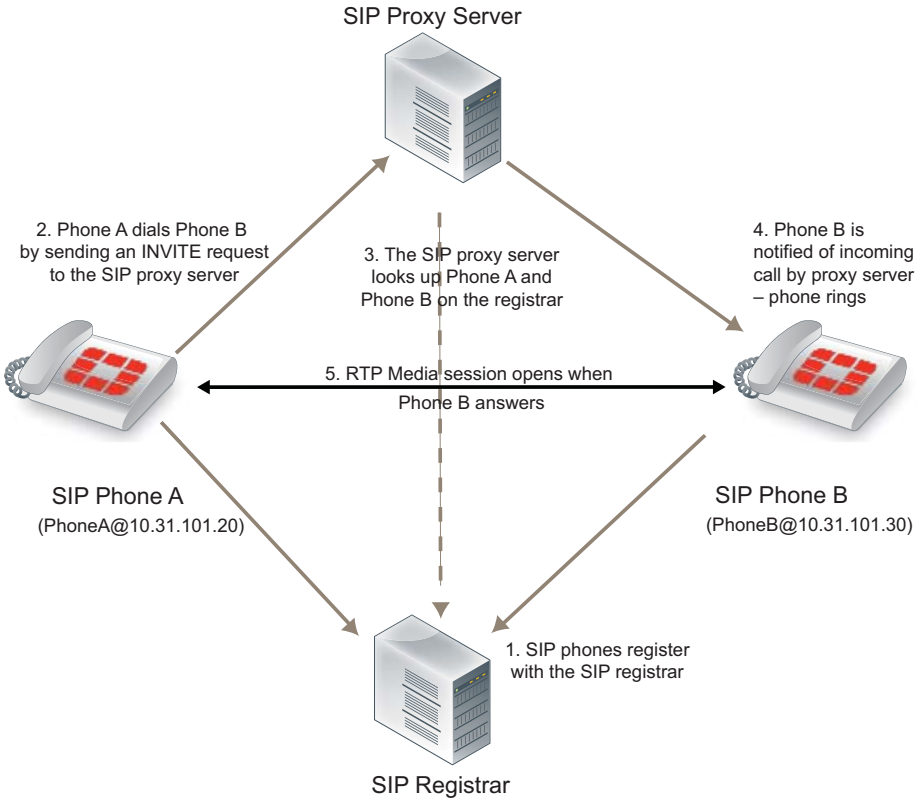
Figure 349:SIP in redirect model



SIP registrar configuration

A SIP registrar accepts SIP REGISTER requests from SIP phones for the purpose of updating a location database with this contact information. This database can then become a SIP location service that can be used by SIP proxy severs and redirect servers to locate SIP clients. As shown in Figure 350, SIP clients send REGISTER requests to the SIP registrar.

Figure 350:SIP registrar and proxy servers

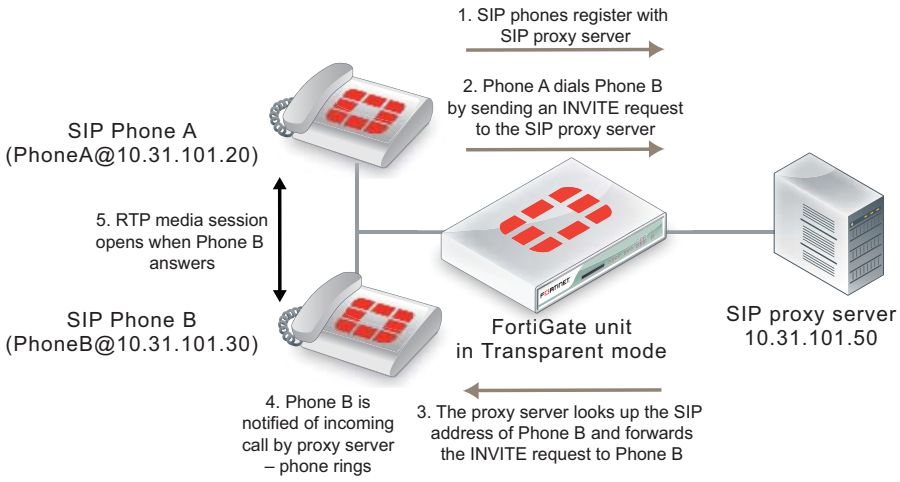


SIP with a FortiGate unit

Depending on your security requirements and network configuration FortiGate units may be in many different places in a SIP configuration. This section shows a few examples.

Figure 351 shows a FortiGate unit installed between a SIP proxy server and SIP phones on the same network. The FortiGate unit is operating in Transparent mode so both the proxy server and the phones are on the same subnet. In this configuration, called SIP inspection without address translation, the FortiGate unit could be protecting the SIP proxy server on the private network by implementing SIP security features for SIP sessions between the SIP phones and the SIP proxy server.

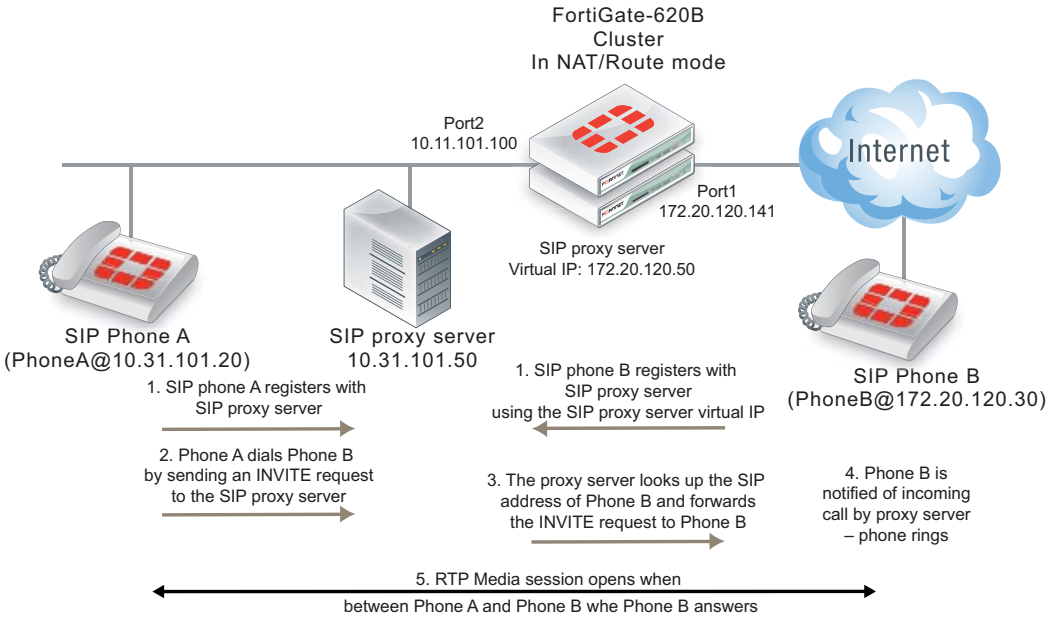
Figure 351:SIP network with FortiGate unit in Transparent mode



The phones and server use the same SIP dialogs as they would if the FortiGate unit was not present. However, the FortiGate unit can be configured to control which devices on the network can connect to the SIP proxy server and can also protect the SIP proxy server from SIP vulnerabilities.

Figure 352 shows a FortiGate unit operating in NAT/Route mode and installed between a private network and the Internet. Some SIP phones and the SIP proxy server are connected to the private network and some SIP phones are connected to the Internet. The SIP phones on the Internet can connect to the SIP proxy server through the FortiGate unit and communication between SIP phones on the private network and SIP phones on the Internet must pass through the FortiGate unit.

Figure 352:SIP network with FortiGate unit in NAT/Route mode



The phones and server use the same SIP dialog as they would if the FortiGate unit was not present. However, the FortiGate unit can be configured to control which devices on the network can connect to the SIP proxy server and can also protect the SIP proxy server from SIP vulnerabilities. In addition, the FortiGate unit has a firewall virtual IP that forwards packets sent to the SIP proxy server Internet IP address (172.20.120.50) to the SIP proxy server internal network IP address (10.31.101.30).

Since the FortiGate unit is operating in NAT/Route mode it must translate packet source and destination IP addresses (and optionally ports) as the sessions pass through the FortiGate unit. Also, the FortiGate unit must translate the addresses contained in the SIP headers and SDP body of the SIP messages. As well the FortiGate unit must open SIP and RTP pinholes through the FortiGate unit. SIP pinholes allow SIP signalling sessions to pass through the FortiGate between phones and between phones and SIP servers. RTP pinholes allow direct RTP communication between the SIP phones once the SIP dialog has established the SIP call. Pinholes are opened automatically by the FortiGate unit. Administrators do not add security policies for pinholes or for RTP sessions. All that is required is a security policy that accepts SIP traffic.

Opening an RTP pinhole means opening a port on a FortiGate interface to allow RTP traffic to use that port to pass through the FortiGate unit between the SIP phones on the Internet and SIP phones on the internal network. A pinhole only accepts packets from one RTP session. Since a SIP call involves at least two media streams (one from Phone A to Phone B and one from Phone B to Phone A) the FortiGate unit opens two RTP pinholes. Phone A sends RTP packets through a pinhole in port2 and Phone B sends RTP packets through a pinhole in port1. The FortiGate unit opens the pinholes when required by the SIP dialog and closes the pinholes when the SIP call is completed. The FortiGate unit opens new pinholes for each SIP call.

Each RTP pinhole actually includes two port numbers. The RTP port number as defined in the SIP message and an RTCP port number, which is the RTP port number plus 1. For example, if the SIP call used RTP port 3346 the FortiGate unit would create a pinhole for ports 3346 and 3347.

SIP messages and media protocols

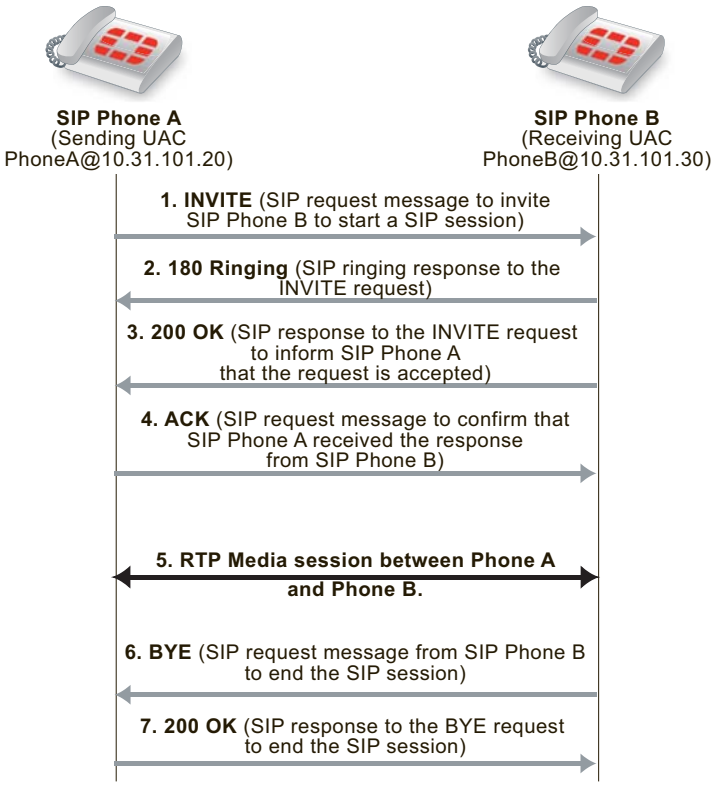
This section provides an overview of SIP messages and how they communicate information about SIP sessions and how SDP, RTP, and RTCP fits in with SIP communications.

SIP uses clear text messages to start, maintain, and end media sessions between SIP user agent clients (UACs) and user agent servers (UASs). These messages form a SIP dialog. A typical SIP dialog begins with an INVITE request message sent from a UAC to another UAC or to a UAS. The first INVITE request message attempts to start a SIP call and includes information about the sending UAC and the receiving UAC as well as information about the communication session.

If only two UACs are involved as shown in Figure 353, the receiving UAC (Phone B) responds with a 180 Ringing and then a 200 OK SIP response message that informs Phone A that Phone B received and accepted the request. Phone A then sends an ACK message to notify Phone B that the SIP response was received. Phone A and Phone B can then participate in the RTP media session set up by the SIP messages.

When the phone call is complete, one of the UACs (in the example Phone B) hangs up sending a BYE request message to Phone A. Phone A then sends a 200 OK response to Phone B acknowledging that the session has ended.

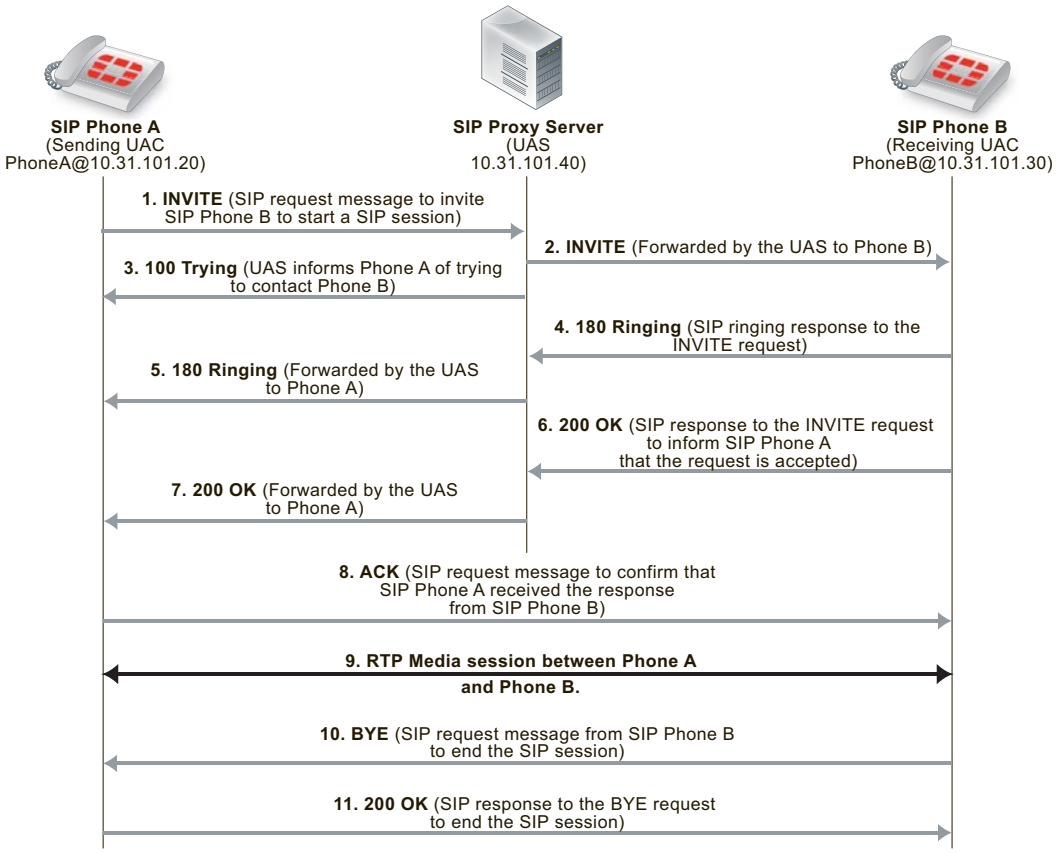
Figure 353: Basic SIP dialog between two UACs



If a UAS in the form of a SIP proxy server is involved, similar messages are sent and received, but the proxy server participates as an intermediary in the initial call setup. In the example in Figure 354 the SIP proxy server receives the INVITE request from Phone A and forwards it to Phone B. The proxy server then sends a 100 Trying response to Phone A. Phone B receives the INVITE request and responds with a 180 Ringing and then a 200 OK SIP response message. These messages are received by the proxy server and forwarded to Phone A to notify Phone A that Phone B received and accepted the request. Phone A then sends an ACK message to notify Phone B that the SIP response was received. This response is received by the proxy server and forwarded to Phone B. Phone A and Phone B can then participate in the media session independently of the proxy server.

When the phone call is complete Phone B hangs up sending a BYE request message to Phone A. Phone A then sends a 200 OK response to Phone B acknowledging that the session has ended.

Figure 354: Basic SIP dialog between UACs with a SIP proxy server UAS



The SIP messages include SIP headers that contain names and addresses of Phone A, Phone B and the proxy server. This addressing information is used by the UACs and the proxy server during the call set up.

The SIP message body includes Session Description Protocol (SDP) statements that Phone A and Phone B use to establish the media session. The SDP statements specify the type of media stream to use for the session (for example, audio for SIP phone calls) and the protocol to use for the media stream (usually the Real Time Protocol (RTP) media streaming protocol).

Phone A includes the media session settings that it would like to use for the session in the INVITE message. Phone B includes its response to these media settings in the 200 OK response. Phone A's ACK response confirms the settings that Phone A and Phone B then use for the media session.

Hardware accelerated RTP processing

FortiGate units can offload RTP packet processing to network processor (NP) interfaces. This acceleration greatly enhance the overall throughput and resulting in near speed RTP performance.

SIP request messages

SIP sessions always start with a SIP request message (also just called a SIP request). SIP request messages also establish, maintain, and terminate SIP communication sessions. Table 113 lists some common SIP request message types.

Table 113: Common SIP request message types

Message Type	Description
INVITE	A client sends an INVITE request to invite another client to participate in a multimedia session. The INVITE request body usually contains the description of the session.
ACK	The originator of an INVITE message sends an ACK request to confirm that the final response to an INVITE request was received. If the INVITE request did not contain the session description, it must be included in the ACK request.
PRACK	In some cases, SIP uses provisional response messages to report on the progress of the response to a SIP request message. The provisional response messages are sent before the final SIP response message. Similar to an ACK request message, a PRACK request message is sent to acknowledge that a provisional response message has been received.
OPTIONS	The UA uses OPTIONS messages to get information about the capabilities of a SIP proxy. The SIP proxy server replies with a description of the SIP methods, session description protocols, and message encoding that are supported.
BYE	A client sends a BYE request to end a session. A BYE request from either end of the SIP session terminates the session.
CANCEL	A client sends a CANCEL request to cancel a previous INVITE request. A CANCEL request has no effect if the SIP server processing the INVITE sends a final response to the INVITE before receiving the CANCEL.
REGISTER	A client sends a REGISTER request to a SIP registrar server with information about the current location (IP address and so on) of the client. A SIP registrar server saves the information it receives in REGISTER requests and makes this information available to any SIP client or server attempting to locate the client.
Info	For distributing mid-session signaling information along the signaling path for a SIP call. I
Subscribe	For requesting the current state and state updates of a remote node.
Notify	Informs clients and servers of changes in state in the SIP network.
Refer	Refers the recipient (identified by the Request-URI) to a third party according to the contact information in the request.

Table 113: Common SIP request message types (continued)

Message Type	Description
Update	Opens a pinhole for new or updated SDP information.
Response codes (1xx, 202, 2xx, 3xx, 4xx, 5xx, 6xx)	Indicates the status of a transaction. For example: 200 OK, 202 Accepted, or 400 Bad Request.

SIP response messages

SIP response messages (often just called SIP responses) provide status information in response to SIP request messages. All SIP response messages include a response code and a reason phrase. There are five SIP response message classes. They are described below.

There are also two types of SIP response messages, provisional and final. Final response messages convey the result of the request processing, and are sent reliably. Provisional responses provide information on the progress of the request processing, but may not be sent reliably. Provisional response messages start with 1xx and are also called informational response messages.

Informational (or provisional)

Informational or provisional responses indicate that a request message was received and imply that the endpoint is going to process the request. Information messages may not be sent reliably and may not require an acknowledgement.

If the SIP implementation uses Provisional Response Acknowledgement (PRACK) (RFC 3262) then informational or provisional messages are sent reliably and require a PRACK message to acknowledge that they have been received.

Informational responses can contain the following reason codes and reason phrases:

```
100 Trying
180 Ringing
181 Call is being forwarded
182 Queued
183 Session progress
```

Success

Success responses indicate that a request message was received, understood, and accepted. Success responses can contain the following reason codes and reason phrases:

```
200 OK
202 Accepted
```

Redirection

Redirection responses indicate that more information is required for the endpoint to respond to a request message. Redirection responses can contain the following reason codes and reason phrases:

```
300 Multiple choices
301 Moved permanently
302 Moved temporarily
305 Use proxy
380 Alternative service
```

Client error

Client error responses indicate that a request message was received by a server that contains syntax that the server cannot understand (i.e. contains a syntax error) or cannot comply with. Client error responses include the following reason codes and reason phrases:

```
400 Bad request                401 Unauthorized
402 Payment required           403 Forbidden
404 Not found                  405 Method not allowed
406 Not acceptable             407 Proxy authentication required
408 Request time-out           409 Conflict
410 Gone                       411 Length required
413 Request entity too large   414 Request-URL too large
415 Unsupported media type     420 Bad extension
480 Temporarily not available
481 Call leg/transaction does not exist
482 Loop detected              483 Too many hops
484 Address incomplete         485 Ambiguous
486 Busy here                  487 Request canceled
488 Not acceptable here
```

Server error

Server error responses indicate that a server was unable to respond to a valid request message. Server error responses include the following reason codes and reason phrases:

```
500 Server internal error
501 Not implemented
502 Bad gateway
502 Service unavailable
504 Gateway time-out
505 SIP version not supported
```

Global failure

Global failure responses indicate that there are no servers available that can respond to a request message. Global failure responses include the following reason codes and reason phrases:

```
600 Busy everywhere
603 Decline
604 Does not exist anywhere
606 Not acceptable
```

SIP message start line

The first line in a SIP message is called the start line. The start line in a request message is called the request-line and the start line in a response message is called the status-line.

Request-line	The first line of a SIP request message. The request-line includes the SIP message type, the SIP protocol version, and a Request URI that indicates the user or service to which this request is being addressed. The following example request-line specifies the INVITE message type, the address of the sender of the message (`inviter@example.com`), and the SIP version: `INVITE sip:inviter@example.com SIP/2.0`
Status-line	The first line of a SIP response message. The status-line includes the SIP protocol version, the response code, and the reason phrase. The example status-line includes the SIP version, the response code (`200`) and the reason phrase (`OK`). `SIP/2.0 200 OK`

SIP headers

Following the start line, SIP messages contain SIP headers (also called SIP fields) that convey message attributes and to modify message meaning. SIP headers are similar to HTTP header fields and always have the following format:

```
<header_name>:<value>
```

SIP messages can include the SIP headers listed in Table 114:

Table 114:SIP headers

SIP Header	Description
Allow	Lists the set of SIP methods supported by the UA generating the message. All methods, including ACK and CANCEL, understood by the UA MUST be included in the list of methods in the Allow header field, when present. For example: `Allow: INVITE, ACK, OPTIONS, CANCEL, BYE`
Call-ID	A globally unique identifier for the call, generated by the combination of a random string and the sender's host name or IP address. The combination of the To, From, and Call-ID headers completely defines a peer-to-peer SIP relationship between the sender and the receiver. This relationship is called a SIP dialog. `Call-ID: ddeg45e793@10.31.101.30`
Contact	Included in SIP request messages, the Contact header contains the SIP URI of the sender of the SIP request message. The receiver uses this URI to contact the sender. For example: `Contact: Sender <sip:sender@10.31.100.20>t`
Content-Length	The number of bytes in the message body (in bytes). `Content-Length: 126`

Table 114:SIP headers (continued)

SIP Header	Description
Content-Type	In addition to SIP headers, SIP messages include a message body that contains information about the content or communication being managed by the SIP session. The Content-Type header specifies what the content of the SIP message is. For example, if you are using SIP with SDP, the content of the SIP message is SDP code. `Content-Type: application/sdp`
CSeq	The command sequence header contains a sequence integer that is increased for each new SIP request message (but is not incremented in the response message). This header also incudes the request name found in the request message request-line. For example: `CSeq: 1 INVITE`
Expires	Gives the relative time after which the message (or content) expires. The actual time and how the header is used depends on the SIP method. For example: `Expires: 5`
From	Identifies the sender of the message. Responses to a message are sent to the address of the sender. The following example includes the sender's name (`Sender`) and the sender's SIP address (`sender@10.31.101.20`.): `From: Sender <sip:sender@10.31.101.20>`
Max-forwards	An integer in the range 0-255 that limits the number of proxies or gateways that can forward the request message to the next downstream server. Also called the number of hops, this value is decreased every time the message is forwarded. This can also be useful when the client is attempting to trace a request chain that appears to be failing or looping in mid-chain. For example: `Max-Forwards: 30`
P-Asserted-Identity	The P-Asserted-Identity header is used among trusted SIP entities to carry the identity of the user sending a SIP message as it was verified by authentication. See RFC 3325. The header contains a SIP URI and an optional display-name, for example: `P-Asserted-Identity: "Example Person" <sip:10.31.101.50>`
RAck	Sent in a PRACK request to support reliability of information or provisional response messages. It contains two numbers and a method tag. For example: `RAck: 776656 1 INVITE`
Record-Route	Inserted into request messages by a SIP proxy to force future requests to be routed through the proxy. In the following example, the host at IP address 10.31.101.50 is a SIP proxy. The `lr` parameter indicates the URI of a SIP proxy in Record-Route headers. `Record-Route: <sip:10.31.101.50;lr>`

Table 114:SIP headers (continued)

SIP Header	Description

Route	Forces routing for a request message through one or more SIP proxies. The following example includes two SIP proxies:
	`Route: <sip:172.20.120.10;lr>,`
	`<sip:10.31.101.50;lr>`

RSeq	The RSeq header is used in information or provisional response messages to support reliability of informational response messages. The header contains a single numeric value. For example: `RSeq: 33456`
To	Identifies the receiver of the message. The address in this field is used to send the message to the receiver. The following example includes the receiver's name (`Receiver`) and the receiver's SIP address (`receiver@10.31.101.30`.): `To: Receiver <sip:receiver@10.31.101.30>`
Via	Indicates the SIP version and protocol to be used for the SIP session and the address to which to send the response to the message that contains the Via field. The following example Via field indicates to use SIP version 2, UDP for media communications, and to send the response to 10.31.101.20 using port 5060. `Via: SIP/2.0/UDP 10.31.101.20:5060`

The SIP message body and SDP session profiles

The SIP message body describes the session to be initiated. For example, in a SIP phone call the body usually includes audio codec types, sampling rates, server IP addresses and so on. For other types of SIP session the body could contain text or binary data of any type which relates in some way to the session. The message body is included in request and response messages.

Two possible SIP message body types:

- Session Description Protocol (SDP), most commonly used for SIP VoIP.
- Multipurpose Internet Mail Extensions (MIME)

SDP is most often used for VoIP and FortiGate units support SDP content in SIP message bodies. SDP is a text-based protocol used by SIP to control media sessions. SDP does not deliver media but provides a session profile that contains media details, transport addresses, parameter negotiation, and other session description metadata for the participants in a media session. The participants use the information in the session profile to negotiate how to communicate and to manage the media session. SDP is described by RFC 4566.

An SDP session profile always contains session information and may contain media information. Session information appears at the start of the session profile and media information (using the `m=` attribute) follows.

SDP session profiles can include the attributes listed in Table 115.

Table 115:SDP session profile attributes

Attribute	Description
a=	Attributes to extend SDP in the form `a=<attribute>` or `a=<attribute>:<value>`.
b=	Contains information about the bandwidth required for the session or media in the form `b=<bandwidth_type>:<bandwidth>`.
c=	Connection data about the session including the network type (usually IN for Internet), address type (IPv4 or IPv6), the connection source address, and other optional information. For example: `c=IN IPv4 10.31.101.20`
i=	A text string that contains information about the session. For example: `i=A audio presentation about SIP`
k=	Can be used to convey encryption keys over a secure and trusted channel. For example: `k=clear:444gdduudjffdee`

m=	Media information, consisting of one or more lines all starting with `m=` and containing details about the media including the media type, the destination port or ports used by the media, the protocol used by the media, and a media format description.
	`m=audio 49170 RTP 0 3`
	`m-video 3345/2 udp 34`
	`m-video 2910/2 RTP/AVP 3 56`
	Multiple media lines are needed if SIP is managing multiple types of media in one session (for example, separate audio and video streams).
	Multiple ports for a media stream are indicated using a slash. `3345/2` udp means UDP ports 3345 and 3346. Usually RTP uses even-numbered ports for data with the corresponding one-higher odd ports used for the RTCP session belonging to the RTP session. So `2910/2 RTP/AVP` means ports 2910 and 2912 are used for RTP and 2911 and 2913 are used for RTCP.
	Media types include `udp` for an unspecified protocol that uses UDP, `RTP` or `RTP/AVP` for standard RTP and `RTP/SAVP` for secure RTP.

o=	The sender's username, a session identifier, a session version number, the network type (usually IN for Internet), the address type (for example, IPv4 or IPv6), and the sending device's IP address. The `o=` field becomes a universal identifier for this version of this session description. For example: `o=PhoneA 5462346 332134 IN IP4 10.31.101.20`

r=	Repeat times for a session. Used if a session will be repeated at one or more timed intervals. Not normally used for VoIP calls. The times can be in different formats. For example.
	`r=7d 1h 0 25h`
	`r=604800 3600 0 90000`

Table 115:SDP session profile attributes (continued)

Attribute	Description
s=	Any text that describes the session or s= followed by a space. For example: `s=Call from inviter`
t=	The start and stop time of the session. Sessions with no time restrictions (most VoIP calls) have a start and stop time of 0. `t=0 0`
v=	SDP protocol version. The current SDP version is 0 so the v= field is always: `v=0`
z=	Time zone adjustments. Used for scheduling repeated sessions that span the time between changing from standard to daylight savings time. `z=2882844526 -1h 2898848070 0`

Example SIP messages

The following example SIP INVITE request message was sent by PhoneA to PhoneB. The first nine lines are the SIP headers. The SDP profile starts with v=0 and the media part of the session profile is the last line, starting with m=.

```
INVITE sip:PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 10.31.101.50:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneA@10.31.101.20
Content-Type: application/sdp
Content-Length: 124
v=0
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
s=Let's Talk
t=0 0
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
```

The following example shows a possible 200 OK SIP response message in response to the previous INVITE request message. The response includes `200 OK` which indicates success, followed by an echo of the original SIP INVITE request followed by PhoneB's SDP profile.

```
SIP/2.0 200 OK
Via: SIP/2.0/UDP 10.31.101.50:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneB@10.31.101.30
Content-Type: application/sdp
Content-Length: 107
v=0
o=PhoneB 124333 67895 IN IP4 172.20.120.30
s=Hello!
t=0 0
c=IN IP4 172.20.120.30
m=audio 3456 RTP 0
```

SIP can support multiple media streams for a single SIP session. Each media steam will have its own c= and m= lines in the body of the message. For example, the following message includes three media streams:

```
INVITE sip:PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 10.31.101.20:5060
From: PhoneA <sip:PhoneA@10.31.101.20>
To: PhoneB <sip:PhoneB@172.20.120.30>
Call-ID: 314159@10.31.101.20
CSeq: 1 INVITE
Contact: sip:PhoneA@10.31.101.20
Content-Type: application/sdp
Content-Length: 124
v=0
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
s=Let's Talk
t=0 0
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
c=IN IP4 10.31.101.20
m=audio 49172 RTP 0 3
c=IN IP4 10.31.101.20
m=audio 49174 RTP 0 3
```

The SIP session helper

The SIP session-helper is a high-performance solution that provides basic support for SIP calls passing through the FortiGate unit by opening SIP and RTP pinholes and by performing NAT of the addresses in SIP messages.

The SIP session helper:

- Understands SIP dialog messages.
- Keeps the states of the SIP transactions between SIP UAs and SIP servers.
- Translates SIP header and SDP information to account for NAT operations performed by the FortiGate unit.
- Opens up and closes dynamic SIP pinholes for SIP signalling traffic.
- Opens up and closes dynamic RTP and RTSP pinholes for RTP and RTSP media traffic.
- Provides basic SIP security as an access control device.
- Uses the intrusion protection (IPS) engine to perform basic SIP protocol checks.

SIP session helper configuration overview

The SIP session helper is enabled by default and set to listen for SIP traffic on TCP or UDP port 5060. SIP sessions using port 5060 accepted by a security policy that does not include a VoIP profile are processed by the SIP session helper.

You can enable and disable the SIP session helper, change the TCP or UDP port that the session helper listens on for SIP traffic, and enable or disable SIP NAT tracing. If the FortiGate unit is operating with multiple VDOMs, each VDOM can have a different SIP session helper configuration.

To have the SIP session helper process SIP sessions you need to add a security policy that accepts SIP sessions on the configured SIP UDP or TCP ports. The security policies can have service set to ANY, or to the SIP pre-defined firewall service, or a custom firewall service. The SIP pre-defined firewall service restricts the security policy to only accepting sessions on UDP port 5060.

If NAT is enabled for security policies that accept SIP traffic, the SIP session helper translates addresses in SIP headers and in the RDP profile and opens up pinholes as required for the SIP traffic. This includes security policies that perform source NAT and security policies that contain virtual IPs that perform destination NAT and port forwarding. No special SIP configuration is required for this address translation to occur, it is all handled automatically by the SIP session helper according to the NAT configuration of the security policy that accepts the SIP session.

To use the SIP session helper you must not add a VoIP profile to the security policy. If you add a VoIP profile, SIP traffic bypasses the SIP session helper and is processed by the SIP ALG.

In most cases you would want to use the SIP ALG since the SIP session helper provides limited functionality. However, the SIP session helper is available and can be useful for high-performance solutions where a high level of SIP security is not a requirement.

Disabling and enable the SIP session helper

You can use the following steps to disable the SIP session helper. You might want to disable the SIP session helper if you don't want the FortiGate unit to apply NAT or other SIP session help features to SIP traffic. With the SIP session helper disabled, the FortiGate unit can still accept SIP sessions if they are allowed by a security policy, but the FortiGate unit will not be able to open pinholes or NAT the addresses in the SIP messages.

To disable the sip session helper

1. Enter the following command to find the sip session helper entry in the session-helper list:

```
show system session-helper
   .
   .
   .
edit 13
   set name sip
   set port 5060
   set protocol 17
next
   .
   .
   .
```

   This command output shows that the sip session helper listens in UDP port 5060 for SIP sessions.

2. Enter the following command to delete session-helper list entry number 13 to disable the sip session helper:

```
config system session-helper
   delete 13
end
```

If you want to use the SIP session helper you can verify whether it is enabled or disabled using the `show system session-helper` command.

You do not have to disable the SIP session helper to use the SIP ALG.

If the SIP session helper has been disable by being removed from the session-helper list you can use the following command to enable the SIP session helper by adding it back to the session helper list:

```
config system session-helper
   edit 0
      set name sip
      set port 5060
      set protocol 17
end
```

Changing the port numbers that the SIP session helper listens on

You can use the following command to change the port number that the SIP session helper listens on for SIP traffic to 5064. The SIP session helper listens on the same port number for UDP and TCP SIP sessions. In this example, the SIP session helper is session helper 13:

```
config system session-helper
  edit 13
    set port 5064
  end
```

The `config system settings` options `sip-tcp-port`, `sip-udp-port`, and `sip-ssl-port` control the ports that the SIP ALG listens on for SIP sessions. See "Changing the port numbers that the SIP ALG listens on" on page 2516.

Your FortiGate unit may use a different session helper number for SIP. Enter the following command to view the session helpers:

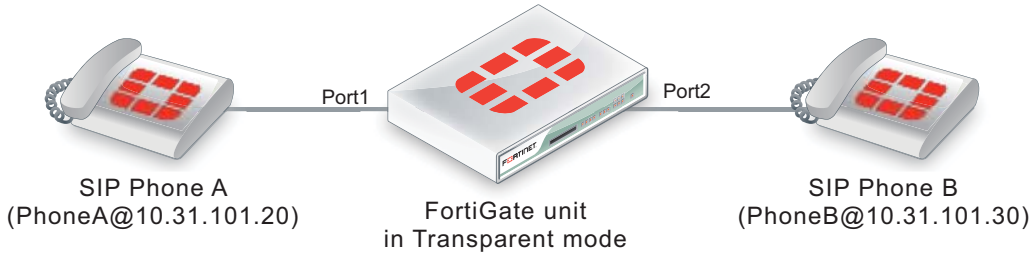
```
show system session-helper
  .
  .
  .
  edit 13
    set name sip
    set port 5060
    set protocol 17
  end
  .
  .
  .
```

Configuration example: SIP session helper in Transparent Mode

Figure 355 shows an example SIP network consisting of a FortiGate unit operating in Transparent mode between two SIP phones. Since the FortiGate unit is operating in Transparent mode both phones are on the same network and the FortiGate unit and the SIP session helper does not perform NAT. Even though the SIP session helper is not performing NAT you can use this configuration to apply SIP session helper security features to the SIP traffic.

The FortiGate unit requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A.

Figure 355:SIP network with FortiGate unit in Transparent mode



General configuration steps

The following general configuration steps are required for this SIP configuration that uses the SIP session helper. This example includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the firewall service to ANY to allow traffic other than SIP on UDP port 5060.

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A.
3. Add a security policy that accepts SIP sessions initiated by Phone B.

Configuration steps - web-based manager

To add firewall addresses for the SIP phones

1. Go to *Firewall Objects* > *Address* > *Addresses*.
2. Select *Create New* to add the following addresses for Phone A and Phone B:

Address Name	Phone_A
Type	Subnet
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	port1

Address Name	Phone_B
Type	Subnet
Subnet / IP Range	10.31.101.30/255.255.255.255
Interface	port2

To add security policies to accept SIP sessions

1. Go to *Policy* > *Policy* > *Policy*.
2. Select *Create New* to add a security policy.
3. Add a security policy to allow Phone A to send SIP request messages to Phone B:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port1
Source Address	Phone_A
Outgoing Interface	port2
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT

4. Select *OK*.
5. Add a security policy to allow Phone B to send SIP request messages to Phone A:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	Phone_B
Outgoing Interface	port1
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT

6. Select *OK*.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to accept SIP sessions

1. Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
  edit Phone_A
    set associated interface port1
    set type ipmask
    set subnet 10.31.101.20 255.255.255.255
  next
  edit Phone_B
    set associated interface port2
    set type ipmask
    set subnet 10.31.101.30 255.255.255.255
  end
```

2. Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr Phone_A
    set dstaddr Phone_B
    set action accept
    set schedule always
    set service SIP
  next
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr Phone_B
    set dstaddr Phone_A
    set action accept
    set schedule always
    set service SIP
    set utm-status enable
  end
```

SIP session helper diagnose commands

You can use the `diagnose sys sip` commands to display diagnostic information for the SIP session helper.

Use the following command to set the debug level for the SIP session helper. Different debug masks display different levels of detail about SIP session helper activity.

```
diagnose sys sip debug-mask <debug_mask_int>
```

Use the following command to display the current list of SIP dialogs being processed by the SIP session help. You can also use the `clear` option to delete all active SIP dialogs being processed by the SIP session helper.

```
diagnose sys sip dialog {clear | list}
```

Use the following command to display the current list of SIP NAT address mapping tables being used by the SIP session helper.

```
diagnose sys sip mapping list
```

Use the following command to display the current SIP session helper activity including information about the SIP dialogs, mappings, and other SIP session help counts. This command can be useful to get an overview of what the SIP session helper is currently doing.

```
diagnose sys sip status
```

The SIP ALG

In most cases you should use the SIP Application Layer Gateway (ALG) for processing SIP sessions. The SIP ALG provides the same basic SIP support as the SIP session helper. Additionally, the SIP ALG provides a wide range of features that protect your network from SIP attacks, can apply rate limiting to SIP sessions, can check the syntax of SIP and SDP content of SIP messages, and provide detailed logging and reporting of SIP activity.

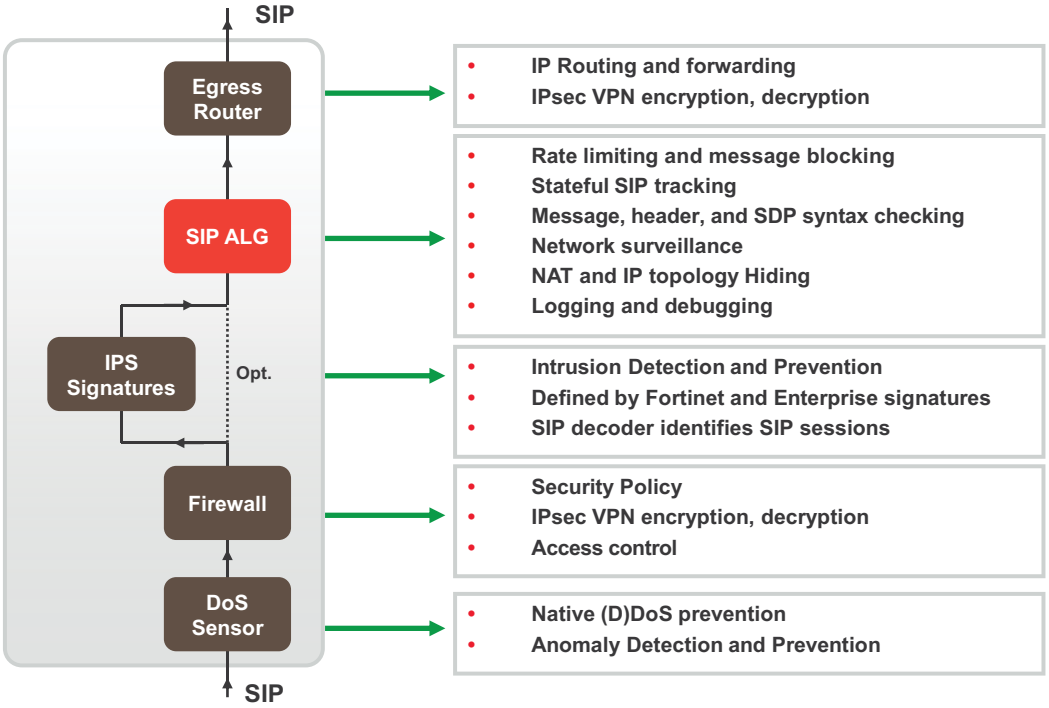
You apply the SIP ALG to SIP traffic by adding a VoIP profile with SIP enabled to a security policy that accepts SIP traffic. The SIP session helper is automatically bypassed by traffic accepted by a security policy that includes a VoIP profile.

As shown in Figure 356, the FortiGate SIP ALG intercepts SIP packets after they have been routed by the routing module, accepted by a security policy and passed through DoS and IPS Sensors (if DoS and IPS are enabled). The ALG raises SIP packets to the application layer, analyzes the SIP and SDP addressing information in the SIP messages, makes adjustments (for example, NAT) to this addressing if required, and then sends the packets out the egress interface to their destination.

The SIP ALG provides:

- All the same features as the SIP session help including NAT and SIP and RTP Pinholes.
- In addition for the ALG you can enable or disable RTP pinholing, SIP register pinholing and SIP contact pinholing. In a signalling only environment where the RTP stream bypasses the FortiGate unit, you can disable RTP pinholing to improve performance.
- SIP TCP and UDP support
- SIP Message order checking
- Configurable Header line length maximums

Figure 356: The SIP ALG works at the application level after ingress packets are accepted by a security policy



- Message fragment assembly (TCP)
- If SIP messages are fragmented across multiple packets, the FortiGate unit assembles the fragments, does inspection and pass the message in its entirety to the SIP server as one packet. This offloads the server from doing all the TCP processing of fragments.
- L4 Protocol Translation
- Message Flood Protection
- Protects a SIP server from intentional or unintentional DoS of flooding INVITE, REGISTER, and other SIP methods by allowing control of the rate that these massages pass through the FortiGate unit.
- SIP message type filtering
- The FortiGate unit can prevent specified SIP message types from passing through the FortiGate unit to a SIP server. For example In a voice only SIP implementation, there may be no need to permit a SUBSCRIBE message to ever make it's way to the SIP call processor. Also, if a SIP server cannot process some SIP message types you can use SIP message type filtering to block them. For example, a SIP server could have a bug that prevents it from

processing certain SIP messages. In this case you can temporarily block these message types until problem with the SIP server has been fixed.

- SIP statistics and logging
- SIP over IPv6
- SIP over SSL/TLS
- Deep SIP message syntax checking (also called deep SIP header inspection or SIP fuzzing protection). Prevents attacks that use malformed SIP messages. Can check many SIP headers and SDP statements. Configurable bypass and modification options.
- Hosted NAT traversal, Resolves IP address issue in SIP and SDP lines due to NAT-PT in far end firewall. Important feature for VoIP access networks.
- SIP High Availability (HA), including active-passive clustering and session pickup (session failover) for SIP sessions.
- Geographical Redundancy. In an HA configuration, if the active SIP server fails (missing SIP heartbeat messages or SIP traffic) SIP sessions can be redirected to a secondary SIP server in another location.
- SIP per request method message rate limitation with configurable threshold for SIP message rates per request method. Protects SIP servers from SIP overload and DoS attacks.
- RTP Bypass, Supports configurations with and without RTP pinholing. May inspect and protect SIP signaling only.
- SIP NAT with IP address conservation. Performs SIP and RTP aware IP Network Address translation. Preserves the lost IP address information in the SDP profile i= line for later processing/debugging in the SIP server. See “NAT with IP address conservation” on page 2544.
- IP topology hiding
- The IP topology of a network can be hidden through NAT and NAPT manipulation of IP and SIP level addressing. For example, see “SIP NAT configuration example: destination address translation (destination NAT)” on page 2539.
- SIP inspection without address translation
- The SIP ALG inspects SIP messages but addresses in the messages are not translated. This feature can be applied to a FortiGate unit operating in Transparent mode or in NAT/Route mode. In Transparent mode you add normal Transparent mode security policies that enable the SIP ALG and include a VoIP profile that causes the SIP ALG to inspect SIP traffic as required. For an example configuration, see “Configuration example: SIP in Transparent Mode” on page 2522.
- For a FortiGate unit operating in NAT/Route mode, if SIP traffic can pass between different networks without requiring NAT because is supported by the routing configuration, you can add security policies that accept SIP traffic without enabling NAT. In the VoIP profile you can configure the SIP ALG to inspect SIP traffic as required.

SIP ALG configuration overview

To apply the SIP ALG, you add a SIP VoIP profile to a security policy that accepts SIP sessions. All SIP sessions accepted by the security policy will be processed by the SIP ALG using the settings in the VoIP profile. The VoIP profile contains settings that are applied to SIP, Session Initiation Protocol for Instant Messaging and Presence Leveraging Extensions (SIMPLE) and Skinny Call Control Protocol (SCCP) sessions. You configure SIP and SCCP settings separately. SIP settings also apply to SIMPLE sessions.

Enabling VoIP support on the web-based manager

Before you begin adding VoIP profiles to security policies you may have to enable VoIP support on the web-based manager. To do this, on the web-based manager go to *System* > *Admin* > *Settings* and make sure that the *VoIP* checkbox is selected.

From the CLI you can also enter the following command enable VoIP support on the GUI:

```
config system global
  set gui-voip-profile enable
end
```

VoIP profiles

To add a new VoIP profile from the web-based manager go to *UTM Security Profiles* > *VoIP* > *Profile* and select *Create New*.

For SIP, from the web-based manager you can configure the VoIP profile to limit the number of SIP REGISTER and INVITE requests and enable logging of SIP sessions and SIP violations. Many additional options for configuring how the ALG processes SIP sessions are available from the CLI.

For SCCP you can limit the call setup time. Additional SCCP options are available from the CLI.

Use the following command to add a VoIP profile named VoIP_Pro_1 from the CLI:

```
config voip profile
  edit VoIP_Pro_1
end
```

FortiGate units include two pre-defined VoIP profiles. On the web-based manager these profiles look identical. However, the CLI-only settings result in the following functionality.

default	The most commonly used VoIP profile. This profile enables both SIP and SCCP and places the minimum restrictions on what calls will be allowed to negotiate. This profile allows normal SCCP, SIP and RTP sessions and enables the following security settings: • `block-long-lines` to block SIP messages with lines that exceed maximum line lengths. • `block-unknown` to block unrecognized SIP request messages. • `log-violations` to write log messages that record SIP violations. • `log-call-summary` to write log messages that record SIP call progress (similar to DLP archiving). • `nat-trace` (see "NAT with IP address conservation" on page 2544). • `contact-fixup` perform NAT on the IP addresses and port numbers in SIP headers in SIP CONTACT messages even if they don't match the session's IP address and port numbers.
strict	This profile is available for users who want to validate SIP messages and to only allow SIP sessions that are compliant with RFC 3261. In addition to the settings in the default VoIP profile, the strict profile sets all SIP deep message inspection header checking to block and drop SIP messages that contain malformed SIP or SDP lines that can be detected by the ALG. For more information about SIP deep header inspection, see "Deep SIP message inspection" on page 2558.

Neither of the default profiles applies SIP rate limiting or message blocking. To apply more ALG features to SIP sessions you can clone (copy) the pre-defined VoIP profiles and make your own modifications to them. For example, to clone the default profile and configure the limit for SIP NOTIFY request messages to 1000 messages per second per security policy and block SIP INFO request messages.

```
config voip profile
  clone default to my_voip_pro
  edit my_voip_pro
    config sip
      set notify-rate 1000
      set block-info enable
    end
end
```

Changing the port numbers that the SIP ALG listens on

Most SIP configurations use TCP or UDP port 5060 for SIP sessions and port 5061 for SIP SSL sessions. If your SIP network uses different ports for SIP sessions you can use the following command to configure the SIP ALG to listen on a different TCP, UDP, or SSL ports. For example, to change the TCP port to 5064, the UDP port to 5065, and the SSL port to 5066.

```
config system settings
  set sip-tcp-port 5064
  set sip-udp-port 5065
  set sip-ssl-port 5066
end
```

You also configure the SIP ALG to listen in two different TCP ports and two differnet UDP ports for SIP sessions. For example, if you receive SIP TCP traffic on port 5060 and 5064 and UDP traffic on ports 5061 and 5065 you can enter the following command to receive the SIP traffic on all of these ports:

```
config system settings
  set sip-tcp-port 5060 5064
  set sip-udp-port 5061 5065
end
```

Disabling the SIP ALG in a VoIP profile

SIP is enabled by default in a VoIP profile. Usually you would want SIP to be enabled in a VoIP profile. But in some cases if you are just using the VoIP profile for SCCP you can use the following command to disable SIP in a VoIP profile.

```
config voip profile
  edit VoIP_Pro_2
    config sip
      set status disable
    end
end
```

SIP ALG get and diagnose commands

You can use the following commands to display diagnostic information for the SIP ALG.

Use the following command to list all active SIP calls being processed by the SIP ALG. You can also use the `clear` option to delete all active SIP calls being processed by the SIP ALG.

```
diagnose sys sip-proxy calls {clear | list}
```

Use the following commands to use filters to display specific information about the SIP ALG and the session that it is processing.

```
diagnose sys sip-proxy filter <filter_options>
diagnose sys sip-proxy log-filter <filter_options>
```

Use the following command to display the active SIP rate limiting meters and their current settings.

```
diagnose sys sip-proxy meters list
```

Use the following command to display status information about the SIP sessions being processed by the SIP ALG. You can also clear all SIP ALG statistics.

```
diagnose sys sip-proxy stats {clear | list}
```

Conflicts between the SIP ALG and the session helper

Even if the SIP session helper is enabled, if a security policy with a VoIP profile that has SIP enabled accepts a SIP session on the TCP or UDP port that the SIP ALG listens on the ALG is used. You don't need to turn off the session helper to use the ALG.

You may find that the session helper is being used for some SIP sessions even when you only want to use the ALG. This happens if a policy that does not include a VoIP profile is accepting SIP sessions. The VoIP profile could have been left out of the policy by mistake or the wrong policy could be accepting SIP sessions.

Consider a configuration with a SIP server on a private network that is contacted by SIP phones on the Internet and on the private network (similar to the configuration in Figure 352 on page 2494). The FortiGate unit that provides NAT between the private network and the Internet requires a security policy with a firewall virtual IP that allows the SIP phones on the Internet to contact the SIP server. The FortiGate unit also requires outgoing security policies to allow the SIP phones and the SIP server to contact the SIP phones on the Internet.

If a VoIP profile is not added to one of the outgoing security policies the SIP sessions accepted by that policy will be processed by the SIP session helper instead of the SIP ALG. Also, its possible that some of the SIP sessions could be accepted by a general outgoing policy instead of the policy intended for SIP traffic. You can fix the first problem by adding a VoIP profile to the policy. You can fix the second problem by reviewing the security policy order and source and destination addresses in the security policies and determining if there is a conflict between these and the IP addresses of the SIP server or SIP phones on the Internal network.

You can use `diagnose sys sip` commands to determine if the SIP session helper is processing SIP sessions. For example, the following command displays the overall status of the SIP sessions being processed by the SIP session helper:

The `diagnose sys sip` commands only display current status information. To see activity the SIP session helper has to actually be processing SIP sessions when you enter the command. For example, if the SIP session helper had been used for processing calls that ended 5 minutes ago, the command output would show no SIP session helper activity.

```
diagnose sys sip status
dialogs: max=32768, used=0
mappings: used=0
dialog hash by ID: size=2048, used=0, depth=0
dialog hash by RTP: size=2048, used=0, depth=0
mapping hash: size=2048, used=0, depth=0
count0: 0
count1: 0
count2: 0
count3: 0
count4: 0
```

This command output shows that the session helper is not processing SIP sessions because all of the used and count fields are 0. If any of these fields contains non-zero values then the SIP session helper may be processing SIP sessions.

Also, you can check to see if some ALG-only features are not being applied to all SIP sessions. For example, the VoIP usage widget on the FortiGate dashboard displays statistics for SIP and SCCP calls processed by the ALG but not for calls processed by the session helper. So if you see fewer calls than expected the session helper may be processing some of them.

Other logging and monitoring features such as log messages and DLP archiving are only supported by the ALG.

Finally, you can check the policy usage and session information dashboard widgets to see if SIP sessions are being accepted by the wrong security policies.

Stateful SIP tracking, call termination, and session inactivity timeout

The SIP ALG tracks SIP dialogs over their lifespan between the first INVITE message and the Final 200 OK and ACK messages. For every SIP dialog, stateful SIP tracking reviews every SIP message and makes adjustment to SIP tracking tables as required. These adjustments include source and destination IP addresses, address translation, dialog expiration information, and media stream port changes. Such changes can also result in dynamically opening and closing pinholes. You can use the `diagnose sys sip-proxy stats list` and the `diagnose sys sip-proxy filter` command to view the SIP call data being tracked by the SIP ALG.

The SIP ALG uses the SIP Expires header line to time out a SIP dialog if the dialog is idle and a Re-INVITE or UPDATE message is not received. The SIP ALG gets the Session-Expires value, if present, from the 200 OK response to the INVITE message. If the SIP ALG receives an INVITE before the session times out, all timeout values are reset to the settings in the new INVITE message or to default values. As a precautionary measure, the SIP ALG uses hard timeout values to set the maximum amount of time a call can exist. This ensures that the FortiGate unit is protected if a call ends prematurely.

When a SIP dialog ends normally, the SIP ALG deletes the SIP call information and closes open pinholes. A SIP call can also end abnormally due to an unexpected signaling or transport event that cuts off the call. When a call ends abnormally the SIP messages to end the call may not be sent or received. A call can end abnormally for the following reasons:

- Phones or servers crash during a call and a BYE message is not received.
- To attack a SIP system, a malicious user never send a BYE message.
- Poor implementations of SIP fail to process Record-Route messages and never send a BYE message.
- Network failures prevent a BYE message from being received.

Any phone or server in a SIP call can cancel the call by sending a CANCEL message. When a CANCEL message is received by the FortiGate unit, the SIP ALG closes open pinholes. Before terminating the call, the ALG waits for the final 200 OK message.

The SIP ALG can be configured to terminate SIP calls if the SIP dialog message flow or the call RTP (media) stream is interrupted and does not recover. You can use the following commands to configure terminating inactive SIP sessions and to set timers or counters to control when the call is terminated by the SIP ALG.

Adding a media stream timeout for SIP calls

Use the following command in a VoIP profile to terminate SIP calls accepted by a security policy containing the VoIP profile when the RTP media stream is idle for 100 seconds.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set call-keepalive 100
    end
end
```

You can adjust this setting between 1 and 10,080 seconds. The default call keepalive setting of 0 disables terminating a call if the media stream is interrupted. Set call keepalive higher if your network has latency problems that could temporarily interrupt media streams. If you have configured call keepalive and the FortiGate unit terminates calls unexpectedly you can increase the call keepalive time to resolve the problem.

Call keep alive should be used with caution because enabling this feature results in extra FortiGate CPU overhead and can cause delay/jitter for the VoIP call. Also, the FortiGate unit terminates the call without sending SIP messages to end the call. And if the SIP endpoints send SIP messages to terminate the call they will be blocked by the FortiGate unit if they are sent after the FortiGate unit terminates the call.

Adding an idle dialog setting for SIP calls

Use the following command in a VoIP profile to terminate SIP calls when for a single security policy, when the configured number of SIP calls (or dialogs) has stopped receiving SIP messages or has not received legitimate SIP messages. Using this command you can configure how many dialogs that have been accepted by a security policy that the VoIP profile is added to become idle before the SIP ALG deletes the oldest ones. The following command sets the maximum number of idle dialogs to 200:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-idle-dialogs 200
    end
end
```

Idle dialogs would usually be dialogs that have been interrupted because of errors or problems or as the result of a SIP attack that opens a large number of SIP dialogs without closing them. This command provides a way to remove these dialogs from the dialog table and recover memory and resources being used by these open and idle dialogs.

You can adjust this setting between 1 and a very high number. The default maximum idle dialogs setting of 0 disables this feature. Set maximum dialogs higher if your network has latency problems that could temporarily interrupt SIP messaging. If you have configured max idle dialogs and the FortiGate unit terminates calls unexpectedly you can increase the max idle dialogs number to resolve the problem.

Changing how long to wait for call setup to complete

In some cases and some configurations your SIP system may experience delays during call setup. If this happens, some SIP ALG timers may expire before call setup is complete and drop the call. In some cases you may also want to reduce the amount of time the SIP ALG allows for call setup to complete.

You can use the `provisional-invite-expiry-time` SIP VoIP profile option to control how long the SIP ALG waits for provisional INVITE messages before assuming that the call setup has been interrupted and the SIP call should be dropped. The default value for this timer is 210 seconds. You can change it to between 10 and 3600 seconds.

Use the following command to change the expiry time to 100 seconds.

```
config voip profile
  edit Profile_name
    config sip
      set provisional-invite-expiry-time 100
    end
end
```

SIP and RTP/RTCP

FortiGate units support the Real Time Protocol (RTP) application layer protocol for the VoIP call audio stream. RTP uses dynamically assigned port numbers that can change during a call. SIP control messages that start a call and that are sent during the call inform callers of the port number to use and of port number changes during the call.

During a call, each RTP session will usually have a corresponding Real Time Control Protocol (RTCP) session. By default, the RTCP session port number is one higher than the RTP port number.

The RTP port number is included in the `m=` part of the SDP profile. In the example above, the SIP INVITE message includes RTP port number is 49170 so the RTCP port number would be 49171. In the SIP response message the RTP port number is 3456 so the RTCP port number would be 3457.

How the SIP ALG creates RTP pinholes

The SIP ALG requires the following information to create a pinhole. The SIP ALG finds this information in SIP messages and some is provided by the SIP ALG:

Protocol	UDP (Extracted from SIP messages by the SIP ALG.)
Source IP	Any
Source port	Any

Destination IP	The SIP ALG extracts the destination IP address from the c= line in the SDP profile. The c= line can appear in either the session or media part of the SDP profile. The SIP ALG uses the IP address in the c= line of the media part of the SDP profile first. If the media part does not contain a c= line, the SIP ALG checks the c= line in the session part of the SDP profile. If the session part of the profile doesn't contain a c= line the packet is dropped. Pinholes for RTP and RTCP sessions share the same destination IP address.
Destination port	The SIP ALG extracts the destination port number for RTP from the m= field and adds 1 to this number to get the RTCP port number.
Lifetime	The length of time during which the pinhole will be open. When the lifetime ends, the SIP ALG removes the pinhole.

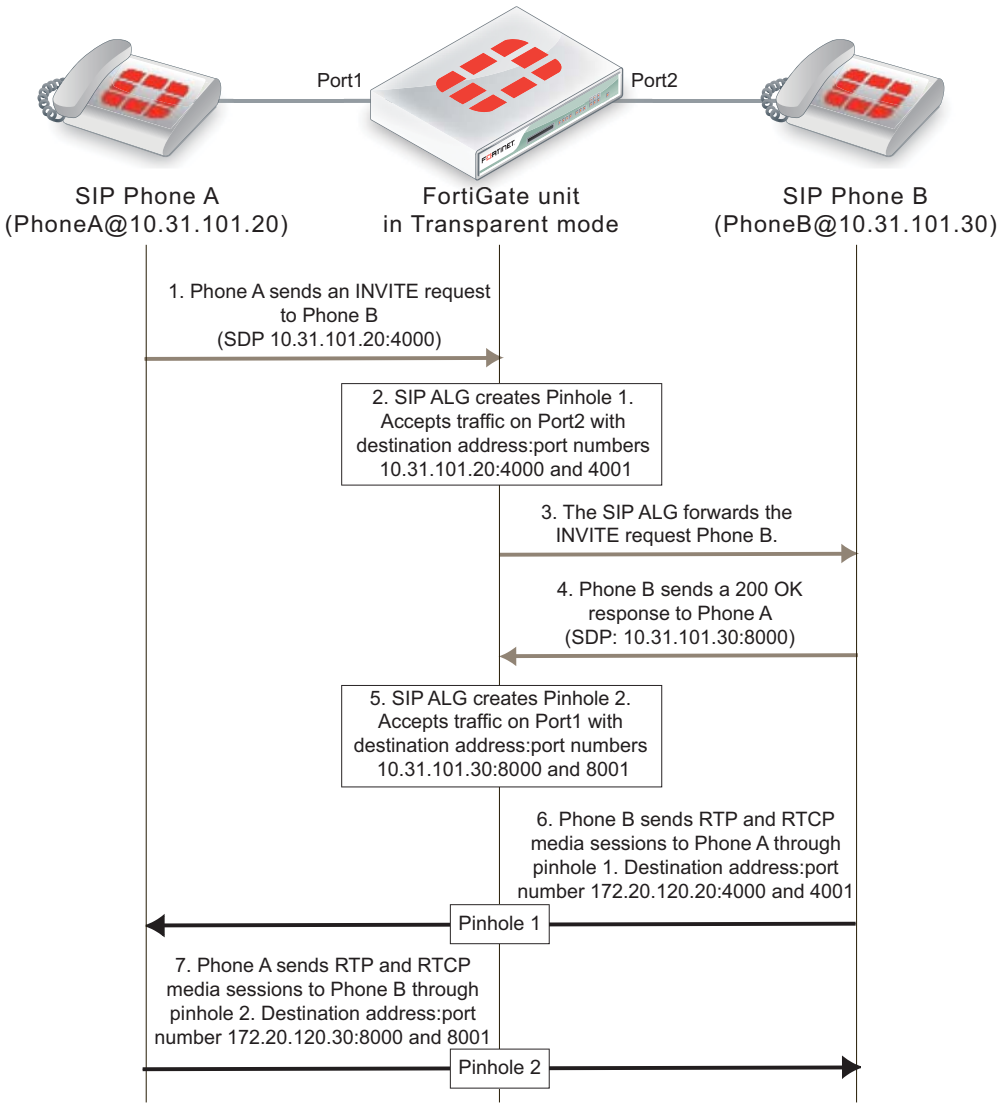
The SIP ALG keeps RTP pinholes open as long as the SIP session is alive. When the associated SIP session is terminated by the SIP ALG or the SIP phones or servers participating in the call, the RTP pinhole is closed.

Figure 357 shows a simplified call setup sequence that shows how the SIP ALG opens pinholes. Phone A and Phone B are installed on either side of a FortiGate unit operating in Transparent mode. Phone A and Phone B are on the same subnet. The FortiGate unit includes a security policy that accepts SIP sessions from port1 to port2 and from port2 to port1. The FortiGate unit does not require an RTP security policy, just the SIP policy.

You can see from this diagram that the SDP profile in the INVITE request from Phone A indicates that Phone A is expecting to receive a media stream sent to its IP address using port 4000 for RTP and port 4001 for RTCP. The SIP ALG creates pinhole 1 to allow this media traffic to pass through the FortiGate unit. Pinhole 1 is opened on the Port2 interface and will accept media traffic sent from Phone B to Phone A.

When Phone B receives the INVITE request from Phone A, Phone B will know to send media streams to Phone A using destination IP address 10.31.101.20 and ports 4000 and 4001. The 200 OK response sent from Phone B indicates that Phone B is expecting to receive a media stream sent to its IP address using ports 8000 and 8001. The SIP ALG creates pinhole 2 to allow this media traffic to pass through the FortiGate unit. Pinhole 2 is opened on the Port1 interface and will accept media traffic sent from Phone A to Phone B.

Figure 357:SIP call setup with a FortiGate unit in Transparent mode

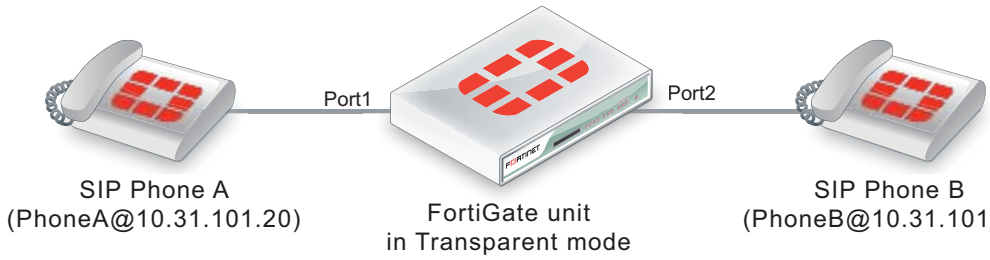


Configuration example: SIP in Transparent Mode

Figure 358 shows an example SIP network consisting of a FortiGate unit operating in Transparent mode between two SIP phones. Since the FortiGate unit is operating in Transparent mode both phones are on the same network and the FortiGate unit and the SIP ALG does not perform NAT. Even though the SIP ALG is not performing NAT you can use this configuration to apply SIP security features to the SIP traffic.

The FortiGate unit requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A.

Figure 358:SIP network with FortiGate unit in Transparent mode



General configuration steps

The following general configuration steps are required for this SIP configuration. This example uses the default VoIP profile. The example also includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the security service to ANY to allow traffic other than SIP on UDP port 5060.

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A and includes the default VoIP profile.
3. Add a security policy that accepts SIP sessions initiated by Phone B and includes the default VoIP profile.

Configuration steps - web-based manager

Before you begin this procedure you may have to enable VoIP support on the web-based manager by going to *System* > *Admin* > *Settings* and selecting the *VoIP* checkbox.

To add firewall addresses for the SIP phones

1. Go to *Firewall Objects* > *Address* > *Addresses*.
2. Add the following addresses for Phone A and Phone B:

Address Name	Phone_A
Type	Subnet
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	port1

Address Name	Phone_B
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.30/255.255.255.255
Interface	port2

To add security policies to apply the SIP ALG to SIP sessions

1. Go to *Policy* > *Policy* > *Policy*.
2. Select Create New to add a security policy.

3. Add a security policy to allow Phone A to send SIP request messages to Phone B:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port1
Source Address	Phone_A
Outgoing Interface	port2
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT

4. Under *UTM Security Profiles*, select *Use Standard UTM Profiles*.
5. Turn on *VoIP* and select the *default* VoIP profile.
6. Select *OK*.
7. Add a security policy to allow Phone B to send SIP request messages to Phone A:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	Phone_B
Outgoing Interface	port1
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT

8. Under *UTM Security Profiles*, select *Use Standard UTM Profiles*.
9. Turn on *VoIP* and select the *default* VoIP profile.
10. Select *OK*.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to apply the SIP ALG to SIP sessions

1. Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
  edit Phone_A
    set associated interface port1
    set type ipmask
    set subnet 10.31.101.20 255.255.255.255
  next
  edit Phone_B
    set associated interface port2
    set type ipmask
    set subnet 10.31.101.30 255.255.255.255
  end
```

2. Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr Phone_A
    set dstaddr Phone_B
    set action accept
    set schedule always
    set service SIP
    set utm-status enable
    set voip-profile default
  next
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr Phone_B
    set dstaddr Phone_A
    set action accept
    set schedule always
    set service SIP
    set utm-status enable
    set voip-profile default
  end
```

RTP enable/disable (RTP bypass)

You can configure the SIP ALG to stop from opening RTP pinholes. Called RTP bypass, this configuration can be used when you want to apply SIP ALG features to SIP signalling messages but do not want the RTP media streams to pass through the FortiGate unit. The FortiGate unit only acts as a signalling firewall and RTP media session bypass the FortiGate unit and no pinholes need to be created.

Enter the following command to enable RTP bypass in a VoIP profile by disabling opening RTP pinholes:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set rtp disable
    end
end
```

Opening and closing SIP register, contact, via and record-route pinholes

You can use the `open-register-pinhole`, `open-contact-pinhole`, `open-via-port`, and `open-record-route-pinhole` VoIP profile CLI options to control whether the FortiGate unit opens various pinholes.

If `open-register-pinhole` is enabled (the default setting) the FortiGate unit opens pinholes for SIP Register request messages. You can disable `open-register-pinhole` so that the FortiGate unit does not open pinholes for SIP Register request messages.

If `open-contact-pinhole` is enabled (the default setting) the FortiGate unit opens pinholes for non-Register SIP request messages. You can disable `open-contact-pinhole` so that the FortiGate unit does not open pinholes for non-register requests. Non-register pinholes are usually opened for SIP INVITE requests.

If `open-via-pinhole` is disabled (the default setting) the FortiGate unit does not open pinholes for Via messages. You can enable `open-via-pinhole` so that the FortiGate unit opens pinholes for Via messages.

If `open-record-route-pinhole` is enabled (the default setting) the FortiGate unit opens pinholes for Record-Route messages. You can disable `open-record-route-pinhole` so that the FortiGate unit does not open pinholes for Record-Route messages.

Usually you would want to open these pinholes. Keeping them closed may prevent SIP from functioning properly through the FortiGate unit. They can be disabled, however, for interconnect scenarios (where all SIP traffic is between proxies and traveling over a single session). In some cases these settings can also be disabled in access scenarios if it is known that all users will be registering regularly so that their contact information can be learned from the register request.

You might want to prevent pinholes from being opened to avoid creating a pinhole for every register or non-register request. Each pinhole uses additional system memory, which can affect system performance if there are hundreds or thousands of users, and requires refreshing which can take a relatively long amount of time if there are thousands of active calls.

To configure a VoIP profile to prevent opening register and non-register pinholes:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set open-register-pinhole disable
      set open-contact-pinhole disable
    end
end
```

In some cases you may not want to open pinholes for the port numbers specified in SIP Contact headers. For example, in an interconnect scenario when a FortiGate unit is installed between two SIP servers and the only SIP traffic through the FortiGate unit is between these SIP servers pinholes may not need to be opened for the port numbers specified in the Contact header lines.

If you disable `open-register-pinhole` then pinholes are not opened for ports in Contact header lines in SIP Register messages. If you disable `open-contact-pinhole` then pinholes are not opened for ports in Contact header lines in all SIP messages except SIP Register messages.

Accepting SIP register responses

You can enable the VoIP profile `open-via-pinhole` options to accept a SIP Register response message from a SIP server even if the source port of the Register response message is different from the destination port.

Most SIP servers use 5060 as the source port in the SIP register response. Some SIP servers, however, may use a different source port. If your SIP server uses a different source port, you can enable `open-via-pinhole` and the SIP ALG will create a temporary pinhole when the Register request from a SIP client includes a different source port. The FortiGate unit will accept a SIP Register response with any source port number from the SIP server.

Enter the following command to enable accepting any source port from a SIP server:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set open-via-pinhole enable
    end
end
```

How the SIP ALG performs NAT

In most Network Address Translation (NAT) configurations, multiple hosts in a private network share a single public IP address to access the Internet. For sessions originating on the private network for the Internet, NAT replaces the private IP address of the PC in the private subnet with the public IP address of the NAT device. The NAT device converts the public IP address for responses from the Internet back into the private address before sending the response over the private network to the originator of the session.

Using NAT with SIP is more complex because of the IP addresses and media stream port numbers used in SIP message headers and bodies. When a caller on the private network sends a SIP message to a phone or SIP server on the Internet, the SIP ALG must translate the private network addresses in the SIP message to IP addresses and port numbers that are valid on the Internet. When the response message is sent back to the caller, the SIP ALG must translate these addresses back to valid private network addresses.

In addition, the media streams generated by the SIP session are independent of the SIP message sessions and use varying port numbers that can also change during the media session. The SIP ALG opens pinholes to accept these media sessions, using the information in the SIP messages to determine the pinholes to open. The ALG may also perform port translation on the media sessions.

When an INVITE message is received by the SIP ALG, the FortiGate unit extracts addressing and port number information from the message header and stores it in a SIP dialog table. Similar to an IP session table the data in the dialog table is used to translate addresses in subsequent SIP messages that are part of the same SIP call.

When the SIP ALG receives a response to the INVITE message arrives, (for example, an ACK or 200 OK), the SIP ALG compares the addresses in the message fields against the entries in the SIP dialog table to identify the call context of the message. The SIP ALG then translates addresses in the SIP message before forwarding them to their destination.

The addressing and port number information in SDP fields is used by the ALG to reserve ports for the media session and create a NAT mapping between them and the ports in the SDP fields. Because SDP uses sequential ports for the RTP and RTCP channels, the ALG provides consecutive even-odd ports.

Source address translation

When a SIP call is started by a phone on a private network destined for a phone on the Internet, only source address translation is required. The phone on the private network attempts to contact the actual IP address of the phone on the Internet. However, the source address of the phone on the private network is not routable on the Internet so the SIP ALG must translate all private IP addresses in the SIP message into public IP addresses.

To configure the FortiGate for source address translation you add security policy that accepts sessions from the internal network destined for the Internet. You must enable NAT for the security policy and add a VoIP profile.

When a SIP request is received from the internal to the external network, the SIP ALG replaces the private network IP addresses and port numbers in the SIP message with the IP address of the FortiGate interface connected to the Internet. Depending on the content of the message, the ALG translates addresses in the Via:, Contact:, Route:, and Record-Route: SIP header fields. The message is then forwarded to the destination (either a VoIP phone or a SIP server on the Internet).

The VoIP phone or server in the Internet sends responses to these SIP messages to the external interface of the FortiGate unit. The addresses in the response messages are translated back into private network addresses and the response is forwarded to the originator of the request.

For the RTP communication between the SIP phones, the SIP ALG opens pinholes to allow media through the FortiGate unit on the dynamically assigned ports negotiated based on information in the SDP and the Via:, Contact:, and Record-Route: header fields. The pinholes also allow incoming packets to reach the Contact:, Via:, and Record-Route: IP addresses and ports. When processing return traffic, the SIP ALG inserts the original Contact:, Via:, Route:, and Record-Route: SIP fields back into the packets.

Destination address translation

Incoming calls are directed from a SIP phone on the Internet to the interface of the FortiGate unit connected to the Internet. To receive these calls you must add a security policy to accept SIP sessions from the Internet. The security policy requires a firewall virtual IP. SIP INVITE messages from the Internet connect to the external IP address of the virtual IP. The SIP ALG uses the destination address translation defined in the virtual IP to translated the addresses in the SIP message to addresses on the private network.

When a 200 OK response message arrives from the private network, the SIP ALG translates the addresses in the message to Internet addresses and opens pinholes for media sessions from the private network to the Internet.

When the ACK message is received for the 200 OK, it is also intercepted by the SIP ALG. If the ACK message contains SDP information, the SIP ALG checks to determine if the IP addresses and port numbers are not changed from the previous INVITE. If they are, the SIP ALG deletes pinholes and creates new ones as required. The ALG also monitors the Via:, Contact:, and Record-Route: SIP fields and opens new pinholes as required.

Call Re-invite messages

SIP Re-INVITE messages can dynamically add and remove media sessions during a call. When new media sessions are added to a call the SIP ALG opens new pinholes and update SIP dialog data. When media sessions are ended, the SIP ALG closes pinholes that are no longer needed and removes SIP dialog data.

How the SIP ALG translates IP addresses in SIP headers

The SIP ALG applies NAT to SIP sessions by translating the IP addresses contained in SIP headers. For example, the following SIP message contains most of the SIP fields that contain addresses that need to be translated:

```
INVITE PhoneB@172.20.120.30 SIP/2.0
Via: SIP/2.0/UDP 172.20.120.50:5434
From: PhoneA@10.31.101.20
To: PhoneB@172.20.120.30
Call-ID: a12abcde@172.20.120.50
Contact: PhoneA@10.31.101.20:5434
Route: <sip:example@172.20.120.50:5060>
Record-Route: <sip:example@172.20.120.50:5060>
```

How IP address translation is performed depends on whether source NAT or destination NAT is applied to the session containing the message:

Source NAT translation of IP addresses in SIP messages

Source NAT translation occurs for SIP messages sent from a phone or server on a private network to a phone or server on the Internet. The source addresses in the SIP header fields of the message are typically set to IP addresses on the private network. The SIP ALG translates these addresses to the address the FortiGate unit interface connected to the Internet.

Table 116: Source NAT translation of IP addresses in SIP request messages

SIP header	NAT action
To:	None
From:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.
Call-ID:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.
Via:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.
Request-URI:	None
Contact:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.
Record-Route:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.
Route:	Replace private network address with IP address of FortiGate unit interface connected to the Internet.

Response messages from phones or servers on the Internet are sent to the FortiGate unit interface connected to the Internet where the destination addresses are translated back to addresses on the private network before forwarding the SIP response message to the private network.

Table 117: Source NAT translation of IP addresses in SIP response messages

SIP header	NAT action
To:	None
From:	Replace IP address of FortiGate unit interface connected to the Internet with private network address.
Call-ID:	Replace IP address of FortiGate unit interface connected to the Internet with private network address.
Via:	Replace IP address of FortiGate unit interface connected to the Internet with private network address.
Request-URI:	N/A
Contact:	None
Record-Route:	Replace IP address of FortiGate unit interface connected to the Internet with private network address.
Route:	Replace IP address of FortiGate unit interface connected to the Internet with private network address.

Destination NAT translation of IP addresses in SIP messages

Destination NAT translation occurs for SIP messages sent from a phone or server on the Internet to a firewall virtual IP address. The destination addresses in the SIP header fields of the message are typically set to the virtual IP address. The SIP ALG translates these addresses to the address of a SIP server or phone on the private network on the other side of the FortiGate unit.

Table 118: Destination NAT translation of IP addresses in SIP request messages

SIP header	NAT action
To:	Replace VIP address with address on the private network as defined in the firewall virtual IP.
From:	None
Call-ID:	None
Via:	None
Request-URI:	Replace VIP address with address on the private network as defined in the firewall virtual IP.
Contact:	None
Record-Route:	None
Route:	None

SIP response messages sent in response to the destination NAT translated messages are sent from a server or a phone on the private network back to the originator of the request messages on the Internet. These reply messages are accepted by the same security policy that accepted the initial request messages, The firewall VIP in the original security policy contains the information that the SIP ALG uses to translate the private network source addresses in the SIP headers into the firewall virtual IP address.

Table 119: Destination NAT translation of IP addresses in SIP response messages

SIP header	NAT action
To:	None
From:	Replace private network address with firewall VIP address.
Call-ID:	None
Via:	None
Request-URI:	N/A
Contact:	Replace private network address with firewall VIP address.
Record-Route:	Replace private network address with firewall VIP address.
Route:	None

How the SIP ALG translates IP addresses in the SIP body

The SDP session profile attributes in the SIP body include IP addresses and port numbers that the SIP ALG uses to create pinholes for the media stream.

The SIP ALG translates IP addresses and port numbers in the o=, c=, and m= SDP lines. For example, in the following lines the ALG could translate the IP addresses in the o= and c= lines and the port number (49170) in the m= line.

```
o=PhoneA 5462346 332134 IN IP4 10.31.101.20
c=IN IP4 10.31.101.20
m=audio 49170 RTP 0 3
```

If the SDP session profile includes multiple RTP media streams, the SIP ALG opens pinholes and performs the required address translation for each one.

The two most important SDP attributes for the SIP ALG are c= and m=. The c= attribute is the connection information attribute. This field can appear at the session or media level. The syntax of the connection attribute is:

```
c=IN {IPV4 | IPV6} <destination_ip_address>
```

Where

- `IN` is the network type. FortiGate units support the `IN` or Internet network type.
- `{IPV4 | IPV6}` is the address type. FortiGate units support IPv4 or IPv6 addresses in SDP statements. However, FortiGate units do not support all types of IPv6 address translation. See “SIP over IPv6” on page 2558.
- `<destination_IP_address>` is the unicast numeric destination IP address or domain name of the connection in either IPv4 or IPv6 format.

The syntax of the media attribute is:

```
m=audio <port_number> RTP <format_list>
```

Where

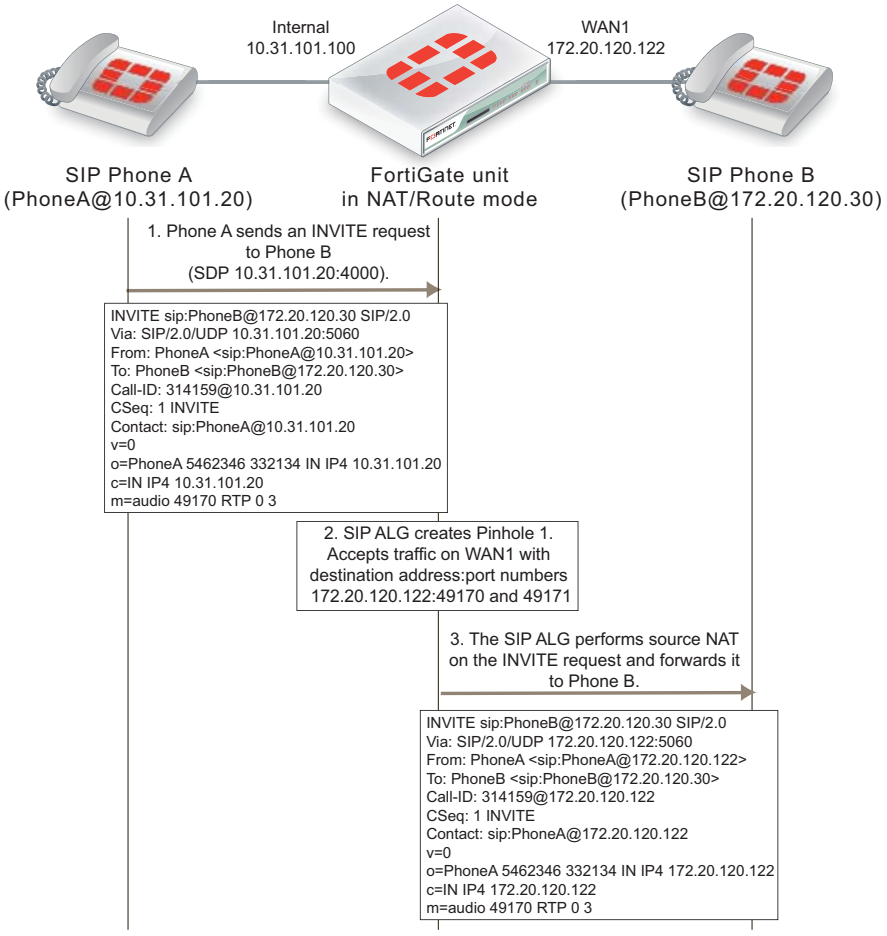
- `audio` is the media type. FortiGate units support the `audio` media type.
- `<port_number>` is the destination port number used by the media stream.
- `RTP` is the application layer transport protocol used for the media stream. FortiGate units support the Real Time Protocol (RTP) transport protocol.
- `<format_list>` is the format list that provides information about the application layer protocol that the media uses.

SIP NAT scenario: source address translation (source NAT)

Figure 359 and Figure 360 show a source address translation scenario involving two SIP phones on different networks, separated by a FortiGate unit. In the scenario, SIP Phone A sends an INVITE request to SIP Phone B and SIP Phone B replies with a 200 OK response and then the two phones start media streams with each other.

To simplify the diagrams, some SIP messages are not included (for example, the Ringing and ACK response messages) and some SIP header lines and SDP profile lines have been removed from the SIP messages.

Figure 359:SIP source NAT scenario part 1: INVITE request sent from Phone A to Phone B

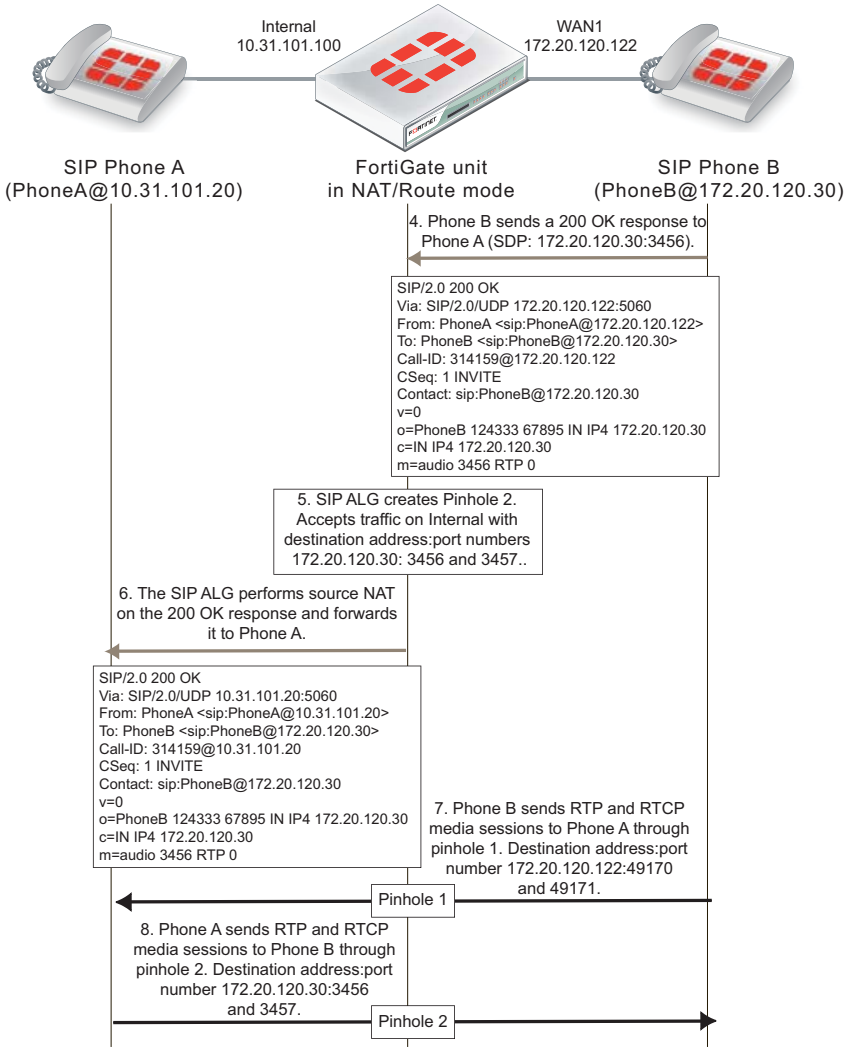


For the replies to SIP packets sent by Phone A to be routable on Phone Bs network, the FortiGate unit uses source NAT to change their source address to the address of the WAN1 interface. The SIP ALG makes similar changes the source addresses in the SIP headers and SDP profile. For example, the original INVITE request from Phone A includes the address of Phone A (10.31.101.20) in the from header line. After the INVITE request passes through the FortiGate unit, the address of Phone A in the From SIP header line is translated to 172.20.120.122, the address of the FortiGate unit WAN1 interface. As a result, Phone B will reply to SIP messages from Phone A using the WAN1 interface IP address.

The FortiGate unit also opens a pinhole so that it can accept media sessions sent to the WAN1 IP address using the port number in the m= line of the INVITE request and forward them to Phone A after translating the destination address to the IP address of Phone A.

Phone B sends the 200 OK response to the INVITE message to the WAN1 interface. The SDP profile includes the port number that Phone B wants to use for its media stream. The FortiGate unit forwards 200 OK response to Phone A after translating the addresses in the SIP and SDP lines back to the IP address of Phone A. The SIP ALG also opens a pinhole on the Internal interface that accepts media stream sessions from Phone A with destination address set to the IP address of Phone B and using the port that Phone B added to the SDP m= line.

Figure 360:SIP source NAT scenario part 2: 200 OK returned and media streams established



SIP NAT scenario: destination address translation (destination NAT)

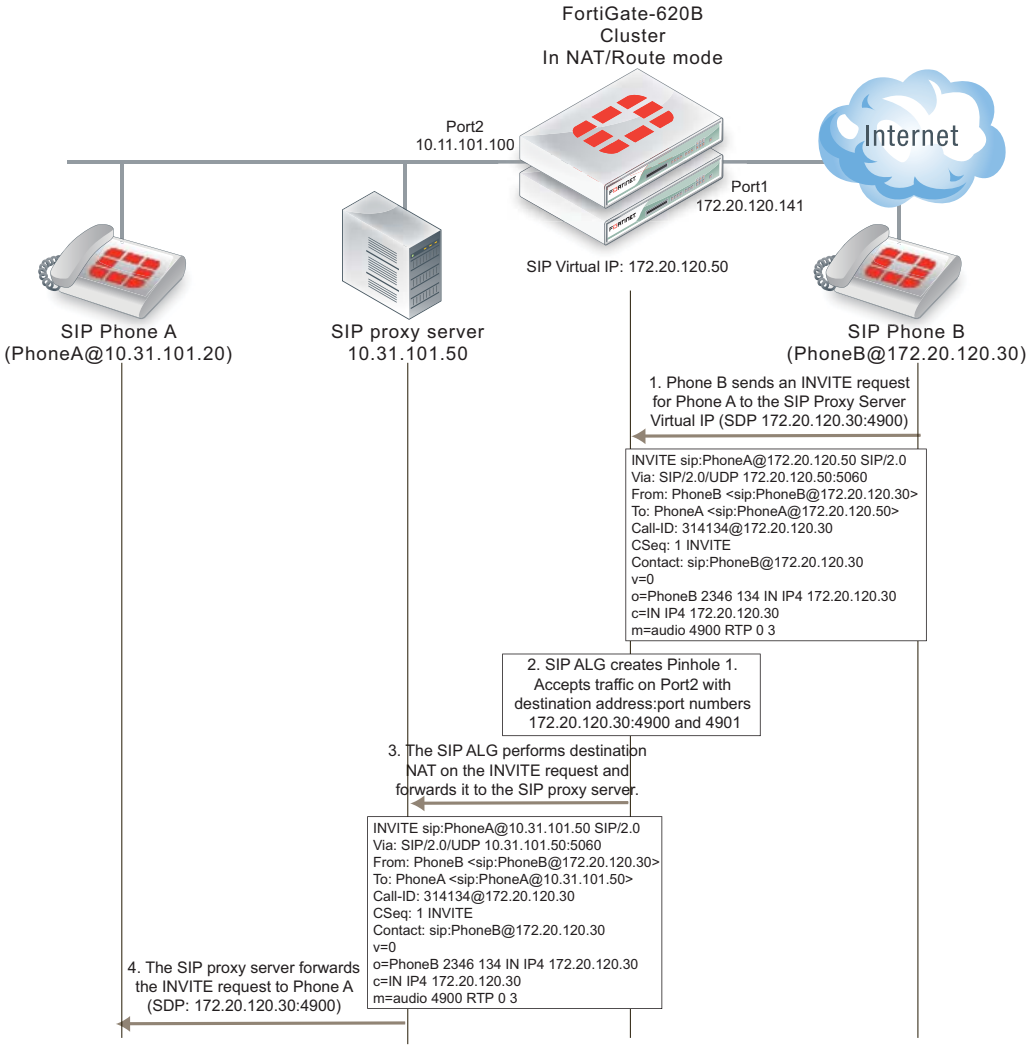
Figure 361 and Figure 362 show how the SIP ALG translates addresses in a SIP INVITE message sent from SIP Phone B on the Internet to SIP Phone A on a private network using the SIP proxy server. Because the addresses on the private network are not visible from the Internet, the security policy on the FortiGate unit that accepts SIP sessions includes a virtual IP. Phone A sends SIP the INVITE message to the virtual IP address. The FortiGate unit accepts the INVITE message packets and using the virtual IP, translates the destination address of the packet to the IP address of the SIP proxy server and forwards the SIP message to it.

To simplify the diagrams, some SIP messages are not included (for example, the Ringing and ACK response messages) and some SIP header lines and SDP profile lines have been removed from the SIP messages.

The SIP ALG also translates the destination addresses in the SIP message from the virtual IP address (172.20.120.50) to the SIP proxy server address (10.31.101.50). For this configuration to work, the SIP proxy server must be able to change the destination addresses for Phone A in the SIP message from the address of the SIP proxy server to the actual address of Phone A.

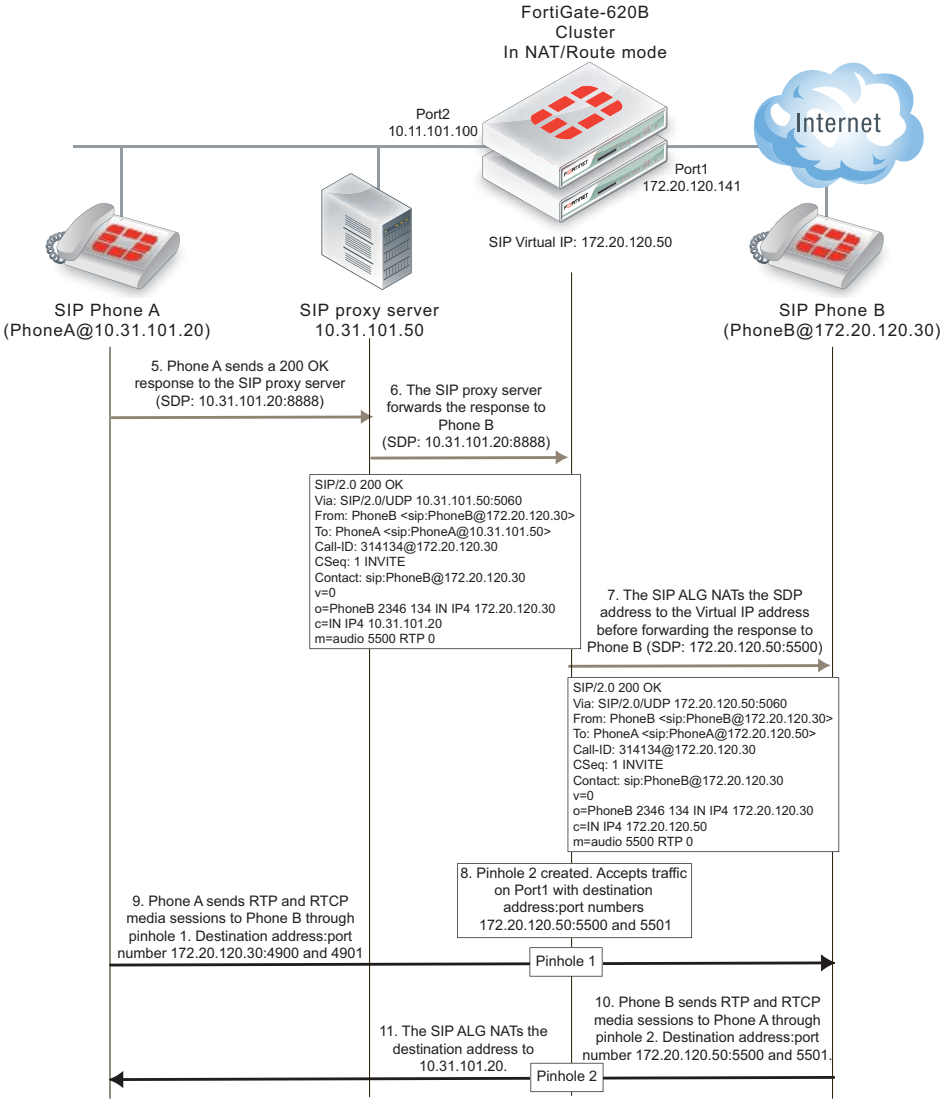
The SIP ALG also opens a pinhole on the Port2 interface that accepts media sessions from the private network to SIP Phone B using ports 4900 and 4901.

Figure 361:SIP destination NAT scenario part 1: INVITE request sent from Phone B to Phone A



Phone A sends a 200 OK response back to the SIP proxy server. The SIP proxy server forwards the response to Phone B. The FortiGate unit accepts the 100 OK response. The SIP ALG translates the Phone A addresses back to the SIP proxy server virtual IP address before forwarding the response back to Phone B. The SIP ALG also opens a pinhole using the SIP proxy server virtual IP which is the address in the o= line of the SDP profile and the port number in the m= line of the SDP code.

Figure 362:SIP destination NAT scenario part 2: 200 OK returned to Phone B and media streams established

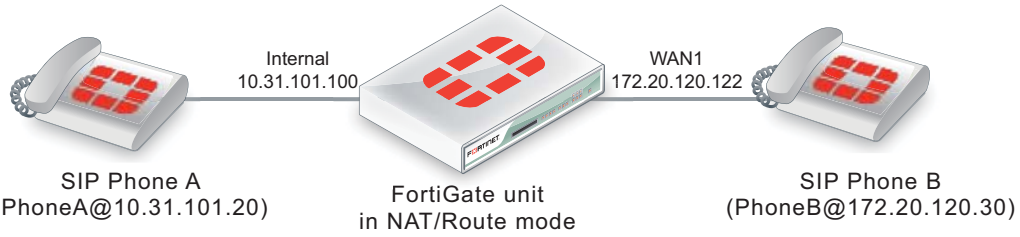


The media stream from Phone A is accepted by pinhole one and forwarded to Phone B. The source address of this media stream is changed to the SIP proxy server virtual IP address. The media stream from Phone B is accepted by pinhole 2 and forwarded to Phone B. The destination address of this media stream is changed to the IP address of Phone A.

SIP NAT configuration example: source address translation (source NAT)

This configuration example shows how to configure the FortiGate unit to support the source address translation scenario shown in Figure 363. The FortiGate unit requires two security policies that accept SIP packets. One to allow SIP Phone A to start a session with SIP Phone B and one to allow SIP Phone B to start a session with SIP Phone A. Both of these policies must include source NAT. In this example the networks are not hidden from each other so destination NAT is not required.

Figure 363:SIP source NAT configuration



General configuration steps

The following general configuration steps are required for this SIP configuration. This example uses the default VoIP profile. The example also includes security policies that specifically allow SIP sessions using UDP port 5060 from Phone A to Phone B and from Phone B to Phone A. In most cases you would have more than two phones so would use more general security policies. Also, you can set the firewall service to ANY to allow traffic other than SIP on UDP port 5060.

1. Add firewall addresses for Phone A and Phone B.
2. Add a security policy that accepts SIP sessions initiated by Phone A and includes the default VoIP profile.
3. Add a security policy that accepts SIP sessions initiated by Phone B and includes the default VoIP profile.

Configuration steps - web-based manager

To add firewall addresses for the SIP phones

1. Go to *Firewall Objects* > *Address*.
2. Add the following addresses for Phone A and Phone B:

Address Name	Phone_A
Type	Subnet
Subnet / IP Range	10.31.101.20/255.255.255.255
Interface	Internal

Address Name	Phone_B
Type	Subnet
Subnet / IP Range	172.20.120.30/255.255.255.255
Interface	wan1

To add security policies to apply the SIP ALG to SIP sessions

1. Go to *Policy* > *Policy* > *Policy*.
2. Select Create New to add a security policy.
3. Add a security policy to allow Phone A to send SIP request messages to Phone B:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	internal
Source Address	Phone_A
Outgoing Interface	wan1
Destination Address	Phone_B
Schedule	always
Service	SIP
Action	ACCEPT

4. Select *Enable NAT* and select *Use Destination Interface Address*.
5. Under *UTM Security Profiles*, select *Use Standard UTM Profiles*.
6. Turn on *VoIP* and select the *default* VoIP profile.
7. Select *OK*.
8. Add a security policy to allow Phone B to send SIP request messages to Phone A:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	wan1
Source Address	Phone_B
Outgoing Interface	internal
Destination Address	Phone_A
Schedule	always
Service	SIP
Action	ACCEPT

9. Select *Enable NAT* and select *Use Destination Interface Address*.
10. Under *UTM Security Profiles*, select *Use Standard UTM Profiles*.
11. Turn on *VoIP* and select the *default* VoIP profile.
12. Select *OK*.

Configuration steps - CLI

To add firewall addresses for Phone A and Phone B and security policies to apply the SIP ALG to SIP sessions

1 Enter the following command to add firewall addresses for Phone A and Phone B.

```
config firewall address
  edit Phone_A
    set associated interface internal
    set type ipmask
    set subnet 10.31.101.20 255.255.255.255
  next
  edit Phone_B
    set associated interface wan1
    set type ipmask
    set subnet 172.20.120.30 255.255.255.255
  end
```

2 Enter the following command to add security policies to allow Phone A to send SIP request messages to Phone B and Phone B to send SIP request messages to Phone A.

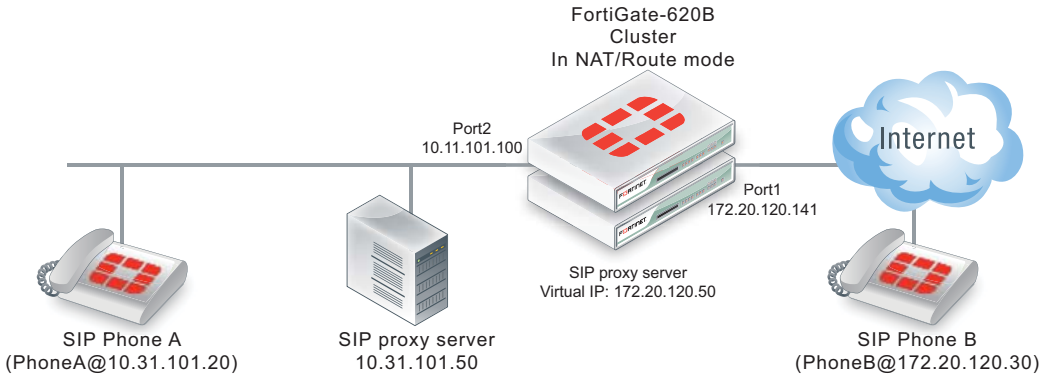
```
config firewall policy
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr Phone_A
    set dstaddr Phone_B
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set voip-profile default
  next
  edit 0
    set srcintf wan1
    set dstintf internal
    set srcaddr Phone_B
    set dstaddr Phone_A
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set voip-profile default
  end
```

SIP NAT configuration example: destination address translation (destination NAT)

This configuration example shows how to configure the FortiGate unit to support the destination address translation scenario shown in Figure 364. The FortiGate unit requires two SIP security policies:

- A destination NAT security policy that allows SIP messages to be sent from the Internet to the private network. This policy must include destination NAT because the addresses on the private network are not routable on the Internet.
- A source NAT security policy that allows SIP messages to be sent from the private network to the Internet.

Figure 364: SIP destination NAT scenario part two: 200 OK returned to Phone B and media streams established



General configuration steps

The following general configuration steps are required for this destination NAT SIP configuration. This example uses the default VoIP profile.

1 Add the SIP proxy server firewall virtual IP.

2 Add a firewall address for the SIP proxy server on the private network.

3 Add a destination NAT security policy that accepts SIP sessions from the Internet destined for the SIP proxy server virtual IP and translates the destination address to the IP address of the SIP proxy server on the private network.

4 Add a security policy that accepts SIP sessions initiated by the SIP proxy server and destined for the Internet.

Configuration steps - web-based manager

To add the SIP proxy server firewall virtual IP

1. Go to *Firewall Objects* > *Virtual IP* > *Virtual IP* and select *Create New*.

2. Add the SIP proxy server virtual IP.

Name	SIP_Proxy_VIP
External Interface	port1
Type	Static NAT
External IP Address/Range	172.20.120.50
Mapped IP Address/Range	10.31.101.50

To add a firewall address for the SIP proxy server

1. Go to *Firewall Objects* > *Address* > *Addresses*.
2 Add the following for the SIP proxy server:

Address Name	SIP_Proxy_Server
Type	Subnet
Subnet / IP Range	10.31.101.50/255.255.255.255
Interface	port2

To add the security policies

1. Go to *Policy* > *Policy* > *Policy*.
2. Add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port1
Source Address	all
Outgoing Interface	port2
Destination Address	SIP_Proxy_VIP
Schedule	always
Service	SIP
Action	ACCEPT

3. Select *Enable NAT* and select *Use Destination Interface Address*.
4. Under *UTM Security Profiles*, select *Use Standard UTM Profiles*.
5. Turn on *VoIP* and select the *default* VoIP profile.
6. Select *OK*.
7. Add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	SIP_Proxy_Server
Outgoing Interface	port1
Destination Address	all

Schedule	always
Service	SIP
Action	ACCEPT

8. Select *Enable NAT* and select *Use Destination Interface Address*.
9. Under *UTM Security Profiles*, select *Use Standard UTM Profiles*.
10. Turn on *VoIP* and select the *default* VoIP profile.
11. Select *OK*.

Configuration steps - CLI

To add the SIP proxy server firewall virtual IP and firewall address

1. Enter the following command to add the SIP proxy server firewall virtual IP.

```
config firewall vip
  edit SIP_Proxy_VIP
    set type static-nat
    set extip 172.20.120.50
    set mappedip 10.31.101.50
    set extintf port1
  end
```

2 Enter the following command to add the SIP proxy server firewall address.

```
config firewall address
  edit SIP_Proxy_Server
    set associated interface port2
    set type ipmask
    set subnet 10.31.101.50 255.255.255.255
  end
```

To add security policies

1. Enter the following command to add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr SIP_Proxy_VIP
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set voip-profile default
  end
```

2. Enter the following command to add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr SIP_Proxy_Server
    set dstaddr all
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set voip-profile default
  end
```

Additional SIP NAT scenarios

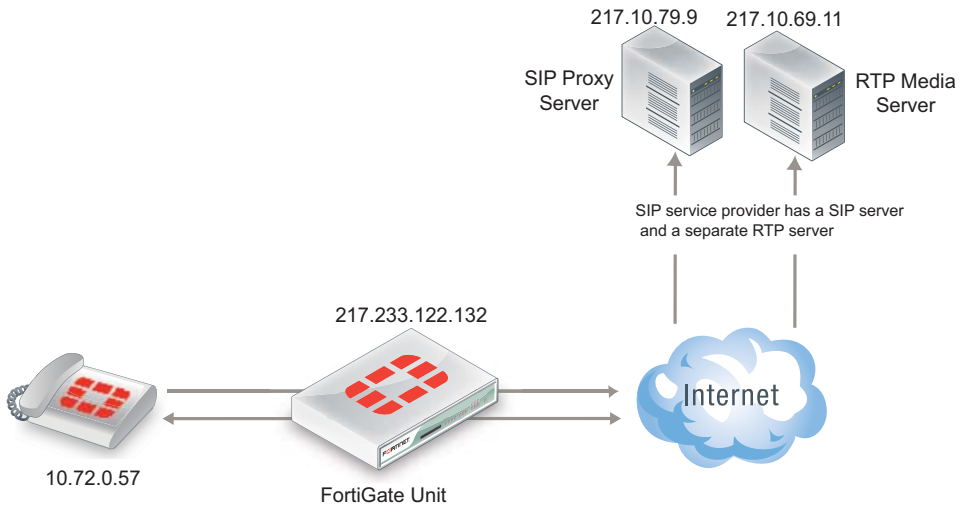
This section lists some additional SIP NAT scenarios.

Source NAT (SIP and RTP)

In the source NAT scenario shown in Figure 365, a SIP phone connects to the Internet through a FortiGate unit with and IP address configured using PPPoE. The SIP ALG translates all private IPs in the SIP contact header into public IPs.

You need to configure an internal to external SIP security policy with NAT selected, and include a VoIP profile with SIP enabled.

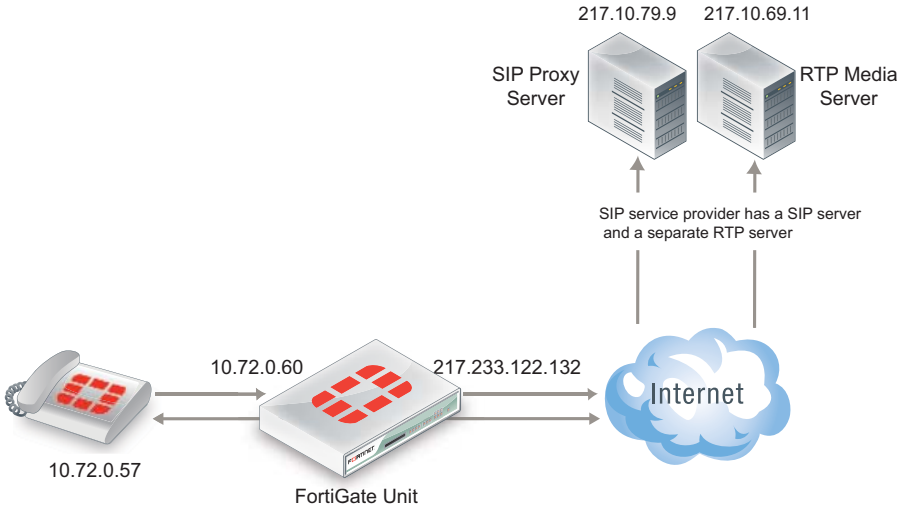
Figure 365:SIP source NAT



Destination NAT (SIP and RTP)

In the following destination NAT scenario, a SIP phone can connect through the FortiGate unit to private IP address using a firewall virtual IP (VIP). The SIP ALG translates the SIP contact header to the IP of the real SIP proxy server located on the Internet.

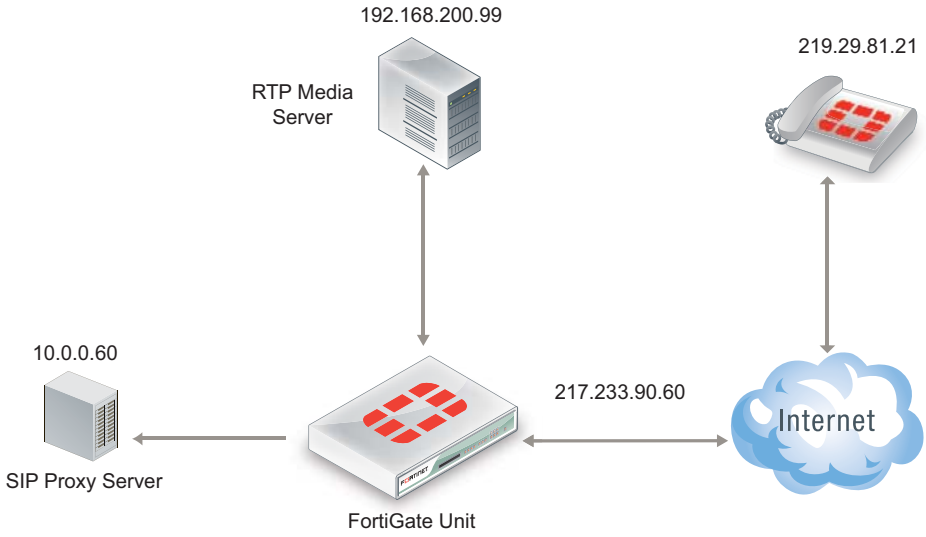
Figure 366:SIP destination NAT



In the scenario, shown in Figure 366, the SIP phone connects to a VIP (10.72.0.60). The SIP ALG translates the SIP contact header to 217.10.79.9, opens RTP pinholes, and manages NAT.

The FortiGate unit also supports a variation of this scenario where the RTP media server's IP address is hidden on a private network or DMZ.

Figure 367:SIP destination NAT-RTP media server hidden



In the scenario shown in Figure 367, a SIP phone connects to the Internet. The VoIP service provider only publishes a single public IP. The FortiGate unit is configured with a firewall VIP. The SIP phone connects to the FortiGate unit (217.233.90.60) and using the VIP the FortiGate unit translates the SIP contact header to the SIP proxy server IP address (10.0.0.60). The SIP proxy server changes the SIP/SDP connection information (which tells the SIP phone which RTP media server IP it should contact) also to 217.233.90.60.

Source NAT with an IP pool

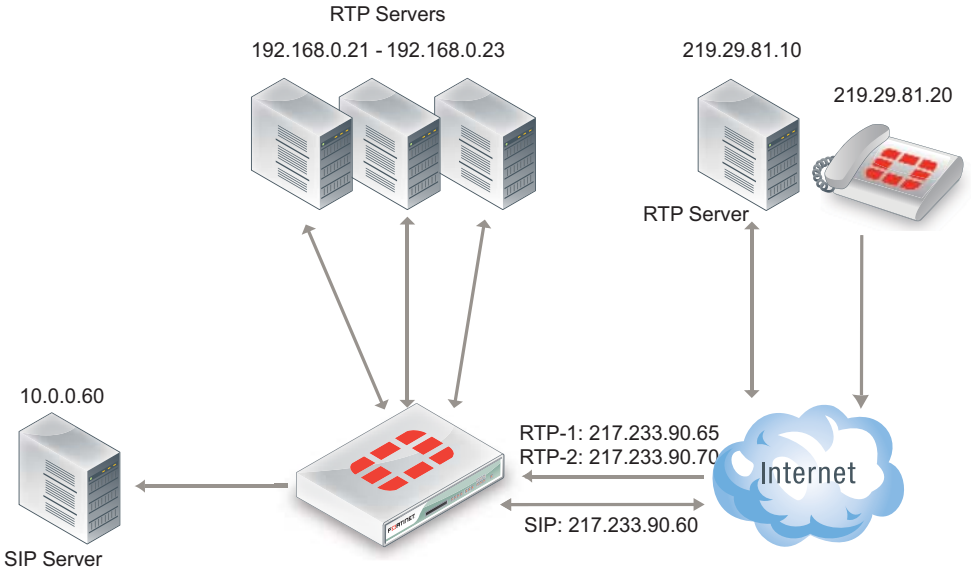
You can choose *NAT* with the *Dynamic IP Pool* option when configuring a security policy if the source IP of the SIP packets is different from the interface IP. The FortiGate ALG interprets this configuration and translates the SIP header accordingly.

This configuration also applies to destination NAT.

Different source and destination NAT for SIP and RTP

This is a more complex scenario that a SIP service provider may use. It can also be deployed in large-scale SIP environments where RTP has to be processed by the FortiGate unit and the RTP server IP has to be translated differently than the SIP server IP.

Figure 368: Different source and destination NAT for SIP and RTP



In this scenario, shown in Figure 368, assume there is a SIP server and a separate media gateway. The SIP server is configured so that the SIP phone (219.29.81.20) will connect to 217.233.90.60. The media gateway (RTP server: 219.29.81.10) will connect to 217.233.90.65.

What happens is as follows:

1. The SIP phone connects to the SIP VIP. The FortiGate ALG translates the SIP contact header to the SIP server: 219.29.81.20 > 217.233.90.60 (> 10.0.0.60).
2. The SIP server carries out RTP to 217.233.90.65.
3. The FortiGate ALG opens pinholes, assuming that it knows the ports to be opened.
4. RTP is sent to the RTP-VIP (217.233.90.65.) The FortiGate ALG translates the SIP contact header to 192.168.0.21.

NAT with IP address conservation

In a source or destination NAT security policy that accepts SIP sessions, you can configure the SIP ALG or the SIP session helper to preserve the original source IP address of the SIP message in the i= line of the SDP profile. NAT with IP address conservation (also called SIP NAT tracing) changes the contents of SIP messages by adding the source IP address of the originator of the message into the SDP i= line of the SIP message. The SDP i= line is used for free-form text. However, if your SIP server can retrieve information from the SDP i= line, it can be useful for keeping a record of the source IP address of the originator of a SIP message when operating in a NAT environment. You can use this feature for billing purposes by extracting the IP address of the originator of the message.

Configuring SIP IP address conservation for the SIP ALG

You can use the following command to enable or disable SIP IP address conservation in a VoIP profile for the SIP ALG. SIP IP address conservation is enabled by default in a VoIP profile.

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set nat-trace disable
    end
end
```

If the SIP message does not include an i= line and if the original source IP address of the traffic (before NAT) was 10.31.101.20 then the FortiGate unit would add the following i= line.

```
i=(o=IN IP4 10.31.101.20)
```

You can also use the `preserve-override` option to configure the SIP ALG to either add the original o= line to the end of the i= line or replace the i= line in the original message with a new i= line in the same form as above for adding a new i= line.

By default, `preserver-override` is disabled and the SIP ALG adds the original o= line to the end of the original i= line. Use the following command to configure the SIP ALG to replace the original i= line:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set preserve-override enable
    end
end
```

Configuring SIP IP address conservation for the SIP session helper

You can use the following command to enable or disable SIP IP address conservation for the SIP session helper. IP address conservation is enabled by default for the SIP session helper.

```
config system settings
  set sip-nat-trace disable
end
```

If the SIP message does not include an i= line and if the original source IP address of the traffic (before NAT) was 10.31.101.20 then the FortiGate unit would add the following i= line.

```
i=(o=IN IP4 10.31.101.20)
```

Controlling how the SIP ALG NATs SIP contact header line addresses

You can enable `contact-fixup` so that the SIP ALG performs normal SIP NAT translation to SIP contact headers as SIP messages pass through the FortiGate unit.

Disable `contact-fixup` if you do not want the SIP ALG to perform normal NAT translation of the SIP contact header if a Record-Route header is also available. If `contact-fixup` is disabled, the FortiGate ALG does the following with contact headers:

- For Contact in Requests, if a Record-Route header is present and the request comes from the external network, the SIP Contact header is not translated.
- For Contact in Responses, if a Record-Route header is present and the response comes from the external network, the SIP Contact header is not translated.

If `contact-fixup` is disabled, the SIP ALG must be able to identify the external network. To identify the external network, you must use the `config system interface` command to set the `external` keyword to `enable` for the interface that is connected to the external network.

Enter the following command to perform normal NAT translation of the SIP contact header:

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set contact-fixup enable
    end
end
```

Controlling NAT for addresses in SDP lines

You can use the `no-sdp-fixup` option to control whether the FortiGate unit performs NAT on addresses in SDP lines in the SIP message body.

The `no-sdp-fixup` option is disabled by default and the FortiGate unit performs NAT on addresses in SDP lines. Enable this option if you don't want the FortiGate unit to perform NAT on the addresses in SDP lines.

```
config voip profile
  edit VoIP_Pro_1
    config sip
      set no-sdp-fixup enable
    end
end
```

Translating SIP session destination ports

Using port forwarding virtual IPs you can change the destination port of SIP sessions as they pass through the FortiGate unit.

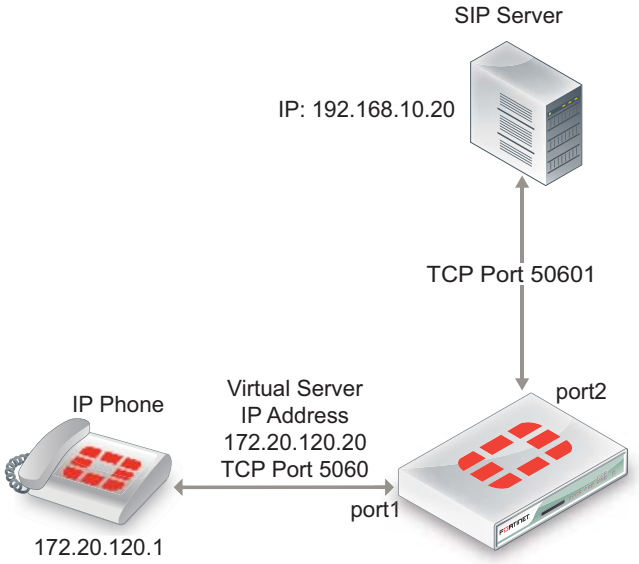
This section describes:

- Translating SIP sessions to a different destination port
- Translating SIP sessions to multiple destination ports

Translating SIP sessions to a different destination port

To configure translating SIP sessions to a different destination port you must add a static NAT virtual IP that translates tie SIP destination port to another port destination. In the example the destination port is translated from 5060 to 50601. This configuration can be used if SIP sessions uses different destination ports on different networks.

Figure 369: Example translating SIP sessions to a different destination port



To translate SIP sessions to a different destination port

1. Add the static NAT virtual IP.

   This virtual IP forwards traffic received at the port1 interface for IP address 172.20.120.20 and destination port 5060 to the SIP server at IP address 192.168.10.20 with destination port 5061.

```
config firewall vip
  edit "sip_port_trans_vip"
    set type static-nat
    set portforward enable
    set protocol tcp
    set extip 172.20.120.20
    set extport 5060
    set extintf "port1"
    set mappedip 192.168.10.20
    set mappedport 50601
    set comment "Translate SIP destination port"
  end
```

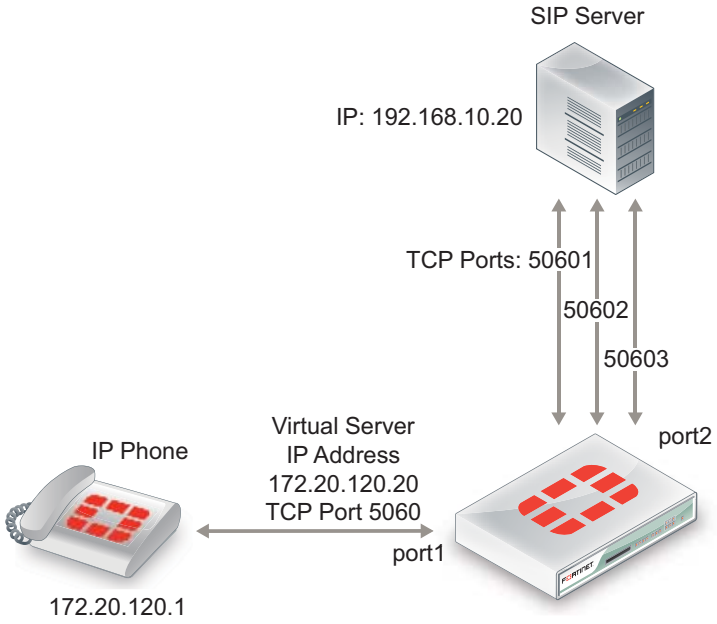
2 Add a security policy that includes the virtual IP and the default VoIP profile.

```
config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "all"
    set dstaddr "sip_port_trans_vip"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable
    set profile-protocol-options default
    set comments "Translate SIP destination port"
  end
```

Translating SIP sessions to multiple destination ports

You can use a load balance virtual IP to translate SIP session destination ports to a range of destination ports. In this example the destination port is translated from 5060 to the range 50601 to 50603. This configuration can be used if your SIP server is configured to receive SIP traffic on multiple ports.

Figure 370: Example translating SIP traffic to multiple destination ports



To translated SIP sessions to multiple destination ports

1. Add the load balance virtual IP.

   This virtual IP forwards traffic received at the port1 interface for IP address 172.20.120.20 and destination port 5060 to the SIP server at IP address 192.168.10.20 with destination port 5061.

```
config firewall vip
  edit "sip_port_ldbl_vip"
    set type load-balance
    set portforward enable
    set protocol tcp
    set extip 172.20.120.20
    set extport 5060
    set extintf "port1"
    set mappedip 192.168.10.20
    set mappedport 50601-50603
    set comment "Translate SIP destination port range"
  end
```

2 Add a security policy that includes the virtual IP and VoIP profile.

```
config firewall policy
  edit 1
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "all"
    set dstaddr "sip_port_ldbl_vip"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable
    set voip-profile default
    set comments "Translate SIP destination port"
  end
```

Adding the original IP address and port to the SIP message header after NAT

In some cases your SIP configuration may require that the original IP address and port from the SIP contact request is kept after NAT. For example, the original SIP contact request could include the following:

```
Contact: <sip:0150302438@172.20.120.110:5060>;
```

After the packet goes through the FortiGate unit and NAT is performed, the contact request could normally look like the following (the IP address translated to a different IP address and the port to a different port):

```
Contact: <sip:0150302438@10.10.10.21:33608>;
```

You can enable `register-contact-trace` in a VoIP profile to have the SIP ALG add the original IP address and port in the following format:

```
Contact: <sip:0150302438@<nated-ip>:<nated-port>;o=<original-ip>:
    <original-port>>;
```

So the contact line after NAT could look like the following:

```
Contact: <sip:0150302438@10.10.10.21:33608;o=172.20.120.110:5060>;
```

Enter the following command to enable keeping the original IP address and port:

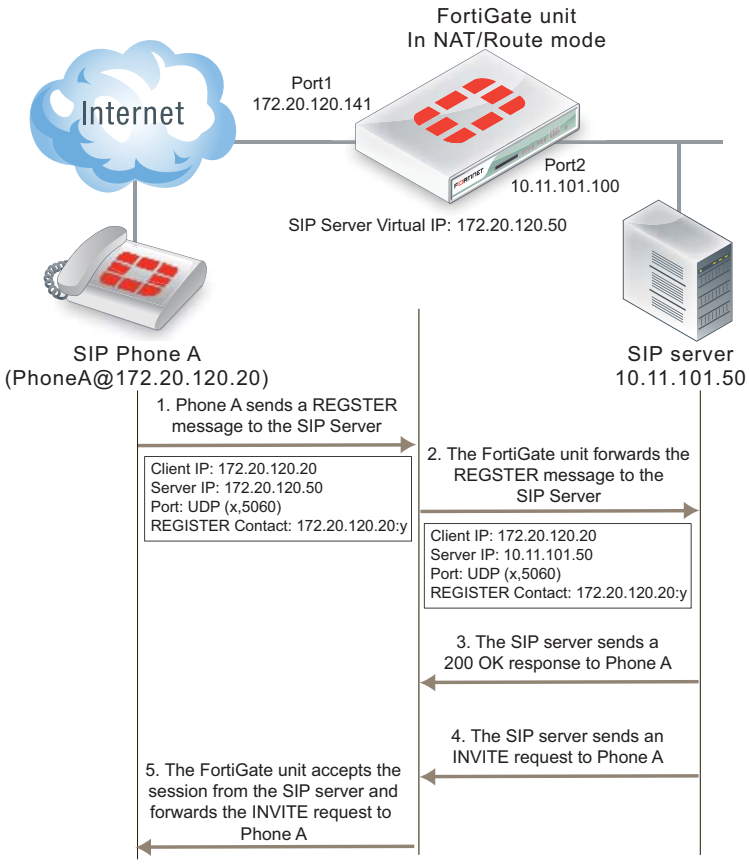
```
config voip profile
  edit Profile_name
    config sip
      set register-contract-trace enable
  end
```

Enhancing SIP pinhole security

You can use the `strict-register` option in a SIP VoIP profile to open smaller pinholes.

As shown in Figure 371 when FortiGate unit is protecting a SIP server on a private network, the FortiGate unit does not have to open a pinhole for the SIP server to send INVITE requests to a SIP Phone on the Internet after the SIP Phone has registered with the server.

Figure 371: FortiGate unit protecting a SIP server on a private network



In the example, a client (SIP Phone A) sends a REGISTER request to the SIP server with the following information:

```
Client IP: 10.31.101.20
Server IP: 10.21.101.50
Port: UDP (x,5060)
REGISTER Contact: 10.31.101.20:y
```

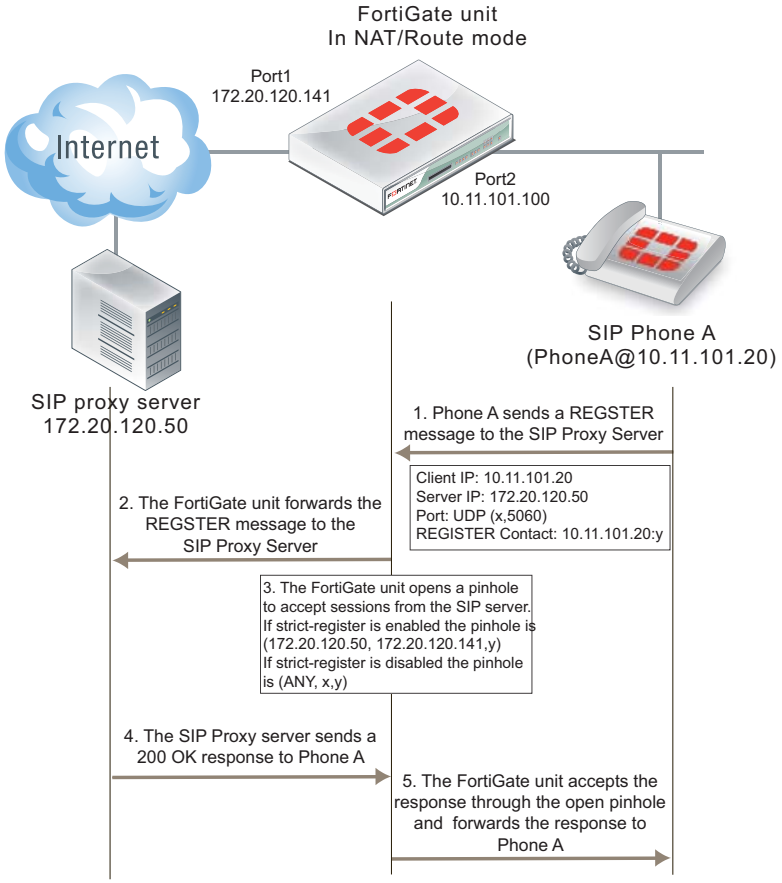
Where `x` and `y` are ports chosen by Phone A.

As soon as the server sends the 200 OK reply it can forward INVITE requests from other SIP phones to SIP Phone A. If the SIP proxy server uses the information in the REGISTER message received from SIP Phone A the INVITE messages sent to Phone A f will only get through the FortiGate unit if an policy has been added to allow the server to send traffic from the private network to the Internet. Or the SIP ALG must open a pinhole to allow traffic from the server to the Internet. In most cases the FortiGate unit is protecting the SIP server so there is no reason not to add a security policy to all the SIP server to send outbound traffic to the Internet.

In a typical SOHO scenario shown in Figure 372, SIP Phone A is being protected from the Internet by a FortiGate unit. In most cases the FortiGate unit would not allow incoming traffic from the Internet to reach the private network. So the only way that an INVITE request from the SIP server can reach SIP Phone A is if the SIP ALG creates an incoming pinhole. All pinholes have three attributes:

```
(source address, destination address, destination port)
```

Figure 372:SOHO configuration, FortiGate unit protecting a network with SIP phones



The more specific a pinhole is the more secure it is because it will accept less traffic. In this situation, the pinhole would be more secure if it only accepted traffic from the SIP server. This is what happens if `strict-register` is enabled in the VoIP profile that accepts the REGISTER request from Phone A.

```
(SIP server IP address, client IP address, destination port)
```

If `strict-register` is disabled (the default configuration) the pinhole is set up with the following attributes

```
(ANY IP address, client IP address, destination port)
```

This pinhole allows connections through the FortiGate unit from ANY source address which is a much bigger and less secure pinhole. In most similar network configurations you should enable `strict-register` to improve pinhole security.

Enabling `strict-register` can cause problems when the SIP registrar and SIP proxy server are separate entities with separate IP addresses.

Enter the following command to enable `strict-register` in a VoIP profile.

```
config voip profile
  edit Profile_name
    config sip
      set strict-register enable
  end
```

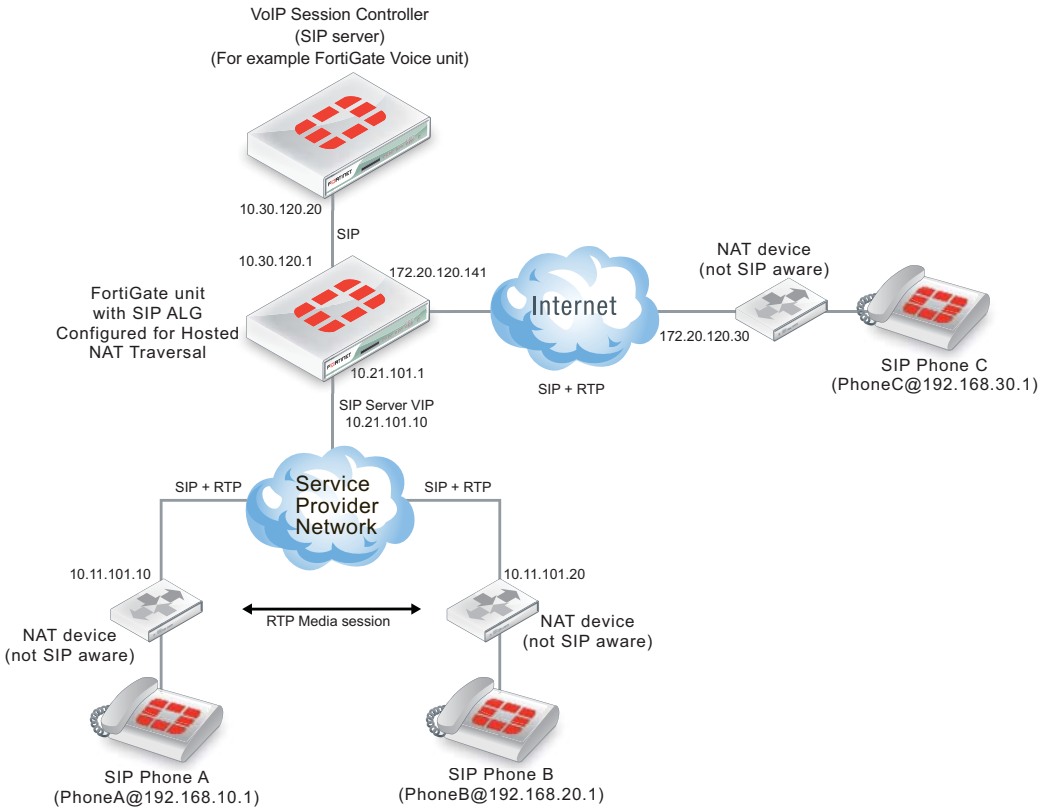
Hosted NAT traversal

With the increase in the use of VoIP and other media traffic over the Internet, service provider network administrators must defend their networks from threats while allowing voice and multimedia traffic to flow transparently between users and servers and among users. A common scenario could involve providing SIP VoIP services for customers with SIP phones installed behind NAT devices that are not SIP aware. NAT devices that are not SIP aware cannot translate IP addresses in SIP headers and SDP lines in SIP packets but can and do perform source NAT on the source or addresses of the packets. In this scenario the user's SIP phones would communicate with a SIP proxy server to set up calls between SIP phones. Once the calls are set up RTP packets would be communicated directly between the phones through each user's NAT device.

The problem with this configuration is that the SIP headers and SDP lines in the SIP packets sent from the phones and received by the SIP proxy server would contain the private network addresses of the VoIP phones that would not be routable on the service provider network or on the Internet. One solution could be to for each customer to install and configure SIP aware NAT devices. If this is not possible, another solution requires implement hosted NAT traversal.

In a hosted NAT traversal (HNT) configuration (for example, see Figure 373), a FortiGate unit is installed between the NAT device and the SIP proxy server and configured with a VoIP profile that enables SIP hosted NAT traversal. Security policies that include the VoIP profile also support destination NAT using a firewall virtual IP. When the SIP phones connect to the SIP server IP address the security policy accepts the SIP packets, the virtual IP translates the destination addresses of the packets to the SIP server IP address, and the SIP ALG NAT traversal configuration translates the source IP addresses on the SIP headers and SDP lines to the source address of the SIP packets (which would be the external IP address of the NAT devices). The SIP server then sees the SIP phone IP address as the external IP address of the NAT device. As a result SIP and RTP media sessions are established using the external IP addresses of the NAT devices instead of the actual IP addresses of the SIP phones.

Figure 373: FortiGate SIP Hosted NAT Traversal configuration



Configuration example: Hosted NAT traversal for calls between SIP Phone A and SIP Phone B

The following address translation takes place to allow a SIP call from SIP Phone A to SIP Phone B in Figure 373.

1. SIP Phone A sends a SIP Invite message to the SIP server. Packet source IP address: 192.168.10.1, destination IP address: 10.21.101.10.
2. The SIP packets are received by the NAT device which translates the source address of the SIP packets from 192.168.10.1 to 10.11.101.20.
3. The SIP packets are received by the FortiGate unit which translates the packet destination IP address to 10.30 120.20. The SIP ALG also translates the IP address of the SIP phone in the SIP header and SDP lines from 192.168.10.1 to 10.11.101.20.
4. The SIP server accepts the Invite message and forwards it to SIP Phone B at IP address10.11.101.20. The SIP server has this address for SIP Phone B because SIP packets from SIP Phone B have also been translated using the hosted NAT traversal configuration of the SIP ALG.
5. When the SIP call is established, the RTP session is between 10.11.101.10 and 10.11.101.20 and does not pass through the FortiGate unit. The NAT devices translated the destination address of the RTP packets to the private IP addresses of the SIP phones.

General configuration steps

The following general configuration steps are required for this destination NAT SIP configuration. This example uses the default VoIP profile.

1. Add a VoIP profile that enables hosted NAT translation.
2. Add a SIP proxy server firewall virtual IP.

3. Add a firewall address for the SIP proxy server on the private network.
4. Add a destination NAT security policy that accepts SIP sessions from the Internet destined for the SIP proxy server virtual IP and translates the destination address to the IP address of the SIP proxy server on the private network.
5. Add a security policy that accepts SIP sessions initiated by the SIP proxy server and destined for the Internet.

Configuration steps - web-based manager

To add the SIP proxy server firewall virtual IP

1. Go to *Firewall Objects* > *Virtual IP* > *Virtual IP*.
2. Add the SIP proxy server virtual IP.

Name	SIP_Proxy_VIP
External Interface	port1
Type	Static NAT
External IP Address/Range	172.20.120.50
Mapped IP Address/Range	10.31.101.50

To add a firewall address for the SIP proxy server

1. Go to *Firewall Objects* > *Address* > *Addresses*.
2. Add the following for the SIP proxy server:

Address Name	SIP_Proxy_Server
Type	Subnet
Subnet / IP Range	10.31.101.50/255.255.255.255
Interface	port2

To add the security policies

1. Go to *Policy* > *Policy* > *Policy*.
2. Add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone B (and other SIP phones on the Internet) to send SIP request messages to the SIP proxy server.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port1
Source Address	all
Outgoing Interface	port2
Destination Address	SIP_Proxy_VIP
Schedule	always

Service	SIP
Action	ACCEPT

3. Select *Enable NAT* and select *Use Destination Interface Address*.
4. Under *UTM Security Profiles*, select *Use Standard UTM Profiles*.
5. Turn on *VoIP* and select the *default* VoIP profile.
6. Select *OK*.
7. Add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B and the Internet:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	SIP_Proxy_Server
Outgoing Interface	port1
Destination Address	all
Schedule	always
Service	SIP
Action	ACCEPT

8. Select *Enable NAT* and select *Use Destination Interface Address*.
9. Under *UTM Security Profiles*, select *Use Standard UTM Profiles*.
10. Turn on *VoIP* and select the *default* VoIP profile.
11. Select *OK*.

Configuration steps - CLI

To add a VoIP profile that enables hosted NAT translation

1 Enter the following command to add a VoIP profile named HNT that enables hosted NAT traversal. This command shows how to clone the default VoIP profile and enable hosted NAT traversal.

```
config voip profile
  clone default to HNT
  edit HNT
    config sip
      set hosted-nat-traversal enable
    end
end
```

To add the SIP proxy server firewall virtual IP and firewall address

1. Enter the following command to add the SIP proxy server firewall virtual IP.

```
config firewall vip
  edit SIP_Proxy_VIP
    set type static-nat
    set extip 10.21.101.10
    set mappedip 10.30.120.20
    set extintf port1
  end
```

2. Enter the following command to add the SIP proxy server firewall address.

```
config firewall address
  edit SIP_Proxy_Server
    set associated interface port2
    set type ipmask
    set subnet 10.30.120.20 255.255.255.255
  end
```

To add security policies

1. Enter the following command to add a destination NAT security policy that includes the SIP proxy server virtual IP that allows Phone A to send SIP request messages to the SIP proxy server.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr SIP_Proxy_VIP
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set profile-protocol-options default
    set voip-profile HNT
  end
```

2. Enter the following command to add a source NAT security policy to allow the SIP proxy server to send SIP request messages to Phone B:

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr SIP_Proxy_Server
    set dstaddr all
    set action accept
    set schedule always
    set service SIP
    set nat enable
    set utm-status enable
    set profile-protocol-options default
    set voip-profile default
  end
```

Hosted NAT traversal for calls between SIP Phone A and SIP Phone C

The following address translation takes place to allow a SIP call from SIP Phone A to SIP Phone C in Figure 373 on page 2552.

1. SIP Phone A sends a SIP Invite message to the SIP server. Packet source IP address: 192.168.10.1 and destination IP address: 10.21.101.10.
2. The SIP packets are received by the NAT device which translates the source address of the SIP packets from 192.168.10.1 to 10.11.101.20.
3. The SIP packets are received by the FortiGate unit which translates the packet destination IP address to 10.30 120.20. The SIP ALG also translates the IP address of the SIP phone in the SIP header and SDP lines from 192.168.10.1 to 10.11.101.20.
4. The SIP server accepts the Invite message and forwards it to SIP Phone C at IP address 172.20.120.30. The SIP server has this address for SIP Phone C because SIP packets from SIP Phone C have also been translated using the hosted NAT traversal configuration of the SIP ALG.
5. When the SIP call is established, the RTP session is between 10.11.101.10 and 172.20.120.30. The packets pass through the FortiGate unit which performs NAT as required.

Restricting the RTP source IP

Use the following command in a VoIP profile to restrict the RTP source IP to be the same as the SIP source IP when hosted NAT traversal is enabled.

```
config voip profile
  edit VoIP_HNT
    config sip
      set hosted-nat-traversal enable
      set hnt-restrict-source-ip enable
    end
end
```

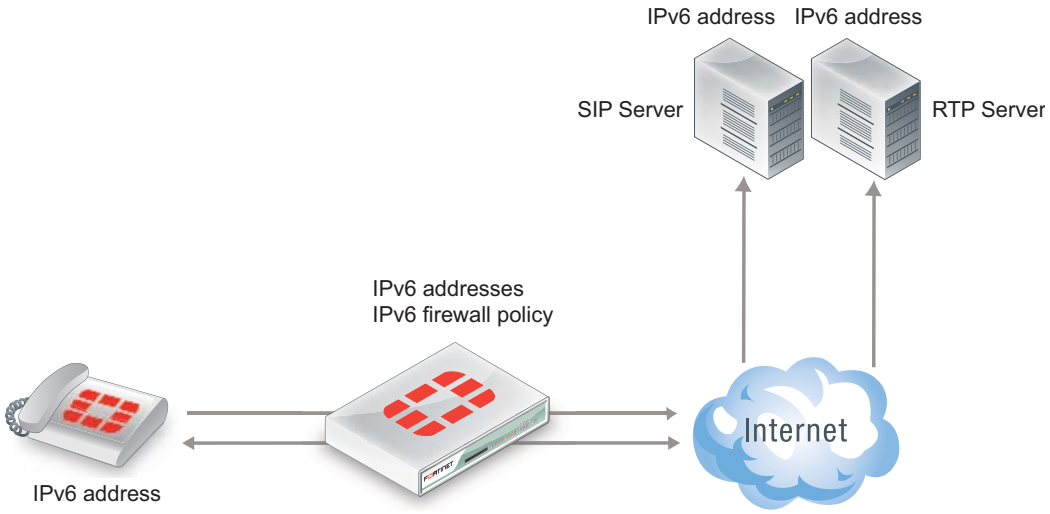
SIP over IPv6

FortiGate units operating in NAT/Route and in Transparent mode support SIP over IPv6. The SIP ALG can process SIP messages that use IPv6 addresses in the headers, bodies, and in the transport stack. The SIP ALG cannot modify the IPv6 addresses in the SIP headers so FortiGate units cannot perform SIP or RTP NAT over IPv6 and also cannot translate between IPv6 and IPv4 addresses.

In the scenario shown in Figure 374, a SIP phone connects to the Internet through a FortiGate unit operating. The phone and the SIP and RTP servers all have IPv6 addresses.

The FortiGate unit has IPv6 security policies that accept SIP sessions. The SIP ALG understands IPv6 addresses and can forward IPv6 sessions to their destinations. Using SIP application control features the SIP ALG can also apply rate limiting and other settings to SIP sessions.

Figure 374:SIP support for IPv6

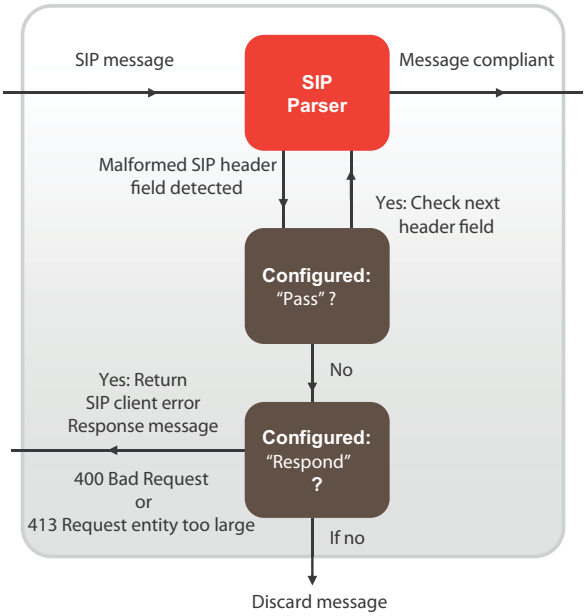


To enable SIP support for IPv6 add an IPv6 security policy that accepts SIP packets and includes a VoIP profile.

Deep SIP message inspection

Deep SIP message syntax inspection (also called Deep SIP header inspection or SIP fuzzing protection) provides protection against malicious SIP messages by applying SIP header and SDP profile syntax checking. SIP Fuzzing attacks can be used by attackers to discover and exploit vulnerabilities of a SIP entity (for example a SIP proxy server). Most often these attacks could crash or compromise the SIP entity.

Figure 375: Deep SIP message inspection



- **Checks the SIP request message Request-line**
- **Checks the following SIP header fields:**
  - **Allow, Call-id, Contact, Content-length, Content-type, CSeq, Expires, From, Max-Forwards, P-asserted-identity, Rack, Record-Route, Route, Rseq, To, Via**
- **Checks all SDP profile lines**
- **Configurable header and body length checks**
- **Optional logging of message violations**

Deep SIP message inspection checks the syntax of each SIP header and SDP profile line to make sure they conform to the syntax defined in the relevant RFC and IETF standard. You can also configure the SIP ALG to inspect for:

- Unknown SIP message types (message types not defined in a SIP RFC) this option is enabled by default and can be disabled. When enabled unknown message types are discarded. Configured using the `block-unknown` option.
- Unknown line types (message line types that are not defined in any SIP or SDP RFC). Configured using the `unknown-header` option.
- Messages that are longer than a configured maximum size. Configured using the `max-body-length` option.
- Messages that contain one or more lines that are longer that a set maximum line length (default 998 characters). Configured using the `max-line-length` option.

Actions taken when a malformed message line is found

When a malformed message line or other error is found the SIP ALG can be configured to discard the message containing the error, pass the message without any other actions, or responding to the message with a 400 Bad Request or 413 Request entity too large client error SIP response message and then discard the message. (For information about client error SIP response messages, see “Client error” on page 2499.)

If a message line is longer than the configured maximum, the SIP ALG sends the following message:

```
SIP/2.0 413 Request Entity Too Large, <optional_info>
```

If a message line is incorrect or in an unknown message line is found, the SIP ALG sends the following message:

```
SIP/2.0 400 Bad Request, <optional_info>
```

The `<optional_info>` provides more information about why the message was rejected. For example, if the SIP ALG finds a malformed Via header line, the response message may be:

```
SIP/2.0 400 Bad Request, malformed Via header
```

If the SIP ALG finds a malformed message line, and the action for this message line type is discard, the message is discarded with no further checking or responses. If the action is pass, the SIP ALG continues parsing the SIP message for more malformed message lines. If the action is respond, the SIP ALG sends the SIP response message and discards the message containing the malformed line with no further checking or response. If only malformed message line types with action set to pass are found, the SIP ALG extracts as much information as possible from the message (for example for NAT and opening pinholes, and forwards the message to its destination).

If a SIP message containing a malformed line is discarded the SIP ALG will not use the information in the message for call processing. This could result in the call being terminated. If a malformed line in a SIP message includes information required for the SIP call that the SIP ALG cannot interpret (for example, if an IP address required for SIP NAT is corrupted) the SIP ALG may not be able to continue processing the call and it could be terminated. Discarded messages are counted by SIP ALG static message counters.

Logging and statistics

To record a log message each time the SIP ALG finds a malformed header, enable logging SIP violations in a VoIP profile. In all cases, when the SIP ALG finds an error the FortiGate unit records a malformed header log message that contains information about the error. This happens even if the action is set to pass.

If, because of recording log messages for deep message inspection, the CPU performance is affected by a certain amount, the FortiGate unit records a critical log message about this event and stops writing log messages for deep SIP message inspection.

The following information is recorded in malformed header messages:

- The type of message line in which the error was found.
- The content of the message line in which the error was found (it will be truncated if it makes the log message too long)
- The column or character number in which the error was found (to make it easier to determine what caused the error)

Deep SIP message inspection best practices

Because of the risks imposed by SIP header attacks or incorrect data being allowed and because selecting drop or respond does not require more CPU overhead that pass you would want to set all tests to drop or respond. However, in some cases malformed lines may be less of a threat or risk. For example, the SDP i= does not usually contain information that is parsed by any SIP device so a malformed i= line may not pose a threat.

You can also used the pre-defined VoIP profiles to apply different levels of deep message inspection. The default VoIP profile sets all deep message inspection options to pass and the strict VoIP profile sets all deep message inspection options to discard. From the CLI you can use the `clone` command to copy these pre-defined VoIP profiles and then customize them for your requirements.

Configuring deep SIP message inspection

You configure deep SIP message inspection in a VoIP profile. All deep SIP message inspection options are available only from the CLI.

Enter the following command to configure deep SIP message inspection to discard messages with malformed Request-lines (the first line in a SIP request message):

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set malformed-request-line respond
    end
end
```

You cannot configure message inspection for the Status-line, which is the first line in a SIP response message.

Table 120 lists the SIP header lines that the SIP ALG can inspect and the CLI command for configuring the action for each line type. The table also lists the RFC that the header line is defined in.

Table 120:SIP header lines that the SIP ALG can inspect for syntax errors

SIP Header line	VoIP profile option	RFC
Allow	`malformed-header-allow`	RFC 3261
Call-ID	`malformed-header-call-id`	RFC 3261
Contact	`malformed-header-contact`	RFC 3261
Content-Length	`malformed-header-content-length`	RFC 3261
Content-Type	`malformed-header-content-type`	RFC 3261
CSeq	`malformed-header-cseq`	RFC 3261
Expires	`malformed-header-expires`	RFC 3261
From	`malformed-header-from`	RFC 3261
Max-forwards	`malformed-header-max-forwards`	RFC 3261
P-Asserted-Identity	`malformed-header-p-asserted-identity`	RFC 3325
RAck	`malformed-header-rack`	RFC 3262
Record-Route	`malformed-header-record-route`	RFC 3261
Route	`malformed-header-route`	RFC 3261
RSeq	`malformed-header-rseq`	RFC 3262
To	`malformed-header-to`	RFC 3261
Via	`malformed-header-via`	RFC 3261

Table 121 lists the SDP profile lines that the SIP ALG inspects and the CLI command for configuring the action for each line type. SDP profile lines are defined by RFC 4566 and RFC 2327.

Table 121:SDP profile lines that the SIP ALG can inspect for syntax errors

Attribute	VoIP profile option
a=	`malformed-header-sdb-a`
b=	`malformed-header-sdp-b`
c=	`malformed-header-sdp-c`
i=	`malformed-header-sdp-i`
k=	`malformed-header-sdp-k`
m=	`malformed-header-sdp-m`
o=	`malformed-header-sdp-o`
r=	`malformed-header-sdp-r`
s=	`malformed-header-sdp-s`
t=	`malformed-header-sdp-t`
v=	`malformed-header-sdp-v`
z=	`malformed-header-sdp-z`

Discarding SIP messages with some malformed header and body lines

Enter the following command to configure deep SIP message inspection to discard SIP messages with a malformed Via line, a malformed route line or a malformed m= line but to pass messages with a malformed i= line or a malformed Max-Forwards line

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set malformed-header-via discard
      set malformed-header-route discard
      set malformed-header-sdp-m discard
      set malformed-header-sdp-i pass
      set malformed-header-max-forwards pass
    end
end
```

Discarding SIP messages with an unknown SIP message type

Enter the following command to discard SIP messages with an unknown SIP message line type as defined in all current SIP RFCs:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set unknown-header discard
    end
end
```

Discarding SIP messages that exceed a message size

Enter the following command to set the maximum size of a SIP message to 200 bytes. Messages longer than 200 bytes are discarded.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-body-length 200
    end
end
```

The `max-body-length` option checks the value in the SIP Content-Length header line to determine body length. The Content-Length can be larger than the actual size of a SIP message if the SIP message content is split over more than one packet. SIP message sizes vary widely. The size of a SIP message can also change with the addition of Via and Record-Route headers as the message is transmitted between users and SIP servers.

Discarding SIP messages with lines longer than 500 characters

Enter the following command to set the length of a SIP message line to 500 characters and to block messages that include lines with 500 or more characters:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-line-length 500
      set block-long-lines enable
    end
end
```

Blocking SIP request messages

You may want to block different types of SIP requests:

- to prevent SIP attacks using these messages.
- If your SIP server cannot process some SIP messages because of a temporary issue (for example a bug that crashes or compromises the server when it receives a message of a certain type).
- Your SIP implementation does not use certain message types.

When you enable message blocking for a message type in a VoIP profile, whenever a security policy containing the VoIP profile accepts a SIP message of this type, the SIP ALG silently discards the message and records a log message about the action.

Use the following command to configure a VoIP profile to block SIP CANCEL and Update request messages:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set block-cancel enable
      set block-update enable
    end
end
```

SIP uses a variety of text-based messages or requests to communicate information about SIP clients and servers to the various components of the SIP network. Since SIP requests are simple text messages and since the requests or their replies can contain information about network components on either side of the FortiGate unit, it may be a security risk to allow these messages to pass through.

Table 122 lists all of the VoIP profile SIP request message blocking options. All of these options are disabled by default.

Blocking SIP OPTIONS messages may prevent a redundant configuration from operating correctly. See "Supporting geographic redundancy when blocking OPTIONS messages" on page 2571 for information about resolving this problem.

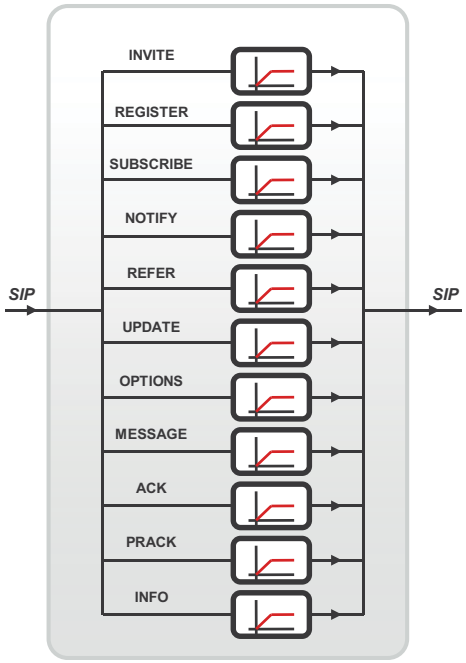
Table 122: Options for blocking SIP request messages

SIP request message	SIP message blocking CLI Option
ACK	block-ack
BYE	block-bye
Cancel	block-cancel
INFO	block-info
INVITE	block-invite
Message	block-message
Notify	block-notify
Options	block-options
PRACK	block-prack
Publish	block-publish
Refer	block-refer
Register	block-register
Subscribe	block-subscribe
Update	block-update

SIP rate limiting

Configurable threshold for SIP message rates per request method. Protects SIP servers from SIP overload and DoS attacks.

Figure 376:SIP rate limiting



- **SIP message rate limitation**
- **Individually configurable per SIP method**
- **When threshold is hit additional messages with this method will be discarded**
- **Prevents SIP server from getting overloaded by flash crowds or Denial-of-Service attacks.**
- **May block some methods at all** (with extra "block" option)
- **Can be disabled (unlimited rate)**

FortiGate units support rate limiting for the following types of VoIP traffic:

- Session Initiation Protocol (SIP)
- Skinny Call Control Protocol (SCCP) (most versions)
- Session Initiation Protocol for Instant Messaging and Presence Leveraging Extensions (SIMPLE).

You can use rate limiting of these VoIP protocols to protect the FortiGate unit and your network from SIP and SCCP Denial of Service (DoS) attacks. Rate limiting protects against SIP DoS attacks by limiting the number of SIP REGISTER and INVITE requests that the FortiGate unit receives per second. Rate limiting protects against SCCP DoS attacks by limiting the number of SCCP call setup messages that the FortiGate unit receives per minute.

You configure rate limiting for a message type by specifying a limit for the number of messages that can be received per second. The rate is limited per security policy. When VoIP rate limiting is enabled for a message type, if the a single security policy accepts more messages per second than the configured rate, the extra messages are dropped and log messages are written when the messages are dropped.

Use the following command to configure a VoIP profile to limit the number of INVITE messages accepted by each security policy that the VoIP profile is added to 100 INVITE messages a second:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set invite-rate 100
    end
end
```

If you are experiencing denial of service attacks from traffic using these VoIP protocols, you can enable VoIP rate limiting and limit the rates for your network. Limit the rates depending on the amount of SIP and SCCP traffic that you expect the FortiGate unit to be handling. You can adjust the settings if some calls are lost or if the amount of SIP or SCCP traffic is affecting FortiGate unit performance.

Table 123 lists all of the VoIP profile SIP rate limiting options. All of these options are set to 0 so are disabled by default.

Blocking SIP OPTIONS messages may prevent a redundant configuration from operating correctly. See "Supporting geographic redundancy when blocking OPTIONS messages" on page 2571 for information about resolving this problem.

Table 123: Options for SIP rate limiting

SIP request message	Rate Limiting CLI Option
ACK	`ack-rate`
BYE	`bye-rate`
Cancel	`cancel-rate`
INFO	`info-rate`
INVITE	`invite-rate`
Message	`message-rate`
Notify	`notify-rate`
Options	`options-rate`
PRACK	`prack-rate`
Publish	`publish-rate`
Refer	`refer-rate`
Register	`register-rate`
Subscribe	`subscribe-rate`
Update	`update-rate`

Limiting the number of SIP dialogs accepted by a security policy

In addition to limiting the rates for receiving SIP messages, you can use the following command to limit the number of SIP dialogs (or SIP calls) that the FortiGate unit accepts.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set max-dialogs 2000
    end
end
```

This command sets the maximum number of SIP dialogs that can be open for SIP sessions accepted by any security policy that you add the VoIP profile to. The default setting of 0 does not limit the number of dialogs. You can add a limit to control the number of open dialogs and raise and lower it as required. You might want to limit the number of open dialogs for protection against SIP-based attackers opening large numbers of SIP dialogs. Every dialog takes memory and FortiGate CPU resources to process. Limiting the number of dialogs may improve the overall performance of the FortiGate unit. Limiting the number of dialogs will not drop calls in progress but may prevent new calls from connecting.

SIP logging and DLP archiving

You can enable SIP logging and logging of SIP violations, and SIP DLP archiving a VoIP profile. To record SIP log messages you must also enable VoIP event logging in the FortiGate unit event logging configuration.

To view SIP log messages go to *Log&Report* > *Log Access* > *Event*.

To view SIP DLP archive messages to go *Log&Report* > *Archive Access* > *VoIP*.

Use the following command enable SIP logging, SIP archiving, and logging of SIP violations in a VoIP profile:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set log-call-summary enable
      set log-violations enable
    end
end
```

Inspecting SIP over SSL/TLS (secure SIP)

Some SIP phones and SIP servers can communicate using SSL or TLS to encrypt the SIP signalling traffic. To allow SIP over SSL/TLS calls to pass through the FortiGate unit, the encrypted signalling traffic has to be unencrypted and inspected. To do this, the FortiGate SIP ALG intercepts and unencrypts and inspects the SIP packets. The packets are then re-encrypted and forwarded to their destination.

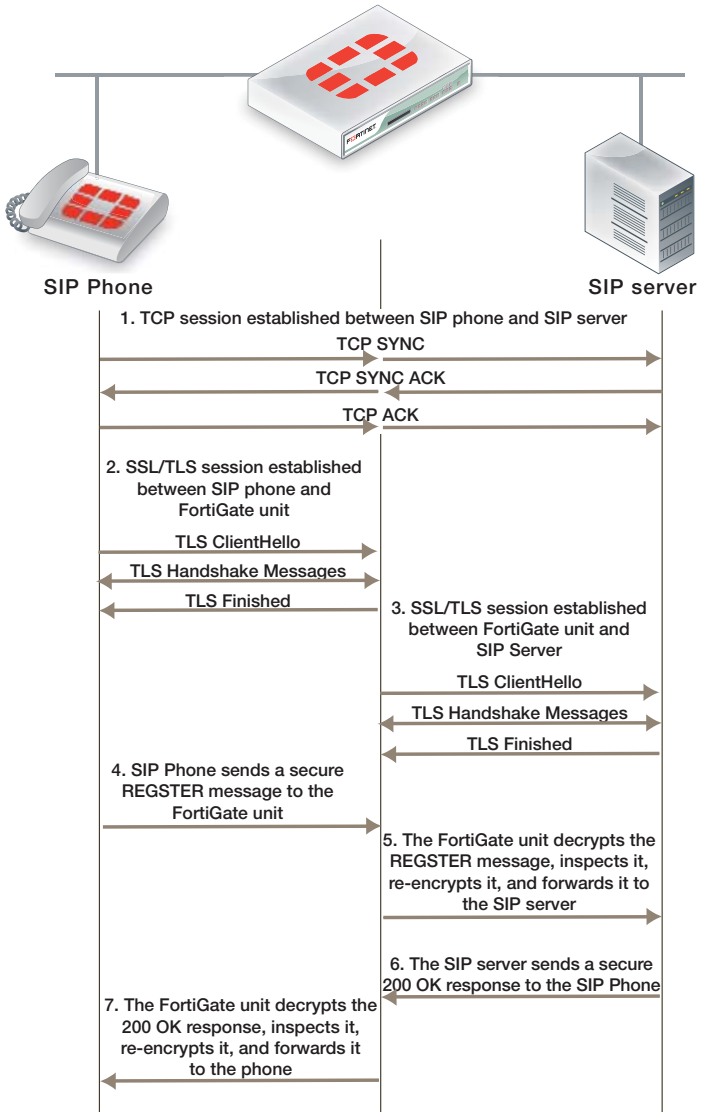
Normally SIP over SSL/TLS uses port 5061. You can use the following command to change the port that the FortiGate listens on for SIP over SSL/TLS sessions to port 5066:

```
config system settings
  set sip-ssl-port 5066
end
```

The SIP ALG supports full mode SSL/TLS only. Traffic between SIP phones and the FortiGate unit and between the FortiGate unit and the SIP server is always encrypted.

You enable SSL/TLS SIP communication by enabling SSL mode in a VoIP profile. You also need to install the SIP server and client certificates on your FortiGate unit and add them to the SSL configuration in the VoIP profile.

Figure 377:SIP over SSL/TLS between a SIP phone and a SIP server



Other than enabling SSL mode and making sure the security policies accept the encrypted traffic, the FortiGate configuration for SSL/TLS SIP is the same as any SIP configuration. SIP over SSL/TLS is supported for all supported SIP configurations.

Adding the SIP server and client certificates

A VoIP profile that supports SSL/TLS SIP requires one certification for the SIP server and one certificate that is used by all of the clients. Use the following steps to add these certificates to the FortiGate unit. Before you start, make sure the client and server certificate files and their key files are accessible from the management computer.

1. Go to *System* > *Certificates* > *Local Certificates* and select *Import.*
2. Set *Type* to *Certificate*.
3. Browse to the *Certificate file* and the *Key file* and select *OK*.
4. Enter a password for the certificate and select *OK*.

   The certificate and key are uploaded to the FortiGate unit and added to the *Local Certificates* List.
5. Repeat to upload the other certificate.

The certificates are added to the list of Local Certificates as the filenames you uploaded. You can add comments to make it clear where its from and how it is intended to be used.

Adding SIP over SSL/TLS support to a VoIP profile

Use the following commands to add SIP over SSL/TLS support to the default VoIP profile. The following command enables SSL mode and adds the client and server certificates and passwords, the same ones you entered when you imported the certificates:

```
config voip profile
  edit default
    config sip
      set ssl-mode full
      set ssl-client-certificate "Client_cert"
      set ssl-server-certificate "Server_cert"
      set ssl-auth-client "check-server"
      set ssl-auth-server "check-server-group"
  end
end
```

Other SSL mode options are also available:

`ssl-send-empty-frags {disable | enable}`	Enable to send empty fragments to avoid CBC IV attacks. Compatible with SSL 3.0 and TLS 1.0 only. Default is `enable`.
`ssl-client-renegotiation {allow | deny | secure}`	Control how the ALG responds when a client attempts to renegotiate the SSL session. You can allow renegotiation or block sessions when the client attempts to renegotiate. You can also select `secure` to reject an SSL connection that does not support RFC 5746 secure renegotiation indication. Default is `allow`.
`ssl-algorithm {high | low | medium}`	Select the relative strength of the algorithms that can be selected. You can select `high`, the default, to allow only AES or 3DES, `medium`, to allow AES, 3DES, or RC4 or `low`, to allow AES, 3DES, RC4, or DES.
`ssl-pfs {allow | deny | reqqure}`	Select whether to `allow`, `deny`, or `require` perfect forward secrecy (PFS). Default is `allow`.
`ssl-min-version {ssl-3.0 | tls-1.0 | tls-1.1}`	Select the minimum level of SSL support to allow. The default is `ssl-3.0`.
`ssl-max-version {ssl-3.0 | tls-1.0 | tls-1.1}`	Select the maximum level of SSL support to allow. The default is `tls-1.1`.

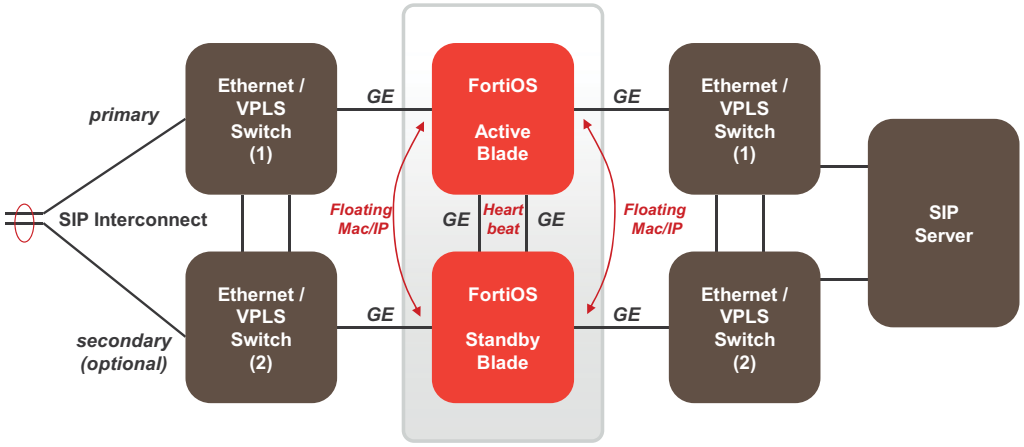
SIP and HA: session failover and geographic redundancy

FortiGate high availability supports SIP session failover (also called stateful failover) for active-passive HA. To support SIP session failover, create a standard HA configuration and select the Enable Session Pick-up option.

SIP session failover replicates SIP states to all cluster units. If an HA failover occurs, all in progress SIP calls (setup complete) and their RTP flows are maintained and the calls will continue after the failover with minimal or no interruption.

SIP calls being set up at the time of a failover may lose signaling messages. In most cases the SIP clients and servers should use message retransmission to complete the call setup after the failover has completed. As a result, SIP users may experience a delay if their calls are being set up when an HA a failover occurs. But in most cases the call setup should be able to continue after the failover.

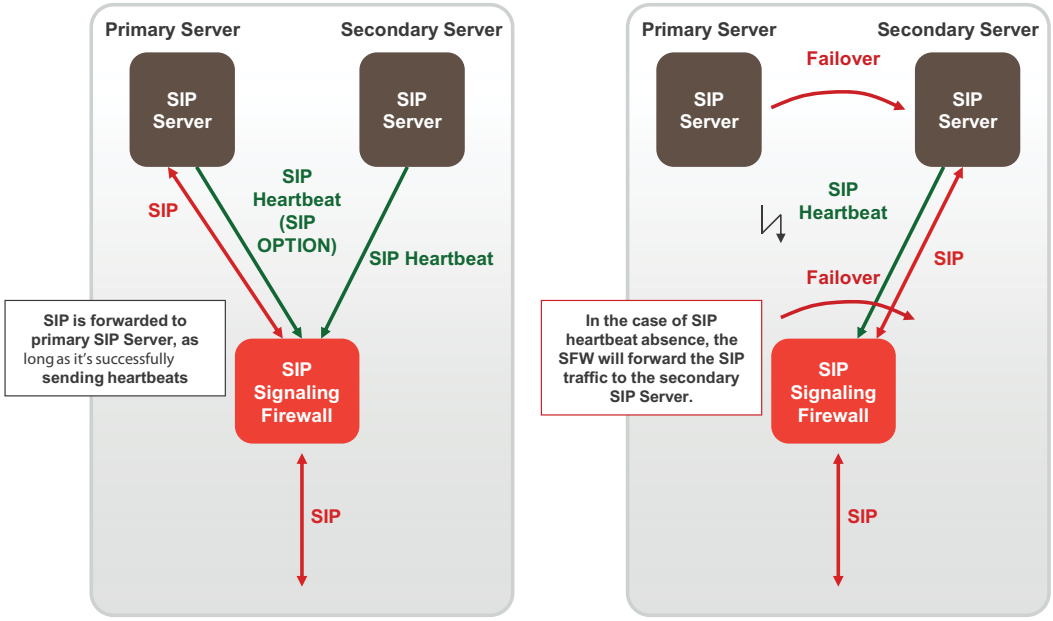
Figure 378:SIP HA session failover



SIP geographic redundancy

Maintains a active-standby SIP server configuration, which even supports geographical distribution. If the active SIP server fails (missing SIP heartbeat messages or SIP traffic) FortiOS will redirect the SIP traffic to a secondary SIP server. SIP geographic redundancy

Figure 379: Geographic redundancy



Supporting geographic redundancy when blocking OPTIONS messages

For some geographic redundant SIP configurations, the SIP servers may use SIP OPTIONS messages as heartbeats to notify the FortiGate unit that they are still operating (or alive). This is a kind of passive SIP monitoring mechanism where the FortiGate unit isn't actively monitoring the SIP servers and instead the FortiGate unit passively receives and analyzes OPTIONS messages from the SIP servers.

If FortiGate units block SIP OPTIONS messages because `block-options` is enabled, the configuration may fail to operate correctly because the OPTIONS messages are blocked by one or more FortiGate units.

However, you can work around this problem by enabling the `block-geo-red-options` application control list option. This option causes the FortiGate unit to refresh the local SIP server status when it receives an OPTIONS message before dropping the message. The end result is the heartbeat signals between geographically redundant SIP servers are maintained but OPTIONS messages do not pass through the FortiGate unit.

Use the following command to block OPTIONS messages while still supporting geographic redundancy:

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set block-options disable
      set block-geo-red-options enable
    end
end
```

The `block-options` option setting overrides the `block-geo-red-options` option. If `block-options` is enabled the FortiGate unit only blocks SIP OPTIONS messages and does not refresh local SIP server status.

Support for RFC 2543-compliant branch parameters

RFC 3261 is the most recent SIP RFC, it obsoletes RFC 2543. However, some SIP implementations may use RFC 2543-compliant SIP calls.

The `rfc2543-branch` VoIP profile option allows the FortiGate unit to support SIP calls that include an RFC 2543-compliant branch parameter in the SIP Via header. This option also allows FortiGate units to support SIP calls that include Via headers that are missing the branch parameter.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set rfc2543-branch enable
    end
end
```

SIP and IPS

You can enable IPS in security policies that also accept SIP sessions to protect the SIP traffic from SIP-based attacks. If you enable IPS in this way then by default the pinholes that the SIP ALG creates to allow RTP and RTCP to flow through the firewall will also have IPS enabled.

This inheritance of the IPS setting can cause performance problems if the RTP traffic volume is high since IPS checking may reduce performance in some cases. Also if you are using network processor (NP) interfaces to accelerate VoIP performance, when IPS is enabled for the pinhole traffic is diverted to the IPS and as a result is not accelerated by the network processors.

You can use the following CLI command to disable IPS for the RTP pinhole traffic.

```
config voip profile
  edit VoIP_Pro_Name
    config sip
      set ips-rtp disable
    end
end
```

SIP debugging

SIP debug log format

Assuming that `diagnose debug console timestamp` is enabled then the following shows the debug that is generated for an INVITE if `diag debug appl sip -1` is enabled:

```
2010-01-04 21:39:59 sip port 26 locate session for 192.168.2.134:5061 ->
172.16.67.192:5060

```

SIP-proxy filter per VDOM

You can use the `diagnose sys sip-proxy xxx` command in a VDOM to get info about how SIP is operating in each VDOM.

SIP-proxy filter command

Use the `diagnose system sip-proxy filter` to filter diagnose information for the SIP ALG. The following filters are available:

```
diag sys sip-proxy filter vd
diag sys sip-proxy filter dst-addr4
diag sys sip-proxy filter dst-addr6
diag sys sip-proxy filter dst-port
diag sys sip-proxy filter identity-policy
diag sys sip-proxy filter negate
diag sys sip-proxy filter policy
diag sys sip-proxy filter policy-type
diag sys sip-proxy filter profile-group
diag sys sip-proxy filter src-addr4
diag sys sip-proxy filter src-addr6
diag sys sip-proxy filter src-port
diag sys sip-proxy filter vd
diag sys sip-proxy filter voip-profile
```

You can clear, view and negate/invert the sense of a filter using these commands:

```
diag sys sip-proxy filter clear
diag sys sip-proxy filter list
diag sys sip-proxy filter negate
```

SIP debug log filtering

You can filter by VDOM/IP/PORT and by policy and VoIP profile. The filtering can be controlled by:

```
diagnose system sip-proxy log-filter
```

The list of filters is:

```
diag sys sip-proxy log-filter vd
diag sys sip-proxy log-filter dst-addr4
diag sys sip-proxy log-filter dst-addr6
diag sys sip-proxy log-filter dst-port
diag sys sip-proxy log-filter identity-policy
diag sys sip-proxy log-filter policy
diag sys sip-proxy log-filter policy-type
diag sys sip-proxy log-filter profile-group
diag sys sip-proxy log-filter src-addr4
diag sys sip-proxy log-filter src-addr6
diag sys sip-proxy log-filter src-port
diag sys sip-proxy log-filter vd
diag sys sip-proxy log-filter voip-profile
```

You can clear, view and negate/invert the sense of a filter using these commands:

```
diag sys sip-proxy log-filter clear
diag sys sip-proxy log-filter list
diag sys sip-proxy log-filter negate
```

SIP debug setting

Control of the SIP debug output is governed by the following command

```
diagnose debug application sip <debug_level_int>
```

Where the `<debug_level_int>` is a bitmask and the individual values determine whether the listed items are logged or not. The `<debug_level_int>` can be

1 - configuration changes. Mainly addition/deletion/modification of virtual domains.

2 - (TCP) connection accepts or connects, redirect creation

4 - create or delete a session

16 - any IO read or write

32 - an ASCII dump of all data read or written

64 - Include HEX dump in the above output

128 - any activity related to the use of the FortiCarrier dynamic profile feature to determine the correct profile-group to use

256 - log summary of interesting fields in a SIP call

1024 - any activity related to SIP geo-redundancy.

2048 - any activity related to HA syncing of SIP calls.

Display SIP rate-limit data

You can use the `diagnose sys sip-proxy meters` command to display SIP rate limiting data.

For the following command output `rate 1` shows that the current (over last second) measured rate for INVITE/ACK and BYTE was 1 per second, the `peak 1` shows that the peak rate recorded is 1 per second, the `max 0` shows that there is no maximum limit set, the `count 18` indicates that 18 messages were received and `drop 0` indicates that none were dropped due to being over the limit.

```
diag sys sip-proxy meters
sip
sip vd: 0
sip policy: 1
sip identity-policy: 0
sip policy-type: IPv4
sip profile-group:
sip dialogs: 18
sip dialog-limit: 0
sip UNKNOWN:  rate 0  peak 0  max 0  count 0  drop 0
sip ACK:  rate 1  peak 1  max 0  count 18  drop 0
sip BYE:  rate 1  peak 1  max 0  count 18  drop 0
sip CANCEL:  rate 0  peak 0  max 0  count 0  drop 0
sip INFO:  rate 0  peak 0  max 0  count 0  drop 0
sip INVITE:  rate 1  peak 1  max 0  count 18  drop 0
sip MESSAGE:  rate 0  peak 0  max 0  count 0  drop 0
sip NOTIFY:  rate 0  peak 0  max 0  count 0  drop 0
sip OPTIONS:  rate 0  peak 0  max 0  count 0  drop 0
sip PRACK:  rate 0  peak 0  max 0  count 0  drop 0
sip PUBLISH:  rate 0  peak 0  max 0  count 0  drop 0
sip REFER:  rate 0  peak 0  max 0  count 0  drop 0
sip REGISTER:  rate 0  peak 0  max 0  count 0  drop 0
sip SUBSCRIBE:  rate 0  peak 0  max 0  count 0  drop 0
sip UPDATE:  rate 0  peak 0  max 0  count 0  drop 0
sip PING:  rate 0  peak 0  max 0  count 0  drop 0
sip YAHOOREF:  rate 0  peak 0  max 0  count 0  drop 0
```

Chapter 22 WAN Optimization, Web Cache, Explicit Proxy, and WCCP for FortiOS 5.0

Welcome and thank you for selecting Fortinet products for your network protection.

You can use FortiGate WAN optimization and web caching to improve performance and security of traffic passing between locations on your wide area network (WAN) or from the Internet to your web servers. You can also use the FortiGate unit as an explicit FTP and web proxy server. If your FortiGate unit supports web caching, you can also add web caching to any HTTP sessions including WAN optimization, explicit web proxy and other HTTP sessions.

This document describes how FortiGate WAN optimization, web caching, explicit web proxy, explicit FTP proxy and WCCP work and also describes how to configure these features.

Before you begin

Before you begin to configure WAN optimization, Web caching, explicit proxies or WCCP, take a moment to note the following:

- To use WAN optimization and web caching your FortiGate unit must support these features and not all do. In general your FortiGate unit must include a hard disk to support these features. See "FortiGate models that support WAN optimization" on page 2578. Most FortiGate units support the explicit web and FTP proxies.
- To be able to configure WAN optimization and web caching from the web-based manager you should begin by going to the System Information dashboard widget and enabling *WAN Opt. & Cache*.
- To be able to configure the Explicit Web and FTP proxies from the web-based manager you should begin by going to the System Information dashboard widget and enabling *Explicit Proxy*.
- If you enable virtual domains (VDOMs) on the FortiGate unit, WAN optimization, web caching, and the explicit web and FTP proxies are available separately for each VDOM.
- This guide is based on the assumption that you are a FortiGate administrator. It is not intended for others who may also use the FortiGate unit, such as FortiClient administrators or end users.
- FortiGate WAN optimization is proprietary to Fortinet. FortiGate WAN optimization is compatible only with FortiClient WAN optimization, and will not work with other vendors' WAN optimization or acceleration features.
- FortiGate web caching, explicit web and FTP proxies, and WCCP support known standards for these features. See the appropriate chapters of this document for details.

At this stage, the following installation and configuration conditions are assumed:

- For WAN optimization you have already successfully installed two or more FortiGate units at various locations across your WAN by following the instructions in the appropriate FortiGate unit QuickStart or Installation Guide. You can download FortiGate installation guides from the FortiGate documentation page: http://docs.fortinet.com/fgt.html.
- For web caching, the explicit proxies and WCCP you have already successfully installed one or more FortiGate units on your network by following the instructions in the appropriate FortiGate unit QuickStart Guide. You can download FortiGate installation guides from the FortiGate documentation page: http://docs.fortinet.com/fgt.html.
- You have administrative access to the web-based manager and/or CLI.
- The FortiGate units are integrated into your WAN or other networks
- The operation mode has been configured.
- The system time, DNS settings, administrator password, and network interfaces have been configured.
- Firmware, FortiGuard Antivirus and FortiGuard Antispam updates are completed.
- You have added security policies to allow your FortiGate units to process traffic.
- You Fortinet products have been registered. Register your Fortinet products at the Fortinet Technical Support web site, https://support.fortinet.com.

FortiGate models that support WAN optimization

WAN optimization is available on FortiGate models with internal storage that also support SSL acceleration. Internal storage includes high-capacity internal hard disks, AMC hard disk modules, FortiGate Storage Modules (FSMs) or over 4 Gbytes of internal flash storage. All of these storage locations can provide similar web caching and byte caching performance. If you add more than one storage location (for example, by creating multiple partitions on a storage device, by using more than one FSM, or by using an FSM and AMC hard disk in the same FortiGate unit) you can configure different storage locations for web caching and byte caching.

You can configure WAN optimization storage options from the FortiGate CLI. See “Storage” on page 2716.

How this chapter is organized

This FortiOS Handbook chapter describes how to implement WAN optimization, web caching and the web proxy on supported FortiGate units.

The FortiOS Handbook chapter contains the following sections:

Example network topologies: Provides an overview of FortiGate WAN optimization best practices and technologies and some of the concepts and rules for using them. We recommend that you begin with this chapter before attempting to configure your FortiGate unit to use WAN optimization.

Storage: Describes how to configure WAN optimization storage settings to control how data is stored for web caching and byte caching.

Peers and authentication groups: Describes how to use WAN optimization peers and authentication groups to control access to WAN optimization tunnels.

Configuring WAN optimization: Provides basic configuration for WAN optimization rules, including adding rules, organizing rules in the rule list and using WAN optimization addresses. This chapter also explains how WAN optimization accepts sessions, as well as how and when you can apply security profile to WAN optimization traffic.

Configuration examples: Describes basic active-passive and peer-to-peer WAN optimization configuration examples. This chapter is a good place to start learning how to put an actual WAN optimization network together.

Web caching and SSL offloading: Describes how web caching works to cache HTTP and HTTPS, how to use SSL offloading to improved performance of HTTPS websites, and includes web caching configuration examples.

FortiClient WAN optimization: Describes how FortiGate and FortiClient WAN optimization work together and includes an example configuration.

The FortiGate explicit web proxy: Describes how to configure the FortiGate explicit web proxy, how users connect to the explicit web proxy, and how to add web caching to the explicit web proxy.

The FortiGate explicit FTP proxy: Describes how to configure the FortiGate explicit FTP proxy and how users connect to the explicit FTP proxy.

FortiGate WCCP: Describes FortiGate WCCP and how to configure WCCP and the WCCP client.

Diagnose commands: describes get and diagnose commands available for troubleshooting WAN optimization, web cache, and WCCP.

Example network topologies

FortiGate WAN optimization consists of a number of techniques that you can apply to improve the efficiency of communication across your WAN. These techniques include protocol optimization, byte caching, web caching, SSL offloading, and secure tunnelling. Protocol optimization can improve the efficiency of traffic that uses the CIFS, FTP, HTTP, or MAPI protocol, as well as general TCP traffic. Byte caching caches files and other data on FortiGate units to reduce the amount of data transmitted across the WAN. Web caching stores web pages on FortiGate units to reduce latency and delays between the WAN and web servers. SSL offloading offloads SSL decryption and encryption from web servers onto FortiGate SSL acceleration hardware. Secure tunnelling secures traffic as it crosses the WAN.

You can apply different combinations of these WAN optimization techniques to a single traffic stream depending on the traffic type. For example, you can apply byte caching and secure tunneling to any TCP traffic. For HTTP and HTTPS traffic, you can also apply protocol optimization and web caching.

You can configure a FortiGate unit to be an explicit web proxy server for both IPv4 and IPv6 traffic and an explicit FTP proxy server. Users on your internal network can browse the Internet through the explicit web proxy server or connect to FTP servers through the explicit FTP proxy server. You can also configure these proxies to protect access to web or FTP servers behind the FortiGate unit using a reverse proxy configuration.

Web caching can be applied to any HTTP or HTTPS traffic, this includes normal traffic accepted by a security policy, explicit web proxy traffic, and WAN optimization traffic.

You can also configure a FortiGate unit to operate as a Web Cache Communication Protocol (WCCP) client or server. WCCP provides the ability to offload web caching to one or more redundant web caching servers.

FortiGate units can also apply security profiles to traffic as part of a WAN optimization, explicit web proxy, explicit FTP proxy, web cache and WCCP configuration. Security policies that include any of these options can also include settings to apply all forms of security profile inspection supported by your FortiGate unit.

This chapter describes:

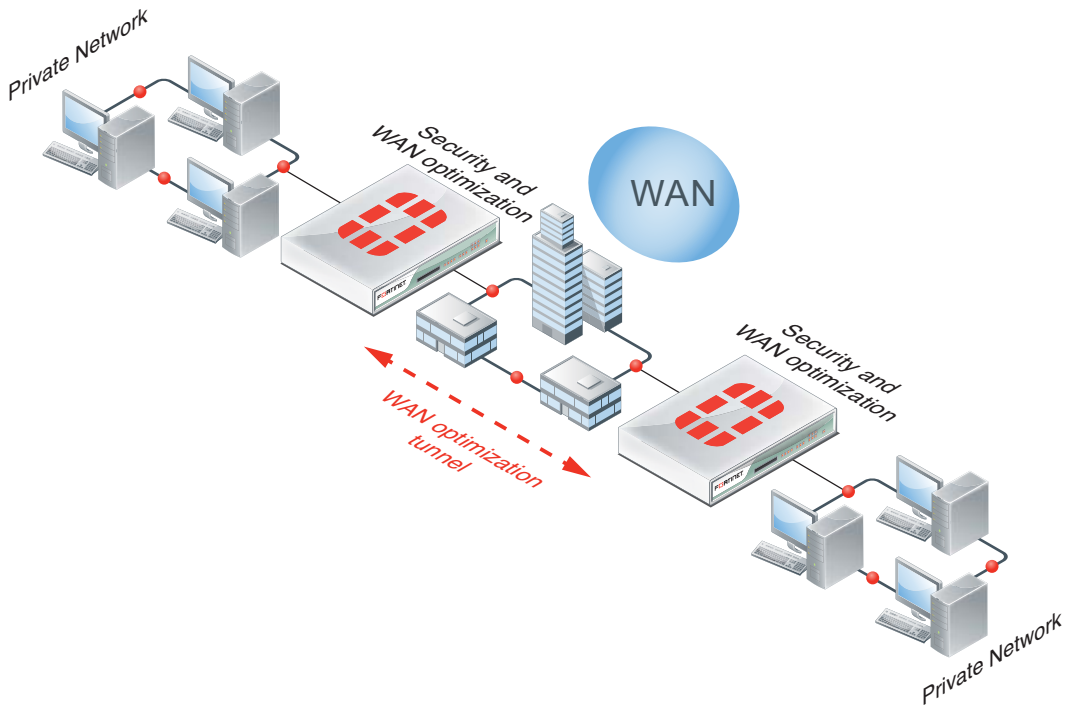
WAN optimization topologies

This section describes some common WAN optimization topologies:

Basic WAN optimization topologies

The basic FortiGate WAN optimization topology consists of two FortiGate units operating as WAN optimization peers intercepting and optimizing traffic crossing the WAN between the private networks.

Figure 380: Security device and WAN optimization topology



As shown in Figure 380, FortiGate units can be deployed as security devices that protect private networks connected to the WAN and also perform WAN optimization. In this configuration, the FortiGate units are configured as typical security devices for the private networks and are also configured for WAN optimization. The WAN optimization configuration intercepts traffic to be optimized as it passes through the FortiGate unit and uses a WAN optimization tunnel with another FortiGate unit to optimize the traffic that crosses the WAN.

As shown in Figure 381, you can also deploy WAN optimization on single-purpose FortiGate units that only perform WAN optimization. In Figure 381, the WAN optimization FortiGate units are located on the WAN outside of the private networks. You can also install the WAN optimization FortiGate units behind the security devices on the private networks.

The WAN optimization configuration is the same for FortiGate units deployed as security devices and for single-purpose WAN optimization FortiGate units. The only differences would result from the different network topologies.

Out-of-path topology

In an out-of-path topology, one or both of the FortiGate units configured for WAN optimization are not directly in the main data path. Instead, the out-of-path FortiGate unit is connected to a device on the data path, and the device is configured to redirect sessions to be optimized to the out-of-path FortiGate unit.

Figure 381: Single-purpose WAN optimization topology

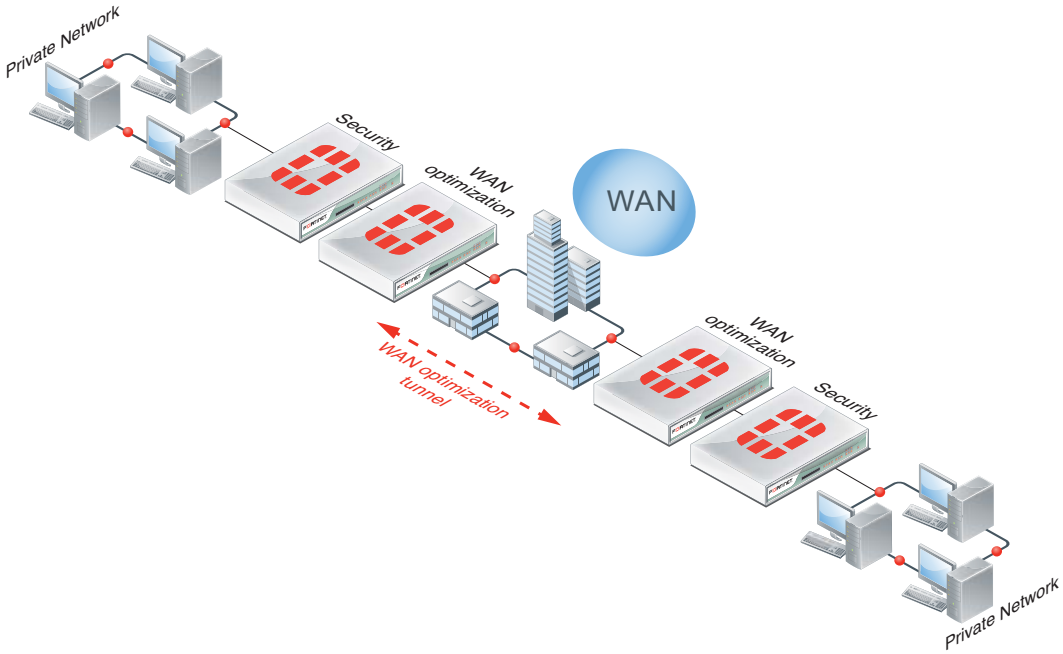


Figure 382 shows out-of-path FortiGate units configured for WAN optimization and connected directly to FortiGate units in the data path. The FortiGate units in the data path use a method such as policy routing to redirect traffic to be optimized to the out-of-path FortiGate units. The out-of-path FortiGate units establish a WAN optimization tunnel between each other and optimize the redirected traffic.

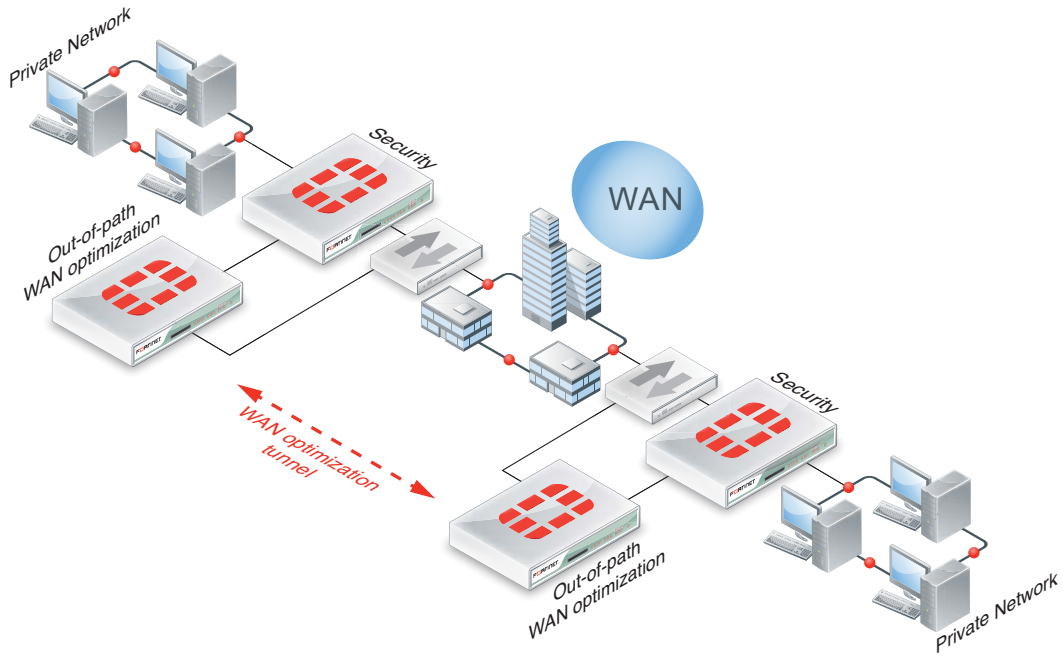
Figure 382: Out-of-path WAN optimization



One of the benefits of out-of-path WAN optimization is that out-of-path FortiGate units only perform WAN optimization and do not have to process other traffic. An in-path FortiGate unit configured for WAN optimization also has to process other non-optimized traffic on the data path.

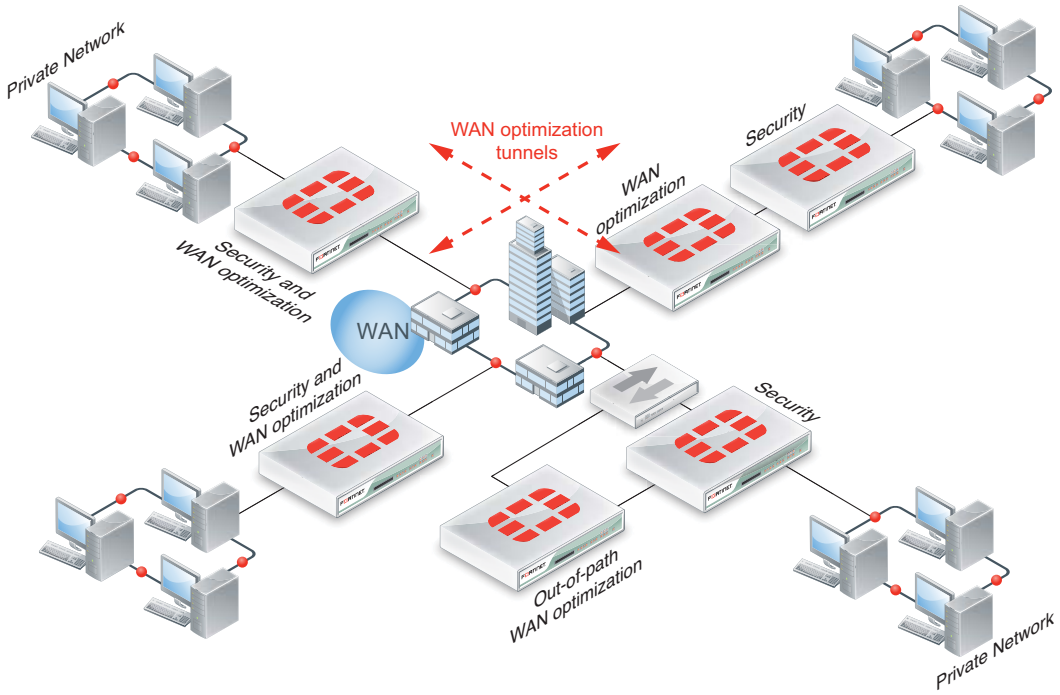
The out-of-path FortiGate units can operate in NAT/Route or Transparent mode.

Other out-of-path topologies are also possible. For example, you can install the out-of-path FortiGate units on the private networks instead of on the WAN. Also, the out-of-path FortiGate units can have one connection to the network instead of two. In a one-arm configuration such as this, security policies and routing have to be configured to send the WAN optimization tunnel out the same interface as the one that received the traffic.

Topology for multiple networks

As shown in Figure 383, you can create multiple WAN optimization configurations between many private networks. Whenever WAN optimization occurs, it is always between two FortiGate units, but you can configure any FortiGate unit to perform WAN optimization with any of the other FortiGate units that are part of your WAN.

Figure 383:WAN optimization among multiple networks

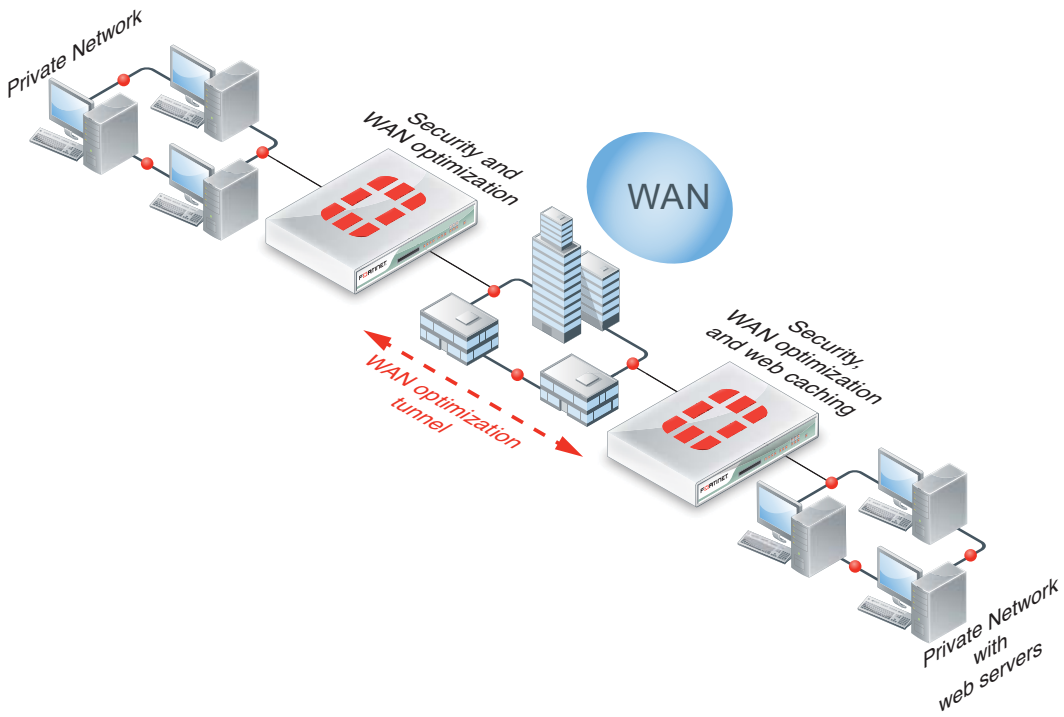


You can also configure WAN optimization between FortiGate units with different roles on the WAN. FortiGate units configured as security devices and for WAN optimization can perform WAN optimization as if they are single-purpose FortiGate units just configured for WAN optimization.

WAN optimization with web caching

You can add web caching to a WAN optimization topology when users on a private network communicate with web servers located across the WAN on another private network.

Figure 384:WAN optimization with web caching topology

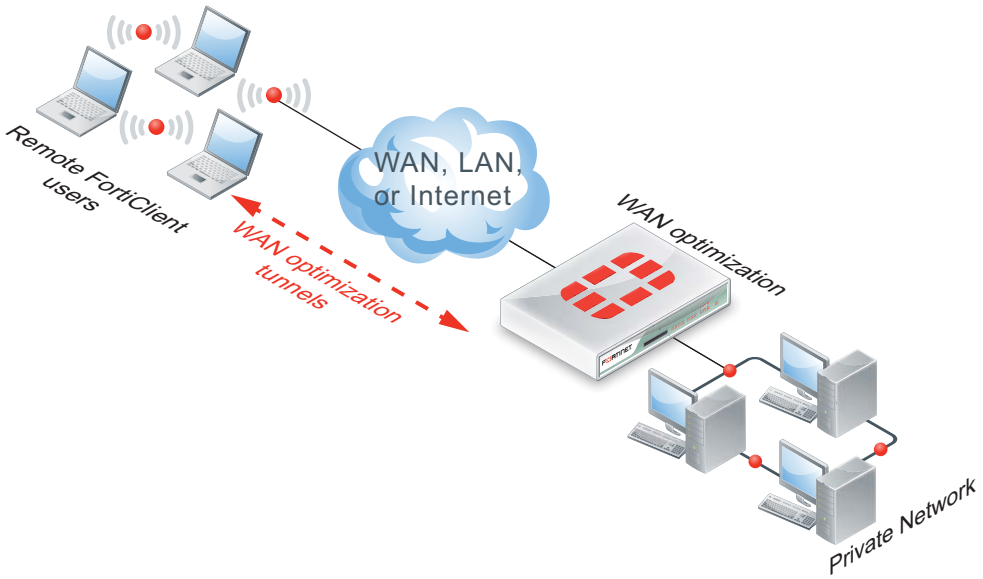


The topology in Figure 384 is the same as that of Figure 380 on page 2581 with the addition of web caching to the FortiGate unit in front of the private network that includes the web servers. You can also add web caching to the FortiGate unit that is protecting the private network. In a similar way, you can add web caching to all of the topologies shown in "WAN optimization topologies" on page 2580.

WAN optimization and web caching with FortiClient peers

FortiClient WAN optimization works with FortiGate WAN optimization to accelerate remote user access to the private networks behind FortiGate units. The FortiClient application requires a simple WAN optimization configuration to automatically detect if WAN optimization is enabled on the FortiGate unit. Once WAN optimization is enabled, the FortiClient application transparently makes use of the WAN optimization and web caching features available.

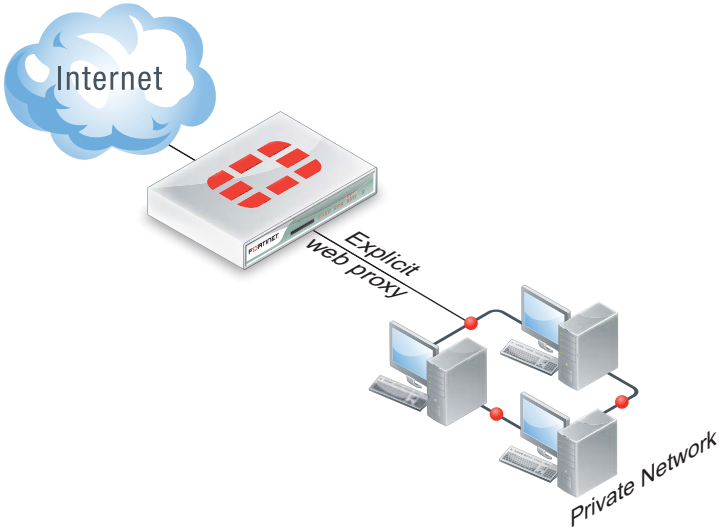
Figure 385: FortiClient WAN optimization topology



Explicit Web proxy topologies

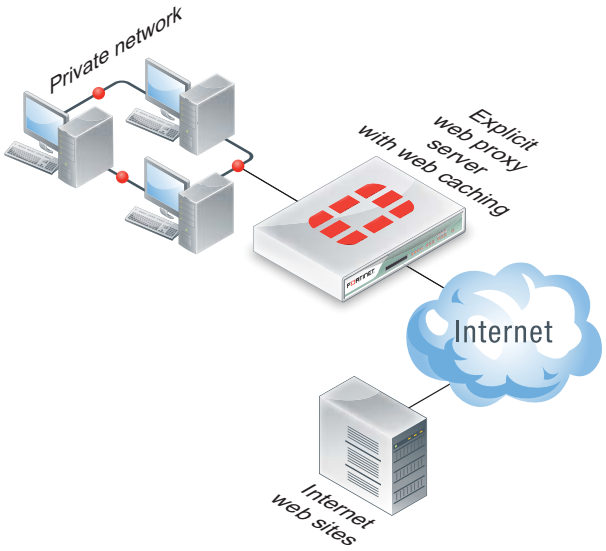
You can configure a FortiGate unit to be an explicit web proxy server for Internet web browsing of IPv4 and IPv6 web traffic. To use the explicit web proxy, users must add the IP address of the FortiGate interface configured for the explicit web proxy to their web browser proxy configuration.

Figure 386: Explicit web proxy topology



If the FortiGate unit supports web caching, you can also add web caching to the security policy that accepts explicit web proxy sessions The FortiGate unit then caches Internet web pages on a hard disk to improve web browsing performance.

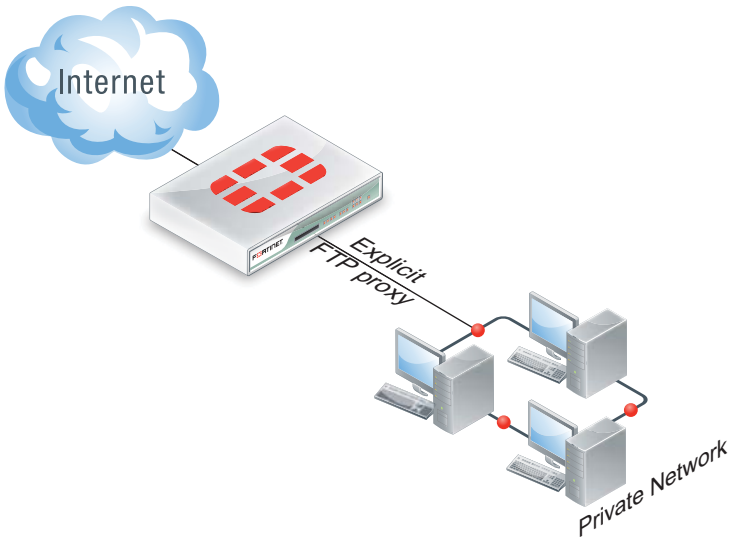
Figure 387: Explicit web proxy with web caching topology



Explicit FTP proxy topologies

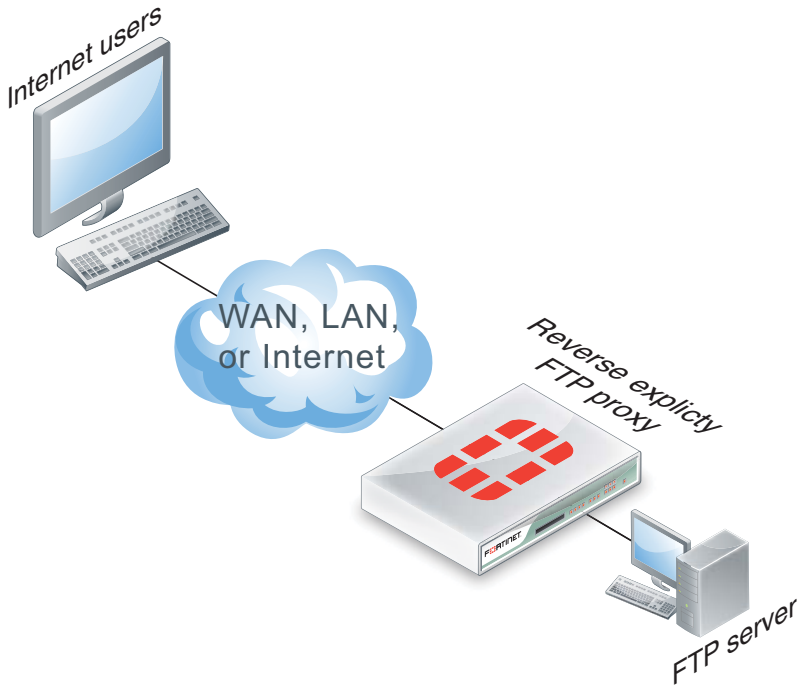
You can configure a FortiGate unit to be an explicit FTP proxy server for FTP users. To use the explicit web proxy, FTP users must connect to and authenticate with the explicit FTP proxy before connecting to an FTP server.

Figure 388: Explicit FTP proxy topology



You can also configure reverse explicit FTP proxy (Figure 389). In this configuration, users on the Internet connect to the explicit web proxy before connecting to an FTP server installed behind a FortiGate unit.

Figure 389: Reverse explicit FTP proxy topology

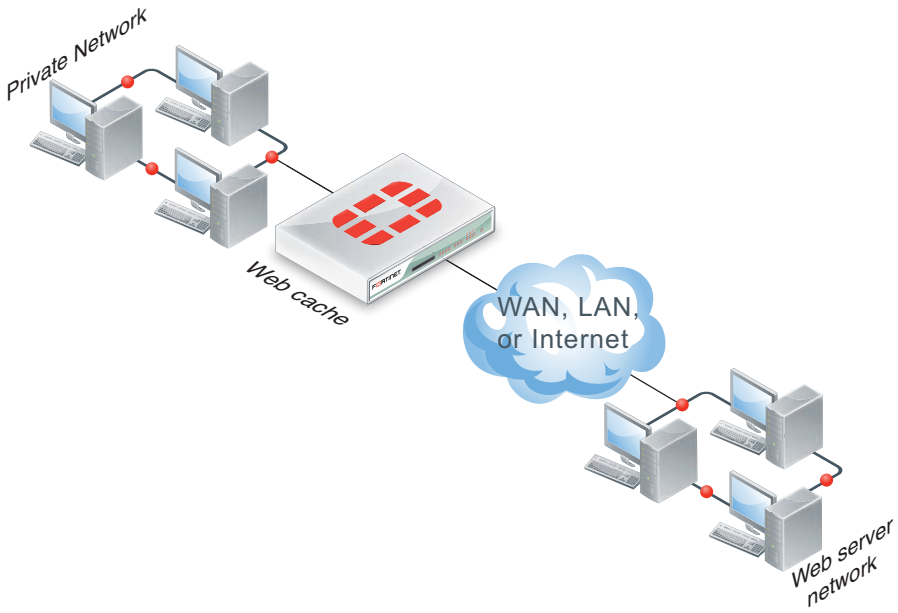


Web caching topologies

FortiGate web caching can be added to any security policy and any HTTP or HTTPS traffic accepted by that security policy can be cached on the FortiGate unit hard disk. This includes WAN optimization and explicit web proxy traffic. The network topologies for these scenarios are very similar. They involved a FortiGate unit installed between users and web servers with web caching enabled.

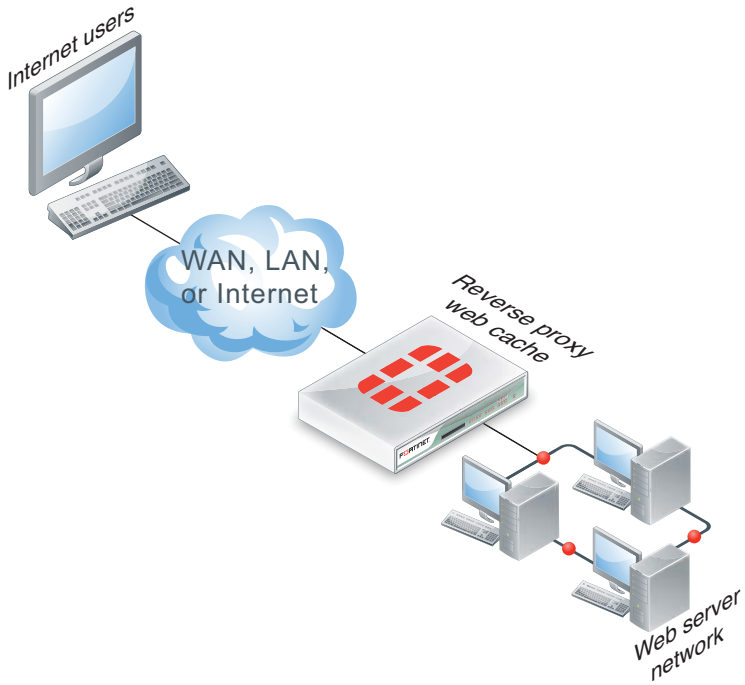
A typical web-caching topology includes one FortiGate unit that acts as a web cache server (Figure 390). Web caching is enabled in a security policy and the FortiGate unit intercepts web page requests accepted by the security policy, requests web pages from the web servers, caches the web page contents, and returns the web page contents to the users. When the FortiGate unit intercepts subsequent requests for cached web pages, the FortiGate unit contacts the destination web server just to check for changes.

Figure 390: Web caching topology



You can also configure reverse proxy web-caching (Figure 391). In this configuration, users on the Internet browse to a web server installed behind a FortiGate unit. The FortiGate unit intercepts the web traffic (HTTP and HTTPS) and caches pages from the web server. Reverse proxy web caching on the FortiGate unit reduces the number of requests that the web server must handle, leaving it free to process new requests that it has not serviced before.

Figure 391: Reverse proxy web caching topology

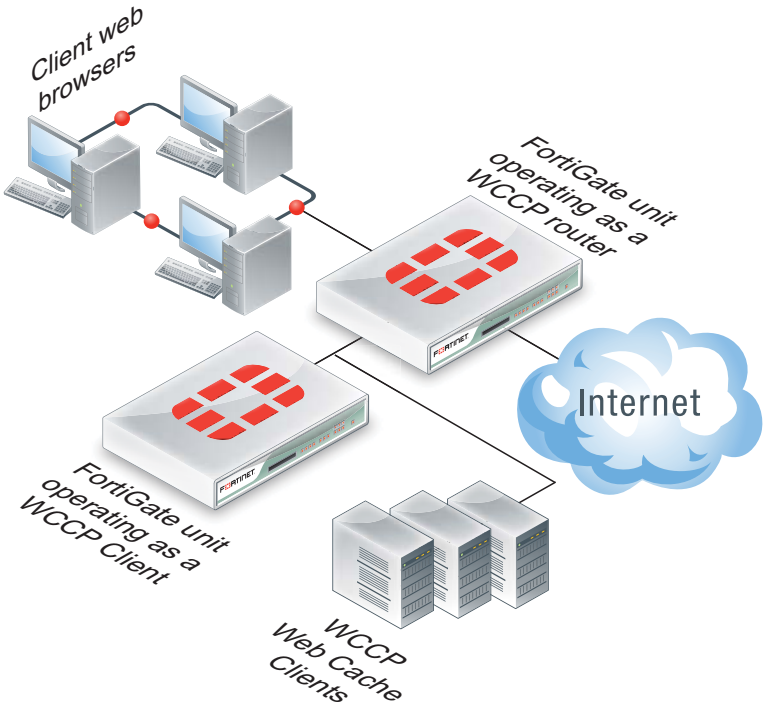


WCCP topologies

You can operate a FortiGate unit as a Web Cache Communication Protocol (WCCP) router or cache engine. As a router, the FortiGate unit intercepts web browsing requests from client web

browsers and forwards them to a WCCP cache engine. The cache engine returns the required cached content to the client web browser. If the cache server does not have the required content it accesses the content, caches it and returns the content to the client web browser.

Figure 392:WCCP topology



FortiGate units can also operate as WCCP cache servers, communicating with WCCP routers, caching web content and providing it to client web browsers as required.

WCCP is transparent to client web browsers. The web browsers do not have to be configured to use a web proxy.

Configuring WAN optimization

This chapter describes FortiGate WAN optimization client server architecture and other concepts you need to understand to be able to configure FortiGate WAN optimization.

This chapter describes:

Client/server architecture

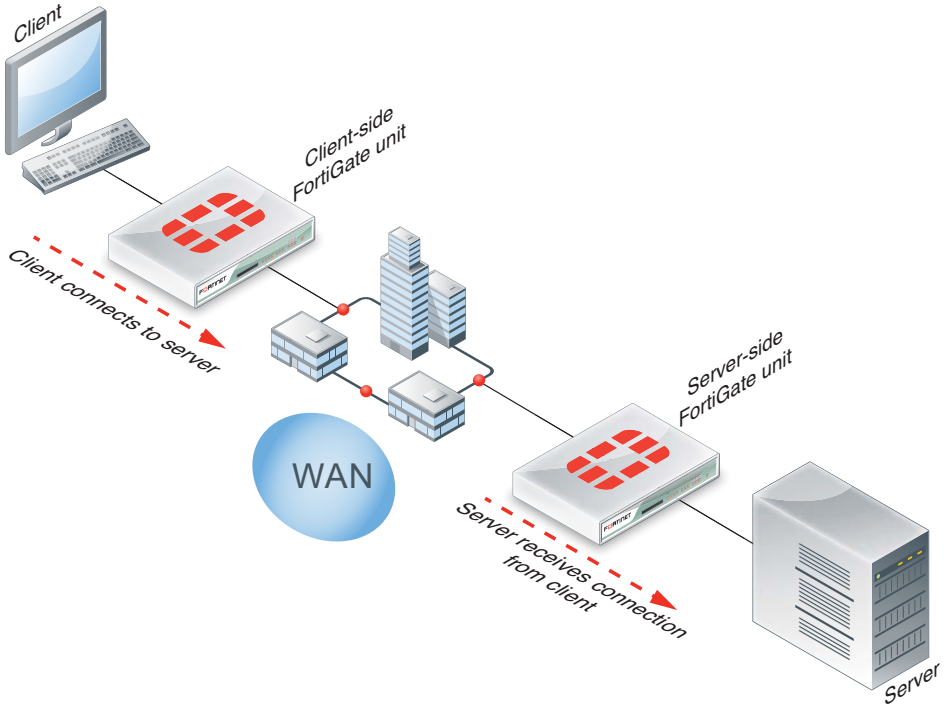
Traffic across a WAN typically consists of clients on a client network communicating across a WAN with a remote server network. The clients do this by starting communication sessions from the client network to the server network. To optimize these sessions, you can add ***WAN optimization security policies*** to the ***client-side FortiGate unit*** to accept sessions from the client network that are destined for the server network. The client-side FortiGate unit is located between the client network and the WAN (see Figure 393). WAN optimization security policies include ***WAN optimization profiles*** that control how the traffic is optimized.

The client-side FortiGate unit must also include the IP address of the ***server-side FortiGate unit*** in its WAN optimization ***peer*** configuration. The server-side FortiGate unit is located between the server network and the WAN, The peer configuration allows the client-side FortiGate unit to find the server-side FortiGate unit and attempt to establish a WAN optimization ***tunnel*** with it.

For the server-side FortiGate unit you must add a security policy with *wanopt* as the *Incoming Interface*. This security policy allows the FortiGate unit to accept WAN optimization sessions from the client-side FortiGate unit. For the server-side FortiGate unit to accept a WAN optimization connection it must have the client-side FortiGate unit in its WAN optimization peer configuration.

WAN optimization profiles are only added to the client-side WAN optimization security policy. The server-side FortiGate unit employs the WAN optimization settings set in the WAN optimization profile on the client-side FortiGate unit.

Figure 393: Client/server architecture



When both peers are identified the FortiGate units attempt to establish a WAN optimization ***tunnel*** between them. WAN optimization tunnels use port 7810. All optimized data flowing across the WAN between the client-side and server-side FortiGate units use this tunnel. WAN optimization tunnels can be encrypted use SSL encryption to keep the data in the tunnel secure.

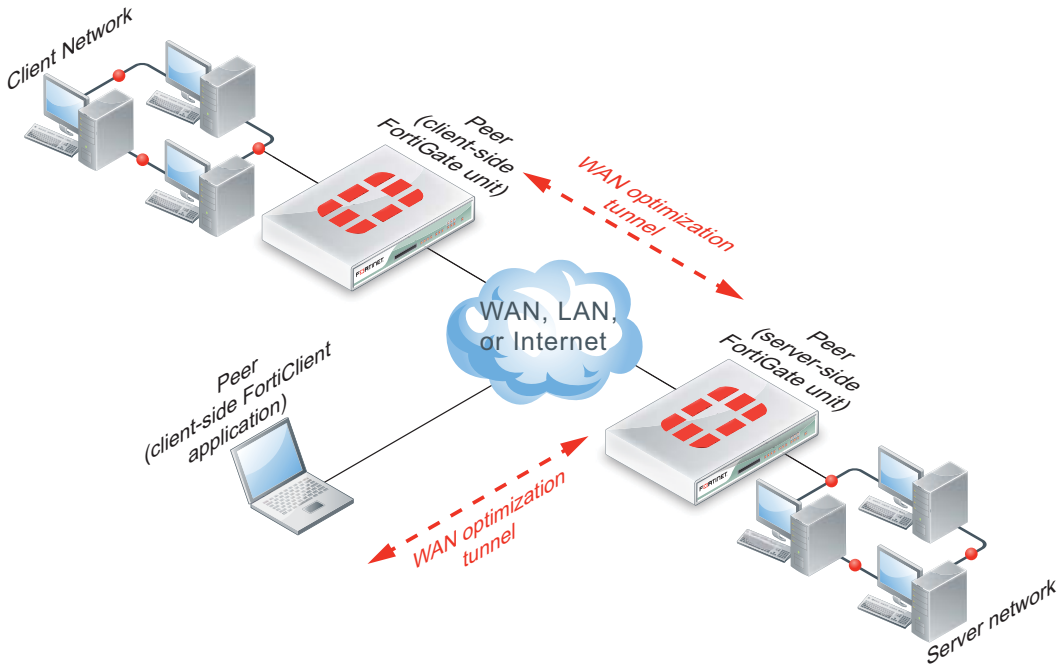
In addition to basic identification by peer host ID and IP address you can configure WAN optimization ***authentication*** using certificates and pre-shared keys to improve security. You can also configure FortiGate units involved in WAN optimization to accept connections from any identified peer or restrict connections to specific peers.

The FortiClient application can act in the same manner as a client-side FortiGate unit to optimize traffic between a computer running FortiClient and a FortiGate unit.

WAN optimization peers

The client-side and server-side FortiGate units are called WAN optimization peers (see Figure 394) because all of the FortiGate units in a WAN optimization network have the same peer relationship with each other. The client and server roles just relate to how a session is started. Any FortiGate unit configured for WAN optimization can be a client-side and a server-side FortiGate unit at the same time, depending on the direction of the traffic. Client-side FortiGate units initiate WAN optimization sessions and server-side FortiGate units respond to the session requests. Any FortiGate unit can simultaneously be a client-side FortiGate unit for some sessions and a server-side FortiGate unit for others.

Figure 394:WAN optimization peer and tunnel architecture



To identify all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with, you add host IDs and IP addresses of all of the peers to the FortiGate unit configuration. The peer IP address is actually the IP address of the peer unit interface that communicates with the FortiGate unit.

Manual (peer-to-peer) and active-passive WAN optimization

You can create ***manual*** (peer-to-peer) and ***active-passive*** WAN optimization configurations.

Manual (peer to peer) configurations

Manual configurations allow for WAN optimization between one client-side FortiGate unit and one server-side FortiGate unit. To create a manual configuration you add a ***manual mode*** WAN optimization security policy to the client-side FortiGate unit. The manual mode policy includes the peer ID of a server-side FortiGate unit.

In a manual mode configuration, the client-side peer can only connect to the named server-side peer. When the client-side peer initiates a tunnel with the server-side peer, the packets that initiate the tunnel include extra information so that the server-side peer can determine that it is a peer-to-peer tunnel request. This extra information is required because the server-side peer does not require a WAN optimization policy; you just need to add the client peer host ID and IP address to the server-side FortiGate unit peer list and a security policy with the wanopt interface as the incoming interface. WAN optimization tunnel requests are accepted by the policy and if the client-side peer is in the server side peer's address list the traffic is forwarded to its destination.

Manual mode client-side policy

Add a manual mode policy to the client-side FortiGate unit from the CLI. The policy enables WAN optimization, sets `wanopt-detection` to `off`, and uses the `wanopt-peer` option to specify the server-side peer. The following example uses the default WAN optimization profile and also enables virus scanning using the default virus scanning profile.

```
config firewall policy
  edit 2
    set srcintf "internal"
    set dstintf "wan1"
    set srcaddr "client-subnet"
    set dstaddr "server-subnet"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable
    set av-profile default
    set profile-protocol-options default
    set wanopt enable
    set wanopt-detection off
    set wanopt-profile "default"
    set wanopt-peer "server"
  next
end
```

Server-side tunnel policy

The server-side policy allows WAN optimization tunnel connections by including the *wanopt* tunnel interface as the *Incoming Interface*. From the CLI the policy could look like the following:

```
configure firewall policy
  edit 3
    set srcintf "wanopt"
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "server-subnet"
    set action accept
    set schedule "always"
    set service "ANY"
  next
end
```

Active-passive configurations

Active-passive WAN optimization requires an ***active*** WAN optimization policy on the client-side FortiGate unit and a ***passive*** WAN optimization policy on the server-side FortiGate unit. The server-side FortiGate unit also requires a security policy with the *wanopt* tunnel interface as the *Incoming Interface*.

You can use the passive policy to control WAN optimization address translation by specifying ***transparent mode*** or non-transparent mode. See "WAN optimization transparent mode" on page 2599. You can also use the passive policy to apply security profiles, web caching, and other FortiGate features at the server-side FortiGate unit. For example, if a server-side FortiGate unit is protecting a web server, the passive policy could enable web caching.

A single passive policy can accept tunnel requests from multiple FortiGate units as long as the server-side FortiGate unit includes their peer IDs and all of the client-side FortiGate units include the server-side peer ID.

Active client-side policy

Add an active policy to the client-side FortiGate unit by selecting *Enable WAN Optimization* and selecting *active*. Then select a WAN optimization *Profile.* From the CLI the policy could look like the following:

```
config firewall policy
  edit 2
    set srcintf "internal"
    set dstintf "wan1"
    set srcaddr "client-subnet"
    set dstaddr "server-subnet"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable
    set av-profile default
    set profile-protocol-options default
    set wanopt enable
    set wanopt-detection active
    set wanopt-profile "default"
  next
end
```

Server-side tunnel policy

The server-side requires a policy that allows WAN optimization tunnel connections by including the *wanopt* tunnel interface as the *Incoming Interface*. From the CLI the policy could look like the following:

```
configure firewall policy
  edit 3
    set srcintf "wanopt"
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "server-subnet"
    set action accept
    set schedule "always"
    set service "ANY"
  next
end
```

Server-side passive policy

Add a passive policy to the client-side FortiGate unit by selecting *Enable WAN Optimization* and selecting *passive*. Then set the *Passive Option* to transparent. From the CLI the policy could look like the following:

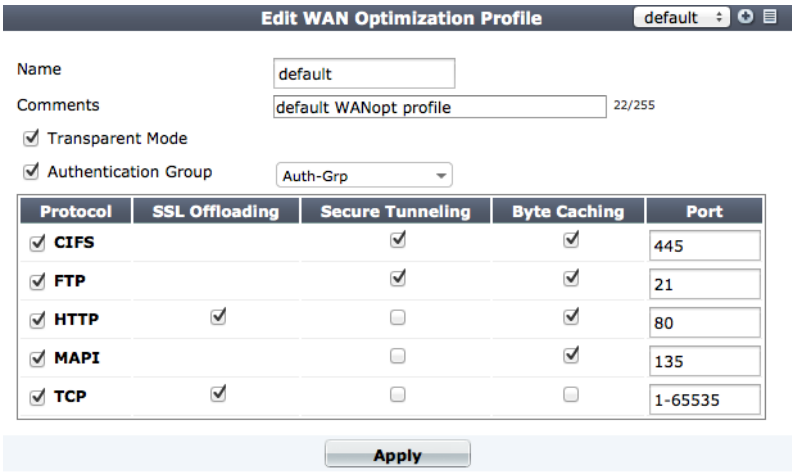
```
config firewall policy
   edit 2
    set srcintf "wan1"
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable
    set av-profile default
    set profile-protocol-options default
    set wanopt enable
    set wanopt-detection passive
    set wanopt-passive-opt transparent
  next
```

WAN optimization profiles

Use WAN optimization profiles to apply WAN optimization techniques to traffic to be optimized. In a WAN optimization profile you can select the protocols to be optimized and for each protocol you can enable SSL offloading (if supported), secure tunneling, byte caching and set the port or port range the protocol uses. You can also enable transparent mode and optionally select an authentication group. You can edit the default WAN optimization profile or create new ones.

To configure a WAN optimization profile go to *WAN Opt & Cache* > *WAN Opt. Profile* > *Profile* and edit a profile or create a new one.

Figure 395: Configuring a WAN optimization profile



From the CLI you can use the following command to configure a WAN optimization profile to optimize HTTP traffic.

```
config wanopt profile
  edit new-profile
    config http
      set status enable
  end
```

Transparent Mode	Servers receiving packets after WAN optimization "see" different source addresses depending on whether or not you select *Transparent Mode*. For more information, see "WAN optimization transparent mode" on page 2599.
Authentication Group	Select this option and select an authentication group so that the client and server-side FortiGate units must authenticate with each other before starting the WAN optimization tunnel. You must also select an authentication group if you select *Secure Tunneling* for any protocol. You must add identical authentication groups to both of the FortiGate units that will participate in the WAN optimization tunnel. For more information, see "Configuring authentication groups" on page 2612.
Protocol	Select CIFS, FTP, HTTP or MAPI to apply protocol optimization for the selected protocols. See "Protocol optimization" on page 2598. Select TCP if the WAN optimization tunnel accepts sessions that use more than one protocol or that do not use the CIFS, FTP, HTTP, or MAPI protocol.
SSL Offloading	Select to apply SSL offloading for HTTPS or other SSL traffic. You can use SSL offloading to offload SSL encryption and decryption from one or more HTTP servers to the FortiGate unit. If you enable this option, you must configure the security policy to accept SSL-encrypted traffic. If you enable SSL offloading, you must also use the CLI command `config wanopt ssl-server` to add an SSL server for each HTTP server that you want to offload SSL encryption/decryption for. For more information, see "Turning on web caching and SSL offloading for HTTPS traffic" on page 2644.

Secure Tunnelling	The WAN optimization tunnel is encrypted using SSL encryption. You must also add an authentication group to the profile. For more information, see "Secure tunneling" on page 2615.
Byte Caching	Select to apply WAN optimization byte caching to the sessions accepted by this rule. For more information, see "Byte caching" on page 2598.
Port	Enter a single port number or port number range. Only packets whose destination port number matches this port number or port number range will be optimized.

Processing non-HTTP sessions accepted by a WAN optimization profile with HTTP optimization

From the CLI, you can use the following command to configure how to process non-HTTP sessions when a rule configured to accept and optimize HTTP traffic accepts a non-HTTP session. This can occur if an application sends non-HTTP sessions using an HTTP destination port.

```
config wanopt profile
  edit default
    config http
      set status enable
      set tunnel-non-http {disable | enable}
    end
```

To drop non-HTTP sessions accepted by the rule set `tunnel-non-http` to `disable`, or set it to `enable` to pass non-HTTP sessions through the tunnel without applying protocol optimization, byte-caching, or web caching. In this case, the FortiGate unit applies TCP protocol optimization to non-HTTP sessions.

Processing unknown HTTP sessions

Unknown HTTP sessions are HTTP sessions that do not comply with HTTP 0.9, 1.0, or 1.1. From the CLI, use the following command to specify how a rule handles such HTTP sessions.

```
config wanopt profile
  edit default
    config http
      set status enable
      set unknown-http-version {best-effort | reject | tunnel}
    end
```

To assume that all HTTP sessions accepted by the rule comply with HTTP 0.9, 1.0, or 1.1, select `best-effort`. If a session uses a different HTTP version, WAN optimization may not parse it correctly. As a result, the FortiGate unit may stop forwarding the session and the connection may be lost. To reject HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, select `reject`.

To pass HTTP sessions that do not use HTTP 0.9, 1.0, or 1.1, but without applying HTTP protocol optimization, byte-caching, or web caching, you can also select `tunnel`. TCP protocol optimization is applied to these HTTP sessions.

Protocol optimization

Protocol optimization techniques optimize bandwidth use across the WAN. These techniques can improve the efficiency of communication across the WAN optimization tunnel by reducing the amount of traffic required by communication protocols. You can apply protocol optimization to Common Internet File System (CIFS), FTP, HTTP, MAPI, and general TCP sessions. You can apply general TCP optimization to MAPI sessions.

For example, CIFS provides file access, record locking, read/write privileges, change notification, server name resolution, request batching, and server authentication. CIFS is a fairly "chatty" protocol, requiring many background transactions to successfully transfer a single file. This is usually not a problem across a LAN. However, across a WAN, latency and bandwidth reduction can slow down CIFS performance.

When you select the CIFS protocol in a WAN optimization profile, the FortiGate units at both ends of the WAN optimization tunnel use a number of techniques to reduce the number of background transactions that occur over the WAN for CIFS traffic.

If a policy accepts a range of different types of traffic, you can set *Protocol* to *TCP* to apply general optimization techniques to TCP traffic. However, applying this TCP optimization is not as effective as applying more protocol-specific optimization to specific types of traffic. TCP protocol optimization uses techniques such as TCP SACK support, TCP window scaling and window size adjustment, and TCP connection pooling to remove TCP bottlenecks.

Protocol optimization and MAPI

By default the MAPI service uses port number 135 for RPC port mapping and may use random ports for MAPI messages. The random ports are negotiated through sessions using port 135. The FortiOS DCE-RPC session helper learns these ports and opens pinholes for the messages. WAN optimization is also aware of these ports and attempts to apply protocol optimization to MAPI messages that use them. However, to configure protocol optimization for MAPI you should set the WAN optimization profile to a single port number (usually port 135). Specifying a range of ports may reduce performance.

Byte caching

Byte caching breaks large units of application data (for example, a file being downloaded from a web page) into small chunks of data, labelling each chunk of data with a hash of the chunk and storing those chunks and their hashes in a database. The database is stored on a WAN optimization storage device. Then, instead of sending the actual data over the WAN tunnel, the FortiGate unit sends the hashes. The FortiGate unit at the other end of the tunnel receives the hashes and compares them with the hashes in its local byte caching database. If any hashes match, that data does not have to be transmitted over the WAN optimization tunnel. The data for any hashes that does not match is transferred over the tunnel and added to that byte caching database. Then the unit of application data (the file being downloaded) is reassembled and sent to its destination.

The stored byte caches are not application specific. Byte caches from a file in an email can be used to optimize downloading that same file or a similar file from a web page.

The result is less data transmitted over the WAN. Initially, byte caching may reduce performance until a large enough byte caching database is built up.

To enable byte caching, you select *Byte Caching* in a WAN optimization profile.

Byte caching cannot determine whether or not a file is compressed (for example a zip file), and caches compressed and non-compressed versions of the same file separately.

Dynamic data chunking for byte caching

Dynamic data chunking can improve byte caching by improving detection of data chunks that are already cached in changed files or in data embedded in traffic using an unknown protocol. Dynamic data chunking is available for HTTP, CIFS and FTP.

Use the following command to enable dynamic data chunking for HTTP in the default WAN optimization profile.

```
config wanopt profile
  edit default
       config http
          set prefer-chunking dynamic
    end
```

By default dynamic data chunking is disabled and `prefer-chunking` is set to `fix`.

WAN optimization transparent mode

WAN optimization is transparent to users. This means that with WAN optimization in place, clients connect to servers in the same way as they would without WAN optimization. However, servers receiving packets after WAN optimization "see" different source addresses depending on whether or not transparent mode is selected for WAN optimization. If transparent mode is selected, WAN optimization keeps the original source address of the packets, so servers appear to receive traffic directly from clients. Routing on the server network should be configured to route traffic with client source IP addresses from the server-side FortiGate unit to the server and back to the server-side FortiGate unit.

Some protocols, for example CIFS, may not function as expected if transparent mode is ***not*** selected. In most cases, for CIFS WAN optimization you should select transparent mode and make sure the server network can route traffic as described to support transparent mode.

If transparent mode is not selected, the source address of the packets received by servers is changed to the address of the server-side FortiGate unit interface that sends the packets to the servers. So servers appear to receive packets from the server-side FortiGate unit. Routing on the server network is simpler in this case because client addresses are not involved. All traffic appears to come from the server-side FortiGate unit and not from individual clients.

Do not confuse WAN optimization transparent mode with FortiGate transparent mode. WAN optimization transparent mode is similar to source NAT. FortiGate Transparent mode is a system setting that controls how the FortiGate unit (or a VDOM) processes traffic.

FortiClient WAN optimization

PCs running the FortiClient application are client-side peers that initiate WAN optimization tunnels with server-side peer FortiGate units. However, you can have an ever-changing number of FortiClient peers with IP addresses that also change regularly. To avoid maintaining a list of such peers, you can instead configure WAN optimization to accept any peer and use authentication to identify FortiClient peers.

Together, the WAN optimization peers apply the WAN optimization features to optimize the traffic flow over the WAN between the clients and servers. WAN optimization reduces bandwidth requirements, increases throughput, reduces latency, offloads SSL encryption/decryption and improves privacy for traffic on the WAN.

Operating modes and VDOMs

To use WAN optimization, the FortiGate units can operate in either NAT/Route or Transparent mode. The client-side and server-side FortiGate units do not have to be operating in the same mode.

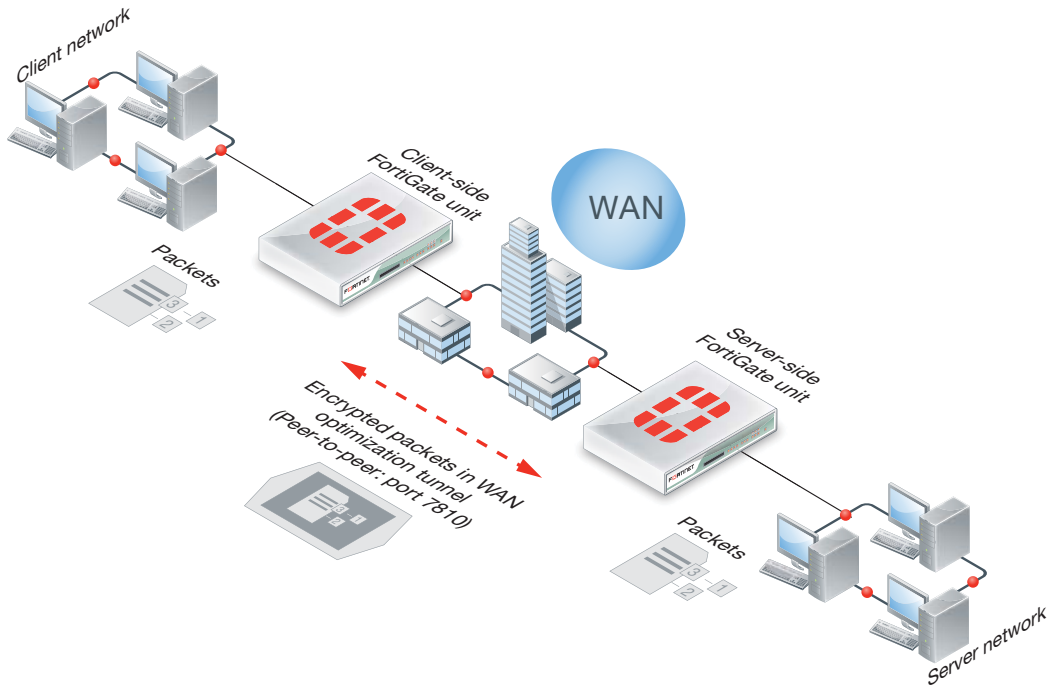
As well, the FortiGate units can be configured for multiple virtual domain (VDOM) operation. You configure WAN optimization for each VDOM and configure one or both of the units to operate with multiple VDOMs enabled.

If a FortiGate unit or VDOM is operating in Transparent mode with WAN optimization enabled, WAN optimization uses the management IP address as the peer IP address of the FortiGate unit instead of the address of an interface.

WAN optimization tunnels

All optimized traffic passes between the FortiGate units or between a FortiClient peer and a FortiGate unit over a WAN optimization tunnel. Traffic in the tunnel can be sent in plain text or encrypted using AES-128bit-CBC SSL.

Figure 396:WAN optimization tunnels



Both plain text and the encrypted tunnels use TCP destination port 7810.

Before a tunnel can be started, the peers must be configured to authenticate with each other. Then, the client-side peer attempts to start a WAN optimization tunnel with the server-side peer. Once the peers authenticate with each other, they bring up the tunnel and WAN optimization communication over the tunnel starts. After a tunnel has been established, multiple WAN optimization sessions can start and stop between peers without restarting the tunnel.

Tunnel sharing

You can use the `tunnel-sharing` WAN optimization profile CLI keyword to configure tunnel sharing for WAN optimization rules. Tunnel sharing means multiple WAN optimization sessions share the same tunnel. Tunnel sharing can improve performance by reducing the number of WAN optimization tunnels between FortiGate units. Having fewer tunnels means less data to manage. Also, tunnel setup requires more than one exchange of information between the ends of the tunnel. Once the tunnel is set up, each new session that shares the tunnel avoids tunnel setup delays.

Tunnel sharing also uses bandwidth more efficiently by reducing the chances that small packets will be sent down the tunnel. Processing small packets reduces network throughput, so reducing the number of small packets improves performance. A shared tunnel can combine all the data from the sessions being processed by the tunnel and send the data together. For example, suppose a FortiGate unit is processing five WAN optimization sessions and each session has 100 bytes to send. If these sessions use a shared tunnel, WAN optimization combines the packets from all five sessions into one 500-byte packet. If each session uses its own private tunnel, five 100-byte packets will be sent instead. Each packet also requires a TCP ACK reply. The combined packet in the shared tunnel requires one TCP ACK packet. The separate packets in the private tunnels require five.

Use the following command to configure tunnel sharing for HTTP traffic in a WAN optimization profile.

```
config wanopt profile
  edit default
    config http
      set tunnel-sharing {express-shared | private | shared}
    end
```

Tunnel sharing is not always recommended and may not always be the best practice. Aggressive and non-aggressive protocols should not share the same tunnel. An aggressive protocol can be defined as a protocol that is able to get more bandwidth than a non-aggressive protocol. (The aggressive protocols can “starve” the non-aggressive protocols.) HTTP and FTP are considered aggressive protocols. If aggressive and non-aggressive protocols share the same tunnel, the aggressive protocols may take all of the available bandwidth. As a result, the performance of less aggressive protocols could be reduced. To avoid this problem, rules for HTTP and FTP traffic should have their own tunnel. To do this, set `tunnel-sharing` to `private` for WAN optimization rules that accept HTTP or FTP traffic.

It is also useful to set `tunnel-sharing` to `express-shared` for applications, such as Telnet, that are very interactive but not aggressive. Express sharing optimizes tunnel sharing for Telnet and other interactive applications where latency or delays would seriously affect the user’s experience with the protocol.

Set `tunnel-sharing` to `shared` for applications that are not aggressive and are not sensitive to latency or delays. WAN optimization rules set to `shared` and `express-shared` can share the same tunnel.

WAN optimization and user and device identity policies, load balancing and traffic shaping

Please note the following about WAN optimization and firewall policies:

- WAN optimization is not compatible with firewall load balancing.
- WAN optimization is compatible with source and destination NAT options in firwall policies (including firewall virtual IPs). If a virtual IP is added to a policy the traffic that exits the WAN

optimization tunnel has its destination address changed to the virtual IPs mapped to IP address and port.

- WAN optimization is compatible with user identity-based and device identity security policies. If a session is allowed after authentication or device identification the session can be optimized.

Traffic shaping

Traffic shaping works for WAN optimization traffic that is not in a WAN optimization tunnel. So traffic accepted by a WAN optimization security policy on a client-side FortiGate unit can be shaped on ingress. However, when the traffic enters the WAN optimization tunnel, traffic shaping is not applied.

In manual mode:

- Traffic shaping works as expected on the client-side FortiGate unit.
- Traffic shaping cannot be applied to traffic on the server-side FortiGate unit.

In active-passive mode:

- Traffic shaping works as expected on the client-side FortiGate unit.
- If transparent mode is enabled in the WAN optimization profile, traffic shaping also works as expected on the server-side FortiGate unit.
- If transparent mode is not enabled, traffic shaping works partially on the server-side FortiGate unit.

WAN optimization and HA

You can configure WAN optimization on a FortiGate HA cluster. The recommended best practice HA configuration for WAN optimization is active-passive mode. When the cluster is operating, all WAN optimization sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance WAN optimization sessions.

You can also form a WAN optimization tunnel between a cluster and a standalone FortiGate unit or between two clusters.

In a cluster, only the primary unit stores the byte cache database. This database is not synchronized to the subordinate units. So, after a failover, the new primary unit must rebuild its byte cache. Rebuilding the byte cache can happen relatively quickly because the new primary unit gets byte cache data from the other FortiGate unit that it is participating with in WAN optimization tunnels.

WAN optimization, web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency FortiOS WAN optimization uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, WAN optimization requires a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When WAN optimization is enabled you will see a reduction in available memory. The reduction increases when more WAN optimization sessions are being processed. If you are thinking of enabling WAN optimization on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods.

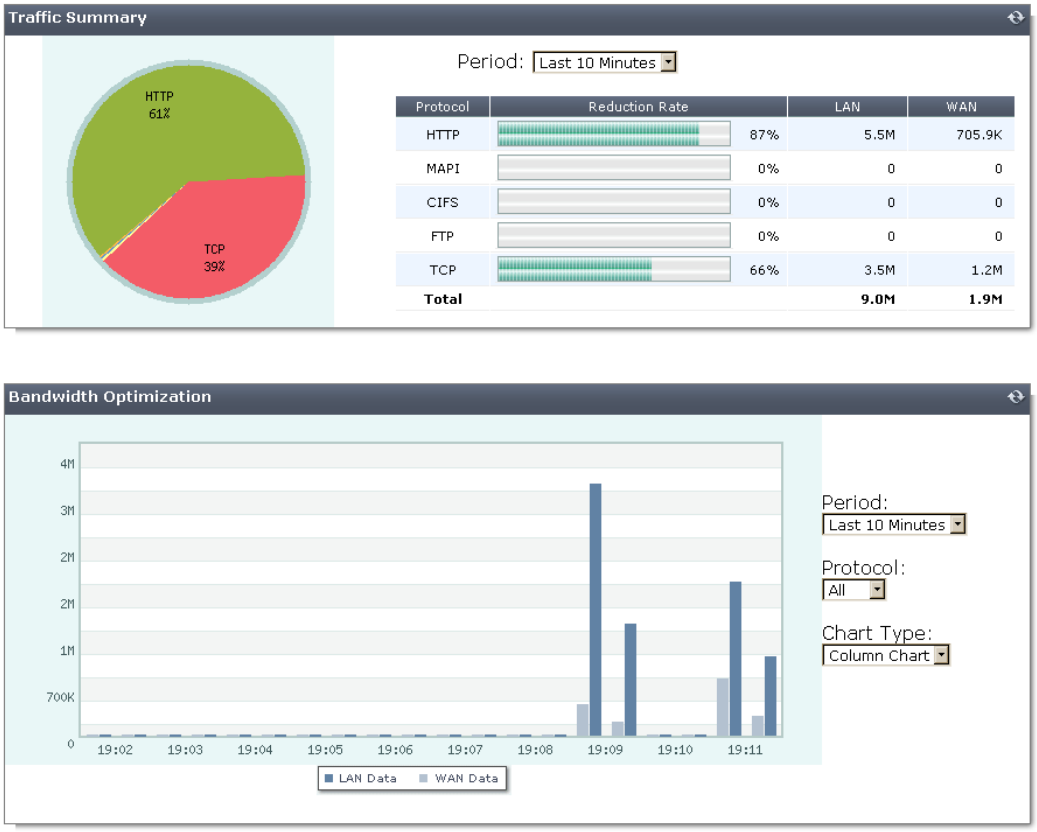
In addition to using the system dashboard to see the current memory usage you can use the `get test wad 1` command to see how much memory is currently being used by WAN optimization. See “get test {wa_cs | wa_dbd | wad | wad_diskd | wccpd} <test_level>” on page 2719 for more information.

Monitoring WAN optimization performance

Using WAN optimization monitoring, you can confirm that a FortiGate unit is optimizing traffic and view estimates of the amount of bandwidth saved. The WAN optimization monitor presents collected log information in a graphical format to show network traffic summary and bandwidth optimization information.

To view the WAN optimization monitor, go to *WAN Opt. & Cache* > *Monitor* > *WAN Opt Monitor*.

Figure 397:WAN optimization monitor



Traffic Summary

The traffic summary shows how WAN optimization is reducing the amount of traffic on the WAN for each WAN optimization protocol by showing the traffic reduction rate as a percentage of the total traffic. The traffic summary also shows the amount of WAN and LAN traffic. If WAN optimization is being effective the amount of WAN traffic should be lower than the amount of LAN traffic.

You can use the refresh icon to update the traffic summary display at any time. You can also set the amount of time for which the traffic summary shows data. The time period can vary from the last 10 minutes to the last month.

Bandwidth Optimization

This section shows network bandwidth optimization per time period. A line or column chart compares an application's pre-optimized size (LAN data) with its optimized size (WAN data). You can select the chart type, the monitoring time period, and the protocol for which to display data. If WAN optimization is being effective the WAN bandwidth should be lower than the LAN bandwidth.

WAN optimization configuration summary

This section describes:

- client-side configuration summary
- server-side configuration summary

client-side configuration summary

WAN optimization profile

Enter the following command to view WAN optimization profile CLI options:

```
tree wanopt profile
-- [profile] --*name (36)
             |- transparent
             |- comments
             |- auth-group (36)
             |- <http> -- status
                        |- secure-tunnel
                        |- byte-caching
                        |- prefer-chunking
                        |- tunnel-sharing
                        |- log-traffic
                        |- port
                        |- ssl
                        |- ssl-port
                        |- unknown-http-version
                        +- tunnel-non-http
             |- <cifs> -- status
                        |- secure-tunnel
                        |- byte-caching
                        |- prefer-chunking
                        |- tunnel-sharing
                        |- log-traffic

                       |- tunnel-sharing
                       |- log-traffic
                       |- port
                       |- ssl
```

```
                              +- ssl-port
```

Local host ID and peer settings

```
config wanopt settings
  set host-id "client"
end
config wanopt peer
  edit "server"
  set ip 10.10.2.82
end
```

Security policies

Two client-side WAN optimization security policy configurations are possible. One for active-passive WAN optimization and one for manual WAN optimization.

Active/passive mode on the client-side

```
config firewall policy
  edit 2
    set srcintf "internal"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable <<< enable security profiles
    set av-profile default <<< select an antivirus profile
    set profile-protocol-options default
    set wanopt enable <<< enable WAN optimization
    set wanopt-detection active <<< set the mode to active/passive
    set wanopt-profile "default" <<< select the wanopt profile
  next
end
```

Manual mode on the client-side

```
config firewall policy
  edit 2
    set srcintf "internal"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable <<< enable security profiles
    set av-profile default <<< select an antivirus profile
    set profile-protocol-options default
    set wanopt enable <<< enable WAN optimization
    set wanopt-detection off <<< sets the mode to manual
    set wanopt-profile "default" <<< select the wanopt profile
    set wanopt-peer "server" <<< set the only peer to do wanopt with
                                 (required for manual mode)
  next
end
```

server-side configuration summary

Local host ID and peer settings

```
config wanopt settings
  set host-id "server"
end
config wanopt peer
  edit "client"
    set ip 10.10.2.81
end
```

Security policies

Two server-side WAN optimization security policy configurations are possible. One for active-passive WAN optimization and one for manual WAN optimization.

Active/passive mode on server-side

```
config firewall policy
   edit 2 <<< the passive mode policy
     set srcintf "wan1"
     set dstintf "internal"
     set srcaddr "all"
     set dstaddr "all"
     set action accept
     set schedule "always"
     set service "ANY"
     set utm-status enable <<< enable security profiles
     set av-profile default <<< select an antivirus profile
     set profile-protocol-options default
     set wanopt enable
     set wanopt-detection passive
     set wanopt-passive-opt transparent
   next
   edit 3 <<< policy that accepts wanopt tunnel connections from the
             server
     set srcintf "wanopt" <<< wanopt tunnel interface
     set dstintf "internal"
     set srcaddr "all"
     set dstaddr "all"
     set action accept
     set schedule "always"
     set service "ANY"
   next
end
```

Manual mode on server-side

```
configure firewall policy
   edit 3 <<< wanopt tunnel policy
     set srcintf "wanopt" <<< wanopt tunnel interface
     set dstintf "internal"
     set srcaddr "all"
     set dstaddr "all"
     set action accept
     set schedule "always"
     set service "ANY"
     set utm-status enable <<< enable security profiles
     set av-profile default <<< select an antivirus profile
     set profile-protocol-options default
   next
end
```

Best practices

This is a short list of WAN optimization and explicit proxy best practices.

- WAN optimization tunnel sharing is recommended for similar types of WAN optimization traffic. However, tunnel sharing for different types of traffic is not recommended. For example, aggressive and non-aggressive protocols should not share the same tunnel. See “Tunnel sharing” on page 2601.
- Active-passive HA is the recommended HA configuration for WAN optimization. See “WAN optimization and HA” on page 2602.
- Configure WAN optimization authentication with specific peers. Accepting any peer is not recommended as this can be less secure. See “Accepting any peers” on page 2610.
- Set the explicit HTTP proxy *Default Policy Action* to *Deny*. This means that a security policy is required to use the explicit web proxy. See “Explicit web proxy configuration overview” on page 2667.
- Set the explicit FTP proxy *Default Policy Action* to *Deny*. This means that a security policy is required to use the explicit FTP proxy. See “Explicit FTP proxy configuration overview” on page 2692.

Peers and authentication groups

All communication between WAN optimization peers begins with one WAN optimization peer (or client-side FortiGate unit) sending a WAN optimization tunnel request to another peer (or server-side FortiGate unit). During this process, the WAN optimization peers identify and optionally authenticate each other.

This chapter describes:

Basic WAN optimization peer requirements

WAN optimization requires the following configuration on each peer. For information about configuring local and peer host IDs, see "Configuring peers" on page 2611.

- The peer must have a unique host ID.
- Unless authentication groups are used, peers authenticate each other using host ID values. Do not leave the local host ID at its default value.
- The peer must know the host IDs and IP addresses of all of the other peers that it can start WAN optimization tunnels with. This does not apply if you use authentication groups that accept all peers.
- All peers must have the same local certificate installed on their FortiGate units if the units authenticate by local certificate (see "Certificate-based authentication" on page 532). Similarly, if the units authenticate by pre-shared key (password), administrators must know the password. The type of authentication is selected in the authentication group. This applies only if you use authentication groups.

Accepting any peers

Strictly speaking, you do not need to add peers. Instead you can configure authentication groups that accept any peer. However, for this to work, both peers must have the same authentication group (with the same name) and both peers must have the same certificate or pre-shared key.

Accepting any peer is useful if you have many peers or if peer IP addresses change. For example, you could have many travelling FortiClient peers with IP addresses that are always changing as the users travel to different customer sites. This configuration is also useful if you have FortiGate units with dynamic external IP addresses (using DHCP or PPPoE). For most other situations, this method is not recommended and is not a best practice as it is less secure than accepting defined peers or a single peer. For more information, see "Configuring authentication groups" on page 2612.

How FortiGate units process tunnel requests for peer authentication

When a client-side FortiGate unit attempts to start a WAN optimization tunnel with a peer server-side FortiGate unit, the tunnel request includes the following information:

- the client-side local host ID
- the name of an authentication group, if included in the rule that initiates the tunnel
- if an authentication group is used, the authentication method it specifies: pre-shared key or certificate
- the type of tunnel (secure or not).

For information about configuring the local host ID, peers and authentication groups, see "Configuring peers" on page 2611 and "Configuring authentication groups" on page 2612.

The authentication group is optional unless the tunnel is a secure tunnel. For more information, see "Secure tunneling" on page 2615.

If the tunnel request includes an authentication group, the authentication will be based on the settings of this group as follows:

- The server-side FortiGate unit searches its own configuration for the name of the authentication group in the tunnel request. If no match is found, the authentication fails.
- If a match is found, the server-side FortiGate unit compares the authentication method in the client and server authentication groups. If the methods do not match, the authentication fails.
- If the authentication methods match, the server-side FortiGate unit tests the peer acceptance settings in its copy of the authentication group.
- If the setting is *Accept Any Peer*, the authentication is successful.
- If the setting is *Specify Peer*, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the peer name in the server-side authentication group. If the names match, authentication is successful. If a match is not found, authentication fails.
- If the setting is *Accept Defined Peers*, the server-side FortiGate unit compares the client-side local host ID in the tunnel request with the server-side peer list. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the tunnel request does not include an authentication group, authentication will be based on the client-side local host ID in the tunnel request. The server-side FortiGate unit searches its peer list to match the client-side local host ID in the tunnel request. If a match is found, authentication is successful. If a match is not found, authentication fails.

If the server-side FortiGate unit successfully authenticates the tunnel request, the server-side FortiGate unit sends back a tunnel setup response message. This message includes the server-side local host ID and the authentication group that matches the one in the tunnel request.

The client-side FortiGate unit then performs the same authentication procedure as the server-side FortiGate unit did. If both sides succeed, tunnel setup continues.

Configuring peers

When you configure peers, you first need to add the local host ID that identifies the FortiGate unit for WAN optimization and then add the peer host ID and IP address of each FortiGate unit with which a FortiGate unit can create WAN optimization tunnels.

To configure WAN optimization peers - web-based manager

1. Go to *Wan Opt. & Cache* > *WAN Opt. Peer* > *Peer*.

2 For *Local Host ID*, enter the local host ID of ***this*** FortiGate unit and select *Apply*. If you add this FortiGate unit as a peer to another FortiGate unit, use this ID as its ***peer*** host ID.

The local or host ID can contain up to 25 characters and can include spaces.

3 Select *Create New* to add a new peer.

4 For *Peer Host ID*, enter the peer host ID of the peer FortiGate unit. This is the local host ID added to the peer FortiGate unit.

5 For *IP Address*, add the IP address of the peer FortiGate unit. This is the source IP address of tunnel requests sent by the peer, usually the IP address of the FortiGate interface connected to the WAN.

6 Select *OK*.

To configure WAN optimization peers - CLI

In this example, the local host ID is named `HQ_Peer` and has an IP address of `172.20.120.100`. Three peers are added, but you can add any number of peers that are on the WAN.

1. Enter the following command to set the local host ID to `HQ_Peer`.

```
config wanopt settings
  set host-id HQ_peer
end
```

2 Enter the following commands to add three peers.

```
config wanopt peer
  edit Wan_opt_peer_1
    set ip 172.20.120.100
  next
  edit Wan_opt_peer_2
    set ip 172.30.120.100
  next
  edit Wan_opt_peer_3
    set ip 172.40.120.100
  end
```

Configuring authentication groups

You need to add authentication groups to support authentication and secure tunneling between WAN optimization peers.

To perform authentication, WAN optimization peers use a certificate or a pre-shared key added to an authentication group so they can identify each other before forming a WAN optimization tunnel. Both peers must have an authentication group with the same name and settings. You add the authentication group to a peer-to-peer or active rule on the client-side FortiGate unit. When the server-side FortiGate unit receives a tunnel start request from the client-side FortiGate unit that includes an authentication group, the server-side FortiGate unit finds an authentication group in its configuration with the same name. If both authentication groups have the same certificate or pre-shared key, the peers can authenticate and set up the tunnel.

Authentication groups are also required for secure tunneling. See “Secure tunneling” on page 2615.

To add authentication groups, go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group*.

To add an authentication group - web-based manager

Use the following steps to add any kind of authentication group. It is assumed that if you are using a local certificate to authenticate, it is already added to the FortiGate unit. For more information about FortiGate units and certificates, see the *FortiGate Certificate Management Guide*.

1. Go to *Wan Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group*.
2. Select *Create New*.
3. Add a *Name* for the authentication group.

   You will select this name when you add the authentication group to a WAN optimization rule.

4 Select the *Authentication Method*.

   Select *Certificate* if you want to use a certificate to authenticate and encrypt WAN optimization tunnels. You must select a local certificate that has been added to this FortiGate unit. (To add a local certificate, go to *System* > *Certificates* > *Local Certificates*.) Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and certificate.

   Select *Pre-shared key* if you want to use a pre-shared key or password to authenticate and encrypt WAN optimization tunnels. You must add the *Password* (or pre-shared key) used by the authentication group. Other FortiGate units that participate in WAN optimization tunnels with this FortiGate unit must have an authentication group with the same name and password. The password must contain at least 6 printable characters and should be known only by network administrators. For optimum protection against currently known attacks, the key should consist of a minimum of 16 randomly chosen alphanumeric characters.

5 Configure *Peer Acceptance* for the authentication group.

   Select *Accept Any Peer* if you do not know the peer host IDs or IP addresses of the peers that will use this authentication group. This setting is most often used for WAN optimization with the FortiClient application or with FortiGate units that do not have static IP addresses, for example units that use DHCP.

   Select *Accept Defined Peers* if you want to authenticate with peers added to the peer list only.

   Select *Specify Peer* and select one of the peers added to the peer list to authenticate with the selected peer only.

   For more information, see "Configuring peers" on page 2611.

6 Select *OK*.

7 Add the authentication group to a WAN optimization rule to apply the authentication settings in the authentication group to the rule.

To add an authentication group that uses a certificate- CLI

Enter the following command to add an authentication group that uses a certificate and can authenticate all peers added to the FortiGate unit configuration.

In this example, the authentication group is named `auth_grp_1` and uses a certificate named `Example_Cert`.

```
config wanopt auth-group
  edit auth_grp_1
    set auth-method cert
    set cert Example_Cert
    set peer-accept defined
  end
```

To add an authentication group that uses a pre-shared key - CLI

Enter the following command to add an authentication group that uses a pre-shared key and can authenticate only the peer added to the authentication group.

In this example, the authentication group is named `auth_peer`, the peer that the group can authenticate is named `Server_net`, and the authentication group uses `123456` as the pre-shared key. In practice you should use a more secure pre-shared key.

```
config wanopt auth-group
  edit auth_peer
    set auth-method psk
    set psk 123456
    set peer-accept one
    set peer Server_net
  end
```

To add an authentication group that accepts WAN optimization connections from any peer - web-based manager

Add an authentication group that accepts any peer for situations where you do not have the *Peer Host IDs* or *IP Addresses* of the peers that you want to perform WAN optimization with. This setting is most often used for WAN optimization with the FortiClient application or with FortiGate units that do not have static IP addresses, for example units that use DHCP. An authentication group that accepts any peer is less secure than an authentication group that accepts defined peers or a single peer.

The example below sets the authentication method to *Pre-shared key*. You must add the same password to all FortiGate units using this authentication group.

1. Go to *Wan Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group*.
2. Select *Create New* to add a new authentication group.
3. Configure the authentication group:

Name	Specify any name.
Authentication Method	Pre-shared key
Password	Enter a pre-shared key.
Peer Acceptance	Accept Any Peer

To add an authentication group that accepts WAN optimization connections from any peer - CLI

In this example, the authentication group is named `auth_grp_1`. It uses a certificate named `WAN_Cert` and accepts any peer.

```
config wanopt auth-group
  edit auth_grp_1
    set auth-method cert
    set cert WAN_Cert
    set peer-accept any
  end
```

Secure tunneling

You can configure WAN optimization rules to use AES-128bit-CBC SSL to encrypt the traffic in the WAN optimization tunnel. WAN optimization uses FortiASIC acceleration to accelerate SSL decryption and encryption of the secure tunnel. Peer-to-peer secure tunnels use the same TCP port as non-secure peer-to-peer tunnels (TCP port 7810).

To use secure tunneling, you must select *Enable Secure Tunnel* in a WAN optimization rule and add an authentication group. The authentication group specifies the certificate or pre-shared key used to set up the secure tunnel. The *Peer Acceptance* setting of the authentication group does not affect secure tunneling.

The FortiGate units at each end of the secure tunnel must have the same authentication group with the same name and the same configuration, including the same pre-shared key or certificate. To use certificates you must install the same certificate on both FortiGate units.

For active-passive WAN optimization you can select *Enable Secure Tunnel* only in the active rule. In peer-to-peer WAN optimization you select *Enable Secure Tunnel* in the WAN optimization rule on both FortiGate units. For information about active-passive and peer-to-peer WAN optimization, see “Configuring WAN optimization” on page 2590.

For a secure tunneling configuration example, see “Example: Adding secure tunneling to an active-passive WAN optimization configuration” on page 2634.

Monitoring WAN optimization peer performance

The WAN optimization peer monitor lists all of the WAN optimization peers that a FortiGate unit can perform WAN optimization with. These include peers manually added to the configuration as well as discovered peers.

The monitor lists each peer’s name, IP address, and peer type. The peer type indicates whether the peer was manually added or discovered. To show WAN optimization performance, for each peer the monitor lists the percent of traffic reduced by the peer in client-side WAN optimization configurations and in server-side configurations (also called gateway configurations).

To view the peer monitor, go to *WAN Opt. & Cache* > *Monitor* > *Peer Monitor*.

Configuration examples

This chapter provides the basic examples to illustrate WAN optimization configurations introduced in the previous chapters. This chapter contains the following sections:

Example: Basic manual (peer-to-peer) WAN optimization configuration

In a manual (peer to peer) configuration the WAN optimization tunnel can be set up between one client-side FortiGate unit and one server-side FortiGate unit. The peer ID of the server-side FortiGate unit is added to the client-side WAN optimization policy. When the client-side FortiGate unit initiates a tunnel with the server-side FortiGate unit, the packets that initiate the tunnel include information that allows the server-side FortiGate unit to determine that it is a manual tunnel request. The server-side FortiGate unit does not require a WAN optimization profile; you just need to add the client peer host ID and IP address to the server-side FortiGate unit peer list and a security policy to accept WAN optimization tunnel connections.

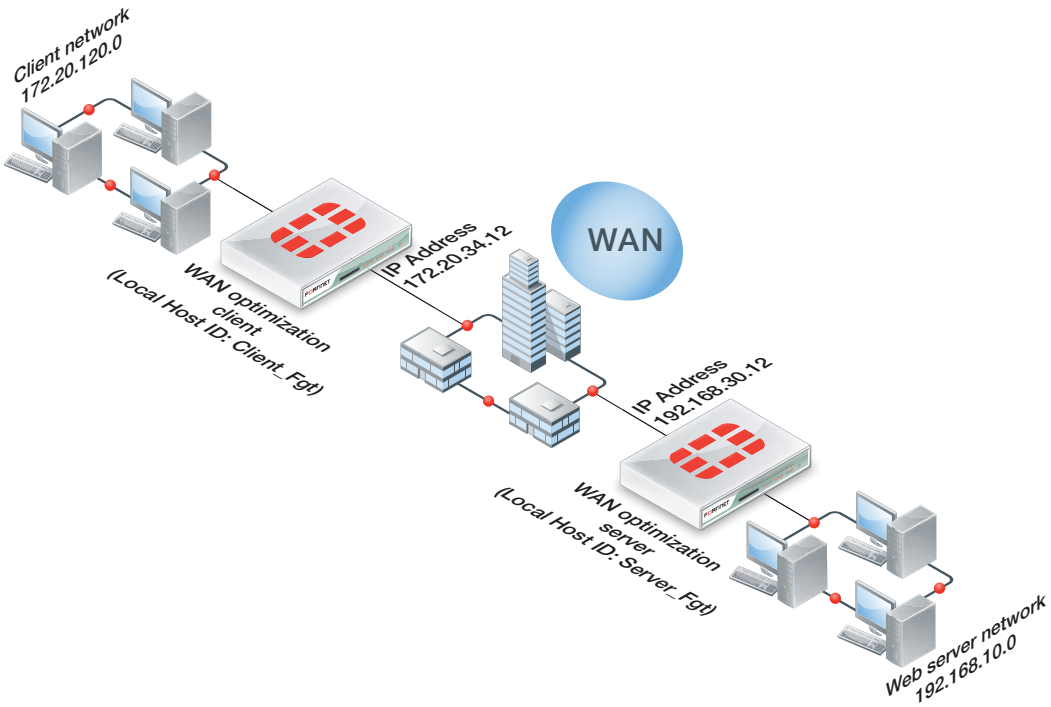
In a manual WAN optimization configuration, you create a manual WAN optimization security policy on the client-side FortiGate unit. To do this you must use the CLI to set `wanopt-detection` to `off` and to add the peer host ID of the server-side FortiGate unit to the WAN optimization security policy.

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Peer-Fgt-1 with a WAN IP address of 172.20.34.12. This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Peer-Fgt-2 with a WAN IP address of 192.168.30.12. This unit is in front of a web server network with IP address 192.168.10.0.

This example customizes the default WAN optimization profile on the client-side FortiGate unit and adds it to the WAN optimization policy. You can also create a new WAN optimization profile. This example also applies virus scanning and application control to WAN optimization traffic on the server-side FortiGate unit by adding the default Antivirus Profile and default Application Control sensor to the WAN optimization security policy.

Figure 398: Example manual (peer-to-peer) topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
   - Add peers.
   - Configure the default WAN optimization profile to optimize HTTP traffic.
   - Add a manual WAN optimization security policy.
2. Configure the server-side FortiGate unit:
   - Add peers.
   - Add a WAN optimization tunnel policy.

Configuring basic peer-to-peer WAN optimization - web-based manager

Use the following steps to configure the example configuration from the web-based manager.

To configure the client-side FortiGate unit

1. Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the client-side FortiGate unit:

Local Host ID	Client-Fgt

2. Select *Apply*.

3. Select *Create New* and add the server-side FortiGate unit *Peer Host ID* and *IP Address* for the server-side FortiGate:

Peer Host ID	Server-Fgt
IP Address	192.168.30.12

4. Select *OK*.
5. Go to *Firewall Objects* > *Address* > *Address* and select *Create New* to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

6. Select *Create New* to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

7. Go to *WAN Opt. & Cache* > *WAN Opt. Profile* > *Profile* and edit the default profile.
8. Select *Transparent Mode*.
9. Under Protocol, select *HTTP* and for HTTP select *Byte Caching*. Leave the HTTP *Port* set to 80.
10. Select *Apply* to save your changes.
11. Go to *Policy* > *Policy* > *Policy* and add a WAN optimization security policy to the client-side FortiGate unit that accepts traffic to be optimized:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port1
Source Address	all
Outgoing Interface	port2
Destination Address	all
Schedule	always

Service	ALL
Action	ACCEPT

12. Under *Security Profiles* turn on Antivirus and select the *default* antivirus profile.
13. Turn on *Application Control* and select the *default* application control sensor.
14. Select *Enable WAN Optimization* and configure the following settings:

Enable WAN Optimization	active
Profile	default

15. Select *OK*.
16. Edit the policy from the CLI to turn off `wanopt-detection`, add the peer ID of the server-side FortiGate unit, and the default WAN optimization profile. The following example assumes the ID of the policy is 5:

```
config firewall policy
  edit 5
    set wanopt-detection off
    set wanopt-peer Server-Fgt
    set wanopt-profile default
  end
```

When you set the detection mode to off the policy becomes a manual mode WAN optimization policy. On the web-based manager the WAN optimization part of the policy changes to the following:

Enable WAN Optimization	Manual (Profile: default, Peer: Peer-Fgt-2)

To configure the server-side FortiGate unit

1. Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server-side FortiGate unit:

Local Host ID	Server-Fgt

2. Select *Apply*.
3. Select *Create New* and add a *Peer Host ID* and the *IP Address* for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.20.34.12

4. Select *OK*.
5. Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a security policy to accept WAN optimization tunnel connections.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	wanopt

Source Address	all
Outgoing Interface	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

Configuring basic peer-to-peer WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
  set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Server-Fgt
  set ip 192.168.30.12
end
```

3. Add a firewall address for the client network.

```
config firewall address
  edit Client-Net
    set type ipmask
    set subnet 172.20.120.0 255.255.255.0
    set associated-interface port1
  end
```

4. Add a firewall address for the web server network.

```
config firewall address
  edit Web-Server-Net
    set type ipmask
    set subnet 192.168.10.0 255.255.255.0
    set associated-interface port2
  end
```

5. Edit the default WAN optimization profile, select transparent mode, enable HTTP WAN optimization and enable byte caching for HTTP. Leave the HTTP Port set to 80.

```
config wanopt profile
  edit default
    set transparent enable
      config http
        set status enable
        set byte-caching enable
      end
  end
```

6. Add a WAN optimization security policy to the client-side FortiGate unit to accept the traffic to be optimized:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr all
    set dstaddr all
    set action accept
    set service ALL
    set schedule always
    set utm-status enable
    set av-profile default
    set application-list default
    set profile-protocol-options default
    set wanopt enable
    set wanopt-profile default
    set wanopt-detection off
    set wanopt-peer Server-Fgt
  end
```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
  set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
  edit Client-Fgt
  set ip 192.168.30.12
end
```

3. Add a WAN optimization tunnel policy.

```
config firewall policy
  edit 0
    set srcintf wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set service ALL
    set schedule always
  end
```

Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network browse to the IP address of a web server on the web server network, for example http://192.168.10.100. Even though this address is not on the client network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring (go to *WAN Opt. & Cache* > *Monitor* > *Monitor*). If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the client-side FortiGate unit is accepting traffic for the 192.168.10.0 network. You can do this by checking the policy monitor (*Policy* > *Monitor* > *Policy Monitor*). Look for sessions that use the policy ID of this policy.
- Check routing on the FortiGate units and on the client and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the client network must allow packets destined for the web server network to be received by the client-side FortiGate unit, and packets from the server-side FortiGate unit must be able to reach the web servers.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating

Enter the following command on the client-side FortiGate unit to display WAN optimization tunnel protocol statistics. The http tunnel and tcp tunnel parts of the command output below shows that WAN optimization has been processing HTTP and TCP packets.

```
get test wad 11
wad tunnel protocol stats:
  http tunnel
    bytes_in=1751767 bytes_out=325468
  ftp tunnel
    bytes_in=0 bytes_out=0
  cifs tunnel
    bytes_in=0 bytes_out=0
  mapi tunnel
    bytes_in=0 bytes_out=0
  tcp tunnel
    bytes_in=3182253 bytes_out=200702
  maintenance tunnel
    bytes_in=11800 bytes_out=15052
```

Enter the following command to display the current WAN optimization peers. You can use this command to make sure all peers are configured correctly. The command output for the client-side FortiGate unit shows one peer with IP address 192.168.20.1, peer name `Web-servers`, and with 10 active tunnels.

```
get test wad 26
name: Web-servers, vd: 0, ip: 192.168.20.1 ref: 1 type:manual
    traffic:
client:  LAN in:0, LAN out:0, WAN in:0, WAN out:0
gateway: LAN in:0, LAN out:0, WAN in:0, WAN out:0
client 0x40e2b4cc, server 0x40e2b4ec
    version=0 tunnels(active/connecting/failover/passive)=10/0/0/0
    ssl tunnels active/connecting/passive)=0/0/0
    sessions=0 n_retries=0 version_valid=true

total peers: 1, manual peers: 1 auto peers: 0
```

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output for the client-side FortiGate unit shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list

Tunnel: id=100 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web-servers id=100 ip=192.168.30.12
    SSL-secured-tunnel=no auth-grp=
    bytes_in=348 bytes_out=384

Tunnel: id=99 type=manual

    SSL-secured-tunnel=no auth-grp=
    bytes_in=1228 bytes_out=1264

Tunnels total=10 manual=10 auto=0
```

Example: Active-passive WAN optimization

In active-passive WAN optimization you add an active WAN optimization policy to the client-side FortiGate unit and you add a WAN optimization tunnel policy and a passive WAN optimization policy to the server-side FortiGate unit.

The active policy accepts the traffic to be optimized and sends it down the WAN optimization tunnel to the server-side FortiGate unit. The active policy can also apply security profiles and other features to traffic before it exits the client-side FortiGate unit.

The tunnel policy on the sever-side FortiGate unit allows the server-side FortiGate unit to form a WAN optimization tunnel with the client-side FortiGate unit. The passive WAN optimization policy is required because of the active policy on the client-side FortiGate unit. You can also use the passive policy to apply WAN optimization transparent mode and features such as security profiles, logging, traffic shaping and web caching to the traffic before it exits the server-side FortiGate unit.

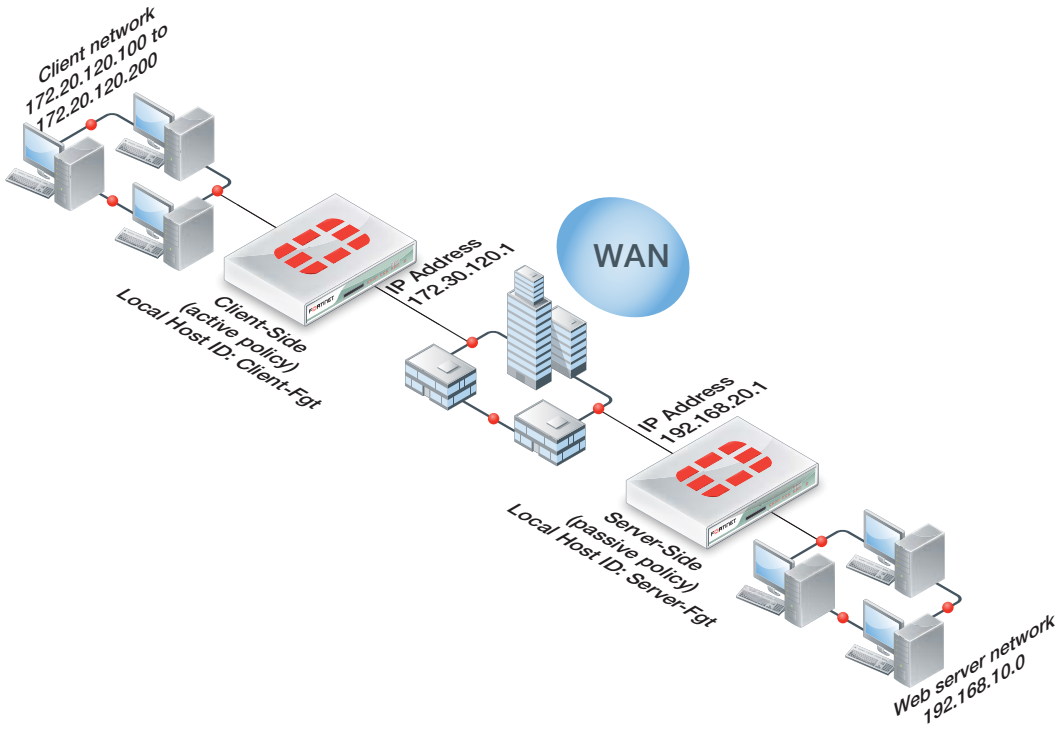
Network topology and assumptions

On the client-side FortiGate unit this example configuration includes a WAN optimization profile that optimizes CIFS, HTTP, and FTP traffic and an active WAN optimization policy. The active policy also applies virus scanning to the WAN optimization traffic.

On the server-side FortiGate unit, the passive policy applies application control to the WAN optimization traffic.

In this example, WAN optimization transparent mode is selected in the WAN optimization profile and the passive WAN optimization policy accepts this transparent mode setting. This means that the optimized packets maintain their original source and destination addresses. As a result, routing on the client network must be configured to route packets for the server network to the client-side FortiGate unit. Also the routing configuration on the server network must be able to route packets for the client network to the server-side FortiGate unit.

Figure 399: Example active-passive WAN optimization topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
   - Add peers.
   - Add a WAN optimization profile to optimize CIFS, FTP, and HTTP traffic.
   - Add firewall addresses for the client and web server networks.
   - Add an active WAN optimization policy that applies virus scanning.
2. Configure the server-side FortiGate unit by:
   - Add peers.
   - Add firewall addresses for the client and web server networks.
   - Add a WAN optimization tunnel policy.
   - Add a passive WAN optimization policy that applies application control.

Configuring basic active-passive WAN optimization - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager.

To configure the client-side FortiGate unit

1. Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the client-side FortiGate unit:

Local Host ID	Client-Fgt

2. Select *Apply*.
3. Select *Create New* and add a Peer Host ID and the *IP Address* for the server-side FortiGate unit:

Peer Host ID	Server-Fgt
IP Address	192.168.20.1

4. Select *OK*.
5. Go to *WAN Opt. & Cache* > *WAN Opt. Profile* > *Profile* and select Create New to add a WAN optimization profile to optimize CIFS, HTTP, and FTP traffic:

Name	Custom-wan-opt-pro
Transparent Mode	Select

6. Select the *CIFS* protocol, select *Byte Caching* and set the *Port* to 445.
7. Select the *FTP* protocol, select *Byte Caching* and set the *Port* to 21.
8. Select the *HTTP* protocol, select *Byte Caching* and set the *Port* to 80.
9. Select *OK*.
10. Go to *Firewall Objects* > *Address* > *Address* and select *Create New* to add a firewall address for the client network.

Category	Address
Address Name	Client-Net
Type	IP Range
Subnet / IP Range	172.20.120.[100-200]
Interface	port1

11. Select *Create New* to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	IP Range
Subnet / IP Range	192.168.10.0/24
Interface	port2

12. Go to *Policy* > *Policy* > *Policy* and add an active WAN optimization security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port1
Source Address	Client-Net

Outgoing Interface	port2
Destination Address	Web-Server-Net
Schedule	always
Service	HTTP FTP SMB
Action	ACCEPT

13. Turn on Antivirus and select the *default* antivirus profile.
14. Select *Enable WAN Optimization* and configure the following settings:

Enable WAN Optimization	active
Profile	Custom-wan-opt-pro

15. Select *OK*.

To configure the server-side FortiGate unit

1. Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server-side FortiGate unit:

Local Host ID	Server-Fgt

2. Select *Apply*.
3. Select *Create New* and add a *Peer Host ID* and the *IP Address* for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.30.120.1

4. Select *OK*.
5. Go to *Firewall Objects* > *Address* > *Address* and select *Create New* to add a firewall address for the client network.

Category	Address
Address Name	Client-Net
Type	IP Range
Subnet / IP Range	172.20.120.[100-200]
Interface	port1

6. Select *Create New* to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net

Type	IP Range
Subnet / IP Range	192.168.10.0/24
Interface	port2

7. Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a WAN optimization tunnel policy.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	wanopt
Source Address	all
Outgoing Interface	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

8. Select *OK*.
9. Select *Create New* to add a passive WAN optimization policy that applies application control.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	Client-Net
Outgoing Interface	port1
Destination Address	Web-Server-Net
Schedule	always
Service	ALL
Action	ACCEPT

10. Turn on *Application Control* and select the *default* application control sensor.
11. Select *Enable WAN Optimization* and configure the following settings:

Enable WAN Optimization	passive
Passive Option	default

12. Select *OK*.

Configuring basic active-passive WAN optimization - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To configure the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
  set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Server-Fgt
  set ip 192.168.20.1
end
```

3. Add a WAN optimization profile to optimize CIFS, HTTP, and FTP traffic.

```
config wanopt profile
  edit Custom-wan-opt-pro
    config cifs
      set status enable
      set byte-caching enable
      set port 445
    end
    config http
      set status enable
      set byte-caching enable
      set port 80
    end
    config ftp
      set status enable
      set byte-caching enable
      set port 21
    end
  end
```

4. Add a firewall address for the client network.

```
config firewall address
  edit Client-Net
    set type iprange
    set startip 172.20.120.100
    set endip 172.20.120.200
    set associated-interface port1
  end
```

5. Add a firewall address for the web server network.

```
config firewall address
  edit Web-Server-Net
    set type ipmask
    set subnet 192.168.10.0 255.255.255.0
    set associated-interface port2
  end
```

6. Add add an active WAN optimization security policy that applies virus scanning:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr Client-net
    set dstaddr Web-Server-Net
    set action accept
    set service HTTP FTP SMB
    set schedule always
    set wanopt enable
    set wanopt-detection active
    set wanopt-profile Custom-wan-opt-pro
    set utm-status enable
    set av-profile default
  end
```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
  set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
  edit Client-Fgt
  set ip 172.20.120.1
end
```

3. Add a firewall address for the client network.

```
config firewall address
  edit Client-Net
    set type iprange
    set startip 172.20.120.100
    set endip 172.20.120.200
    set associated-interface port1
  end
```

4. Add a firewall address for the web server network.

```
config firewall address
  edit Web-Server-Net
    set type ipmask
    set subnet 192.168.10.0 255.255.255.0
    set associated-interface port2
  end
```

5. Add a WAN optimization tunnel policy.

```
config firewall policy
  edit 0
    set srcintf wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set service ALL
    set schedule always
  end
```

6. Add a passive WAN optimization policy that applies application control.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr Client-Net
    set dstaddr Web-Server-Net
    set action accept
    set service ALL
    set schedule always
    set wanopt enable
    set wanopt-detection passive
    set wanopt-passive-opt default
    set utm-status enable
    set application-list default
  end
```

Testing and troubleshooting the configuration

To test the configuration attempt to start a web browsing session between the client network and the web server network. For example, from a PC on the client network browse to the IP address of a web server on the web server network, for example http://192.168.10.100. Even though this address is not on the client network you should be able to connect to this web server over the WAN optimization tunnel.

If you can connect, check WAN optimization monitoring (go to *WAN Opt. & Cache* > *Monitor* > *Monitor*). If WAN optimization has been forwarding the traffic the WAN optimization monitor should show the protocol that has been optimized (in this case HTTP) and the reduction rate in WAN bandwidth usage.

If you can't connect you can try the following to diagnose the problem:

- Review your configuration and make sure all details such as address ranges, peer names, and IP addresses are correct.
- Confirm that the security policy on the Client-Side FortiGate unit is accepting traffic for the 192.168.10.0 network and that this security policy does not include security profiles. You can do this by checking the FortiGate session table from the dashboard. Look for sessions that use the policy ID of this policy
- Check routing on the FortiGate units and on the client and web server networks to make sure packets can be forwarded as required. The FortiGate units must be able to communicate with each other, routing on the client network must allow packets destined for

the web server network to be received by the client-side FortiGate unit, and packets from the server-side FortiGate unit must be able to reach the web servers etc.

You can use the following `get` and `diagnose` commands to display information about how WAN optimization is operating

Enter the following command to display WAN optimization tunnel protocol statistics. The http tunnel and tcp tunnel parts of the command output below shows that WAN optimization has been processing HTTP and TCP packets.

```
get test wad 11
wad tunnel protocol stats:
  http tunnel

```

Enter the following command to display the current WAN optimization peers. You can use this command to make sure all peers are configured correctly. The command output for the client-side FortiGate unit shows one peer with IP address 192.168.20.1, peer name `Web-servers`, and with 10 active tunnels.

```
get test wad 26
peer name=Web-servers ip=192.168.20.1 vd=0 version=1
     tunnels(active/connecting/failover)=10/0/0
       sessions=0 n_retries=0 version_valid=true
```

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 3 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to on).

```
diagnose wad tunnel list

Tunnel: id=139 type=auto
    vd=0 shared=no uses=0 state=1
    peer name= id=0 ip=unknown

    SSL-secured-tunnel=no auth-grp=test
    bytes_in=727 bytes_out=76

Tunnels total=3 manual=0 auto=3
```

Example: Adding secure tunneling to an active-passive WAN optimization configuration

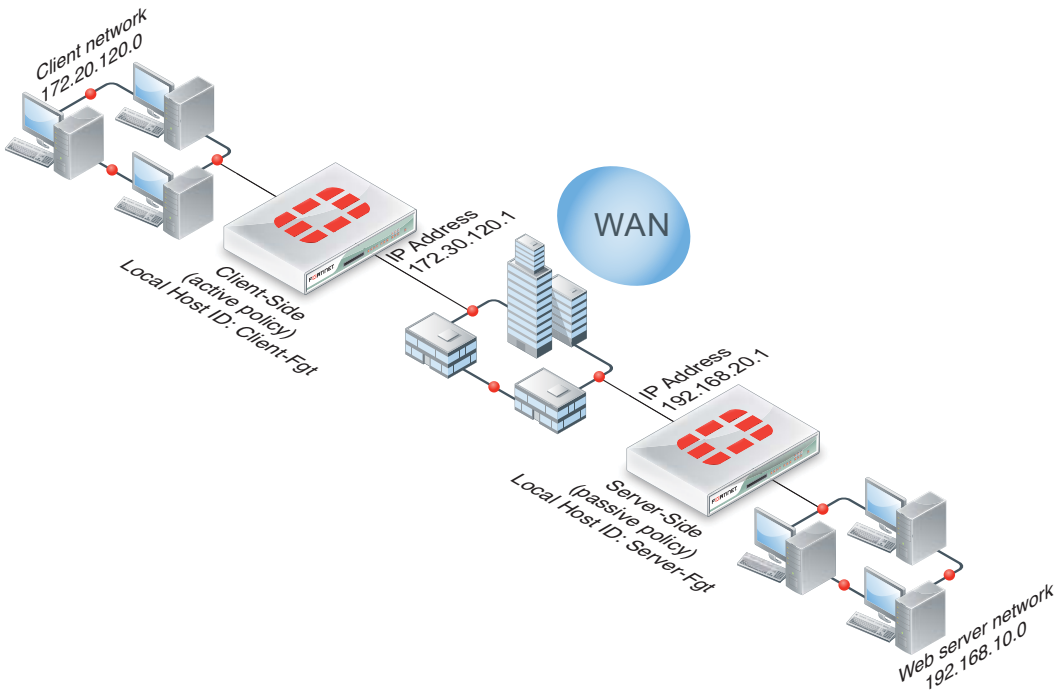
This example shows how to configure two FortiGate units for active-passive WAN optimization with secure tunneling. The same authentication group is added to both FortiGate units. The authentication group includes a password (or pre-shared key) and has *Peer Acceptance* set to *Accept any Peer*. An active policy is added to the client-side FortiGate unit and a passive policy to the server-side FortiGate unit. The active policy includes a profile that performs secure tunneling, optimizes HTTP traffic, and uses Transparent Mode and byte caching.

The authentication group is named *Auth-Secure-Tunnel* and the password for the pre-shared key is *2345678*. The topology for this example is shown in Figure 400. This example includes web-based manager configuration steps followed by equivalent CLI configuration steps. For information about secure tunneling, see “Secure tunneling” on page 2615.

Network topology and assumptions

This example configuration includes a client-side FortiGate unit called Client-net with a WAN IP address of 172.30.120.1.This unit is in front of a network with IP address 172.20.120.0. The server-side FortiGate unit is called Web-servers and has a WAN IP address of 192.168.20.1. This unit is in front of a web server network with IP address 192.168.10.0.

Figure 400: Example active-passive WAN optimization and secure tunneling topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the client-side FortiGate unit:
   - Add peers.
   - Add an authentication group.
   - Add an active WAN optimization policy.
2. Configure the server-side FortiGate unit.
   - Add peers.
   - Add the same authentication group
   - Add a WAN optimization tunnel policy.
   - Add a passive WAN optimization policy that applies application control.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuring WAN optimization with secure tunneling - web-based manager

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit web-based manager. (CLI steps follow.)

To configure the client-side FortiGate unit

1. Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the client-side FortiGate unit:

Local Host ID	Client-Fgt

2. Select *Apply* to save your setting.
3. Select *Create New* and add a *Peer Host ID* and the *IP Address* for the server-side FortiGate unit:

Peer Host ID	Server-Fgt
IP Address	192.168.20.1

4. Select *OK*.
5. Go to *Wan Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group* and select *Create New* to add the authentication group to be used for secure tunneling:

Name	Auth-Secure-Tunnel
Authentication Method	Pre-shared key
Password	2345678
Peer Acceptance	Accept Any Peer

6. Select *OK*.
7. Go to *Wan Opt. & Cache* > *WAN Opt. Profile* > *Profile* and select *Create New* to add a WAN optimization profile that enables secure tunneling and includes the authentication group:

Name	Secure-wan-op-pro
Transparent Mode	Select
Authentication Group	Auth-Secure-tunnel

8. Select the *HTTP* protocol, select Secure Tunneling and *Byte Caching* and set the *Port* to 80.
9. Select *OK*.
10. Go to *Firewall Objects* > *Address* > *Address* and select *Create New* to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

11. Select *Create New* to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet

Subnet / IP Range	192.168.10.0/24
Interface	port2

12. Go to *Policy* > *Policy* > *Policy* and select *Create New* to add an active WAN optimization security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port1
Source Address	Client-Net
Outgoing Interface	port2
Destination Address	Web-Server-Net
Schedule	always
Service	HTTP
Action	ACCEPT

13. Turn on Antivirus and select the *default* antivirus profile.
14. Select *Enable WAN Optimization* and configure the following settings:

Enable WAN Optimization	active
Profile	Secure-wan-opt-pro

15. Select *OK*.

To configure the server-side FortiGate unit

1. Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Peer* and enter a *Local Host ID* for the server-side FortiGate unit:

Local Host ID	Server-Fgt

2. Select *Apply* to save your setting.
3. Select *Create New* and add a *Peer Host ID* and the *IP Address* for the client-side FortiGate unit:

Peer Host ID	Client-Fgt
IP Address	172.30.120.1

4. Select *OK*.

5. Go to *Wan Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group* and select *Create New* and add an authentication group to be used for secure tunneling:

Name	Auth-Secure-Tunnel
Authentication Method	Pre-shared key
Password	2345678
Peer Acceptance	Accept Any Peer

6. Select *OK*.
7. Go to *Firewall Objects* > *Address* > *Address* and select *Create New* to add a firewall address for the client network.

Category	Address
Name	Client-Net
Type	Subnet
Subnet / IP Range	172.20.120.0/24
Interface	port1

8. Select *Create New* to add a firewall address for the web server network.

Category	Address
Address Name	Web-Server-Net
Type	Subnet
Subnet / IP Range	192.168.10.0/24
Interface	port2

9. Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a WAN optimization tunnel policy.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	wanopt
Source Address	all
Outgoing Interface	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

10. Select *OK*.
11. Select *Create New* to add a passive WAN optimization policy that applies application control.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	Client-Net
Outgoing Interface	port1
Destination Address	Web-Server-Net
Schedule	always
Service	ALL
Action	ACCEPT

12. Turn on *Application Control* and select the *default* application control sensor.
13. Select *Enable WAN Optimization* and configure the following settings:

Enable WAN Optimization	passive
Passive Option	default

14. Select *OK*.

Configuring WAN optimization with secure tunneling - CLI

Use the following steps to configure the example WAN optimization configuration from the client-side and server-side FortiGate unit CLI.

To the client-side FortiGate unit

1. Add the Local Host ID to the client-side FortiGate configuration:

```
config wanopt settings
  set host-id Client-Fgt
end
```

2. Add the server-side Local Host ID to the client-side peer list:

```
config wanopt peer
  edit Server-Fgt
  set ip 192.168.20.1
end
```

3. Add a new authentication group to be used for secure tunneling:

```
config wanopt auth-group
  edit Auth-Secure-Tunnel
    set auth-method psk
    set psk 2345678
  end
```

Leave `peer-accept` at its default value.

4. Add a WAN optimization profile that enables secure tunneling and includes the authentication group, enables HTTP protocol optimization, and enables secure tunneling and byte caching for HTTP traffic:

```
config wanopt profile
  edit Secure-wan-op-pro
    set auth-group Auth-Secure-Tunnel
    config http
      set status enable
      set secure-tunnel enable
      set byte-caching enable
      set port 80
    end
  end
```

5. Add a firewall address for the client network.

```
config firewall address
  edit Client-Net
    set type ipmask
    set subnet 172.20.120.0 255.255.255.0
    set associated-interface port1
  end
```

6. Add a firewall address for the web server network.

```
config firewall address
  edit Web-Server-Net
    set type ipmask
    set subnet 192.168.10.0 255.255.255.0
    set associated-interface port2
  end
```

7. Add an active WAN optimization security policy that includes the WAN optimization profile that enables secure tunneling and that applies virus scanning:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr Client-Net
    set dstaddr Web-Server-Net
    set action accept
    set service HTTP
    set schedule always
    set wanopt enable
    set wanopt-detection active
    set wanopt-profile Secure-wan-opt-pro
    set utm-status enable
    set av-profile default
  end
```

To configure the server-side FortiGate unit

1. Add the Local Host ID to the server-side FortiGate configuration:

```
config wanopt settings
  set host-id Server-Fgt
end
```

2. Add the client-side Local Host ID to the server-side peer list:

```
config wanopt peer
  edit Client-Fgt
  set ip 172.20.120.1
end
```

3. Add an authentication group to be used for secure tunneling:

```
config wanopt auth-group
  edit Auth-Secure-Tunnel
    set auth-method psk
    set psk 2345678
  end
```

   Leave `peer-accept` at its default value.

4. Add a firewall address for the client network.

```
config firewall address
  edit Client-Net
    set type ipmask
    set subnet 172.20.120.0 255.255.255.0
    set associated-interface port1
  end
```

5. Add a firewall address for the web server network.

```
config firewall address
  edit Web-Server-Net
    set type ipmask
    set subnet 192.168.10.0 255.255.255.0
    set associated-interface port2
  end
```

6. Add a WAN optimization tunnel policy.

```
config firewall policy
  edit 0
    set srcintf wanopt
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set service ALL
    set schedule always
  end
```

7. Add a passive WAN optimization policy.

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf port2
    set srcaddr Client-Net
    set dstaddr Web-Server-Net
    set action accept
    set service ALL
    set schedule always
    set wanopt enable
    set wanopt-detection passive
    set wanopt-passive-opt default
    set utm-status enable
    set application-list default
  end
```

Web caching and SSL offloading

FortiGate web caching is a form of object caching that accelerates web applications and web servers by reducing bandwidth usage, server load, and perceived latency. Web caching supports caching of HTTP 1.0 and HTTP 1.1 web sites. See RFC 2616 for information about web caching for HTTP 1.1.

Web caching does not cache audio and video streams including Flash videos and streaming content.

Web caching caches compressed and non-compressed versions of the same file separately. If the HTTP protocol considers the compressed and uncompressed versions of a file the same object, only the compressed or uncompressed file will be cached.

Web caching involves storing HTML pages, images, servlet responses and other web-based objects for later retrieval. You can also go to *System* > *Config* > *Advanced* > *Disk Management* to view the storage locations on the FortiGate unit hard disks. You can change the default storage configuration using the `config wanopt storage` command.

There are three significant advantages to using web caching to improve HTTP and WAN performance:

- reduced bandwidth consumption because fewer requests and responses go over the WAN or Internet.
- reduced web server load because there are fewer requests for web servers to handle.
- reduced latency because responses for cached requests are available from a local FortiGate unit instead of from across the WAN or Internet.

You can use web caching to cache any web traffic that passes through the FortiGate unit, including web pages from web servers on a LAN, WAN or on the Internet. You apply web caching by enabling the web caching option in any security policy. When enabled in a security policy, web caching is applied to all HTTP sessions accepted by the security policy. If the security policy is an explicit web proxy security policy, the FortiGate unit caches explicit web proxy sessions.

This section contains the following topics:

Turning on web caching for HTTP and HTTPS traffic

Web caching can be applied to any HTTP or HTTPS traffic by enabling web caching in a security policy that accepts the traffic. This includes WAN optimization and explicit web proxy traffic. Web caching caches all HTTP traffic accepted by a policy on TCP port 80.

You can add web caching to a security policy to:

- Cache Internet HTTP traffic for users on an internal network to reduce Internet bandwidth use. Do this by selecting the web cache option for security policies that allow users on the internal network to browse web sites on the Internet.
- Reduce the load on a public facing web server by caching objects on the FortiGate unit. This is a reverse proxy with web caching configuration. Do this by selecting the web cache option for a security policy that allows users on the Internet to connect to the web server.
- Cache outgoing explicit web proxy traffic when the explicit proxy is used to proxy users in an internal network who are connecting to the web servers on the Internet. Do this by selecting the web cache option for explicit web proxy security policies that allow users on the internal network to browse web sites on the Internet.
- Combine web caching with WAN optimization. You can enable web caching in any WAN optimization security policy. This includes manual, active, and passive WAN optimization policies and WAN optimization tunnel policies. You can enable web caching on both the client-side and the server-side FortiGate units or on just one or the other. For optimum performance you can enable web caching on both the client-side and server-side FortiGate units. In this way only uncached content is transmitted through the WAN optimization tunnel. All cached content is access locally by clients from the client side FortiGate unit.

One important use for web caching is to cache software updates (for example, Windows Updates or iOS updates. When updates occur a large number of users may all be trying to download these updates at the same time. Caching these updates will be a major performance improvement and also have a potentially large impact on reducing Internet bandwidth use. You may want to adjust the maximum cache object size to make sure these updates are cached. See “Max cache object size” on page 2648.

Turning on web caching and SSL offloading for HTTPS traffic

Web caching can also cache the content of HTTPS traffic on TCP port 443. With HTTPS web caching, the FortiGate unit receives the HTTPS traffic on behalf of the client, opens up the encrypted traffic and extracts content to be cached. Then FortiGate unit re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack. You enable HTTPS web caching from the CLI in a security policy that accepts the traffic to be cached using `webcache-https`:

```
config firewall policy
  edit 0
    .
    .
    .
    set webcache enable
    set webcache-https any
    .
    .
    .
  end
```

The `any` setting causes the FortiGate unit to re-encrypt the traffic with the FortiGate unit's certificate rather than the original certificate. This configuration can cause errors for HTTPS clients because the name on the certificate does not match the name on the web site.

You can stop these errors from happening by configuring HTTPS web caching to use the web server's certificate by setting `webcache-https` to `ssl-server`:

```
config firewall policy
  edit 0
    .
    .
    .
    set webcache enable
    set webcache-https ssl-server
    .
    .
    .
  end
```

The `ssl-server` option causes the FortiGate unit to re-encrypt the traffic with the certificate that you imported into the FortiGate unit. The certificate is added to an SSL server configuration using the following command:

```
config wanopt ssl-server
  edit example_server
    set ip <Web-Server-IP>
    set port 443
    set ssl-mode { full | half}
    set ssl-cert <Web-Server-Cert>
  end
```

Where:

`Web-Server-IP` is the web server's IP address.

`Web-Server-Cert` is the original web server certificate imported into the FortiGate unit.

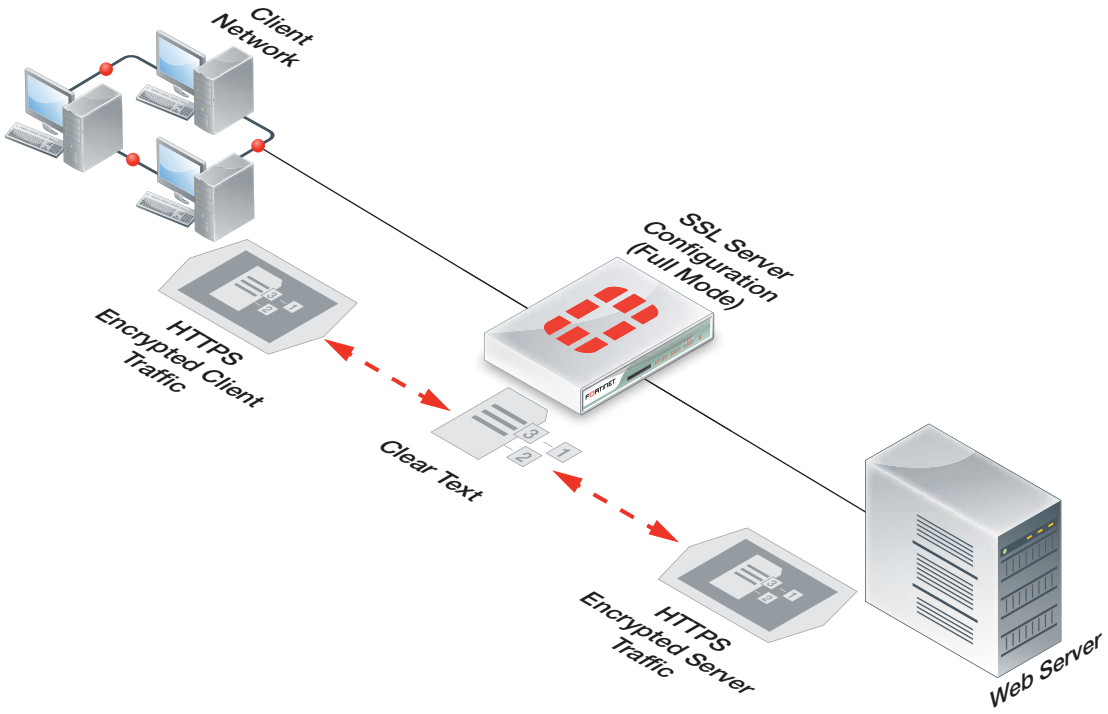
The SSL server configuration also determines whether the SSL server is operating in half or full mode and the port used for the HTTPS traffic.

Using the SSL server configuration, web caching also supports SSL offloading that uses the FortiGate unit's FortiASIC SSL encryption/decryption engine to accelerate SSL performance.

Full mode SSL server configuration

The `ssl-mode` option determines whether the SSL server operates in half or full mode. In full mode the FortiGate unit performs both decryption and encryption of the HTTPS traffic. The full mode sequence is shown in Figure 401.

Figure 401: Full mode SSL server configuration



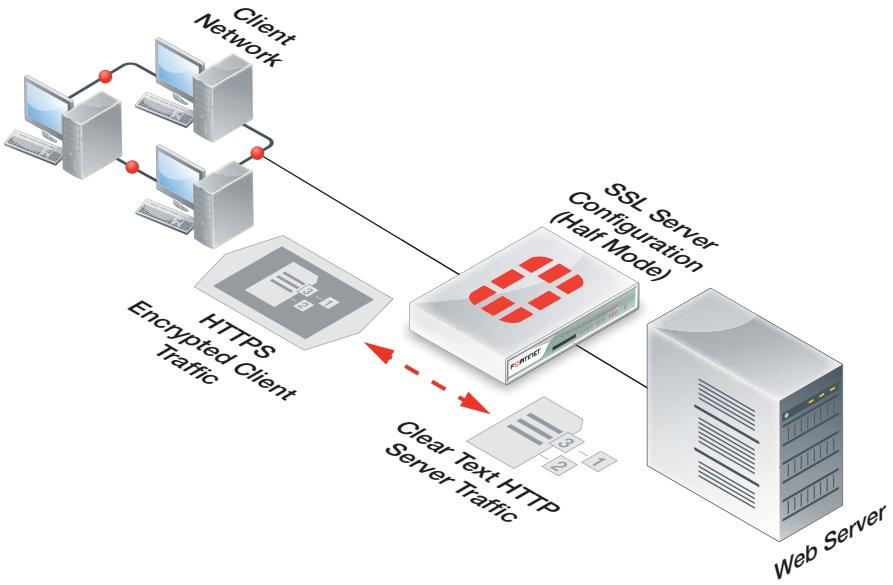
In full mode the FortiGate unit is acting as a man in the middle, decrypting and encrypting the traffic. So both the client and the web server see encrypted packets.

Usually the port of the encrypted HTTPS traffic is always 443. However, in the SSL server configuration you can set the port used for HTTPS traffic. This port is not altered by the SSL Server. So for example, if the SSL Server receives HTTPS traffic on port 443, the re-encrypted traffic forwarded to the FortiGate unit to the server or client will still use port 443.

Half mode SSL server configuration

In half mode, the FortiGate unit only performs one encryption or decryption action. If HTTP packets are received, the half mode SSL server encrypts them and converts them to HTTPS packets. If HTTPS packets are received, the SSL server decrypts them and converts them to HTTP packets. The half mode sequence is shown in Figure 402:

Figure 402: Half mode SSL server configuration



In half mode, the FortiGate unit is acting like an SSL accelerator, offloading HTTPS decryption from the web server to the FortiGate unit. Since FortiGate units can accelerate SSL processing, the end result could be improved web site performance.

Usually the port of the encrypted traffic is always 443. However, in the SSL server configuration you can set the port used for HTTPS traffic. No matter what port is used for the HTTPS traffic, the decrypted HTTP traffic uses port 80.

Changing the ports on which to look for HTTP and HTTPS traffic to cache

By default FortiOS assumes HTTP traffic uses TCP port 80 and HTTPS traffic uses port 443. So web caching caches all HTTP traffic accepted by a policy on TCP port 80 and all HTTPS traffic on TCP port 443. If you want to cache HTTP or HTTPS traffic on other ports, you can enable security features for the security policy and configure a proxy options profile to that looks for HTTP and HTTPS traffic on other TCP ports.

Setting the HTTP port to *Any* in a proxy options profile is not compatible with web caching. If you set the HTTP port to any, web caching only caches HTTP traffic on port 80.

Web caching and HA

You can configure web caching on a FortiGate HA cluster. The recommended best practice HA configuration for web caching is active-passive mode. When the cluster is operating, all web caching sessions are processed by the primary unit only. Even if the cluster is operating in active-active mode, HA does not load-balance web caching sessions.

In a cluster, only the primary unit stores the web cache database. The databases is not synchronized to the subordinate units. So, after a failover, the new primary unit must build its web cache.

Web caching and memory usage

To accelerate and optimize disk access and to provide better throughput and less latency, web caching uses provisioned memory to reduce disk I/O and increase disk I/O efficiency. In addition, web caching requires a small amount of additional memory per session for comprehensive flow control logic and efficient traffic forwarding.

When web caching is enabled you will see a reduction in available memory. The reduction increases when more web caching sessions are being processed. If you are thinking of enabling web caching on an operating FortiGate unit, make sure its memory usage is not maxed out during high traffic periods.

In addition to using the system dashboard to see the current memory usage you can use the `get test wad 1` command to see how much memory is currently being used by web caching. See "get test {wa_cs | wa_dbd | wad | wad_diskd | wccpd} <test_level>" on page 2719 for more information.

Changing web cache settings

In most cases, the default settings for the WAN optimization web cache are acceptable. However, you may want to change them to improve performance or optimize the cache for your configuration. To change these settings, go to *WAN Opt. & Cache* > *Cache* > *Settings.*

From the FortiGate CLI, you can use the `config wanopt webcache` command to change these WAN optimization web cache settings.

For more information about many of these web cache settings, see RFC 2616.

Always revalidate

Select to always revalidate requested cached objects with content on the server before serving them to the client.

Max cache object size

Set the maximum size of objects (files) that are cached. The default size is 512000 KB and the range is 1 to 4294967 KB. This setting determines the maximum object size to store in the web cache. Objects that are larger than this size are still delivered to the client but are not stored in the FortiGate web cache.

For most web traffic the default maximum cache object size is recommended. However, since web caching can also cache larger objects such as Windows updates, Mac OS updates, iOS updates or other updates delivered using HTTP you might want to increase the object size to make sure these updates are cached. Caching these updates can save a lot of Internet bandwith and improve performance when major updates are released by these vendors.

Negative response duration

Set how long in minutes that the FortiGate unit caches error responses from web servers. If error responses are cached, then subsequent requests to the web cache from users will receive the error responses regardless of the actual object status.

The default is 0, meaning error responses are not cached. The content server might send a client error code (4xx HTTP response) or a server error code (5xx HTTP response) as a response to some requests. If the web cache is configured to cache these negative responses, it returns that response in subsequent requests for that page or image for the specified number of minutes.

Fresh factor

Set the fresh factor as a percentage. The default is 100, and the range is 1 to 100%. For cached objects that do not have an expiry time, the web cache periodically checks the server to see if the objects have expired. The higher the *Fresh Factor* the less often the checks occur.

For example, if you set the *Max TTL* value and *Default TTL* to 7200 minutes (5 days) and set the *Fresh Factor* to 20, the web cache check the cached objects 5 times before they expire, but if you set the *Fresh Factor* to 100, the web cache will check once.

Max TTL

The maximum amount of time (Time to Live) an object can stay in the web cache without the cache checking to see if it has expired on the server. The default is 7200 minutes (120 hours or 5 days) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Min TTL

The minimum amount of time an object can stay in the web cache before the web cache checks to see if it has expired on the server. The default is 5 minutes and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Default TTL

The default expiry time for objects that do not have an expiry time set by the web server. The default expiry time is 1440 minutes (24 hours) and the range is 1 to 5256000 minutes (5256000 minutes in a year).

Proxy FQDN

The fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server. This field is for information only can be changed from the explicit web proxy configuration.

Max HTTP request length

The maximum length of an HTTP request that can be cached. Larger requests will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

Max HTTP message length

The maximum length of an HTTP message that can be cached. Larger messages will be rejected. This field is for information only can be changed from the explicit web proxy configuration.

Ignore

Select the following options to ignore some web caching features.

- If-modified-since
- By default, if the time specified by the if-modified-since (IMS) header in the client's conditional request is greater than the last modified time of the object in the cache, it is a

strong indication that the copy in the cache is stale. If so, HTTP does a conditional GET to the Overlay Caching Scheme (OCS), based on the last modified time of the cached object.

- Enable ignoring if-modified-since to override this behavior.
- HTTP 1.1 conditionals
- HTTP 1.1 provides additional controls to the client over the behavior of caches toward stale objects. Depending on various cache-control headers, the FortiGate unit can be forced to consult the OCS before serving the object from the cache. For more information about the behavior of cache-control header values, see RFC 2616.
- Enable ignoring HTTP 1.1 Conditionals to override this behavior.
- Pragma-no-cache
- Typically, if a client sends an HTTP GET request with a pragma no-cache (PNC) or cache-control no-cache header, a cache must consult the OCS before serving the content. This means that the FortiGate unit always re-fetches the entire object from the OCS, even if the cached copy of the object is fresh.
- Because of this behavior, PNC requests can degrade performance and increase server-side bandwidth utilization. However, if you enable ignoring Pragma-no-cache, then the PNC header from the client request is ignored. The FortiGate unit treats the request as if the PNC header is not present.
- IE Reload
- Some versions of Internet Explorer issue Accept / header instead of Pragma no-cache header when you select *Refresh*. When an Accept header has only the / value, the FortiGate unit treats it as a PNC header if it is a type-N object.
- Enable ignoring IE reload to cause the FortiGate unit to ignore the PNC interpretation of the Accept / header.

Cache Expired Objects

Applies only to type-1 objects. When this option is selected, expired type-1 objects are cached (if all other conditions make the object cacheable).

Revalidated Pragma-no-cache

The pragma-no-cache (PNC) header in a client's request can affect how efficiently the FortiGate unit uses bandwidth. If you do not want to completely ignore PNC in client requests (which you can do by selecting to ignore Pragma-no-cache, above), you can nonetheless lower the impact on bandwidth usage by selecting *Revalidate Pragma-no-cache*.

When you select *Revalidate Pragma-no-cache*, a client's non-conditional PNC-GET request results in a conditional GET request sent to the OCS if the object is already in the cache. This gives the OCS a chance to return the 304 Not Modified response, which consumes less server-side bandwidth, because the OCS has not been forced to otherwise return full content.

By default, *Revalidate Pragma-no-cache* is disabled and is not affected by changes in the top-level profile.

Most download managers make byte-range requests with a PNC header. To serve such requests from the cache, you should also configure byte-range support when you configure the *Revalidate pragma-no-cache* option.

Forwarding URLs to forwarding servers and exempting web sites from web caching

You can go to *WAN Opt. & Cache* > *Cache* > *URL Match List* and use the URL match list to forward URL patterns to forwarding server and create a list of URLs that are exempt from web caching.

- Forwarding URLs and URL patters to forwarding servers
- Exempting web sites from web caching

Forwarding URLs and URL patters to forwarding servers

As part of configuring the explicit web proxy you can configure proxy chaining by adding web proxy forwarding servers. See “Proxy chaining (web proxy forwarding servers)” on page 2578.

You can then use the URL match list to always forward explicit web proxy traffic destined for configured URLs or URL patterns to one of these forwarding servers. For example, you might want to forward all traffic for a specific country to a proxy server located in that country.

To forward traffic destined for a URL to a forwarding server that you have already added, go to *WAN Opt. & Cache* > *Cache* > *URL Match List* and select *Create New*. Add a name for the URL match entry and enter the URL or URL pattern. You can use wildcards such as * and ? and you can use a numeric IP address. Select *Forward to Server* and select a web proxy forwarding server from the list.

You can also exempt the URL or URL pattern from web caching.

Use the following command to forward all .ca traffic to a proxy server and all .com traffic to another proxy server.

```
config web-proxy url-match
  edit "com"
    set forward-server "server-commercial"
    set url-pattern "com"
  next
  edit "ca"
    set forward-server "server-canada"
    set url-pattern "ca"
  next
  edit "www.google.ca"
    set cache-exemption enable
    set url-pattern "www.google.ca"
  next
end
```

Exempting web sites from web caching

You may want to exempt some URLs from web caching for a number of reasons. For example, if your users access websites that are not compatible with FortiGate web caching you can add the URLs of these web sites to the web caching exempt list. You can add URLs and numeric IP addresses to the web cache exempt list.

You can also add URLs to the web cache exempt list by going to *WAN Opt. & Cache* > *Cache* > *URL Match List* and selecting *Create New*. Add a URL pattern to be exempt and select *Exempt from Cache*.

You can also add URLs and addresses to be exempt from the CLI. Enter the following command to add www.example.com to the web cache exempt list.

```
config web-proxy url-match
  set cache-exemption enable
  set url-pattern www.example.com
end
```

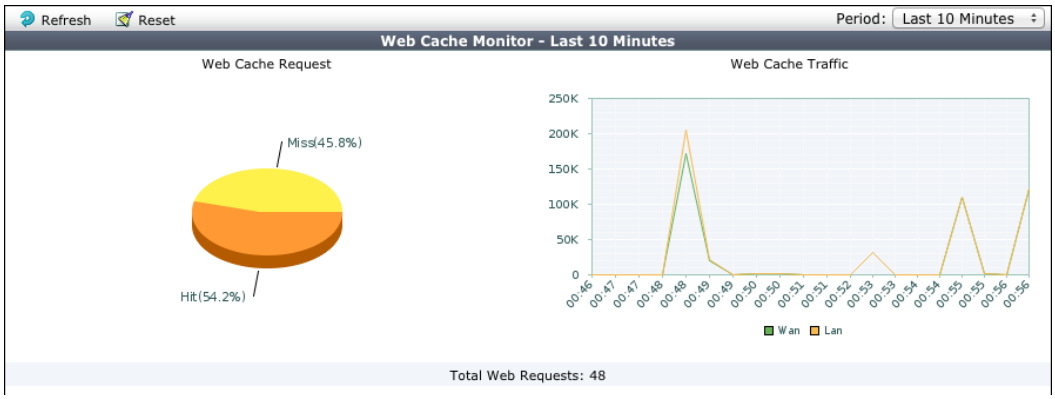
Monitoring Web caching performance

The web cache monitor shows the percentage of web cache requests that retrieved content from the cache (hits) and the percentage that did not receive content from the cache (misses). A higher the number of hits usually indicates that the web cache is being more effective at reducing WAN traffic.

The web cache monitor also shows a graph of web traffic on the WAN and LAN. A lower WAN line on the graph indicates the web cache is reducing traffic on the WAN. The web cache monitor also displays the total number of web requests processed by the web cache.

To view the web cache monitor, go to *WAN Opt. & Cache* > *Monitor* > *Cache Monitor*.

Figure 403: Web cache monitor



Example: Web caching of HTTP and HTTPS Internet content for users on an internal network

This example describes how to configure web caching of HTTP and HTTPS for users on a private network connecting to the Internet.

Network topology and assumptions

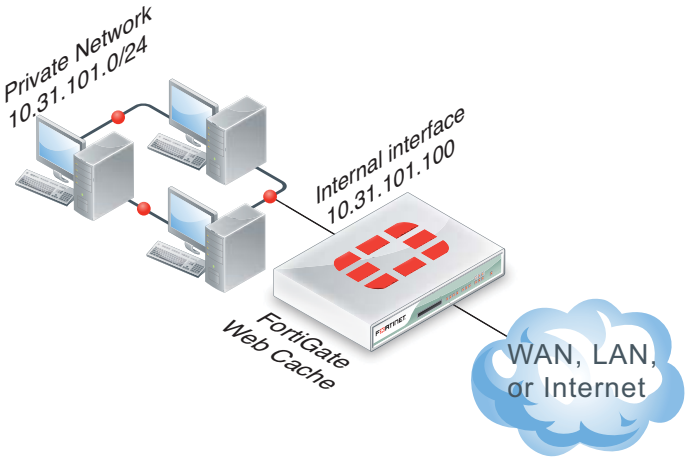
This example includes a client network with subnet address 10.31.101.0 connecting to web servers on the Internet (Figure 404). All of the users on the private network access the Internet though a single general security policy on the FortiGate unit that accepts all sessions connecting to the Internet. Web caching for HTTP and HTTPS traffic is just added to this security policy.

Since users on the private network have unrestricted access to the Internet and can be accessing many web servers the `webcache-https` is set to `any` and users may see error messages on their web browsers when accessing HTTPS content.

Initially, security profiles are not selected so the example caches all HTTP traffic on TCP port 80 and HTTPS traffic on port 443. The example also describes how to configure the security policy

to cache HTTP traffic on port 80 and 8080 by added a proxy options profile that looks for HTTP traffic on TCP ports 80 and 8080. The example also describes how to configure the security policy to cache HTTPS traffic on port 443 and 8443 using the same proxy options profile.

Figure 404: Example web caching topology



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Add HTTP web caching to the security policy that all users on the private network use to connect to the Internet.
2. Add HTTPS web caching.
3. Add a protocol options profile to look for HTTP traffic on ports 80 and 8080 and HTTPS traffic on ports 443 and 8443 and add this protocol options profile to the security policy.

If you perform any additional actions between procedures, your configuration may have different results.

Configuration Steps - web-based manager

Use the following steps to configure the example configuration from the FortiGate web-based manager.

To add HTTP web caching to a security policy

1. Go to *Policy* > *Policy* > *Policy* and add a security policy that allows all users on the internal network to access the Internet.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	Internal
Source Address	all
Outgoing Interface	wan1
Destination Address	all
Schedule	always

Service	ALL
Action	ACCEPT

2. Select *Enable NAT* and select *Use Destination Interface Address*.
3. Select *Enable Web cache*.
4. Select *OK*.

To add HTTPS web caching

1. From the CLI enter the following command to add HTTPS web caching to the security policy.

   Assume the index number of the policy is 5.

```
config firewall policy
  edit 5
    set webcache-https any
  end
```

To cache HTTP traffic on port 80 and 8080 and HTTPS traffic on ports 443 and 8443

1. Go to *Policy* > *Policy* > *Proxy Options* and edit the *default* proxy options profile.

   You could also add a new profile.
2. Under *Protocol Port Mapping* enable *HTTP* and under *Inspection Ports* enter *80,8080*.
3. Under *SSL Inspection Options* enable *HTTPS* and under *Inspection Ports* enter *443,8443*.
4. From the CLI, enter the following command to add the default proxy options profile to the firewall policy.

```
config firewall policy
  edit 5
    set utm-status enable
    set profile-protocol-options default
  end
```

Configuration Steps - CLI

Use the following steps to configure the example configuration from the FortiGate CLI.

To add HTTP and HTTPS web caching to a security policy

1. Enter the following command to add a security policy that allows all users on the internal network to access the Internet and that includes web caching of HTTP and HTTPS traffic.

```
config firewall policy
  edit 0
    set srcintf internal
    set srcaddr all
    set dstintf wan1
    set distinf all
    set schedule always
    set service ANY
    set action accept
    set nat enable
    set webcache enable
    set webcache-https any
end
```

To cache HTTP traffic on port 80 and 8080 and HTTPS traffic on ports 443 and 8443

1. Enter the following command to edit the *default* proxy options profile to configure it to look for HTTP traffic on ports 80 and 8080 and to look for HTTPS traffic on ports 443 and 8443:

```
config firewall profile-protocol-options
  edit default
    config http
      set status enable
      set ports 80 8080
    end
    config https
      set status enable
      set ports 443 8443
    end
end
```

2. Enter the following command to add the protocol options profile to the security policy:

```
config firewall policy
  edit 1
    set utm-status enable
    set profile-protocol-options default
end
```

Example: reverse proxy web caching and SSL offloading for an Internet web server using a static one-to-one virtual IP

This section describes configuring SSL offloading for a reverse proxy web caching configuration using a static one-to-one firewall virtual IP (VIP). While the static one-to-one configuration described in this example is valid, its also common to change the destination port of the unencrypted HTTPS traffic to a commonly used HTTP port such as 8080 using a port forwarding virtual IP.

Network topology and assumptions

In this configuration, clients on the Internet use HTTP and HTTPS to browse to a web server that is behind a FortiGate unit. A policy added to the FortiGate unit forwards the HTTP traffic to the web server. The policy also offloads HTTPS decryption and encryption from the web server so the web server only sees HTTP traffic.

The FortiGate unit also caches HTTP and HTTPS pages from the web server so when users access cached pages the web server does not see the traffic. Replies to HTTPS sessions are encrypted by the FortiGate unit before returning to the clients.

In this configuration, the FortiGate unit is operating as a web cache in reverse proxy mode. Reverse proxy caches can be placed directly in front of a web server. Web caching on the FortiGate unit reduces the number of requests that the web server must handle, therefore leaving it free to process new requests that it has not serviced before.

Using a reverse proxy configuration:

- avoids the capital expense of additional web servers by increasing the capacity of existing servers
- serves more requests for static content from web servers
- serves more requests for dynamic content from web servers
- reduces operating expenses including the cost of bandwidth required to serve content
- accelerates the response time of web servers and of page download times to end users.

When planning a reverse proxy implementation, the web server's content should be written so that it is “cache aware” to take full advantage of the reverse proxy cache.

In reverse proxy mode, the FortiGate unit functions more like a web server for clients on the Internet. Replicated content is delivered from the proxy cache to the external client without exposing the web server or the private network residing safely behind the firewall.

In this example, the site URL translates to IP address 192.168.10.1, which is the port2 IP address of the FortiGate unit. The port2 interface is connected to the Internet.

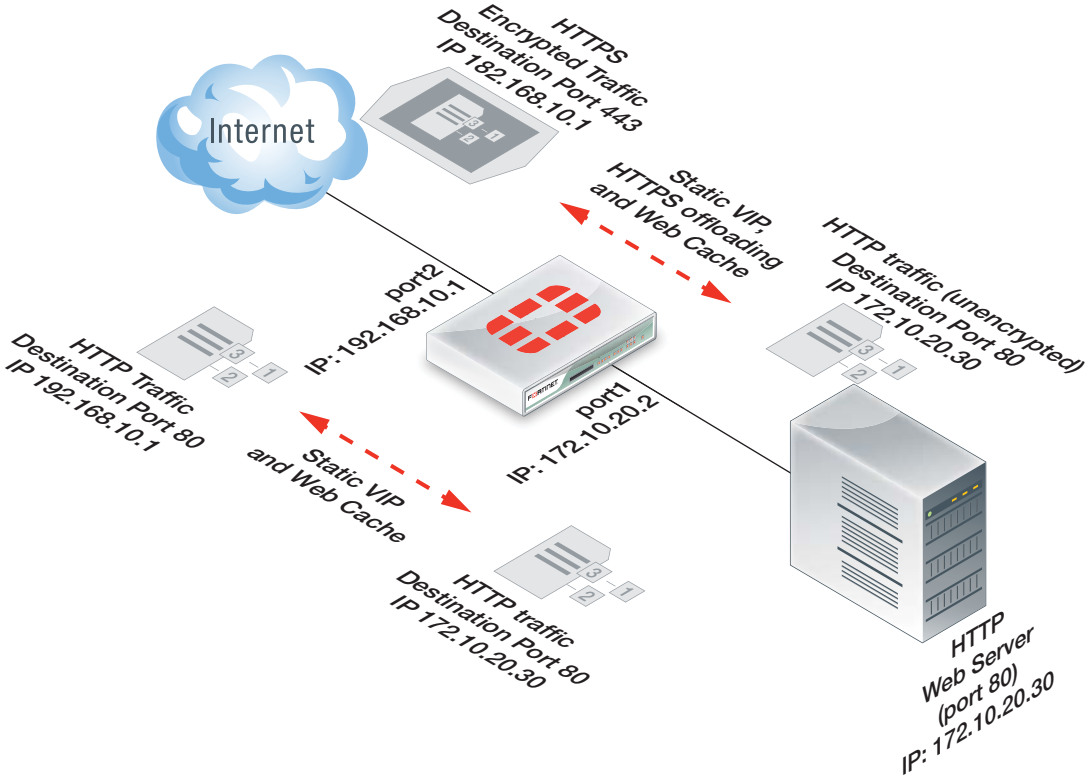
This example assumes that all HTTP traffic uses port 80 and all HTTPS traffic uses port 443.

The FortiGate unit includes the web server CA and an SSL server configuration for IP address 172.10.20.30 and port to 443. The name of the file containing the CA is Rev_Proxy_Cert_1.crt.

The destination address of incoming HTTP and HTTPS sessions is translated to the IP address of the web server using a static one-to-one virtual IP that performs destination address translation (DNAT) for the HTTP packets. The DNAT translates the destination address of the packets from 192.168.10.1 to 172.10.20.30 but does not change the destination port number.

When the SSL server on the FortiGate unit decrypts the HTTPS packets their destination port is changed to port 80.

Figure 405: Reverse proxy web caching and SSL offloading for an Internet web server using static one-to-one virtual IPs



General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Configure the FortiGate unit as a reverse proxy web cache server.
2. Configure the FortiGate unit for SSL offloading of HTTPS traffic.
3. Add an SSL server to offload SSL encryption and decryption for the web server.

Also note that if you perform any additional actions between procedures, your configuration may have different results.

Configuration steps - web-based manager

To configure the FortiGate unit as a reverse proxy web cache server

1. Go to *Firewall Objects* > *Virtual IP* > *Virtual IP* and select *Create New* to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

Name	Reverse_proxy_VIP
External Interface	port2
Type	Static NAT
Source Address Filter	Do not select.
External IP Address/Range	192.168.10.1

Mapped IP Address/Range	172.10.20.30
Port Forwarding	Do not select.

2. Select *OK*.
3. Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a port2 to port1 security policy that accepts HTTP and HTTPS traffic from the Internet.

   Do not select security profiles. Set the destination address to the virtual IP. You do not have to enable NAT.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port2
Source Address	all
Outgoing Interface	port1
Destination Address	Reverse_proxy_VIP
Schedule	always
Service	HTTP HTTPS
Action	ACCEPT

4. Select *Enable Web cache*.
5. Select *OK*.

To configure the FortiGate unit to offload SSL encryption and cache HTTPS content

1. Go to *System* > *Certificates* > *Local Certificates* and select *Import* to import the web server's CA.

   For *Type*, select *Local Certificate*. Select the *Browse* button to locate the file Rev_Proxy_Cert_1.crt.

   The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.
2. From the CLI enter the following command to add HTTPS web caching to the security policy.

   Assume the index number of the policy is 5.

```
config firewall policy
  edit 5
    set webcache-https ssl-server
  end
```

3. From the CLI, enter the following command to add the SSL server.

   The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the

destination port of the SSL traffic (443). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

```
config wanopt ssl-server
  edit rev_proxy_server
    set ip 172.10.20.30
    set port 443
    set ssl-mode half
    set ssl-cert Rev_Proxy_Cert_1
  end
```

Configuration steps - CLI

To configure the FortiGate unit as a reverse proxy web cache server

1. Enter the following command to add a static NAT virtual IP that translates destination IP addresses from 192.168.10.1 to 172.10.20.30 (and does not translate destination ports):

```
config firewall vip
  edit Reverse_proxy_VIP
    set extintf port2
    set type static-nat
    set extip 192.168.10.1
    set mappedip 172.10.20.30
  end
```

2. Enter the following command to add a port2 to port1 security policy that accepts HTTP and HTTPS traffic from the Internet. Enable web caching and HTTPS web caching.

   Do not select security profiles. Set the destination address to the virtual IP. You do not have to enable NAT.

```
config firewall policy
  edit 0
    set srcintf port2
    set srcaddr all
    set dstintf port1
    set dstaddr Reverse_proxy_VIP
    set schedule always
    set service HTTP HTTPS
    set action accept
    set webcache enable
    set webcache-https ssl-server
  end
```

To add an SSL server to offload SSL encryption and decryption for the web server

1. Place a copy of the web server's CA (file name Rev_Proxy_Cert_1.crt) in the root folder of a TFTP server.
2. Enter the following command to import the web server's CA from a TFTP server. The IP address of the TFTP server is 10.31.101.30:

```
execute vpn certificate local import tftp Rev_Proxy_Cert_1.crt
    10.31.101.30
```

   The certificate key size must be 1024 or 2048 bits. 4096-bit keys are not supported.

3. From the CLI, enter the following command to add the SSL server.

   The SSL server `ip` must match the destination address of the SSL traffic after being translated by the virtual IP (172.10.20.30) and the SSL server `port` must match the destination port of the SSL traffic (443). The SSL server operates in half mode since it performs a single-step conversion (HTTPS to HTTP or HTTP to HTTPS).

   ```
   config wanopt ssl-server
     edit rev_proxy_server
       set ip 172.10.20.30
       set port 443
       set ssl-mode half
       set ssl-cert Rev_Proxy_Cert_1
     end
   ```

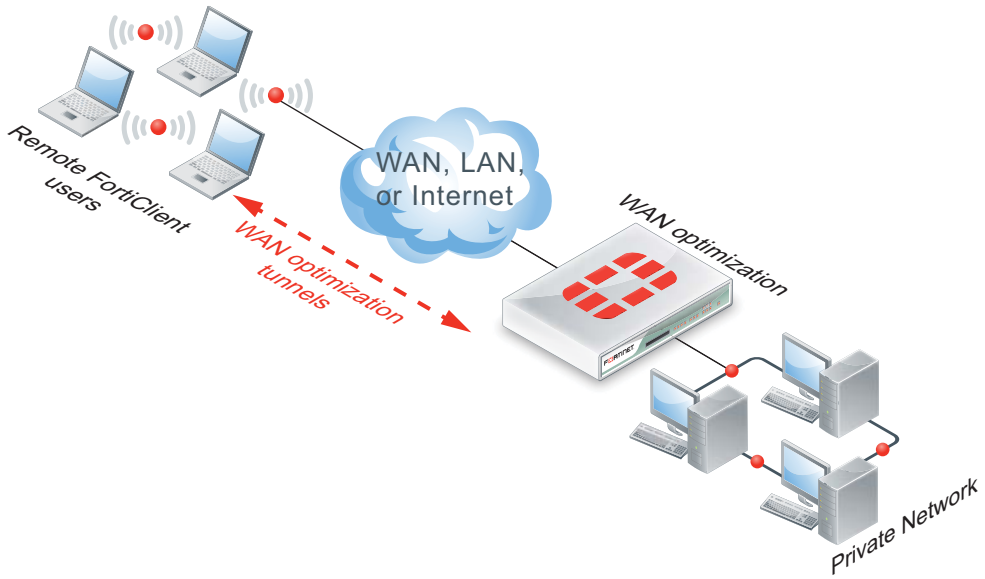
4. Configure other `ssl-server` settings that you may require for your configuration.

FortiClient WAN optimization

FortiClient WAN optimization supports protocol optimization and byte caching in IPsec VPN and SSL VPN tunnels between FortiClient and a FortiGate unit. To add WAN optimization to FortiClient, configure FortiClient Advanced settings and enable WAN optimization. This setting can then apply WAN optimization to any IPsec or SSL VPN tunnel between FortiClient and FortiGate, if the FortiGate IPsec or SSL VPN configuration also includes WAN optimization.

When FortiClient with WAN optimization enabled attempts to connect a server-side FortiGate unit, FortiClient automatically detects if WAN optimization has been added to the FortiGate tunnel configuration. If WAN optimization is detected and FortiClient can successfully negotiate with the FortiGate unit, WAN optimization starts.

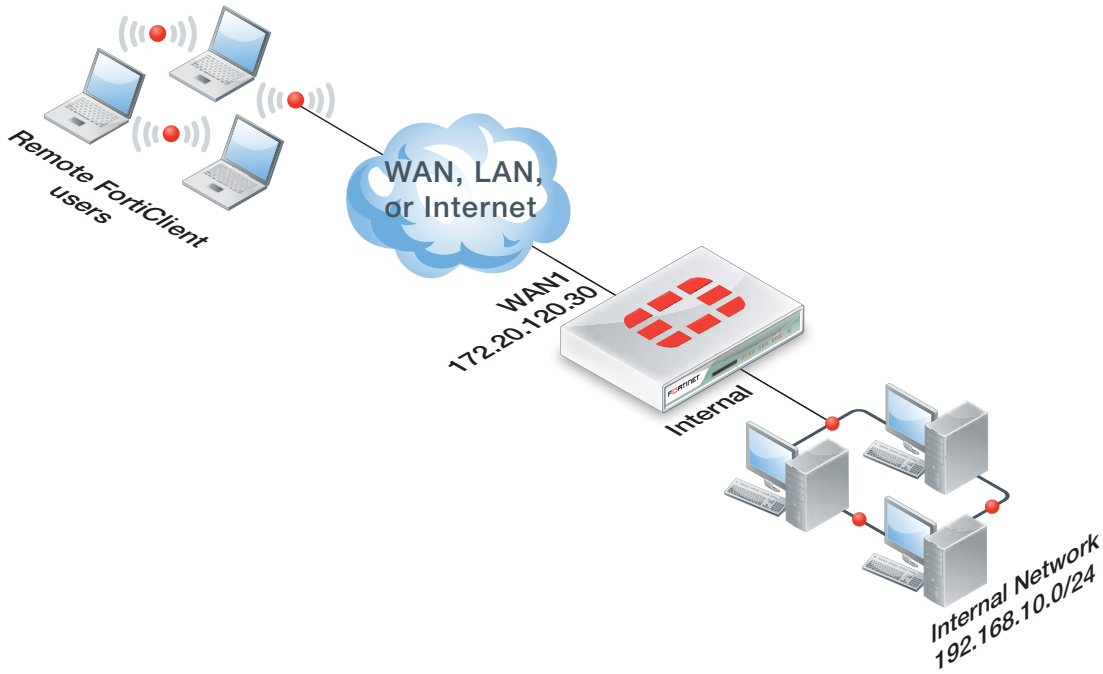
Figure 406: FortiClient WAN optimization topology



FortiClient WAN optimization over SSL VPN configuration example

This example shows how to add WAN optimization to a FortiClient SSL VPN. The SSL VPN tunnel allows remote FortiClient users to connect to the internal network behind the FortiGate unit as shown in Figure 407.

Figure 407: Example FortiClient WAN optimization configuration



To configure the FortiGate unit

Because computers running FortiClient can have IP addresses that change often, it is usually not practical to add FortiClient peers to the FortiGate WAN optimization peer list. Instead, a FortiGate unit that accepts WAN optimization tunnel requests from FortiClient is usually configured to accept any peer (see "Accepting any peers" on page 2610). This example does this by adding a WAN optimization authentication group with *Peer acceptance* set to *Accept Any Peer*.

In addition this example includes a *wanopt* to *internal* policy to allow WAN optimization traffic reach the internal network. Finally passive WAN optimization is added to the ssl.root policy because WAN optimization is accepting traffic from the SSL VPN tunnel.

1. Go to *WAN Opt. & Cache* > *WAN Opt. Peer* > *Authentication Group* and select *Create New*.
2. Configure the WAN optimization authentication group:

Name	auth-fc
Authentication Method	Certificate
Certificate	Fortinet_Firmware
Peer Acceptance	Accept Any Peer

3. Select *OK*.
4. Go to *WAN Opt. & Cache* > *WAN Opt. Profiles* > *Profiles* and select *Create New* (select the + button).

5. Add a profile for FortiClient WAN optimization sessions:

Name	Fclient_Pro
Transparent Mode	Select
Authentication Group	auth-fc

6. Select any Protocols and any settings for each protocol.
7. Select *OK*.
8. Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* to add a firewall address for the internal network that FortiClient users can access.

Category	Address
Address Name	Internal-Server-Net
Type	IP Range
Subnet / IP Range	192.168.10.0/24
Interface	internal

9. Go to *Policy* > *Policy* > *Policy* and select *Create New* to add a WAN optimization tunnel policy.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	wanopt
Source Address	all
Outgoing Interface	internal
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT

10. Select *OK*.
11. Select *Create New* to add an ssl.root policy with passive WAN optimization.

If you already have an ssl.root to internal policy you can edit it and enable passive WAN optimization as shown in Step 13.

Policy Type	Firewall
Policy Subtype	Address

Incoming Interface	ssl.root
Source Address	all
Outgoing Interface	internal
Destination Address	Internal-Server-Net
Schedule	always
Service	ALL
Action	ACCEPT

12. Optionally, select the *Security Profiles* to apply to the WAN optimization traffic.
13. Select *Enable WAN Optimization* and configure the following settings:

Enable WAN Optimization	passive
Passive Option	default

14. Select *OK*.

To configure FortiClient and start the WAN optimization SSL VPN connection

1. Open FortiClient, configure *Advanced* settings, and select *Enable WAN optimization*.
2. Add a new SSL VPN connection.

   Set the Server to the WAN1 IP address of the FortiGate unit (172.20.120.30 in this example) and the correct SSL VPN port number (usually 10443 or 443).

   No other settings are required for this example. You can add authentication in the form of a user name and password if required by the FortiGate unit.
3. Start the SSL VPN tunnel.
4. Accept the certificate.

   You should be connected to the SSL VPN tunnel and traffic in it should be optimized.

The FortiGate explicit web proxy

You can use the FortiGate explicit web proxy to enable explicit HTTP, and HTTPS proxying on one or more FortiGate interfaces. The explicit web proxy also supports proxying FTP sessions from a web browser and proxy auto-config (PAC) to provide automatic proxy configurations for explicit web proxy users. From the CLI you can also configure the explicit web proxy to support IPv6 traffic and SOCKS sessions from a web browser.

The explicit web and FTP proxies can be operating at the same time on the same or on different FortiGate interfaces.

The explicit web proxy is configured for each VDOM when multiple VDOMs are enabled.

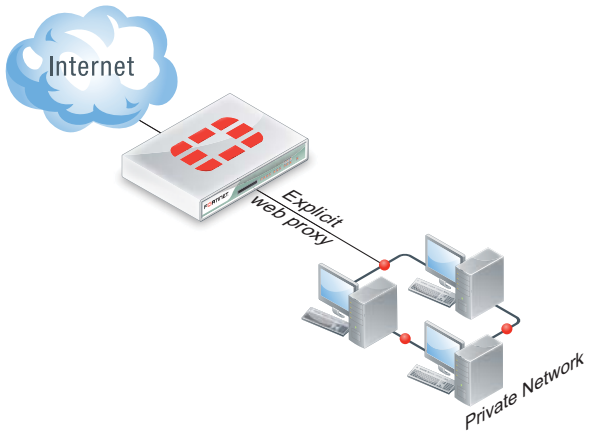
In most cases you would configure the explicit web proxy for users on a network by enabling the explicit web proxy on the FortiGate interface connected to that network. Users on the network would configure their web browsers to use a proxy server for HTTP and HTTPS, FTP, or SOCKS and set the proxy server IP address to the IP address of the FortiGate interface connected to their network. Users could also enter the PAC URL into their web browser PAC configuration to automate their web proxy configuration using a PAC file stored on the FortiGate unit.

Enabling the explicit web proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address.

If the FortiGate unit is operating in Transparent mode, users would configure their browsers to use a proxy server with the FortiGate management IP address.

The web proxy receives web browser sessions to be proxied at FortiGate interfaces with the explicit web proxy enabled. The web proxy uses FortiGate routing to route sessions through the FortiGate unit to a destination interface. Before a session leaves the exiting interface, the explicit web proxy changes the source addresses of the session packets to the IP address of the exiting interface. When the FortiGate unit is operating in Transparent mode the explicit web proxy changes the source addresses to the management IP address. For more information about explicit web proxy sessions, see “Explicit proxy sessions and user limits” on page 2686.

Figure 408: Example explicit web proxy topology



To allow all explicit web proxy traffic to pass through the FortiGate unit you can set the explicit web proxy default firewall proxy action to accept. However, in most cases you would want to use security policies to control explicit web proxy traffic and apply security features such as access control/authentication, security profiles such as antivirus and application control, and traffic logging. You can do this by keeping the default explicit web proxy security policy action to deny and then adding web-proxy security policies.

You can also change the explicit web proxy default security policy action to accept and add explicit web proxy security policies. If you do this, sessions that match web-proxy security policies are processed according to the security policy settings. Connections to the explicit web proxy that do not match a web-proxy security policy are allowed with no restrictions or additional security processing. This configuration is not recommended and is not a best practice.

Web-proxy security policies can selectively allow or deny traffic, apply authentication using user identity-based policies, enable traffic logging, and use security profiles to apply virus scanning, web filtering, IPS, application control, and DLP to explicit web proxy traffic.

You cannot configure Traffic shaping for explicit web proxy traffic. Security policies for the web proxy can only include firewall addresses not assigned to a FortiGate unit interface or with interface set to *Any*. (On the web-based manager you must set the interface to *Any*. In the CLI you must `unset` the `associated-interface`.)

Authentication of explicit web proxy sessions uses HTTP authentication and can be based on the user's source IP address or on cookies from the user's web browser. For more information, see "Explicit web proxy authentication" on page 2677.

To use the explicit web proxy, users must add the IP address of a FortiGate interface on which the explicit web proxy is enabled and the explicit web proxy port number (default 8080) to the proxy configuration settings of their web browsers.

On FortiGate units that support it, you can also enable web caching for explicit web proxy sessions.

This section describes:

- Explicit web proxy configuration overview
- IPv6 Explicit web proxy
- Proxy chaining (web proxy forwarding servers)
- Explicit web proxy authentication
- Security profiles, client reputation, device identification, and the explicit web proxy
- Web Proxy firewall services and service groups
- Example: users on an internal network browsing the Internet through the explicit web proxy with web caching, RADIUS authentication, web filtering and virus scanning
- Explicit proxy sessions and user limits

Explicit web proxy configuration overview

This section describes:

- General configuration steps
- Proxy auto-config (PAC) configuration
- Unknown HTTP version
- Authentication realm
- Other explicit web proxy options
- Restricting the IP address of the explicit web proxy
- Restricting the outgoing source IP address of the explicit web proxy

For explicit FTP proxy options, see “Explicit FTP proxy configuration overview” on page 2692.

For web proxy forwarding server options, see “Proxy chaining (web proxy forwarding servers)” on page 2674.

General configuration steps

You can use the following general steps to configure the explicit web proxy.

To enable the explicit web proxy - web-based manager

1. Go to *System* > *Network* > *Explicit Proxy*. Select *Enable Explicit Web Proxy* to turn on the explicit web proxy for HTTP and HTTPS traffic.

   You can also select FTP to enable the web proxy for FTP over HTTP sessions in a web browser (not an FTP client) and PAC to enable automatic proxy configuration.

   You can also optionally change the HTTP port that the proxy listens on (the default is 8080) and optionally specify different ports for HTTPS, FTP, and PAC.
2. Select *Apply*.

The default explicit web proxy configuration has *Default Firewall Policy Action* set to Deny and requires you to add a security policy to allow access to the explicit web proxy. This configuration is recommended as a best practice because you can use security policies to control access to the explicit web proxy and also apply security features such as logging, security profiles, and authentication (by adding identity-based policies).

3. Go to *System* > *Network* > *Interface* and select one or more interfaces for which to enable the explicit web proxy. Edit the interface configuration and select *Enable Explicit Web Proxy*.

Enabling the explicit web proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you enable the proxy on such an interface make sure authentication is required to use the proxy.

4. Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* to add a firewall address that matches the source address of packets to be accepted by the explicit proxy.

Name	Internal_subnet
Type	IP Range
Subnet / IP Range	10.31.101.1 - 10.31.101.255
Source Address	Internal_subnet
Interface	Any*

*The *Interface* must be set to *Any*.

5. Go to *Policy* > *Policy* > *Policy* and select Create New and set the *Incoming Interface* to *web-proxy.* Configure the security policy as required to accept the traffic that you want to be allowed to use the explicit web proxy.

   The source address of the policy must match client source IP addresses. The interface of this firewall address must be set to *Any*.

   The destination address of the policy should match the IP addresses of web sites that clients are connecting to. Usually the destination address would be *all* if proxying Internet web browsing.

   If *Default Firewall Policy Action* is set to *Deny*, traffic sent to the explicit web proxy that is not accepted by a web-proxy security policy is dropped. If *Default Firewall Policy Action* is set to *Allow* then all web-proxy sessions that don't match with a security policy are allowed.

   For example, the following security policy allows users on an internal network to access the Internet through the wan1 interface of a FortiGate unit.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	web-proxy
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all

Service	webproxy
Action	ACCEPT

Set the *Policy Subtype* to *User Identity* to require authentication to access the explicit web proxy. For example:

Policy Type	Firewall
Policy Subtype	User Identity
Incoming Interface	web-proxy
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Service	webproxy

Select *Create New* to add an *Authentication Rule* and configure the rule as follows:

Groups	Proxy-Group
Users	(optional)
Schedule	always
Action	ACCEPT

Add security profiles as required.

You can add multiple user identity policies to apply different authentication for different user groups and users and also apply different security profile and logging settings for different user groups.

6. Select *OK*.

To enable the explicit web proxy - CLI

1. Enter the following command to turn on the explicit web proxy for HTTP and HTTPS traffic.

```
config web-proxy explicit
  set status enable
end
```

You can also enter the following command to enable the web proxy for FTP sessions in a web browser.

```
config web-proxy explicit
  set ftp-over-http enable
end
```

The default explicit web proxy configuration has `sec-default-action` set to `deny` and requires you to add a security policy to allow access to the explicit web proxy.

2. Enter the following command to enable the explicit web proxy for the internal interface.

```
config system interface
  edit internal
    set explicit-web-proxy enable
  end
end
```

3. Use the following command to add a firewall address that matches the source address of users who connect to the explicit web proxy.

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
  end
```

   The source address for a web-proxy security policy cannot be assigned to a FortiGate interface.

4. Use the following command to add a security policy that allows all users on the 10.31.101.0 subnet to use the explicit web proxy for connections through the wan1 interface to the Internet.

```
config firewall policy
  edit 0
    set srcintf web-proxy
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set service webproxy
    set schedule always
end
```

   You can also add authentication to this policy.

```
config firewall policy
  edit 0
    set srcintf web-proxy
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set service webproxy
    set identity-based enable
      config identity-based-policy
        edit 1
          set groups Internal_users
          set utm-status enable
          set profile-protocol-options default
          set av-profile default
          set logtraffic enable
          set schedule always
      end
end
```

5. Use the following command to change global web proxy settings, for example to set the maximum request length for the explicit web proxy to 10:

```
config web-proxy global
  set max-request-length 10
end
```

Proxy auto-config (PAC) configuration

A proxy auto-config (PAC) file defines how web browsers can choose a proxy server for receiving HTTP content. PAC files include the FindProxyForURL(url, host) JavaScript function that returns a string with one or more access method specifications. These specifications cause the web browser to use a particular proxy server or to connect directly.

To configure PAC for explicit web proxy users, you can use the port that PAC traffic from client web browsers use to connect to the explicit web proxy. explicit web proxy users must configure their web browser's PAC proxy settings to use the PAC port.

PAC File Content

You can edit the default PAC file from the web-based manager or use the following command to upload a custom PAC file:

```
config web-proxy explicit
  set pac-file-server-status enable
  set pac-file-data <pac_file_str>
end
```

Where `<pac_file_str>` is the contents of the PAC file. Enter the PAC file text in quotes. You can copy the contents of a PAC text file and paste the contents into the CLI using this option. Enter the command followed by two sets of quotes then place the cursor between the quotes and paste the file content.

The maximum PAC file size is 256 kbytes. If your FortiGate unit is operating with multiple VDOMs each VDOM has its own PAC file. The total amount of FortiGate memory available to store all of these PAC files 2 MBytes. If this limit is reached you will not be able to load any additional PAC files.

You can use any PAC file syntax that is supported by your users's browsers. The FortiGate unit does not parse the PAC file.

To use PAC, users must add an automatic proxy configuration URL (or PAC URL) to their web browser proxy configuration. The default FortiGate PAC file URL is:

```
http://<interface_ip>:<PAC_port_int>/<pac_file_str>
```

For example, if the interface with the explicit web proxy has IP address 172.20.120.122, the PAC port is the same as the default HTTP explicit web proxy port (8080) and the PAC file name is proxy.pac the PAC file URL would be:

```
http://172.20.120.122:8080/proxy.pac
```

From the CLI you can use the following command to display the PAC file urls:

```
get web-proxy explicit
```

Unknown HTTP version

You can select the action to take when the proxy server must handle an unknown HTTP version request or message. Set unknown HTTP version to Reject or Best Effort. Best Effort attempts to handle the HTTP traffic as best as it can. Reject treats known HTTP traffic as malformed and drops it. The Reject option is more secure.

Authentication realm

You can enter an authentication realm to identify the explicit web proxy. The realm can be any text string of up to 63 characters. If the realm includes spaces enclose it in quotes. When a user authenticates with the explicit web proxy the HTTP authentication dialog includes the realm so you can use the realm to identify the explicitly web proxy for your users.

Other explicit web proxy options

You can change the following explicit web proxy options as required by your configuration.

HTTP port, HTTPS port, FTP port, PAC port	The TCP port that web browsers use to connect to the explicit proxy for HTTP, HTTPS, FTP and PAC services. The default port is 8080 for all services. By default HTTPS, FTP. and PAC use the same port as HTTP. You can change any of these ports as required. Users configuring their web browsers to use the explicit web proxy should add the same port numbers to their browser configurations.
Proxy FQDN	Enter the fully qualified domain name (FQDN) for the proxy server. This is the domain name to enter into browsers to access the proxy server.
Max HTTP request length	Enter the maximum length of an HTTP request in Kbytes. Larger requests will be rejected.
Max HTTP message length	Enter the maximum length of an HTTP message in Kbytes. Larger messages will be rejected.

Restricting the IP address of the explicit web proxy

You can use the following command to restrict access to the explicit web proxy using only one IP address. The IP address that you specify must be the IP address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to require uses to connect to the IP address 10.31.101.100 to connect to the explicit HTTP proxy:

```
config web-proxy explicit
  set incoming-ip 10.31.101.100
end
```

Restricting the outgoing source IP address of the explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IP address. The IP address that you specify must be the IP address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit HTTP proxy is enabled on an interface with multiple IP addresses.

For example, to restrict the outgoing packet source address to 172.20.120.100:

```
config http-proxy explicit
  set outgoing-ip 172.20.120.100
end
```

IPv6 Explicit web proxy

You can use the explicit web proxy for IPv6 web traffic. To do this you need to:

- Enable the IPv6 explicit web proxy from the CLI
- Enable the explicit web proxy for one or more FortiGate interfaces. These interfaces also need an IPv6 address
- Add web proxy security policies and add IPv6 firewall addresses to allow the explicit web proxy to accept IPv6 traffic.

If you have enabled both the IPv4 and the IPv6 explicit web proxy you can combine IPv4 and IPv6 addresses in a single explicit web proxy policy to allow both IPv4 and IPv6 traffic through the proxy.

Use the following steps to set up a FortiGate unit to accept IPv4 and IPv6 traffic for the explicit web proxy at the Internal interface and forward IPv4 and IPv6 explicit proxy traffic out the wan1 interface to the Internet.

1. Enter the following CLI command to enable the IPv6 explicit web proxy:

```
config web-proxy explicit
  set status enable
  set ipv6-status enable
end
```

2. Go to *System* > *Network* > *Interface* and edit the *internal* interface, select *Enable Explicit Web Proxy* and select *OK*.
3. Go to *Policy* > *Policy* > *Policy* and select *Create New* to add an IPv6 explicit web proxy security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	web-proxy
Source Address	Internal-IPv4-subnet
Source IPv6 Address	Internal-IPv6-subnet
Outgoing Interface	wan1
Destination Address	all
Destination IPv6 Address	all
Service	webproxy
Action	ACCEPT

This IPv6 explicit web proxy policy allows traffic from all IPv6 IP addresses to connect through the explicit web proxy and through the wan1 interface to any IPv6 addresses that are accessible from the wan1 interface.

Restricting the IP address of the explicit IPv6 web proxy

You can use the following command to restrict access to the IPv6 explicit web proxy to use only one IP6 IP address. The IPv6 address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to require uses to connect to the IPv6 address 2001:db8:0:2::30 to connect to the explicit IPv6 HTTP proxy:

```
config web-proxy explicit
  set incoming-ipv6 2001:db8:0:2::30
end
```

Restricting the outgoing source IP address of the IPv6 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IPv6 address. The IP address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit HTTP proxy is enabled on an interface with multiple IPv6 addresses.

For example, to restrict the outgoing packet source address to 2001:db8:0:2::50:

```
config http-proxy explicit
  set outgoing-ip6 2001:db8:0:2::50
end
```

Proxy chaining (web proxy forwarding servers)

For the explicit web proxy you can configure web proxy forwarding servers to use proxy chaining to redirect web proxy sessions to other proxy servers. Proxy chaining can be used to forward web proxy sessions from the FortiGate unit to one or more other proxy servers on your network or on a remote network. You can use proxy chaining to integrate the FortiGate explicit web proxy with an already existing web proxy solution.

A FortiGate unit can forward sessions to most web proxy servers including a remote FortiGate unit with the explicit web proxy enabled. No special configuration of the explicit web proxy on the remote FortiGate unit is required.

You can deploy the explicit web proxy with proxy chaining in an enterprise environment consisting of small satellite offices and a main office. If each office has a FortiGate unit, users at each of the satellite offices can use their local FortiGate unit as an explicit web proxy server. The satellite office FortiGate units can forward explicit web proxy sessions to an explicit web proxy server at the central office. From here the sessions can connect to web servers on the Internet.

FortiGate proxy chaining does not support authenticating with the remote forwarding server.

This section also describes:

- Adding a web proxy forwarding server
- Web proxy forwarding server monitoring and health checking
- Adding proxy chaining to an explicit web proxy security policy

Adding a web proxy forwarding server

To add a forwarding server, select *Create New* in the *Web Proxy Forwarding Servers* section of the *Explicit Proxy* page by going to *System* > *Network* > *Explicit Proxy*.

Server Name	Enter the name of the forwarding server.
Proxy Address	Enter the IP address of the forwarding server.
Proxy Address Type	Select the type of IP address of the forwarding server. A forwarding server can have an FQDN or IP address.
Port	Enter the port number.
Server Down action	Select what action the FortiGate unit will take if the forwarding server is down.
Enable Health Monitor	Select to enable health check monitoring.
Health Check Monitor Site	Enter the URL address of the health check monitoring site.

Use the following CLI command to add a web proxy forwarding server named `fwd-srv` at address `proxy.example.com` and port 8080.

```
config web-proxy forward-server
  edit fwd-srv
    set addr-type fqdn
    set fqdn proxy.example.com
    set port 8080
  end
```

Web proxy forwarding server monitoring and health checking

By default, a FortiGate unit monitors web proxy forwarding server by forwarding a connection to the remote server every 10 seconds. If the remote server does not respond it is assumed to be down. Checking continues and when the server does send a response the server is assumed to be back up. If you configure health checking, every 10 seconds the FortiGate unit attempts to get a response from a web server by connecting through the remote forwarding server.

You can configure health checking for each remote server and specify a different website to check for each one.

If the remote server is found to be down you can configure the FortiGate unit to block sessions until the server comes back up or to allow sessions to connect to their destination, bypassing the remote forwarding server. You cannot configure the FortiGate unit to fail over to another remote forwarding server.

Configure the server down action and enable health monitoring from the web-based manager by going to *System* > *Network* > *Explicit Proxy*, selecting a forwarding server, and changing the server down action and changing the health monitor settings.

Use the following CLI command to enable health checking for a web proxy forwarding server and set the server down option to bypass the forwarding server if it is down.

```
config web-proxy forward-server
  edit fwd-srv
    set healthcheck enable
    set monitor http://example.com
    set server-down-option pass
  end
```

Adding proxy chaining to an explicit web proxy security policy

You enable proxy chaining for web proxy sessions by adding a web proxy forwarding server to an explicit web proxy security policy. In a policy you can select one web proxy forwarding server. All explicit web proxy traffic accepted by this security policy is forwarded to the specified web proxy forwarding server.

To add an explicit web proxy forwarding server - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select Create New.
2. Configure the security policy:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	web-proxy
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	webproxy
Action	ACCEPT
Web Proxy Forwarding Server	Select, fwd-srv

3. Select OK to save the security policy.

To add an explicit web proxy forwarding server - CLI

1. Use the following command to add a security policy that allows all users on the 10.31.101.0 subnet to use the explicit web proxy for connections through the wan1 interface to the

Internet. The policy forwards web proxy sessions to a remote forwarding server named fwd-srv

```
config firewall policy
  edit 2
    set srcintf web-proxy
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set schedule always
    set service webproxy
    set webproxy-forward-server fwd-srv
end
```

Explicit web proxy authentication

You can add identity-based policies to apply authentication to explicit web proxy sessions. You can use authentication to control access to the explicit web proxy. You can also use identity-based policies to identify users and apply different security profiles to different users.

Authentication of web proxy sessions uses HTTP basic and digest authentication as described in RFC 2617 (HTTP Authentication: Basic and Digest Access Authentication) and prompts the user for credentials from the browser allowing individual users to be identified by their web browser instead of IP address. HTTP authentication allows the FortiGate unit to identify multiple users accessing services from a shared IP address. You can also select IP-based authentication to authenticate users according to their source IP address.

IP-Based authentication

IP-based authentication applies authentication by source IP address. For explicit web proxy, IP authentication is compatible with basic, digest, NTLM, form or FSSO authentication methods. Once a user authenticates, all sessions to the explicit web proxy from that IP address are assumed to be from that user and are accepted until the authentication timeout ends or the session times out.

This method of authentication is similar to standard (non-web proxy) firewall authentication and may not produce the desired results if multiple users share IP addresses (such as in a network that uses virtualization solutions or includes a NAT device between the users and the explicit web proxy).

To configure IP-based authentication, add a security policy for the explicit web proxy, set the *Policy Subtype* to *User Identity*, set the *Incoming Interface* to *web-proxy*, and make sure *IP Based* is selected before adding identity-based policies. You can also set the authentication method to basic, digest, NTLM, form or FSSO.

Use the following CLI command to add IP-based authentication to a web proxy security policy. IP-based authentication is selected by setting `ip-based` to `enable`.

```
config firewall policy
  edit 3
    set srcintf web-proxy
    set dstintf port1
    set scraddr User_network
    set dstaddr all
    set action accept
    set identity-based enable
    set ip-based enable
      config identity-based-policy
        edit 1
          set groups Internal_users
          set service ANY
          set schedule always
        end
end
```

Per session authentication

If you don't select *IP Based* the FortiGate unit applies HTTP authentication per session. This authentication is browser-based (see Figure 409 on page 2680). When a user enters a user name and password in their browser to authenticate with the explicit web proxy, this information is stored by the browser in a session cookie. Each new session started by the same web browser uses the session cookie for authentication. When the session cooke expires the user has to re-authenticate. If the user starts another browser on the same PC or closes and then re-opens their browser they have to authenticate again.

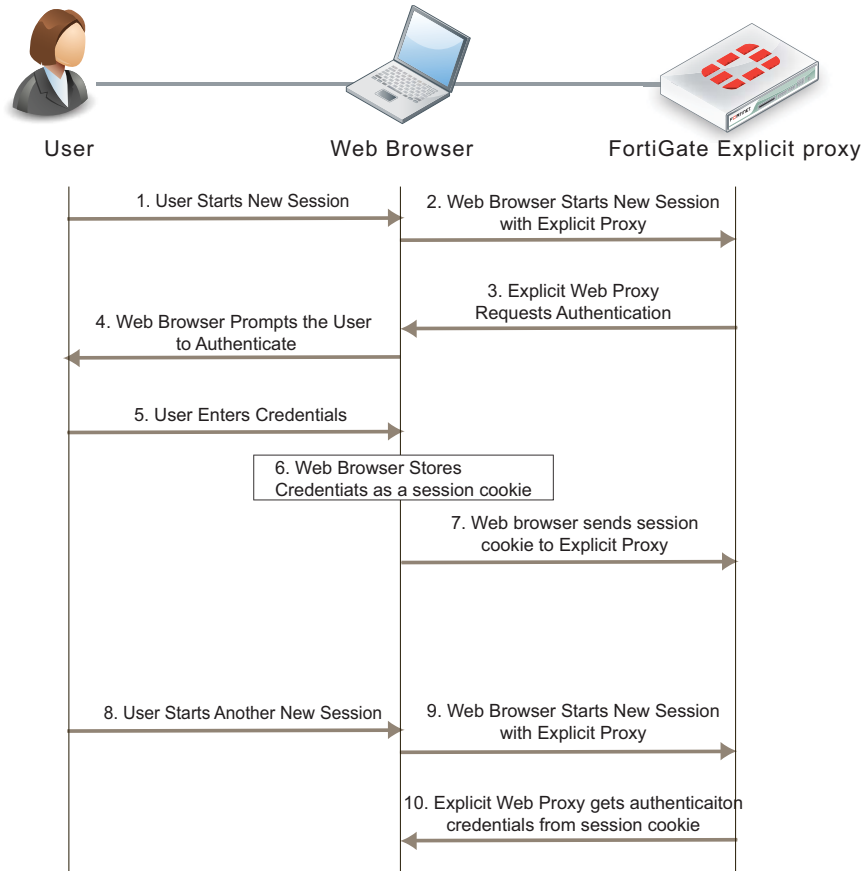
Since the authentication is browser-based, multiple clients with the same IP address can authenticate with the proxy using their own credentials. HTTP authentication provides authentication for multiple user sessions from the same source IP address. This can happen if there is a NAT device between the users and the FortiGate unit. HTTP authentication also supports authentication for other configurations that share one IP address among multiple users. These includes Citrix products and Windows Terminal Server and other similar virtualization solutions.

To configure per session authentication, add a security policy for the explicit web proxy, set the *Policy Subtype* to *User Identity*, set the *Incoming Interface* to *web-proxy*, and make sure *IP Based* is not selected before adding identity-based policies.

Use the following CLI command to add per session authentication to a security policy. Per session authentication is selected by setting `ip-based` to `disable`.

```
config firewall policy
  edit 5
    set srcintf web-proxy
    set dstintf port1
    set scraddr User_network
    set dstaddr all
    set action accept
    set identity-based enable
    set ip-based disable
      config identity-based-policy
        edit 1
          set groups Internal_users
          set service ANY
          set schedule always
        end
end
```

Figure 409: Per session HTTP authentication



Security profiles, client reputation, device identification, and the explicit web proxy

You can apply all security profiles to explicit web proxy sessions. This includes antivirus, web filtering, intrusion protection (IPS), application control, and data leak prevention (DLP) including DLP archiving features to explicit web proxy sessions. Security profiles are applied by selecting them in a web proxy security policy or a user identity policy in a web proxy security policy.

You can also enable client reputation for explicit web proxy policies.

The explicit web proxy is not compatible with device identification.

Since the traffic accepted by the explicit web proxy is known to be either HTTP, HTTPS, or FTP over HTTP and since the ports are already known by the proxy, the explicit web proxy does not use the HTTP or HTTPS proxy options settings. The explicit web proxy does support the following proxy options:

- Enable chunked bypass
- HTTP oversized file action and threshold

The explicit web proxy does not support the following proxy options:

- Client comforting
- Server comforting
- Monitor content information from dashboard. URLs visited by explicit web proxy users are not added to dashboard usage and log and archive statistics widgets.

For explicit web proxy sessions, the FortiGate unit applies antivirus scanning to HTTP POST requests and HTTP responses. The FortiGate unit starts virus scanning a file in an HTTP session when it receives a file in the body of an HTML request. The explicit web proxy can receive HTTP responses from either the originating web server or the FortiGate web cache module.

Flow-based virus scanning is not available for explicit web proxy sessions. Even if the FortiGate unit is configured to use flow-based antivirus, explicit web proxy sessions use the regular virus database.

Web Proxy firewall services and service groups

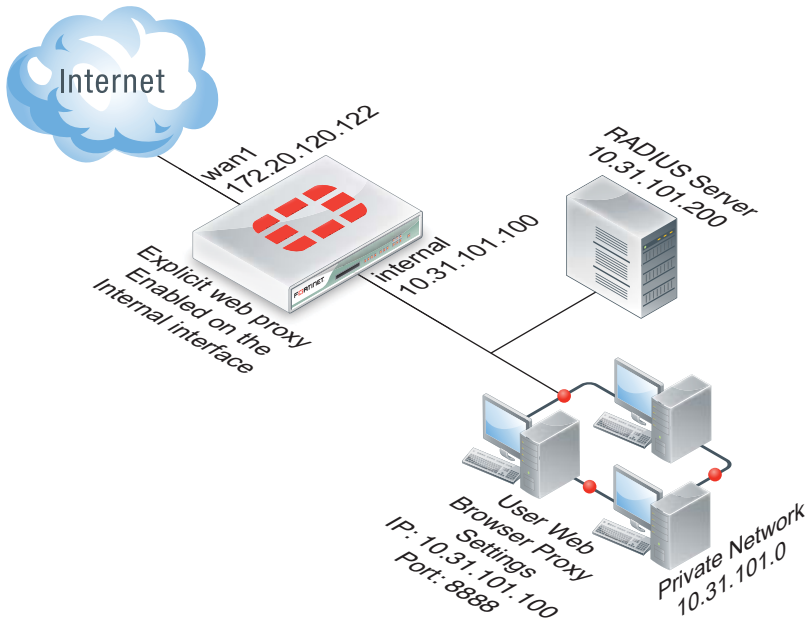
Configure web proxy services by selecting *Explicit Proxy* when configuring a service. Web proxy services can only be selected in a security policy when *web-proxy* is selected as the source interface.

Web proxy services are similar to standard firewall services. You can configure web proxy services to define one or more protocols and port numbers that are associated with each web proxy service. Web proxy services can also be grouped into web proxy service groups.

Example: users on an internal network browsing the Internet through the explicit web proxy with web caching, RADIUS authentication, web filtering and virus scanning

This example describes how to configure the explicit web proxy for the example network shown in Figure 410. In this example, users on the internal network connect to the explicit web proxy through the Internal interface of the FortiGate unit. The explicit web proxy is configured to use port 8888 so users must configure their web browser proxy settings to use port 8888 and IP address 10.31.101.100.

Figure 410: Example explicit web proxy network topology



Explicit web proxy users must authenticate with a RADIUS server before getting access to the proxy. The security policy that accepts explicit web proxy traffic applies per session authentication and includes a RADIUS server user group. The identity based policy also applies web filtering and virus scanning.

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Enable the explicit web proxy for HTTP and HTTPS and change the HTTP and HTTPS ports to 8888.
2. Enable the explicit web proxy on the internal interface.
3. Add a RADIUS server and user group for the explicit web proxy.
4. Add a user identity security policy for the explicit web proxy.

   Enable web caching

   Add an authentication rule and enable antivirus and web filtering.

Configuring the explicit web proxy - web-based manager

Use the following steps to configure the explicit web proxy from FortiGate web-based manager.

To enable and configure the explicit web proxy

1. Go to *System* > *Network* > *Explicit Proxy* and change the following settings:

Enable Explicit Web Proxy	Select *HTTP*/*HTTPS*.
Listen on Interfaces	No change. This field will eventually show that the explicit web proxy is enabled for the Internal interface.
HTTP Port	8888
HTTPS Port	8888
Realm	You are authenticating with the explicit web proxy.
Default Firewall Policy Action	Deny

2. Select *Apply*.

To enable the explicit web proxy on the Internal interface

1. Go to *System* > *Network* > *Interface*.
2. Edit the internal interface.
3. Select *Enable Explicit Web Proxy.*
4. Select *OK*.

To add a RADIUS server and user group for the explicit web proxy

1. Go to *User & Device* > *Authentication* > *RADIUS Server* and select *Create New* to add a new RADIUS server:

Name	RADIUS_1
Primary Server Name/IP	10.31.101.200
Primary Server Secret	RADIUS_server_secret

2. Select OK.

3. Go to *User & Device* > *User* > *User Group* and select *Create New* to add a new user group.

Name	Explict_proxy_user_group
Type	Firewall
Remote authentication servers	RADIUS_1
Group Name	Any

4. Select OK.

To add a security policy for the explicit web proxy

1. Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New*.
2. Add a firewall address for the internal network:

Address Name	Internal_subnet
Type	Subnet / IP Range
Subnet / IP Range	10.31.101.[1-255]
Interface	Any

3. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
4. Configure the explicit web proxy security policy.

Policy Type	Firewall
Policy Subtype	User Identity
Incoming Interface	web-proxy
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Service	webproxy

5. Select *Enable Web cache*.
6. Under *Configure Authentication Rules* select *Create New* to add an authentication rule:

Groups	Explicit_policy
Users	Leave blank
Schedule	always
Action	ACCEPT

7. Turn on *Antivirus* and *Web Filter* and select the *default* profiles for both.
8. Select the *default* proxy options profile.
9. Select OK.

10. Make sure *IP Based* is not selected.
11. Select OK.

Configuring the explicit web proxy - CLI

Use the following steps to configure the example explicit web proxy configuration from the CLI.

To enable the explicit web proxy on the Internal interface

1. Enter the following command to enable the explicit web proxy on the internal interface.

```
config system interface
  edit internal
    set explicit-web-proxy enable
end
```

To enable and configure the explicit web proxy

1. Enter the following command to enable the explicit web proxy and set the TCP port that proxy accepts HTTP and HTTPS connections on to 8888.

```
config web-proxy explicit
  set status enable
  set http-incoming-port 8888
  set https-incoming-port 8888
  set realm "You are authenticating with the explicit web proxy"
  set sec-default-action deny
end
```

To add a RADIUS server and user group for the explicit web proxy

1. Enter the following command to add a RADIUS server:

```
config user radius
  edit RADIUS_1
    set server 10.31.101.200
    set secret RADIUS_server_secret
end
```

2. Enter the following command to add a user group for the RADIUS server.

```
config user group
  edit Explicit_proxy_user_group
    set group-type firewall
    set member RADIUS_1
end
```

To add a security policy for the explicit web proxy

1. Enter the following command to add a firewall address for the internal subnet:

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
end
```

2. Enter the following command to add the explicit web proxy security policy:

```
config firewall policy
  edit 0
    set srcintf web-proxy
    set dstintf wan1
    set srcaddr Internal_subnet
    set dstaddr all
    set action accept
    set service webproxy
    set webcache enable
    set identity-based enable
    set ipbased disable
    set auth-method basic
      config identity-based-policy
        edit 1
          set groups Explicit_Proxy_user_group
          set schedule always
          set utm-status enable
          set av-profile default
          set webfilter-profile default
          set profile-protocol-options default
        end
end
```

Testing and troubleshooting the configuration

You can use the following steps to verify that the explicit web proxy configuration is working as expected:

To test the explicit web proxy configuration

1. Configure a web browser on the internal subnet to use a web proxy server at IP address 10.31.101.100 and port 8888.
2. Browse to an Internet web page.

   The web browser should pop up an authentication window that includes the phrase that you added to the Realm option.
3. Enter the username and password for an account on the RADIUS server.

   If the account is valid you should be allowed to browse web pages on the Internet.
4. Close the browser and clear its cache and cookies.
5. Restart the browser and connect to the Internet.

   You could also start a second web browser on the same PC. Or you could start a new instance of the same browser as long as the browser asks for a user name and password again.

   You should have to authenticate again because identity-based policies are set to session-based authentication.
6. If this basic functionality does not work, check your FortiGate and web browser configuration settings.
7. Browse to a URL on the URL filter list and confirm that the web page is blocked.
8. Browse to http://eicar.org and attempt to download an anti-malware test file.

   The antivirus configuration should block the file.

Sessions for web-proxy security policies do not appear on the Top Sessions dashboard widget and the count column for security policies does not display a count for explicit web proxy security policies.

9. You can use the following command to display explicit web proxy sessions

```
get test wad 60
IP based users:

Session based users:
        user:0x9c20778, username:User1, vf_id:0, ref_cnt:9

Total allocated user:1

Total user count:3, shared user quota:50, shared user count:3
```

This command output shows one explicit proxy user with user name `User1` authenticated using session-based authentication.

Explicit proxy sessions and user limits

Web browsers and web servers open and close multiple sessions with the explicit web proxy. Some sessions open and close very quickly. HTTP 1.1 keepalive sessions are persistent and can remain open for long periods of time. Sessions can remain on the explicit web proxy session list after a user has stopped using the proxy (and has, for example, closed their browser). If an explicit web proxy session is idle for more than 3600 seconds it is torn down by the explicit web proxy. See RFC 2616 for information about HTTP keepalive/persistent HTTP sessions.

This section describes proxy sessions and user limits for both the explicit web proxy and the explicit FTP proxy. Session and user limits for the two proxies are counted and calculated together. However, in most cases if both proxies are active there will be many more web proxy sessions than FTP proxy sessions.

The FortiGate unit adds two sessions to its session table for every explicit proxy session started by a web browser and every FTP session started by an FTP client. An entry is added to the session table for the session from the web browser or client to the explicit proxy. All of these sessions have the same destination port as the explicit web proxy port (usually 8080 for HTTP and 21 for FTP). An entry is also added to the session table for the session between the exiting FortiGate interface and the web or FTP server destination of the session. All of these sessions have a FortiGate interface IP address and the source address of the session and usually have a destination port of 80 for HTTP and 21 for FTP.

Proxy sessions that appear in the Top sessions dashboard widget do not include the Policy ID of the web-proxy or ftp-proxy security policy that accepted them. However, the explicit proxy sessions appear in the Top Sessions dashboard widget with a destination port that matches the explicit proxy port number (usually 8080 for the web proxy and 21 for the FTP proxy). The proxied sessions from the FortiGate unit have their source address set to the IP address of the FortiGate unit interface that the sessions use to connect to their destinations (for example, for connections to the Internet the source address would be the IP address of the FortiGate interface connected to the Internet).

FortiOS limits the number of explicit proxy users. This includes both explicit FTP proxy and explicit web proxy users. The number of users varies by FortiGate model from as low as 10 to up to 18000 for high end models. You can use the following command to display the limit on the number of explicit web proxy users for a FortiGate unit:

```
get test wad 62

Total user count:1, shared user quota:500, shared user count:1
     form_auth_keepalive=0 vd=root max=0 guarantee=0 used=1
```

This command output shows that the explicit proxy user limit (the `shared user quota`) for this FortiGate unit is 500 users.

You cannot change this limit. If your FortiGate unit is configured for multiple VDOMs this limit must be shared by all VDOMs. You can also use VDOM resource limiting to limit the number of explicit proxy users for the FortiGate unit and for each VDOM. To limit the number of explicit proxy users for the FortiGate unit from the web-based manager enable multiple VDOMs and go to *System* > *VDOM* > *Global Resources* set the number of Concurrent explicit proxy users or use the following command:

```
config global
  config system resource-limits
    set proxy 50
  end
end
```

To limit the number of explicit proxy users for a VDOM, from the web-based manager enable multiple VDOMs and go to *System* > *VDOM* > *VDOM* and edit a VDOM or use the following command to change the number of explicit web proxy users for VDOM_1:

```
config global
  config system vdom-property
    edit VDOM_1
      set proxy 25
  end
end
```

The VDOM resource limit pages on the web-based manager also display the current number of explicit web proxy users. You can also use the `get test wad 60` CLI command to view the number of explicit web proxy users. For example:

```
    get test wad 60
IP based users:
       user:0x9ab8350 username:User1, vf_id:0, ip_addr:10.31.101.10,
    ref_cnt:9

Session based users:
       user:0x9ac3c40, username:User2, vf_id:0, ref_cnt:3
       user:0x9ab94f0, username:User3, vf_id:0, ref_cnt:1

Total allocated user:3

Total user count:3, shared user quota:50, shared user count:3
```

Users may be displayed with this command even if they are no longer actively using the proxy. All idle sessions time out after 3600 seconds.

The command output shows three explicit proxy users. The user named User1 has authenticated with a security policy that includes IP-based authentication and the user's source IP address is 10.31.101.10. The users named User2 and User3 have authenticated with a security policy that includes session-based authentication.

You can use the following command to flush all current explicit proxy users. This means delete information about all users and force them re-authenticate.

```
get test wad 61
```

Users that authenticate with explicit web-proxy or ftp-proxy security policies do not appear in the *User & Device* > *Monitor* > *Firewall* list and selecting *De-authenticate All Users* has no effect on explicit proxy users.

How the number of concurrent explicit proxy users is determined depends on their authentication method:

- For session-based authenticated users, each authenticated user is counted as a single user. Since multiple users can have the same user name, the proxy attempts to identify users according to their authentication membership (based upon whether they were authenticated using RADIUS, LADAP, FSAE, local database etc.). If a user of one session has the same name and membership as a user of another session, the explicit proxy assumes this is one user.
- For IP Based authentication, or no authentication, or if no web-proxy security policy has been added, the source IP address is used to determine a user. All sessions from a single source address are assumed to be from the same user.

The explicit proxy does not limit the number of active sessions for each user. As a result the actual explicit proxy session count is usually much higher than the number of explicit web proxy users. If an excessive number of explicit web proxy sessions is compromising system performance you can limit the amount of users if the FortiGate unit is operating with multiple VDOMs.

The FortiGate explicit FTP proxy

You can use the FortiGate explicit FTP proxy to enable explicit FTP proxying on one or more FortiGate interfaces. The explicit web and FTP proxies can be operating at the same time on the same or on different FortiGate interfaces.

Explicit FTP proxies are configured for each VDOM when multiple VDOMs are enabled.

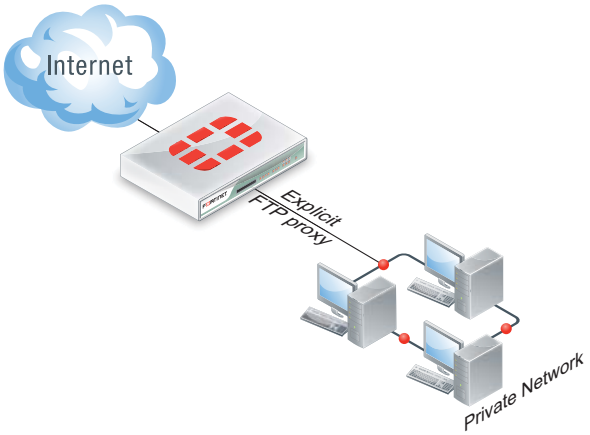
In most cases you would configure the explicit FTP proxy for users on a network by enabling the explicit FTP proxy on the FortiGate interface connected to that network. Users on the network would connect to and authenticate with the explicit FTP proxy before connecting to an FTP server. In this case the IP address of the explicit FTP proxy is the IP address of the FortiGate interface on which the explicit FTP proxy is enabled.

Enabling the explicit FTP proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address.

If the FortiGate unit is operating in Transparent mode, users would configure their browsers to use a proxy server with the FortiGate unit management IP address.

The FTP proxy receives FTP sessions to be proxied at FortiGate interfaces with the explicit FTP proxy enabled. The FTP proxy uses FortiGate routing to route sessions through the FortiGate unit to a destination interface. Before a session leaves the exiting interface, the explicit FTP proxy changes the source addresses of the session packets to the IP address of the exiting interface. When the FortiGate unit is operating in Transparent mode the explicit web proxy changes the source addresses to the management IP address.

Figure 411: Example explicit FTP proxy topology



To allow anyone to anonymously log into explicit FTP proxy and connect to any FTP server you can set the explicit FTP proxy default firewall proxy action to accept. When you do this, users can log into the explicit FTP proxy with any username and password.

In most cases you would want to use security policies to control explicit FTP proxy traffic and apply security features such as access control/authentication, security profiles, and traffic logging. You can do this by keeping the default explicit FTP proxy firewall policy action to deny and then adding ftp-proxy security policies. In most cases you would also want users to authenticate with the explicit FTP proxy. By default an anonymous FTP login is required. Usually you would add authentication, in the form of identity based policies, to ftp-proxy security policies. Users can then authenticate with the explicit FTP proxy according to user groups added to the identity based policies. User groups added to FTP proxy identity based policies can use any authentication method supported by FortiOS including the local user database and RADIUS and other remote servers.

If you leave the default firewall policy action set to deny and add ftp-proxy security policies, all connections to the explicit FTP proxy must match an ftp-proxy security policy or else they will be dropped. Sessions that are accepted are processed according to the ftp-proxy security policy settings.

You can also change the explicit FTP proxy default firewall policy action to accept and add explicit FTP proxy security policies. If you do this, sessions that match ftp-proxy security policies are processed according to the security policy settings. Connections to the explicit FTP proxy that do not match an ftp-proxy security policy are allowed and the users can authenticate with the proxy anonymously user any username and password.

There are some limitations to the security profile features that can be applied to explicit web proxy sessions. See "Security profiles, client reputation, device identification, and the explicit FTP proxy" on page 2697.

You cannot configure IPsec, SSL VPN, or Traffic shaping for explicit FTP proxy traffic. Security policies for the FTP proxy can only include firewall addresses not assigned to a FortiGate unit interface or with interface set to *any*. (On the web-based manager you must set the interface to *Any*. In the CLI you must `unset` the `associated-interface`.)

This section describes:

How to use the explicit FTP proxy to connect to an FTP server

To connect to an FTP server using the explicit FTP proxy, users must run an FTP client and connect to the IP address of a FortiGate interface on which the explicit FTP proxy is enabled. This connection attempt must use the configured explicit FTP proxy port number (default 21).

The explicit FTP proxy is not compatible with using a web browser as an FTP client. To use web browsers as FTP clients configure the explicit web proxy to accept FTP sessions.

The following steps occur when a user starts an FTP client to connect to an FTP server using the explicit FTP proxy. Any RFC-compliant FTP client can be used. This example describes using a command-line FTP client. Some FTP clients may require a custom FTP proxy connection script.

1. The user enters a command on the FTP client to connect to the explicit FTP proxy.

   For example, if the IP address of the FortiGate interface on which the explicit FTP proxy is enabled is 10.31.101.100, enter:

   ```
   ftp 10.31.101.100
   ```

2. The explicit FTP proxy responds with a welcome message and requests the user's FTP proxy user name and password and a username and address of the FTP server to connect to:

   ```
   Connected to 10.31.101.100.
   220 Welcome to Fortigate FTP proxy
   Name (10.31.101.100:user):
   ```

   You can change the message by editing the FTP Explicit Banner Message replacement message.

3. At the prompt the user enters their FTP proxy username and password and a username and address for the FTP server. The FTP server address can be a domain name or numeric IP address. This information is entered using the following syntax:

   ```
   <proxy-user>:<proxy-password>:<server-user>@<server-address>
   ```

   For example, if the proxy username and password are `p-name` and `p-pass` and a valid username for the FTP server is `s-name` and the server's IP address is `ftp.example.com` the syntax would be:

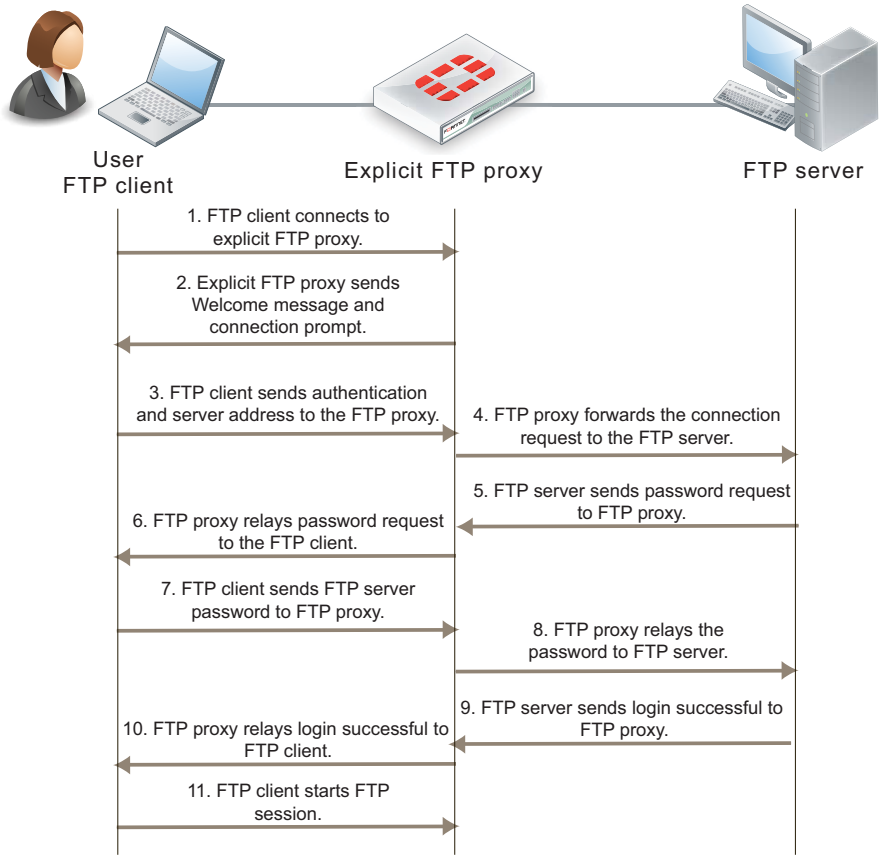
   ```
   p-name:p-pass:s-name@ftp.example.com
   ```

If the FTP proxy accepts anonymous logins `p-name` and `p-pass` can be any characters.

4. The FTP proxy forwards the connection request, including the user name, to the FTP server.
5. If the user name is valid for the FTP server it responds with a password request prompt.
6. The FTP proxy relays the password request to the FTP client.
7. The user enters the FTP server password and the client sends the password to the FTP proxy.
8. The FTP proxy relays the password to the FTP server.
9. The FTP server sends a login successful message to the FTP proxy.
10. The FTP proxy relays the login successful message to the FTP client.
11. The FTP client starts the FTP session.

    All commands entered by the client are relayed by the proxy to the server. Replies from the server are relayed back to the FTP client.

Figure 412: Explicit FTP proxy session



From a simple command line FTP client connecting to an the previous sequence could appear as follows:

```
ftp 10.31.101.100 21
Connected to 10.31.101.100.
220 Welcome to Fortigate FTP proxy
Name (10.31.101.100:user): p-name:p-pass:s-name@ftp.example.com
331 Please specify the password.
Password: s-pass
230 Login successful.
Remote system type is UNIX
Using binary mode to transfer files.
ftp>
```

Explicit FTP proxy configuration overview

This section describes:

- General configuration steps
- Restricting the IP address of the explicit FTP proxy
- Restricting the outgoing source IP address of the explicit FTP proxy

General configuration steps

You can use the following general steps to configure the explicit FTP proxy.

To enable the explicit FTP proxy - web-based manager

1. Go to *System* > *Network* > *Explicit Proxy* > *Explicit FTP Proxy Options*. Select *Enable Explicit FTP Proxy* to turn on the explicit FTP proxy.
2. Select Apply.

   The default explicit FTP proxy configuration has *Default Firewall Policy Action* set to *Deny* and requires you to add a security policy to allow access to the explicit FTP proxy. This configuration is recommended and is a best practice because you can use security policies to control access to the explicit web proxy and also apply security features such as logging, security profiles, and authentication (by adding identity-based policies).
3. Go to *System* > *Network* > *Interface* and select one or more interfaces for which to enable the explicit web proxy. Edit the interface configuration and select *Enable Explicit FTP Proxy*.

Enabling the explicit FTP proxy on an interface connected to the Internet is a security risk because anyone on the Internet who finds the proxy could use it to hide their source address. If you enable the proxy on such an interface make sure authentication is required to use the proxy.

4. Go to *Policy* > *Policy* > *Policy* and select Create New and set the *Source Interface/Zone* to *ftp-proxy.*

   You can add multiple ftp-proxy security policies.

5. Configure the security policy as required to accept the traffic that you want to be processed by the explicit web proxy.

   The source address of the policy should match client source IP addresses. The firewall address selected as the source address cannot be assigned to a FortiGate interface. The Interface field of the firewall address must be blank or it must be set to *Any*.

   The destination address of the policy should match the IP addresses of FTP servers that clients are connecting to. The destination address could be *all* to allow connections to any FTP server.

   If *Default Firewall Policy Action* is set to Deny, traffic sent to the explicit FTP proxy that is not accepted by an ftp-proxy security policy is dropped. If *Default Firewall Policy Action* is set to Allow then all web-proxy sessions that don't match with a security policy are allowed.

   For example the following security policy allows users on an internal network to access FTP servers on the Internet through the wan1 interface of a FortiGate unit.

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	ftp-proxy
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Action	ACCEPT

   The following security policy requires users on an internal network to authenticate with the FortiGate unit before accessing FTP servers on the Internet through the wan1 interface.

Policy Type	Firewall
Policy Subtype	User Identity
Incoming Interface	ftp-proxy
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all

   Select *Create New* to add an *Authentication Rule* and configure the rule as follows:

Groups	Proxy-Group
Users	(optional)
Schedule	always
Action	ACCEPT

   Add security profiles as required and select OK.

You can add multiple user identity policies to apply different authentication for different user groups and users and also apply different security profiles and logging settings for different user groups.

6. You can select other security policy options as required.

   For example, you can apply security profiles to web proxy sessions and log allowed ftp proxy traffic.

7. Select OK.

To enable the explicit web proxy - CLI

1. Enter the following command to turn on the explicit FTP proxy. This command also changes the explicit FTP proxy port to 2121.

```
config ftp-proxy explicit
  set status enable
  set incoming-port 2121
end
```

   The default explicit FTP proxy configuration has `sec-default-action` set to `deny` and requires you to add a security policy to allow access to the explicit FTP proxy.

2. Enter the following command to enable the explicit FTP proxy for the internal interface.

```
config system interface
  edit internal
    set explicit-ftp-proxy enable
  end
end
```

3. Use the following command to add a firewall address that matches the source address of users who connect to the explicit FTP proxy.

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
  end
```

   The source address for a ftp-proxy security policy cannot be assigned to a FortiGate unit interface.

4. Use the following command to add a security policy that allows all FTP proxy users on the 10.31.101.0 subnet to use the explicit FTP proxy for connections through the wan1 interface to the Internet. This policy also applies virus scanning to FTP proxy traffic.

```
config firewall policy
  edit 2
    set srcintf ftp-proxy
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set schedule always
    set utm-status enable
    set profile-protocol-options default
    set av-profile default
end
```

The following command requires FTP proxy users to authenticate with the FortiGate unit before accessing FTP servers on the Internet.

```
config firewall policy
  edit 2
    set srcintf ftp-proxy
    set dstintf wan1
    set scraddr Internal_subnet
    set dstaddr all
    set action accept
    set identity-based enable
      config identity-based-policy
        edit 1
          set groups Internal_users
          set schedule always
          set utm-status enable
          set profile-protocol-options default
          set av-profile default
    end
end
```

Restricting the IP address of the explicit FTP proxy

You can use the following command to restrict access to the explicit FTP proxy using only one IP address. The IP address that you specify must be the IP address of an interface that the explicit FTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to require uses to connect to the IP address 10.31.101.100 to connect to the explicit FTP proxy:

```
config ftp-proxy explicit
  set incoming-ip 10.31.101.100
end
```

Restricting the outgoing source IP address of the explicit FTP proxy

You can use the following command to restrict the source address of outgoing FTP proxy packets to a single IP address. The IP address that you specify must be the IP address of an interface that the explicit FTP proxy is enabled on. You might want to use this option if the explicit FTP proxy is enabled on an interface with multiple IP addresses.

For example, to restrict the outgoing packet source address to 172.20.120.100:

```
config ftp-proxy explicit
  set outgoing-ip 172.20.120.100
end
```

Security profiles, client reputation, device identification, and the explicit FTP proxy

You can apply security profiles to explicit FTP proxy sessions. This includes antivirus, intrusion protection (IPS), application control, and data leak prevention (DLP) including DLP archiving. Security profiles are applied by selecting them in a ftp proxy security policy or an identity based policy in a FTP proxy security policy.

You can also enable client reputation for explicit FTP proxy policies.

The explicit FTP proxy is not compatible with device identification.

Explicit FTP proxy sessions and protocol options

Since the traffic accepted by the explicit FTP proxy is known to be FTP and since the ports are already known by the proxy, the explicit FTP proxy does not use the FTP port protocol options settings.

When adding security profiles to an FTP proxy security policy, you must select a protocol options profile. In most cases you can select the default protocol options profile. You could also create a custom protocol options profile.

The explicit FTP proxy supports the following protocol options:

- FTP oversized file action and threshold

The explicit FTP proxy does not support the following protocol options:

- Client comforting
- Server comforting
- Monitor content information from dashboard. URLs visited by explicit FTP proxy users are not added to dashboard usage and log and archive statistics widgets.

Explicit FTP proxy sessions and antivirus

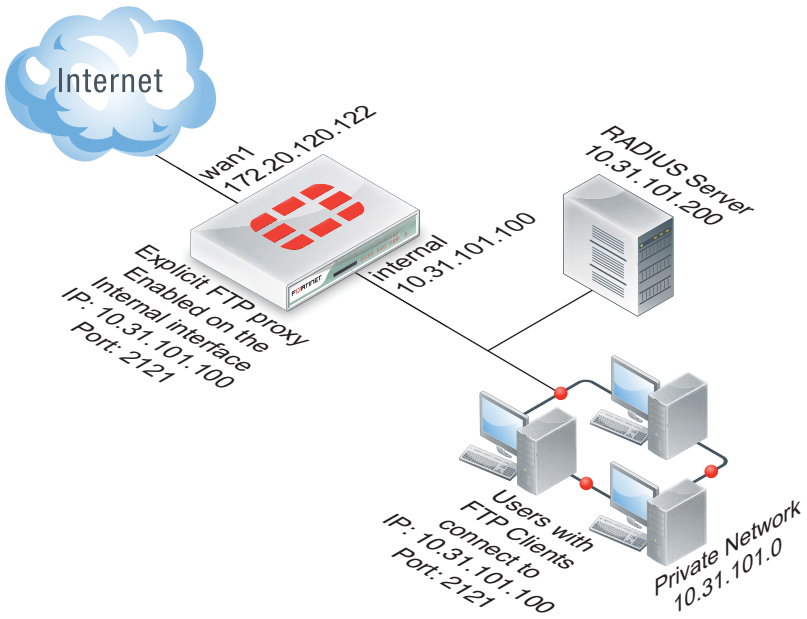
For explicit FTP proxy sessions, the FortiGate unit applies antivirus scanning to FTP file GET and PUT requests. The FortiGate unit starts virus scanning a file in an FTP session when it receives a file in the body of an FTP request.

Flow-based virus scanning is not available for explicit FTP proxy sessions. Even if the FortiGate unit is configured to use flow-based antivirus, explicit FTP proxy sessions use the regular virus database.

Example: users on an internal network connecting to FTP servers on the Internet through the explicit FTP with RADIUS authentication and virus scanning

This example describes how to configure the explicit FTP proxy for the example network shown in Figure 413. In this example, users on the internal network connect to the explicit FTP proxy through the Internal interface with IP address 10.31.101.100 of the FortiGate-51B unit. The explicit web proxy is configured to use port 2121 so to connect to an FTP server on the Internet users must first connect to the explicit FTP proxy using IP address 10.31.101.100 and port 2121.

Figure 413: Example explicit FTP proxy network topology



In this example, explicit FTP proxy users must authenticate with a RADIUS server before getting access to the proxy. To apply authentication, the security policy that accepts explicit FTP proxy traffic includes an identity based policy that applies per session authentication to explicit FTP proxy users and includes a user group with the RADIUS server in it. The identity based policy also applies virus scanning and DLP.

General configuration steps

This section breaks down the configuration for this example into smaller procedures. For best results, follow the procedures in the order given:

1. Enable the explicit FTP proxy and change the FTP port to 2121.
2. Enable the explicit FTP proxy on the internal interface.
3. Add a RADIUS server and user group for the explicit FTP proxy.
4. Add a user identity security policy for the explicit FTP proxy.

   Enable antivirus and DLP features for the identity-based policy.

Configuring the explicit FTP proxy - web-based manager

Use the following steps to configure the explicit FTP proxy from FortiGate web-based manager.

To enable and configure the explicit FTP proxy

1. Go to *System* > *Network* > *Explicit Proxy* > *Explicit FTP Proxy Options* and change the following settings:

Enable Explicit FTP Proxy	Select.
Listen on Interface	No change. This field will eventually show that the explicit web proxy is enabled for the Internal interface.
FTP Port	2121
Default Firewall Policy Action	Deny

2. Select *Apply*.

To enable the explicit FTP proxy on the Internal interface

1. Go to *System* > *Network* > *Interface*.
2. Edit the internal interface.
3. Select *Enable Explicit FTP Proxy.*
4. Select *OK*.

To add a RADIUS server and user group for the explicit FTP proxy

1. Go to *User* > *Remote* > *RADIUS*.
2. Select Create New to add a new RADIUS server:

Name	RADIUS_1
Primary Server Name/IP	10.31.101.200
Primary Server Secret	RADIUS_server_secret

3. Go to *User* > *User Group* > *User Group* and select *Create New*.

Name	Explict_proxy_user_group
Type	Firewall
Remote authentication servers	RADIUS_1
Members	RADIUS_1

4. Select OK.

To add a security policy for the explicit FTP proxy

1. Go to *Firewall Objects* > *Address* > *Address* and select *Create New*.
2. Add a firewall address for the internal network:

Address Name	Internal_subnet
Type	Subnet / IP Range

Subnet / IP Range	10.31.101.[1-255]
Interface	Any

3. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
4. Configure the explicit FTP proxy security policy.

Policy Type	Firewall
Policy Subtype	User Identity
Incoming Interface	ftp-proxy
Source Address	Internal_subnet
Outgoing Interface	wan1
Destination Address	all

5. Select Enable Identity Based Policy, make sure *IP Based* is not selected and *Auth Method* is set to *Basic*.
6. Under *Configure Authentication Rules* select *Create New* to add an authentication rule:

Groups	Explicit_policy
Users	Leave blank
Schedule	always
Action	ACCEPT

7. Select *Antivirus* and *Web Filter* and select the *default* profiles for both.
8. Select the *default* proxy options profile.
9. Select OK.
10. Select OK.

Configuring the explicit FTP proxy - CLI

Use the following steps to configure the example explicit web proxy configuration from the CLI.

To enable and configure the explicit FTP proxy

1. Enter the following command to enable the explicit FTP proxy and set the TCP port that proxy accepts FTP connections on to 2121.

```
config ftp-proxy explicit
  set status enable
  set incoming-port 2121
  set sec-default-action deny
end
```

To enable the explicit FTP proxy on the Internal interface

1. Enter the following command to enable the explicit FTP proxy on the internal interface.

```
config system interface
  edit internal
    set explicit-ftp-proxy enable
end
```

To add a RADIUS server and user group for the explicit FTP proxy

1. Enter the following command to add a RADIUS server:

```
config user radius
  edit RADIUS_1
    set server 10.31.101.200
    set secret RADIUS_server_secret
end
```

2. Enter the following command to add a user group for the RADIUS server.

```
config user group
  edit Explicit_proxy_user_group
    set group-type firewall
    set member RADIUS_1
end
```

To add a security policy for the explicit FTP proxy

1. Enter the following command to add a firewall address for the internal subnet:

```
config firewall address
  edit Internal_subnet
    set type iprange
    set start-ip 10.31.101.1
    set end-ip 10.31.101.255
end
```

2. Enter the following command to add the explicit FTP proxy security policy:

```
config firewall policy
  edit 0
    set srcintf web-proxy
    set dstintf wan1
    set srcaddr Internal_subnet
    set dstaddr all
    set action accept
    set identity-based enable
    set auth-method basic
      config identity-based-policy
        edit 1
          set groups Explicit_Proxy_user_group
          set schedule always
          set utm-status enable
          set av-profile default
          set dlp-sensor default
          set profile-protocol-options default
        end
end
```

Testing and troubleshooting the configuration

You can use the following steps to verify that the explicit FTP proxy configuration is working as expected. These steps use a command line FTP client.

To test the explicit web proxy configuration

1. From a system on the internal network start an FTP client and enter the following command to connect to the FTP proxy:

   ```
   ftp 10.31.101.100
   ```

   The explicit FTP proxy should respond with a message similar to the following:

   ```
   Connected to 10.31.101.100.
   220 Welcome to Fortigate FTP proxy
   Name (10.31.101.100:user):
   ```

2. At the prompt enter a valid username and password for the RADIUS server followed by a user name for an FTP server on the Internet and the address of the FTP server. For example, if a valid username and password on the RADIUS server is ex_name and ex_pass and you attempt to connect to an FTP server at ftp.example.com with user name s_name, enter the following at the prompt:

   ```
   Name (10.31.101.100:user):ex_name:ex_pass:s_name@ftp.example.com
   ```

3. You should be prompted for the password for the account on the FTP server.
4. Enter the password and you should be able to connect to the FTP server.
5. Attempt to explore the FTP server file system and download or upload files.
6. To test security profiles functionality, attempt to upload or download an ECAR test file. Or upload or download a tex file containing text that would be matched by the DLP sensor.

   For eicar test files, go to http://eicar.org.

Explicit FTP proxy sessions and user limits

FTP clients do not open large numbers of sessions with the explicit FTP proxy. Most sessions stay open for a short while depending on how long a user is connected to an FTP server and how large the file uploads or downloads are. So unless you have large numbers of FTP users, the explicit FTP proxy should not be adding large numbers of sessions to the session table.

Explicit FTP proxy sessions and user limits are combined with explicit web proxy session and user limits. For information about explicit proxy session and user limits, see “Explicit proxy sessions and user limits” on page 2686.

FortiGate WCCP

The Web Cache Communication Protocol (WCCP) can be used to provide web caching with load balancing and fault tolerance. In a WCCP configuration, a WCCP server receives HTTP requests from user's web browsers and redirects the requests to one or more WCCP clients. The clients either return cached content or request new content from the destination web servers before caching it and returning it to the server which in turn returns the content to the original requestor. If a WCCP configuration includes multiple WCCP clients, the WCCP server load balances traffic among the clients and can detect when a client fails and failover sessions to still operating clients. WCCP is described by the Web Cache Communication Protocol internet draft.

The sessions that are cached by WCCP depend on the configuration of the WCCP clients. If the client is a FortiGate unit, you can configure the port numbers and protocol number of the sessions to be cached. For example, to cache HTTPS traffic on port 443 the WCCP client port must be set to 443 and protocol must be set to 6. If the WCCP client should also cache HTTPS traffic on port 993 the client ports option should include both port 443 and 993.

On a FortiGate unit, WCCP sessions are accepted by a security policy before being cached. If the security policy that accepts sessions that do not match the port and protocol settings in the WCCP clients the traffic is dropped.

WCCP is configured per-VDOM. A single VDOM can operate as a WCCP server or client (not both at the same time). FortiGate units are compatible with third-party WCCP clients and servers. If a FortiGate unit is operating as an Internet firewall for a private network, you can configure it to cache and serve some or all of the web traffic on the private network using WCCP by adding one or more WCCP clients, configuring WCCP server settings on the FortiGate unit and adding WCCP security policies that accept HTTP session from the private network.

FortiGate units support WCCPv1 and WCCPv2. A FortiGate unit in NAT/Route or transparent mode can operate as a WCCP server. To operate as a WCCP client a FortiGate unit must be in NAT/Route mode. FortiGate units communicate between WCCP servers and clients over UDP port 2048. This communication can be encapsulated in a GRE tunnel or just use layer 2 forwarding.

A WCCP server can also be called a WCCP router. A WCCP client can also be called a WCCP cache engine.

This section describes:

- WCCP service groups, service numbers, service IDs and well known services
- WCCP configuration overview
- Example: caching HTTP sessions on port 80 using WCCP
- Example: caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP
- WCCP packet flow
- Configuring the forward and return methods and adding authentication
- WCCP Messages
- Troubleshooting WCCP

WCCP service groups, service numbers, service IDs and well known services

A FortiGate unit configured as a WCCP server or client can include multiple server or client configurations. Each of these configurations is called a WCCP service group. A service group consists of one or more WCCP servers (or routers) and one or more WCCP clients working together to cache a specific type of traffic. The service group configuration includes information about the type of traffic to be cached, the addresses of the WCCP clients and servers and other information about the service.

A service group is identified with a numeric WCCP service ID (or service number) in the range 0 to 255. All of the servers and clients in the same WCCP service group must have service group configurations with the same WCCP service ID.

The value of the service ID provides some information about the type of traffic to be cached by the service group. Service IDs in the range 0 to 50 are reserved for well known services. A well known service is any service that is defined by the WCCP standard as being well known. Since the service is well known, just the service ID is required to identify the traffic to be cached.

Even though the well known service ID range is 0 to 50, at this time only one well known service has been defined. Its service ID 0, which is used for caching HTTP (web) traffic.

So to configure WCCP to cache HTTP sessions you can add a service group to the WCCP router and WCCP clients with a service ID of 0. No other information about the type of traffic to cache needs to be added to the service group.

Since service IDs 1 to 50 are reserved for well know services and since these services are not defined yet, you should not add service groups with IDs in the range 1 to 50.

FortiOS does allow you to add service groups with IDs between 1 and 50. Since these service groups have not been assigned well known services; however, they will not cache any sessions. Service groups with IDs 51 to 255 allow you to set the port numbers and protocol number of the traffic to be cached. So you can use service groups with IDs 51 to 255 to cache different kinds of traffic based on port numbers and protocol number of the traffic. Service groups 1 to 50; however, do not allow you to set port numbers or protocol numbers so cannot be used to cache any traffic.

To cache traffic other than HTTP traffic you must add service groups with IDs in the range 51 to 255. These service group configurations must include the port numbers and protocol number of the traffic to be cached. It is the port and protocol number configuration in the service group that determines what traffic will be cached by WCCP.

Example WCCP server and client configuration for caching HTTP sessions (service ID = 0)

Enter the following command to add a WCCP service group to a WCCP server that caches HTTP sessions. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service

ID of this service group is 0.

```
config system wccp
  edit 0
    set router-id 10.31.101.100
    set server-list 10.31.101.0 255.255.255.0
  end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures the client to cache HTTP sessions. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group is 0.

```
config system settings
  set wccp-cache-engine enable
end

config system wccp
  edit 0
    set cache-id 10.31.101.1
    set router-list 10.31.101.100
  end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named w.<vdom_name> is added to the FortiGate configuration (for example w.root). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

Example WCCP server and client configuration for caching HTTPS sessions

Enter the following command to add a service group to a WCCP server that caches HTTPS content on port 443 and protocol 6. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service ID of this service group is 80.

```
config system wccp
  edit 80
    set router-id 10.31.101.100
    set server-list 10.31.101.0 255.255.255.0
    set ports 443
    set protocol 6
  end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures client to cache HTTPS sessions on port 443 and protocol 6. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group must be 80 to match the service ID added to the server.

```
config system settings
  set wccp-cache-engine enable
end

config system wccp
  edit 80
    set cache-id 10.31.101.1
    set router-list 10.31.101.100
    set ports 443
    set protocol 6
  end
```

Example WCCP server and client configuration for caching HTTP and HTTPS sessions

You could do this by configuring two WCCP service groups as described in the previous examples. Or you could use the following commands to configure one service group for both types of traffic. The example also caches HTTP sessions on port 8080.

Enter the following command to add a service group to a WCCP server that caches HTTP sessions on ports 80 and 8080 and HTTPS sessions on port 443. Both of these protocols use protocol number 6. The IP address of the server is 10.31.101.100 and the WCCP clients are on the 10.31.101.0 subnet. The service ID of this service group is 90.

```
config system wccp
  edit 90
    set router-id 10.31.101.100
    set server-list 10.31.101.0 255.255.255.0
    set ports 443 80 8080
    set protocol 6
  end
```

Enter the following commands to configure a FortiGate unit to operate as a WCCP client and add a service group that configures client to cache HTTP sessions on port 80 and 8080 and HTTPS sessions on port 443. The IP address of the server is 10.31.101.100 and IP address of this WCCP clients is 10.31.101.1 subnet. The service ID of this service group must be 90 to match the service ID added to the server.

```
config system settings
  set wccp-cache-engine enable
end

config system wccp
  edit 90
    set cache-id 10.31.101.1
    set router-list 10.31.101.100
    set ports 443 80 8080
    set protocol 6
  end
```

Other WCCP service group options

In addition to using WCCP service groups to define the types of traffic to be cached by WCCP the following options are available for servers and clients.

Server configuration options

The server configuration must include the `router-id`, which is the WCCP server IP address. This is the IP address of the interface that the server uses to communicate with WCCP clients.

The `group-address` is used for multicast WCCP configurations to specify the multicast addresses of the clients.

The `server-list` defines the IP addresses of the WCCP clients that the server can connect to. Often the server list can be the address of the subnet that contains the WCCP clients.

The `authentication` option enables or disables authentication for the WCCP service group. Authentication must be enabled on all servers and clients in a service group and members of the group must have the same `password`.

The `forward-method` option specifies the protocol used for communication between the server and clients. The default forwarding method is GRE encapsulation. If required by your network you can also select to use unencapsulated layer-2 packets instead of GRE or select any to allow both. The `return-method` allows you to specify the communication method from the client to the server. Both GRE and layer-2 are supported.

The `assignment-method` determines how the server load balances sessions to the clients if there are multiple clients. Load balancing can be done using hashing or masking.

Client configuration options

The client configuration includes the `cache-id` which is the IP address of the FortiGate interface of the client that communicates with WCCP server. The `router-list` option is the list of IP addresses of the WCCP servers in the WCCP service group.

The `ports` option lists the port numbers of the sessions to be cached by the client and the `protocol` sets the protocol number of the sessions to be cached. For TCP sessions the protocol is 6.

The `service-type` option can be auto, dynamic or standard. Usually you would not change this setting.

The client configuration also includes options to influence load balancing including the `primary-hash`, `priority`, `assignment-weight` and `assignment-bucket-format`.

WCCP configuration overview

To configure WCCP you must create a service group that includes WCCP servers and clients. WCCP servers intercept sessions to be cached (for example, sessions from users browsing the web from a private network). To intercept sessions to be cached the WCCP server must include a security policy that accepts sessions to be cached and WCCP must be enabled in this security policy.

The server must have an interface configured for WCCP communication with WCCP clients. That interface sends and receives encapsulated GRE traffic to and from WCCP clients. The server must also include a WCCP service group that includes a service ID and the addresses of the WCCP clients as well as other WCCP configuration options.

To use a FortiGate unit as a WCCP client, the FortiGate unit must be set to be a WCCP client (or cache engine). You must also configure an interface on the client for WCCP communication. The client sends and receives encapsulated GRE traffic to and from the WCCP server using this interface.

The client must also include a WCCP service group with a service ID that matches a service ID on the server. The client service group also includes the IP address of the servers in the service group and specifies the port numbers and protocol number of the sessions that will be cached on the client.

When the client receives sessions from the server on its WCCP interface, it either returns cached content over the WCCP interface or connects to the destination web servers using the appropriate interface depending on the client routing configuration. Content received from web servers is then cached by the client and returned to the WCCP server over the WCCP link. The server then returns the received content to the initial requesting user web browser.

Finally you may also need to configure routing on the server and client FortiGate units and additional security policies may have to be added to the server to accept sessions not cached by WCCP.

Example: caching HTTP sessions on port 80 using WCCP

In this example configuration (shown in Figure 414), a FortiGate unit with host name WCCP_srv is operating as an Internet firewall for a private network is also configured as a WCCP server. The port1 interface of WCCP_srv is connected to the Internet and the port2 interface is connected to the internal network.

All HTTP traffic on port 80 that is received at the port2 interface of WCCP_srv is accepted by a port2 to port1 security policy with WCCP enabled. All other traffic received at the port2 interface is allowed to connect to the Internet by adding a general port2 to port1 security policy below the HTTP on port 80 security policy.

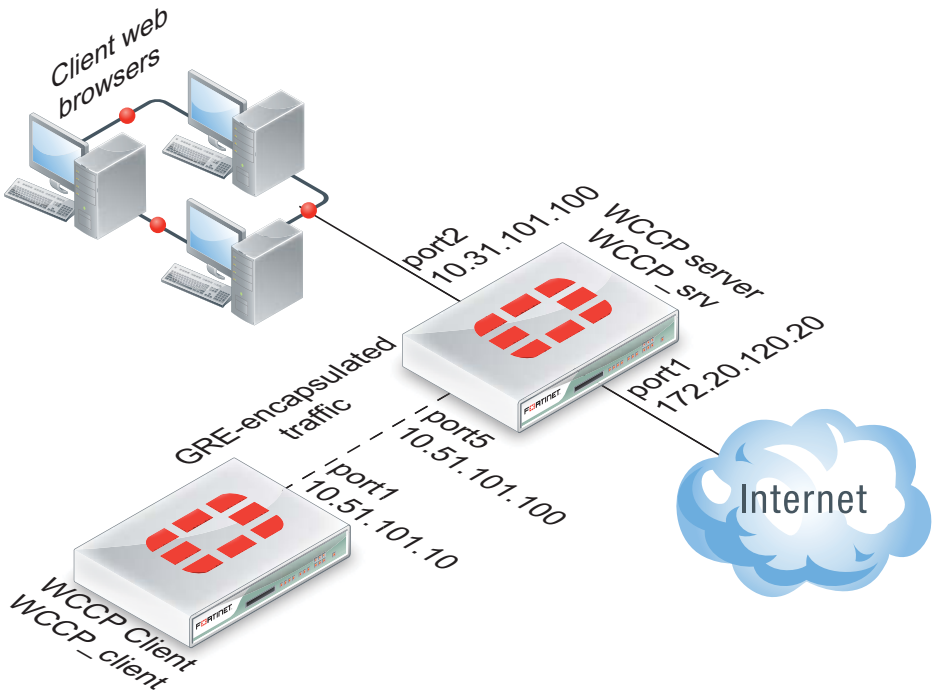
A WCCP service group is added to WCCP_srv with a service ID of 0 for caching HTTP traffic on port 80. The port5 interface of WCCP_srv is configured for WCCP communication.

A second FortiGate unit with host name WCCP_client is operating as a WCCP client. The port1 interface of WCCP_client is connected to port5 of WCCP_srv and is configured for WCCP communication.

WCCP_client is configured to cache HTTP traffic because it also has a WCCP service group with a service ID of 0.

WCCP_client connects to the Internet through WCCP_srv. To allow this, a port5 to port1 security policy is added to WCCP_srv.

Figure 414: FortiGate WCCP server and client configuration



Configuring the WCCP server (WCCP_srv)

Use the following steps to configure WCCP_srv as the WCCP server for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_srv as a WCCP server

1. Add a port2 to port1 security policy that accepts HTTP traffic on port 80 and is configured for WCCP:

```
config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service HTTP
    set wccp enable
    set nat enable
end
```

2 Add another port2 to port1 security policy to allow all other traffic to connect to the Internet.

```
.config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
end
```

3 Move this policy below the WCCP policy in the port2 to port1 policy list.

4 Enable WCCP on the port5 interface.

```
config system interface
  edit port5
    set wccp enable
end
```

5 Add a WCCP service group with service ID 0.

```
config system wccp
  edit 0
    set router-id 10.51.101.100
    set server-list 10.51.101.0 255.255.255.0
end
```

6 Add a firewall address and security policy to allow the WCCP_client to connect to the internet.

```
config firewall address
   edit WCCP_client_addr
      set subnet 10.51.101.10
end

config firewall policy
   edit 0
      set srtintf port5
      set dstintf port1
      set srcaddr WCCP_client_addr
      set dstaddr all
      set action accept
      set schedule always
      set service ANY
      set nat enable
end
```

Configuring the WCCP client (WCCP_client)

Use the following steps to configure WCCP_client as the WCCP client for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_client as a WCCP client

1. Configure WCCP_client to operate as a WCCP client.

```
config system settings
   set wccp-cache-engine enable
end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named w.<vdom_name> is added to the FortiGate configuration (for example w.root). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

2 Enable WCCP on the port1 interface.

```
config system interface
   edit port1
      set wccp enable
end
```

3 Add a WCCP service group with service ID 0.

```
config system wccp
   edit 0
      set cache-id 10.51.101.10
      set router-list 10.51.101.100
end
```

Example: caching HTTP sessions on port 80 and HTTPS sessions on port 443 using WCCP

This example configuration is the same as that shown in Figure 414 and described in “Example: caching HTTP sessions on port 80 using WCCP” on page 2708 except that WCCP now also cached HTTPS traffic on port 443. To cache HTTP and HTTPS traffic the WCCP service group must have a service ID in the range 51 to 255 and you must specify port 80 and 443 and protocol 6 in the service group configuration of the WCCP client.

Also the security policy on the WCCP_srv that accepts sessions from the internal network to be cached must accept HTTP and HTTPS sessions.

Configuring the WCCP server (WCCP_srv)

Use the following steps to configure WCCP_srv as the WCCP server for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_srv as a WCCP server

1. Add a port2 to port1 security policy that accepts HTTP traffic on port 80 and HTTPS traffic on port 443 and is configured for WCCP:

```
config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service HTTP HTTPS
    set wccp enable
    set nat enable
end
```

2 Add another port2 to port1 security policy to allow all other traffic to connect to the Internet.

```
.config firewall policy
  edit 0
    set srtintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
end
```

3 Move this policy below the WCCP policy in the port2 to port1 policy list.

4 Enable WCCP on the port5 interface.

```
config system interface
  edit port5
    set wccp enable
end
```

5 Add a WCCP service group with service ID 90 (can be any number between 51 and 255).

```
config system wccp
  edit 90
    set router-id 10.51.101.100
    set server-list 10.51.101.0 255.255.255.0
end
```

6 Add a firewall address and security policy to allow the WCCP_client to connect to the internet.

```
config firewall address
  edit WCCP_client_addr
    set subnet 10.51.101.10
end

.config firewall policy
  edit 0
    set srtintf port5
    set dstintf port1
    set srcaddr WCCP_client_addr
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
end
```

Configuring the WCCP client (WCCP_client)

Use the following steps to configure WCCP_client as the WCCP client for the example network. The example steps only describe the WCCP-related configuration.

To configure WCCP_client as a WCCP client

1. Configure WCCP_client to operate as a WCCP client.

```
config system settings
  set wccp-cache-engine enable
end
```

You cannot enter the `wccp-cache-engine enable` command if you have already added a WCCP service group. When you enter this command an interface named w.<vdom_name> is added to the FortiGate configuration (for example w.root). All traffic redirected from a WCCP router is considered to be received at this interface of the FortiGate unit operating as a WCCP client. A default route to this interface with lowest priority is added.

2 Enable WCCP on the port1 interface.

```
config system interface
  edit port1
    set wccp enable
end
```

3 Add a WCCP service group with service ID 90. This service group also specifies to cache sessions on ports 80 and 443 (for HTTP and HTTPS) and protocol number 6.

```
config system wccp
  edit 90
    set cache-id 10.51.101.10
    set router-list 10.51.101.100
    ports 80 443
    set protocol 6
end
```

WCCP packet flow

The following packet flow sequence assumes you have configured a FortiGate unit to be a WCCP server and one or more FortiGate units to be WCCP clients.

1. A user's web browser sends a request for web content.
2. The FortiGate unit configured as a WCCP server includes a security policy that intercepts the request and forwards it to a WCCP client.

   The security policy can apply security profiles to traffic accepted by the policy.
3. The WCCP client receives the WCCP session.
4. The client either returns requested content to the WCCP server if it is already cached, or connects to the destination web server, receives and caches the content and then returns it to the WCCP server.
5. The WCCP server returns the requested content to the user's web browser.
6. The WCCP router returns the request to the client web browser.

   The client we browser is not aware that all this is taking place and does not have to be configured to use a web proxy.

Configuring the forward and return methods and adding authentication

The WCCP forwarding method determines how intercepted traffic is transmitted from the WCCP router to the WCCP cache engine. There are two different forwarding methods:

- GRE forwarding (the default) encapsulates the intercepted packet in an IP GRE header with a source IP address of the WCCP router and a destination IP address of the target WCCP cache engine. The results is a tunnel that allows the WCCP router to be multiple hops away from the WCCP cache server.
- L2 forwarding rewrites the destination MAC address of the intercepted packet to match the MAC address of the target WCCP cache engine. L2 forwarding requires that the WCCP router is Layer 2 adjacent to the WCCP client.

You can use the following command on a FortiGate unit configured as a WCCP router to change the forward and return methods to L2:

```
config system wccp
  edit 1
    set forward-method L2
    set return-method L2
end
```

You can also set the forward and return methods to any in order to match the cache server configuration.

By default the WCCP communication between the router and cache servers is unencrypted. If you are concerned about attackers sniffing the information in the WCCP stream you can use the following command to enable hash-based authentication of the WCCP traffic. You must enable authentication on the router and the cache engines and all must have the same password.

```
config system wccp
  edit 1
    set authentication enable
    set password <password>
end
```

WCCP Messages

When the WCCP service is active on a web cache server it periodically sends a WCCP HERE I AM broadcast or unicast message to the FortiGate unit operating as a WCCP router. This message contains the following information:

- Web cache identity (the IP address of the web cache server).
- Service info (the service group to join).

If the information received in the previous message matches what is expected, the FortiGate unit replies with a WCCP I SEE YOU message that contains the following details:

• Router identity (the FortiGate unit's IP address.

• Sent to IP (the web cache IP addresses to which the packets are addressed)

When both ends receive these two messages the connection is established, the service group is formed and the designated web cache is elected.

Troubleshooting WCCP

Two types of debug commands are available for debugging or troubleshooting a WCCP connection between a FortiGate unit operating as a WCCP router and its WCCP cache engines.

Real time debugging

The following commands can capture live WCCP messages:

```
diag debug en
diag debug application wccpd <debug level>
```

Application debugging

The following commands display information about WCCP operations:

```
get test wccpd <integer>
diag test application wccpd <integer>
```

Where `<integer>` is a value between 1 and 5:

1. Display WCCP stats

2 Display WCCP config

3 Display WCCP cache servers

4 Display WCCP services

5 Display WCCP assignment

Enter the following command to view debugging output:

```
diag test application wccpd 3
```

Sample output from a successful WCCP connection:

```
service-0 in vdom-root: num=1, usable=1
cache server ID:
len=44, addr=172.16.78.8, weight=4135, status=0
rcv_id=6547, usable=1, fm=1, nq=0, dev=3(k3),
to=192.168.11.55
ch_no=0, num_router=1:
192.168.11.55
```

Sample output from the same command from an unsuccessful WCCP connection (because of a service group password mismatch):

```
service-0 in vdom-root: num=0, usable=0
diag debug application wccpd -1
Sample output:
wccp_on_recv()-98: vdom-root recv: num=160, dev=3(3),
172.16.78.8->192.168.11.55
wccp2_receive_pkt()-1124: len=160, type=10, ver=0200,
length=152
wccp2_receive_pkt()-1150: found component:t=0, len=20
wccp2_receive_pkt()-1150: found component:t=1, len=24
wccp2_receive_pkt()-1150: found component:t=3, len=44
wccp2_receive_pkt()-1150: found component:t=5, len=20
wccp2_receive_pkt()-1150: found component:t=8, len=24
wccp2_check_security_info()-326: MD5 check failed
```

Storage

WAN optimization storage is used for storing the byte cache and web cache databases. In most cases, you can accept the default WAN optimization storage configuration because all of the disk space available on the FortiGate unit is in one partition. By default WAN optimization and logging and archiving are configured to use this partition.

You only have to configure WAN optimization storage if you have more than one possible storage location. This can happen if you have multiple partitions that you can use for storage locations. If you have more than one storage location you can move WAN optimization storage to it. You can also configure WAN optimization to use multiple storage locations.

You can also optionally configure WAN optimization storage if you want to adjust the relative amounts of disk space available for byte caching and web caching.

This chapter contains the following topics:

Formatting the hard disk

In most cases the hard disks on your FortiGate unit should be formatted with one partition that is used for WAN optimization and Logging and Archiving. If for some reason the hard disk is not formatted you can use the following information to format it. In some cases you might also want to use the following options to erase all data from the hard disk by reformatting it.

From the web-based manager go to *System* > *Config* > *Advanced* > *Disk Management* to display information about the hard disk or disks available to the FortiGate unit. To format a hard disk, select the format icon. The hard disk format takes a few minutes and the FortiGate unit restarts after formatting is complete.

Fro this web-based manager page you can also view and change the WAN optimization and Web Cache Storage size and view how much of the WAN optimization and web cache storage has been used.

From the CLI you can use the following command to view the current disk format and partition status. See the following example for a FortiGate-51B unit.

```
execute disk list

Device I1          29.9 GB      ref: 256        SUPER TALENT (IDE)
  partition 1     29.9 GB     ref: 257       label: 2B6375792136C707
```

You can use the following command to reformat the hard disk. Use this command if for some reason the disk is not formatted correctly. The command includes the device partition reference number (256) so formats the entire disk and not just the partition.

```
execute disk format 256
```

You can use the following command to reformat the partition. The command includes the partition reference number so formats the partition, removing add data from it. You can use this command to delete all data from the partition and to fix partition errors.

```
execute disk format 257
```

Configuring WAN optimization and Web cache storage

You can use the following command to add multiple WAN optimization storage locations if your FortiGate unit has multiple disk partitions and you want to use more than one for WAN optimization storage:

```
config system storage
```

Enter `get` to see the name of the default storage location. You cannot edit this storage location, but you can add new ones:

```
config system storage
  edit new_storage
    set partition <partition_number>
end
```

Where `<partition_number>` is the number of the partition to create a storage location in. This cannot be the same as the partition added to the default storage location. This command automatically adds a WAN optimization storage location with the name `new_storage`.

Changing the amount of space allocated for WAN optimization and Web cache storage

From the web-based manager you can go to *System* > *Config* > *Advanced* > *Disk Management* to edit the WAN optimization & Web Cache storage and change the allocation size to limit the amount of storage available for WAN optimization byte caching and web caching. The size is in Mbytes.

You can use the following command to change the size of any WAN optimization storage location. For example, in the FortiGate-51B the default WAN optimization storage is `Internal`. Use the following command to limit the amount of space allocated for WAN optimization to 20 Gbytes

```
config wanopt storage
  edit Internal
    set size 20000
end
```

Adjusting the relative amount of disk space available for byte caching and web caching

By default the `config wanopt storage` command allocates the same amount disk for byte caching and for web caching. In some cases you may want to adjust the relative amounts of disk space available for these two uses. For example, if you have not implemented web caching you may want to reduce the amount of disk space used for web caching and increase the amount of space used for byte caching.

You can adjust the relative amount of disk space used for byte caching using the `webcache-storage-percentage` option of the `config wanopt storage` command. This option adjusts the percentage in the range of 0 to 100. The default percentage is 50.

To reduce the percentage of space allocated on the Internal disk for web caching to 10% (resulting in the amount of space for byte caching increasing to 90%) enter:

```
config wanopt storage
  edit Internal
    set webcache-storage-percentage 10
end
```

You can enter this command at any time without disrupting web caching or byte caching performance. Data may be lost from the cache that is reduced in size.

Diagnose commands

The following get and diagnose commands are available for troubleshooting WAN optimization, web cache, explicit proxy and WCCP.

- get test {wa_cs | wa_dbd | wad | wad_diskd | wccpd} <test_level>
- diagnose wad
- diagnose wacs
- diagnose wadbd
- diagnose debug application {wa_cs | wa_dbd | wad | wad_diskd | wccpd} [<debug_level>]

get test {wa_cs | wa_dbd | wad | wad_diskd | wccpd} <test_level>

Display usage information about WAN optimization and web-cache-related applications. Use `<test_level>` to display different information.

```
get test wa_cs <test_level>
get test wa_dbd <test_level>
get test wad <test_level>
get test wad_diskd <test_level>
get test wccpd <test_level>
```

Variable	Description
`wad`	Display information about WAN optimization, web caching, the explicit web proxy, and the explicit FTP proxy.
`wa_cs`	Display information about the WAN optimization web cache server.
`wa_dbd`	Display information about the WAN optimization storage server application.
`wad_diskd`	Display information about the WAN optimization disk access daemon application.
`wccpd`	Display information about the WCCP application.

Examples

Enter the following command to display WAN optimization tunnel protocol statistics. The http tunnel and tcp tunnel parts of the command output below shows that WAN optimization has been processing HTTP and TCP packets.

```
get test wad 11
wad tunnel protocol stats:
  http tunnel
    bytes_in=1751767 bytes_out=325468
  ftp tunnel
    bytes_in=0 bytes_out=0
  cifs tunnel
    bytes_in=0 bytes_out=0
```

```
mapi tunnel
  bytes_in=0 bytes_out=0
tcp tunnel
  bytes_in=3182253 bytes_out=200702
maintenance tunnel
  bytes_in=11800 bytes_out=15052
```

Enter the following command to display the current WAN optimization peers. You can use this command to make sure all peers are configured correctly. The command output shows one peer with IP address 172.20.120.141, peer name Web_servers, with 10 active tunnels.

```
get test wad 26
peer name=Web_servers ip=172.20.120.141 vd=0 version=1
     tunnels(active/connecting/failover)=10/0/0
       sessions=0 n_retries=0 version_valid=true
```

Enter the following command to restart the WAN optimization web cache server.

```
get test wa_cs 99
```

Enter the following command to display all test options:

```
get test wad

WAD Test Usage
1: display total memory usage
   3: display proxy status
   4: display all stats and connections
   5: toggle AV conserve mode(for debug purpose).
   8: display all fix-sized advanced memory stats
  10: toggle cifs read-ahead
  11: display tunnel protocol stats
  12: flush tunnel protocol stats
  13: display http protocol stats
  14: flush http protocol stats
  15: display cifs protocol stats
  16: flush cifs protocol stats
  17: display ftp protocol stats
  18: flush ftp protocol stats
  19: display mapi protocol stats
  20: flush mapi protocol stats
  21: display tcp protocol stats
  22: flush tcp protocol stats
  23: display all protocols stats
  24: flush all protocols stats
  25: display all listeners
  26: display all peers
  27: display DNS stats
  28: display security profile mapping for regular firewall policy
  30: display Byte Cache DB state
  31: flush Byte Cache DB stats
  32: display Web Cache DB state
  33: flush Web Cache DB stats
```

```
35: display tunnel compressor state
36: flush tunnel compressor stats
37: discard all wad debug info that is currently pending
38: display rules
39: display video cache rules (patterns)
40: display cache state
41: flush cache stats
42: display all fix-sized advanced memory stats in details
45: display memory cache state
46: flush memory cache stats
47: display SSL stats
48: flush SSL stats
49: display SSL mem stats
50: display Web Cache stats
51: flush Web Cache stats
52: flush idle Web cache objects
53: display firewall policies
54: display WAD tunnel stats.
55: display WAD fsae state.
56yxxx: set xxx concurrent Web Cache session for object storage y.
57yxxx: set xxxK(32K, 64K,...) unconfirmed write/read size per Web
   Cache object for object storage y.
58yxxxx: set xxxxK maximum ouput buffer size for object storage y.
59yxx: set lookup lowmark(only if more to define busy status) to be
   xx for object storage y.
60: display current web proxy users
61: flush current web proxy users
62: display current web proxy user summary
63: display web cache cache sessions
65: display cache exemption patterns
66: toggle dumping URL when daemon crashes.
67: list all used fqdns.
68: list all current ftpproxy sessions.
69: display ftpproxy stats.
70: clear ftpproxy stats.
600000..699999 cmem bucket stats (699999 for usage)
70yxxx: set xxxK maximum ouput buffer size for byte storage y.
71yxxx: set number of buffered add requests to be xxx for byte
   storage y.
72yxxxx: set number of buffered query requests to be xxxx for byte
   storage y.
73yxxxxx: set number of concurrent query requests to be xxxxx for
   byte storage y.
79xxxx: set xxxxMiB maximum AV memory.(0: set to default.
80: display av memory usage
81: toggle av memory protection
800..899: mem_diag commands (800 for help & usage)
800000..899999: mem_diag commands with 1 arg (800 for help & usage)
80000000..89999999: mem_diag commands with 2 args (800 for help &
   usage)
```

```
90: set to test disk failure
91: unset to test disk failure
92: trigger a disk failure event
98: gracefully stopping wad proxy
99: restart proxy
```

diagnose wad

Display diagnostic information about the WAN optimization daemon (wad).

```
diagnose wad console-log {disable | enable)
diagnose wad debug-url {disable | enable)
diagnose wad filter {clear | dport | dst | list | negate | protocol |
     sport | src | vd}
diagnose wad history {clear | list}
diagnose wad session {clear | list}
diagnose wad stats {cache | cifs | clear | crypto | ftp | http | list
     | mapi | mem | scan | scripts | summary | tcp | tunnel}
diagnose wad user {clear | list}
diagnose wad webcache {clear | list}
```

Variable	Description
`console-log`	Enable or disable displaying WAN optimization log messages on the CLI console.
`filter`	Set a filter for listing WAN optimization daemon sessions or tunnels. `clear` reset or clear the current log filter settings. `dport` enter the destination port range to filter by. `dst` enter the destination address range to filter by. `list` display the current log filter settings
`history`	Display statistics for one or more WAN optimization protocols for a specified period of time (the last 10 minutes, hour, day or 30 days).
`session`	Display diagnostics for WAN optimization sessions or clear active sessions.
`stats`	Display statistics for various parts of WAN optimization such as cache statistics, CIFS statistics, MAPI statistics, HTTP statistics, tunnel statistics etc. You can also clear WAN optimization statistics and display a summary.
`tunnel`	Display diagnostic information for one or all active WAN optimization tunnels. Clear all active tunnels. Clear all active tunnels.

Example: diagnose wad tunnel list

Enter the following command to list all of the running WAN optimization tunnels and display information about each one. The command output shows 10 tunnels all created by peer-to-peer WAN optimization rules (auto-detect set to off).

```
diagnose wad tunnel list
```

```
Tunnel: id=100 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=100 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=348 bytes_out=384

Tunnel: id=99 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=99 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=348 bytes_out=384

Tunnel: id=98 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=98 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=348 bytes_out=384

Tunnel: id=39 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=39 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=1068 bytes_out=1104

Tunnel: id=7 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=7 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=1228 bytes_out=1264

Tunnel: id=8 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=8 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=1228 bytes_out=1264

Tunnel: id=5 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=5 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=1228 bytes_out=1264

Tunnel: id=4 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=4 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=1228 bytes_out=1264
```

```
Tunnel: id=1 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=1 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=1228 bytes_out=1264

Tunnel: id=2 type=manual
    vd=0 shared=no uses=0 state=3
    peer name=Web_servers id=2 ip=172.20.120.141
    SSL-secured-tunnel=no auth-grp=
    bytes_in=1228 bytes_out=1264

Tunnels total=10 manual=10 auto=0
```

Example: diagnose wad webcache list

This following command displays the web caching stats for the last 10 minutes of activity. The information displayed is divided into 20 slots and each slot contains stats for 30 seconds

20 * 30 seconds = 600 seconds = 10 minutes

```
diagnose wad webcache list 10min
web cache history vd=0 period=last 10min
```

The first 20 slots are for HTTP requests in the last 10 minutes. Each slot of stats has four numbers, which is the total number of HTTP requests, the number of cacheable HTTP requests, the number of HTTP requests that are processed by the web cache (hits), and the number of HTTP requests that are processed without checking the web cache (bypass). There are many reasons that a HTTP request may bypass web cache.

```
total cacheable hits bypass
------------ ------------ ------------ -------------
36 10 3 1
128 92 1 10
168 97 2 3
79 56 0 3
106 64 5 3
180 118 6 11
88 53 7 3
80 43 4 4
107 44 9 2
84 12 0 2
228 139 52 10
32 2 0 5
191 88 13 7
135 25 40 3
48 10 0 8
193 13 7 7
67 31 1 2
109 35 24 6
117 36 10 5
22 0 0 4
```

The next 20 slots are for video requests in the last 10 minutes. Each slot has two numbers for each 30 seconds: total number of video requests, and the number of video requests that are processing using cached data.

```
video total video hit
------------ -------------
0 0
0 0
0 0
0 0
0 0
0 0
0 0
0 0

0 0
0 0
0 0
0 0
0 0
0 0
0 0
0 0
0 0
0 0
```

These 20 slots are for traffic details in last 10 minutes. Each slot has four numbers for 30 seconds each.

```
--- LAN --- --- WAN ---
bytes_in     bytes_out     bytes_in     bytes_out
------------ ------------- ------------ -------------
34360 150261 141086 32347

```

diagnose wacs

Display diagnostic information for the web cache database daemon (wacs).

```
diagnose wacs clear
diagnose wacs recents
diagnose wacs restart
diagnose wacs stats
```

Variable	Description
clear	Remove all entries from the web cache database.
recents	Display recent web cache database activity.
restart	Restart the web cache daemon and reset statistics.
stats	Display web cache statistics.

diagnose wadbd

Display diagnostic information for the WAN optimization database daemon (waddb).

```
diagnose wadbd {check | clear | recents | restart | stats}
```

Variable	Description
check	Check WAN optimization database integrity.
clear	Remove all entries from the WAN optimization database.
recents	Display recent WAN optimization database activity.
restart	Restart the WAN optimization daemon and reset statistics.
stats	Display WAN optimization statistics.

diagnose debug application {wa_cs | wa_dbd | wad | wad_diskd | wccpd} [<debug_level>]

View or set the debug level for displaying WAN optimization and web cache-related daemon debug messages. Include a <debug_level> to change the debug level. Leave the <debug_level> out to display the current debug level. Default debug level is 0.

```
diagnose debug application wa_cs [<debug_level>]
diagnose debug application wa_dbd [<debug_level>]
diagnose debug application wad [<debug_level>]
```

```
diagnose debug application wccpd [<debug_level>]
```

Variable	Description
wa_cs	Set the debug level for the web cache server.
wa_dbd	Set the debug level for the WAN optimization database server.
wad	Set the debug level for the WAN optimization daemon.
wccpd	Set the debug level for the WCCP daemon.
