Change Log

Date	Change Description
June 15, 2015	New section: “Exception to policy order (VIPs)” on page 956. Also added some info about best practices with VIPs to “Virtual IP Addresses (VIPs)” on page 915 and deny policies and VIPs to “Deny Policies” on page 969.
January 24, 2015	New version collecting Misc updates and fixes.
March 28, 2014	New chapters: “Certifications and Compliances” on page 768, “Hardware Acceleration” on page 1067, “IPv6 for FortiOS 5.0” on page 1828, and “Virtual FortiGate Units for FortiOS 5.0” on page 2445. Updated for FortiOS 5.0 Patch 6. Chapters re-organized to be in alphabetical order by title
2013-09-27	New chapter: “Troubleshooting” on page 2270. Updated for FortiOS 5.0 Patch 4
2013-07-11	New chapter: “FortiOS Carrier” on page 631. Updated for FortiOS 5.0 Patch 3
2013-05-27	New FortiOS 5.0 release.

Introduction

This FortiOS™ Handbook is the definitive guide to configuring and operating FortiOS 5.0. It contains concept and feature descriptions, as well as configuration examples worked out in detail for the web-based manager and the CLI. This document also contains operating and troubleshooting information.

This handbook contains the following chapters:

- Chapter 1, What's New for FortiOS 5.0 describes the new features in FortiOS 5.0.
- Chapter 10, Install and System Administration for FortiOS 5.0 describes a number of administrative tasks to configure and setup the FortiGate unit for the first time. It also describes the best practices and sample configuration tips to secure your network and the FortiGate unit itself.
- Chapter 7, Firewall for FortiOS 5.0 describes the concepts and techniques needed to configure the FortiGate firewall on your FortiGate unit.
- Chapter 13, Logging and Reporting describes how to begin choosing a log device for your logging requirements, the types of log files, how to configure your chosen log device, including detailed explanations of each log type of log message.
- Chapter 15, Unified Threat Management for FortiOS 5.0 describes the Unified Threat Management (UTM) features available on your FortiGate unit, including antivirus, intrusion prevention system (IPS), anomaly protection (DoS), one-armed IPS (sniffer policies), web filtering, email filtering, data leak prevention (DLP), and application control. The chapter includes step-by-step instructions showing how to configure each feature. Example scenarios are included, with suggested configurations.
- Chapter 3, Authentication for FortiOS 5.0 defines authentication and describes the FortiOS options for configuring authentication for FortiOS.
- Chapter 14, Managing Devices for FortiOS 5.0 describes how to control network access for different types of personal mobile devices and apply client reputation.
- Chapter 11, IPsec VPN for FortiOS 5.0 provides a general introduction to IPsec VPN technology, explains the features available with IPsec VPN and gives guidelines to decide what features you need to use, and how the FortiGate unit is configured to implement the features.
- Chapter 16, SSL VPN for FortiOS 5.0 provides a general introduction to SSL VPN technology, explains the features available with SSL VPN and gives guidelines to decide what features you need to use, and how the FortiGate unit is configured to implement the features.
- Chapter 2, Advanced Routing for FortiOS 5.0 provides detailed information about FortiGate dynamic routing including common dynamic routing features, troubleshooting, and each of the protocols including RIP, BGP, and OSPF.
- Chapter 19, Virtual Domains describes FortiGate Virtual Domains (VDOMs) and is intended for administrators who need guidance on solutions to suit different network needs and information on basic and advanced configuration of VDOMs. Virtual Domains (VDOMs)

multiply the capabilities of your FortiGate unit by using virtualization to partition your resources.

- Chapter 9, High Availability for FortiOS 5.0 describes FortiGate HA, the FortiGate Clustering Protocol (FGCP), FortiGate support of VRRP, and FortiGate standalone TCP session synchronization.
- Chapter 17, Traffic Shaping for FortiOS 5.0 describes how to configure FortiOS traffic shaping.
- Chapter 4, FortiOS Carrier describes FortiOS Carrier Multimedia messaging service (MMS) protection and GPRS Tunneling Protocol (GTP) protection.
- Chapter 6, Deploying Wireless Networks for FortiOS 5.0 describes how to configure wireless networks with FortiWiFi, FortiGate, and FortiAP units.
- Chapter 21, VoIP Solutions: SIP for FortiOS 5.0 describes FortiOS SIP support.
- Chapter 22, WAN Optimization, Web Cache, Explicit Proxy, and WCCP for FortiOS 5.0 describes how FortiGate WAN optimization, web caching, and web proxy work and also describes how to configure these features.
- Chapter 12, Load Balancing for FortiOS 5.0 describes firewall HTTP, HTTPS, SSL or generic TCP/UDP or IP server load balancing.

Chapter 1 What's New for FortiOS 5.0

This FortiOS Handbook chapter contains the following sections:

- New Features in FortiOS 5.0 Patch 7 highlights the vulnerability fix for the Heartbleed vulnerability that was added to FortiOS 5.0 in Patch 7.
- New features in FortiOS 5.0 Patch 6 highlights some of the changes in FortiOS 5.0 Patch 6.
- New features in FortiOS 5.0 Patch 5 highlights some of the changes in FortiOS 5.0 Patch 5.
- New features in FortiOS 5.0 Patch 4 highlights some of the changes in FortiOS 5.0 Patch 4.
- New features in FortiOS 5.0 Patch 3 highlights some of the changes in FortiOS 5.0 Patch 3.
- New features in FortiOS 5.0 Patch 2 highlights some of the changes in FortiOS 5.0 Patch 2.
- Security Features describes new Security features.
- Authentication: users and devices describes what's new for FortiOS user authentication and device management.
- FortiOS and BYOD outlines how to configure FortiOS device identification and BYOD protection features.
- Client Reputation introduces the new client reputation feature.
- Wireless describes new wireless features**.**
- IPv6 describes new IPv6 features and how to configure many of them.
- Logging and reporting summarizes new FortiOS 5.0 logging and reporting features.
- Firewall describes the firewall features new to FortiOS 5.0.
- WAN optimization and Web Caching provides an overview and some examples that show how you need to change your FortiOS 4.3 WAN optimization configuration to work with FortiOS 5.0 WAN optimization, which is now policy-based.
- Usability enhancements describes some enhancements that make the web-based manager easier to use and more effective.
- SSL VPN describes some new SSL VPN features
- Other new features lists other new features in FortiOS 5.0.

New Features in FortiOS 5.0 Patch 7

This chapter provides information on the vulnerability fix added in FortiOS 5.0 Patch 7.

OpenSSL Vulnerability (Heartbleed) Fixed

An information disclosure vulnerability, known as Heartbleed, has been discovered in OpenSSL version 1.0.1 up to 1.0.1f. This vulnerability may allow an attacker to access sensitive information from memory by sending crafted TLS heartbeat requests.

This vulnerability has been fixed in OpenSSL 1.0.1g. FortiOS 5.0 Patch 7 has been upgraded to use this version of OpenSSL.

For more information about the Heartbleed vulnerability, go to https://heartbleed.com/.

New features in FortiOS 5.0 Patch 6

This chapter provides a brief introduction to the following features that were added to Patch 6 of FortiOS 5.0. See the release notes for a complete list of new features/resolved issues in this release.

Endpoint Control Daemon Improvement

Endpoint Control has been improved in several ways:

- For FortiGate models 3000 and higher, the maximum limit of FortiClient registration licence has been increased from 8000 to 16000.
- The intervals between KeepAlive messages are now configurable on the FortiGate unit, so that the interval value can be adjusted to get a trade-off between accuracy and the FortiGate workload. This value can be configured in the CLI:

  `set forticlient-keepalive-interval <interval>` (interval measured in seconds).
- The intervals between two system update messages can be configured through the CLI:

  `set forticlient-sys-update-interval <interval>` (interval measured in minutes).
- KeepAlive timestamps are now be stored use a in-memory avl tree structure, in order to decrease the number of CMDB savings.
- A mixed TCP/UDP mechanism now handles the registration sync.
- FortiClient registration information is stored using a hard disk instead of flash disk.

IPS Hardware Acceleration

New CLI commands have been added for configuring IPS hardware acceleration, replacing the previous `set hardware-accel-mode` command, to provide finer control over the settings. There are now two settings that can be chosen, one for the network processor and one for the content processor.

Network processor acceleration can be disabled or set to enable basic acceleration. Content processor acceleration can be disabled or enabled for either basic or advanced acceleration.

Syntax

```
config ips global
   set np-accel-mode {none | basic}
   set cp-accel-mode {none | basic | advanced}
end
```

802.11g Protection Mode

802.11g Protection Mode can now be enabled on managed FortiAP to avoid interference from 802.11b signals. Protection Mode can be set for RTS and CTS protection, or just for CTS.

Syntax

```
config wireless-controller wtp-profile
   edit <name>
      config radio-1
         set protection-mode {ctsonly | disable | rtscts}
      end
   end
end
```

Miglogd Child Processes

The number of miglogd child processes can now be configured directly through CLI to a value between 0-15, in order to keep up with logging requirements. The default number of child processes is 8.

Log messages are not lost if the number of child processes is decreased.

Syntax

```
config system global
   set miglogd-children <integer>
end
```

Increasing the number of child processes may affect a FortiGate unit's performance.

IPv6 in CRL/SCEP

IPv6 is now supported for all certificate revocation list (CRL) and Simple Certificate Enrollment Protocol (SCEP) features.

Extended IPS Database for D-series Desktop Models

The extended IPS database has been added for FortiGate D-series Desktop models. The extended database is disabled by default, but can be enabled in the CLI.

Syntax

```
config ips global
  set database extended
end
```

Enabling the extended IPS database may affect the performance of a FortiGate unit.

Logging Options for 3000 and 5000 Series Models

To increase stability of the 3000 series and 5000 series FortiGate models, the following changes have been made:

- Disk logging is disabled by default, but can be enabled through the CLI.
- When disk logging is disabled, it will not appear disk logging as an option on these models.

The default logging method for these models is now memory logging, which has been reintroduced as an option.

Wireless Controller on FortiGate-30D

The Wireless Controller has been added to the FortiGate-30D, which is now able to manage a maximum of 2 FortiAP units.

By default, this feature is only available through the CLI. To enable the Wireless Controller menu in the web-based manager support, enter the following command in the CLI:

```
config system global
  set gui-wireless-controller enable
end
```

When enabled, the default WiFi menu will be replaced by the full Wireless Controller menu in the web-based manager.

You can also use the command `set gui-ap-profile enable` to enable FortiAP and WIDS profiles.

New features in FortiOS 5.0 Patch 5

This chapter provides a brief introduction to the following features that were added to Patch 5 of FortiOS 5.0. See the release notes for a complete list of new features in this release.

Improvements to Endpoint Control

There have been several improvements made to Endpoint Control.

New menu options

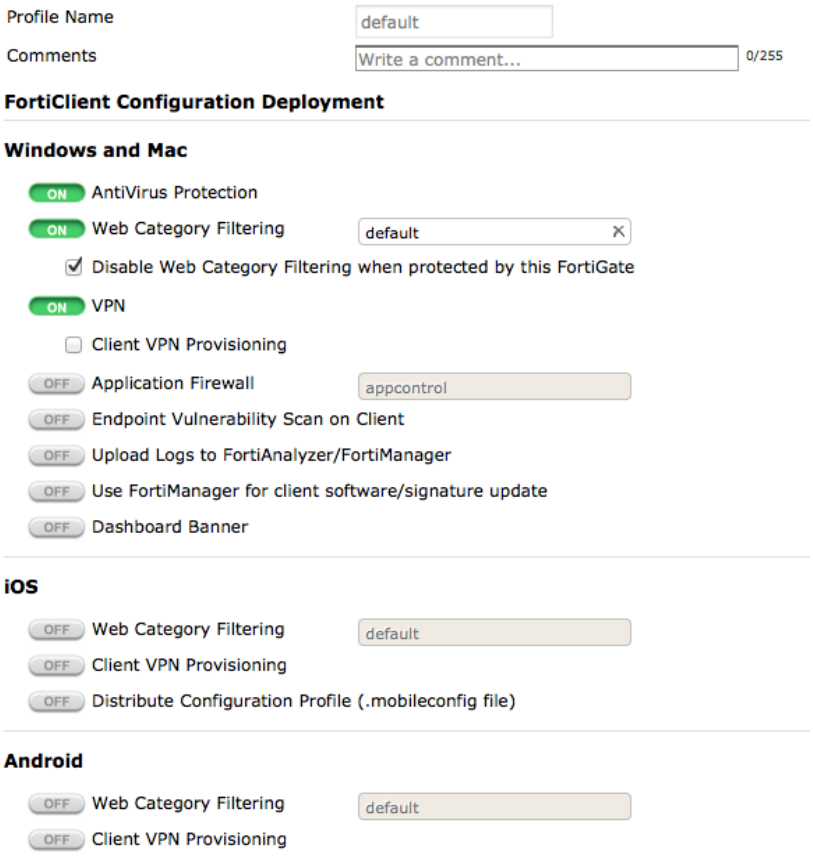
Endpoint Control now has its own menu, which can be found at *User & Device* > *Endpoint Protection.* This menu contains options for creating FortiClient profiles.

Default profile

A default FortiClient profile has been added that enables AntiVirus, Web Filtering, and VPN for Windows and Mac. All other features are disabled.

The profile creation screen has also been simplified to allow for easier configuration.

Figure 1: The default FortiClient profile



FortiClient Monitor

The FortiClient Monitor displays a variety of information about FortiClient users, including current status, device type, and FortiClient version. It can be found by going to *User & Device* > *Monitor* > *FortiClient*.

FortiAP LAN port support

New functions are now available for FortiAP models that have LAN ports (currently the 11C, 14C, and 28C). The LAN port(s) can now be bridged to either an SSID or to the FortiAP unit's WAN port (bridging to the WAN port is the default setting).

LAN port bridging can be done with FortiAP units in either Bridge or Tunnel mode.

Bridging with the FortiAP's SSID(s)

Bridging the LAN port with the FortiAP's SSID(s) allows combines traffic from both sources to provide a single broadcast domain for the wired and wireless users.

This configuration has the following features:

- The IP addresses for LAN clients come from the DHCP server that is serving the wireless clients.
- Traffic from LAN clients is bridged to the VLAN used by the SSID to send traffic to the controller.
- Wireless and LAN clients are on the same network and can communicate locally, via the FortiAP.

Bridging with the WAN port

Bridging the LAN port with the WAN port allows the FortiAP unit to be used as a hub which is also an access point.

This configuration has the following features:

- The IP addresses for LAN clients come from the WAN directly and will typically be in the same range as the AP itself.
- All LAN client traffic is bridged directly to the WAN interface.
- Communication between wireless and LAN clients can only occur if a policy on the FortiGate unit allows it.

Configuring bridging

A FortiAP LAN port can be configured to bridge with an SSID from either the web-based manager or the CLI.

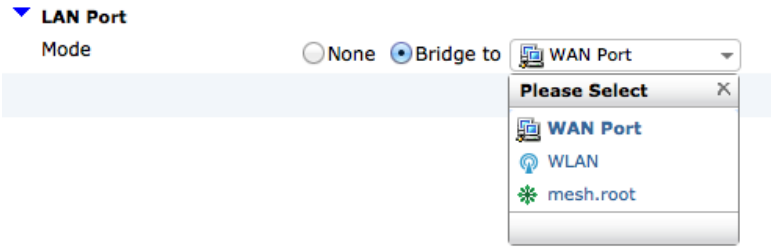
Using the web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *Custom AP Profiles.*

On FortiGate models 100D, 200D, 240D, 600C, 800C, and 1000C, go to *WiFi & Switch Controller* > *WiFi Network* > *Custom AP Profiles.*

2. Create a new custom profile or edit the default profile for your FortiAP model.
3. Under *LAN Port*, change *Mode* to *Bridge to* and select the appropriate option.
4. Select *OK.*

Figure 2: Configuring bridging using the web-based manager



Bridging can also be set up configured on a specific FortiAP unit, rather than through the use of an AP profile by going to *WiFi Controller* > *Managed Devices* > *Managed FortiAPs.*

On FortiGate models 100D, 200D, 240D, 600C, 800C, and 1000C, go to *WiFi & Switch Controller* > *Managed Devices* > *Managed FortiAPs.*

Using the CLI

In the example below, two ports on a FortiAP-28C are configured, with port 1 bridged to the WAN port and port 2 bridged to the SSID(s):

```
config wireless-controller wtp-profile
  edit FAP28C-default
    config lan
      set port1-mode bridge-to-wan
      set port2-mode bridge-to-ssid
    end
  end
end
```

Bridging can also be set up configured on a specific FortiAP unit, rather than through the use of an AP profile:

```
config wireless-controller wtp
  edit FAP28C0123456789
    config lan
      set port1-mode bridge-to-wan
      set port2-mode bridge-to-ssid
    end
  end
end
```

Restrictions

- While the FortiAP-14C has four physical LAN ports, these ports must share the same configuration.
- Any host connected to a LAN port will be taken as authenticated.
- The use of dynamic VLANs for the host behind LAN port is not supported.
- RADIUS MAC authentication for the host behind LAN port is not supported.

Automatically allowing basic applications

Application control profiles can now be configured from the CLI to allow basic, commonly used applications to go through without having to separately configure the profile each application. This is useful when you wish to control the traffic to an entire category of applications without affecting the traffic for basic applications that are required on a daily basis.

For example, an application sensor that blocks the Category "Network.Service" would normally also block DNS service, causing Internet service issues. Using the new command, DNS can now be allowed, eliminating this issue while still blocking other applications within the category.

Basic traffic can also be allowed for ICMP, generic HTTP web browsing, and generic SSL communication.

Syntax

```
config application list
  edit appcontrol
    set options allow-dns allow-icmp allow-http allow-ssl
end
```

DNS is set to be allowed be default for all application control profiles, while the other settings must be enabled to take effect.

Pre-authorizing a FortiAP unit

Users can now pre-authorize a FortiAP unit by before connecting the unit to the FortiGate unit. To pre-authorize a FortiAP unit, do the following:

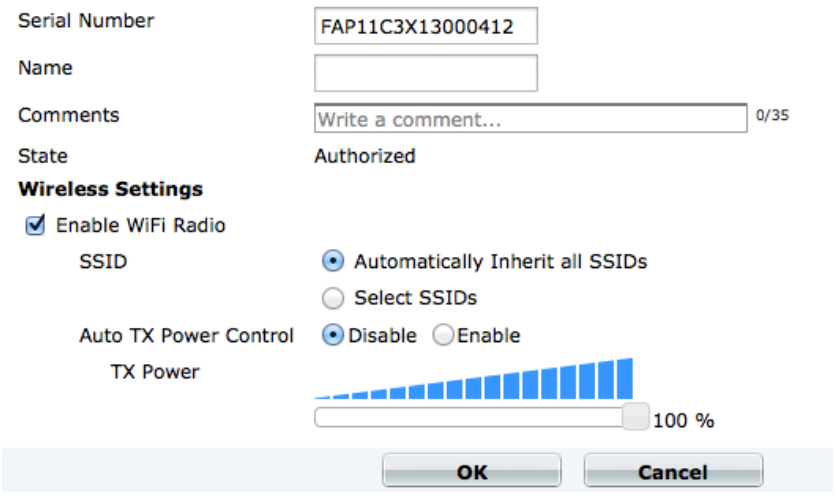
1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAPs* and select *Create New*.

On FortiGate models 100D, 200D, 240D, 600C, 800C, and 1000C, go to *WiFi & Switch Controller* > *Managed Devices* > *Managed FortiAPs*

2. Enter the serial number of the FortiAP unit.
3. Configure the *Wireless Settings* as required.
4. Select *OK*.

The new FortiAP now appear on the Managed FortiAPs list as authorized but off-line. The FortiAP unit can now connect to the FortiGate unit.

Figure 3: Pre-authorizing a FortiAP unit



If the FortiAP unit will be connecting directly to one of the FortiGate unit's ports, the port will still need to have its *Addressing mode* set to *Dedicate to FortiAP*.

Preventing IP fragmentation of packets in CAPWAP tunnels

A common problem with controller-based WiFi networks is reduced performance due to IP fragmentation of the packets in the CAPWAP tunnel.

Fragmentation can occur because of CAPWAP tunnel overhead increasing packet size. If the original wireless client packets are close to the maximum transmission unit (MTU) size for the network (usually 1500 bytes for Ethernet networks unless jumbo frames are used) the resulting CAPWAP packets may be larger than the MTU, causing the packets to be fragmented. Fragmenting packets can result in data loss, jitter, and decreased throughput.

The FortiOS/FortiAP solution to this problem is to cause wireless clients to send smaller packets to FortiAP devices, resulting in1500-byte CAPWAP packets and no fragmentation. The following options configure CAPWAP IP fragmentation control:

```
config wireless-controller wtp-profile
  edit new-wtp
    set ip-fragment-preventing {tcp-mss-adjust | icmp-unreachable}
    set tun-mtu-uplink {0 | 576 | 1500}
    set tun-mtu-downlink {0 | 576 | 1500}
  end
end
```

By default, `tcp-mss-adjust` is enabled, `icmp-unreachable` is disabled, and `tun-mtu-uplink` and `tun-mtu-downlink` are set to 0.

To set `tun-mtu-uplink` and `tun-mtu-downlink`, use the default TCP MTU value of 1500. This default configuration prevents packet fragmentation because the FortiAP unit limits the size of TCP packets received from wireless clients so the packets don't have to be fragmented before CAPWAP encapsulation.

The `tcp-mss-adjust` option causes the FortiAP unit to limit the maximum segment size (MSS) of TCP packets sent by wireless clients. The FortiAP does this by adding a reduced MSS value to the SYN packets sent by the FortiAP unit when negotiating with a wireless client to establish a session. This results in the wireless client sending packets that are smaller than the `tun-mtu-uplink` setting, so that when the CAPWAP headers are added, the CAPWAP packets have an MTU that matches the `tun-mtu-uplink` size.

The `icmp-unreachable` option affects all traffic (UDP and TCP) between wireless clients and the FortiAP unit. This option causes the FortiAP unit to drop packets that have the "Don't Fragment" bit set in their IP header and that are large enough to cause fragmentation and then send an ICMP packet -- type 3 "ICMP Destination unreachable" with code 4 "Fragmentation Needed and Don't Fragment was Set" back to the wireless controller. This should cause the wireless client to send smaller TCP and UDP packets.

Limiting access for unauthenticated users

When configuring User Identity policies, if you select the option *Skip this policy for unauthenticated user* the policy will only apply to users who have already authenticated with the FortiGate unit. This feature is intended for networks with two kinds of users:

- Single sign-on users who have authenticated when their devices connected to their network
- Other users who do not authenticate with the network so are “unauthenticated”

Sessions from authenticated users can match this policy and sessions from unauthenticated users will skip this policy and potentially be matched with policies further down the policy list. Typically, you would arrange a policy with *Skip this policy for unauthenticated user* at the top of a policy list.

You can also use the following CLI command to enable skipping policies for unauthenticated users:

```
config firewall policy
  edit <id>
    set identity-based enable
    set fall-through-unauthenticated enable
    next
```

Use case - allowing limited access for unauthenticated users

Consider an office with open use PCs in common areas. Staff and customers do not have to log in to these PCs and can use them for limited access to the Internet. From their desks, employees of this office log into PCs which are logged into the office network. The FortiGate unit on the office network uses single sign-on to get user credentials from the network authentication server.

The open use PCs have limited access to the Internet. Employee PCs can access internal resources and have unlimited access to the Internet.

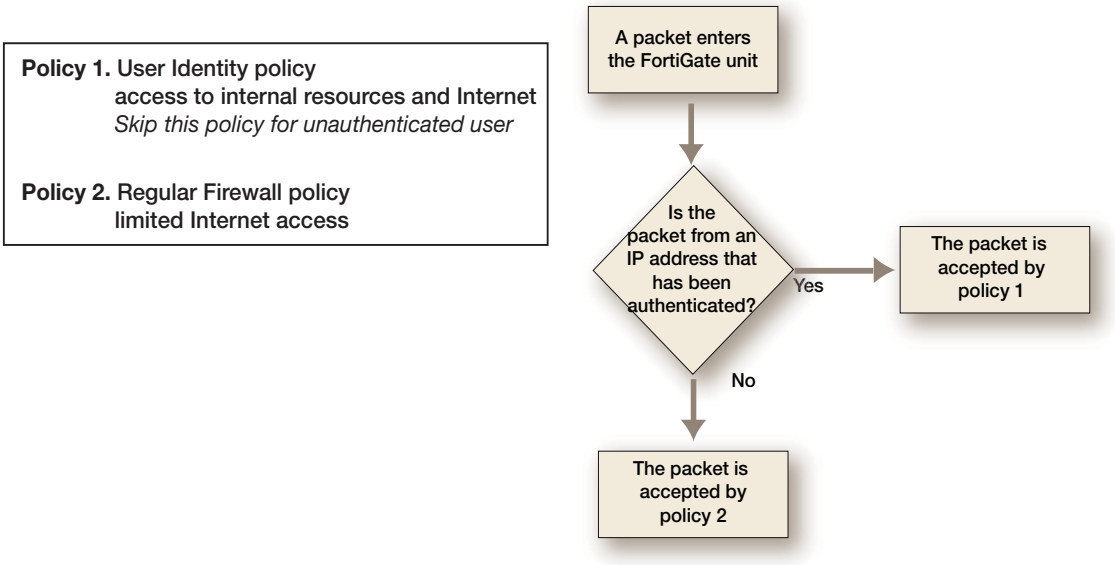
To support these different levels of access you can add a user identity policy to the top of the policy list that allows authenticated users to access internal resources and to have unlimited access to the Internet. In this policy, select *Skip this policy for unauthenticated user*.

Add a normal firewall policy below this policy that allows limited access to the Internet.

Sessions from authenticated PCs will be accepted by the User Identity policy. Sessions from unauthenticated PCs will skip the User Identity policy and be accepted by the normal firewall policy.

Figure 4 shows how the FortiGate unit handles packets received from authenticated and unauthenticated users.

Figure 4: Packet flow for authenticated and unauthenticated users



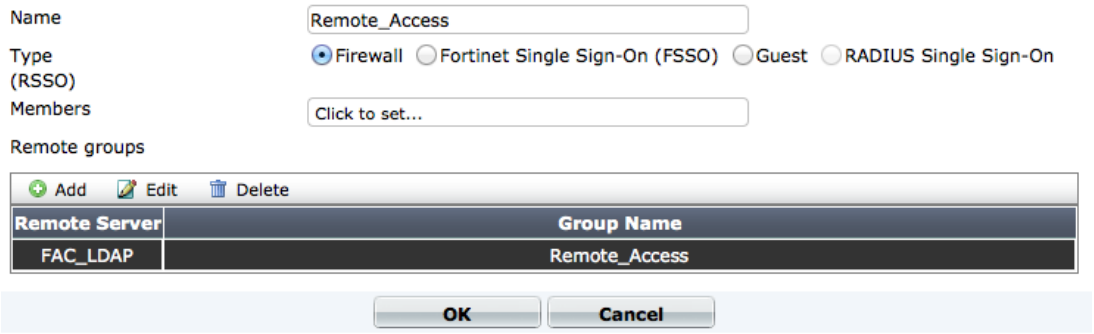
Use case - multiple levels of authentication

As a variation of the above use case, Policy 2 could be a User Identity policy and *Skip this policy for unauthenticated user* would not be selected. Sessions from unauthenticated users that are accepted by Policy2 would now require users to authenticate before traffic can connect through the FortiGate unit. The result is different levels of authentication: Single sign on for some users and firewall authentication for others.

LDAP browser to import users into a user group

You can use the new LDAP browser to add LDAP users to a user group.

Figure 5: The LDAP browser



Dedicated management CPU

FortiGate units in the 2U or High-End categories (models 1000 and above) can now be configured to have a dedicated management CPU. This reserves one CPU core, CPU 0, for running management tasks such as the web GUI, as well as the CLI and related daemons. By having a dedicated management CPU, access to the management GUI and CLI is guaranteed even under when the unit is under a heavy traffic load.

Using a dedicated management CPU may have an impact on the overall performance of the FortiGate unit.

The dedicated management CPU is enabled using the CLI:

```
configure system npu
  set dedicated-management-cpu enable
end
```

Improvements to the Traffic History and Threat History widgets

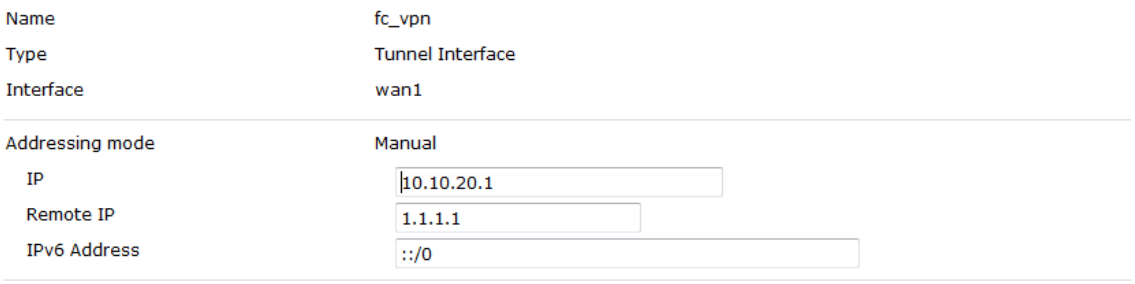
Several changes have been made to the *Traffic History* and *Threat History* widgets:

- The *Show Sessions* and *Show All Incidents* (formerly *Show Threats*) options has been improved to show more information about individual sessions or threats.
- The drilldown page for the *Threat History* widget has been improved by adding new columns and adjusting field formats.
- The *Threat History* widget has replaced the *Reputation Score* monitor used for Client Reputation, which has been removed.

Assigning an IP address to a dynamic IPsec VPN interface

An IP addresses can now be assigned to a dynamic IPsec VPN interface to be used for traffic egressing over the IPsec interface, to avoid traffic being blocked due to an inappropriate address. An IP address is assigned by going to *System* > *Network* > *Interfaces* and editing the interface for the IPsec VPN.

Figure 6: Assigning an IP address to a dynamic IPsec VPN interface



SSL VPN History widget

Login history can now be added to the SSL VPN Portal, which shows a user their past logins. The number of logins shown can be anywhere between 1 and 255 (the default is 5).

The login can be set by going to *VPN* > *SSL* > *Portal,* selecting *Include Login History*, and setting an appropriate *Number of history entries*.

It can also be set using the CLI:

```
config vpn ssl web portal
  edit <portal>
    config widget
      edit <ID>
        set type history
        set display-limit <1-255>
      end
    end
  end
end
```

Port Block Allocation (PBA) for CGN to reduce logs

Port Block Allocation (PBA), a Carrier Grade NAT (CGN) feature, can reduces the number of log messages generated by NAT operations.

PBA can be configured using by going to *Firewall Objects* > *Virtual IPs* > *IP Pools*. It can also be configured using the CLI.

```
config firewall ippool
  edit ippool
    set type port-block-allocation
    set block-size <integer>
    set num-blocks-per-user <integer>
  end
end
```

You configure PBA by creating a private IP address range and assigning multiple port ranges (or blocks) to that IP address range. When a connection is received from the IP range, the source port is translated to a ports in the first range. A log message is written when this happens.

As more connections are received from this IP address range they are assigned to other ports in the first port block. Eventually all of the ports in the block will be used. When a new connection is received, another block of ports is started and a log message is written.

So instead of writing a log message for every NAT event, log messages are only written when a new block of ports is started and again when its used up.

Neighbor cache table for IPv6

A table has now been added to configure IPv6 neighbor cache entries and to save the entries when the FortiGate unit reboots, using the command `config system ipv6-neighbor-cache`.

In the following example, a neighbor cache entry is configured to use the DMZ interface:

```
config system ipv6-neighbor-cache
  edit 1
    set interface dmz
    set ipv6 6666::11
    set mac 00:09:0f:01:02:03
  end
end
```

Improved HA diagnose commands

The new command `diagnose sys ha dump-by` has replaced the command `diagnose sys ha dump`. The new command has the following syntax:

```
diagnose sys ha dump-by {all-xdb | all-vcluster| rcache | all-group |
    memory | debug-zone | vdom | kernel | device | stat| sesync}
```

Each option displays different types of information about the cluster.

The following new HA diagnose commands have also been added:

```
diagnose sys ha sesync-stats
diagnose sys ha extfile-sig
```

Secure disk erasing

All data on the FortiGate boot device and any hard disks installed in a FortiGate unit can now be securely and permanently erased using the `execute erase-disk` command. This command performs a low-level format and also overwrites every block on the device with random data three times.

Anonymize user names in logs

Log messages can now be configured to replace user names with the word ***anonymous***, so that user names are not visible in log messages. This feature can be enabled from the CLI using the following command:

```
config log setting
  set user-anonymize enable
end
```

VLAN interface traffic statistics

A VLAN accounting table has been added to the NP4 driver to poll accounting data from the FortiGate unit in order to monitor traffic statistics from VLAN interfaces. The polling interval is set to 1 second.

Preserving the Class of Service bit

FortiGate units can now preserve the value of the Class of Service (CoS) bit, also called Priority Code Point (PCP), when a packet traverses a VLAN network.

Front panel illustration

An illustrated version of the FortiGate unit's front panel has been added above the list of interfaces, found at *System* > *Network* > *Interfaces*. As with the panel found in the *Unit Operation* widget, interfaces appears green when connected and further details are shown when the mouse pointer hovers over a specific port.

USB entropy token support

Use of a USB entropy token during the boot process is now enabled by default when using a FortiGate in Federal Information Processing Standards-Common Criteria (FIPS-CC) mode. If a FortiGate unit in this mode does not have an USB entropy token inserted, it is unable to complete the boot process will display the following message: `Please insert entropy token to continue boot process`.

Entropy token use can be disabled from the CLI. It can also be enabled on a FortiGate unit in normal mode (by default, entropy tokens are disabled in normal mode).

Syntax

```
config system fips
  set entropy-token {enable | disable}
end
```

The entropy token must be present during boot process when a FortiGate unit is switched to FIPS-CC mode.

Station locate for FortiWiFi units

Station locate allows a FortiWiFi unit to detect all wireless clients whether they are associated or not. A record is kept of MAC address, statistical time interval and RSSI data.

Station locate is enabled using the following CLI command:

```
config wireless-controller wtp-profile
  edit "FAP220B-default"
    config radio-1
      set station-locate enable
      set station-locate-interval 1
    next
    config radio-2
      set station-locate enable
      set station-locate-interval 1
    end
  end
end
```

Switch Controller added models 200D, 240D, 600C, 800C, and 1000C

The Switch Controller, used to managed FortiSwitch units with a FortiGate unit, has been added to the following models: 200D, 240D, 600C, 800C, and 1000C.

Because of this feature, there have been several web-based manager menu changes to these units:

- *WiFi Controller* has changed to *WiFi & Switch Controller*.
- *Managed Access Points* has changed to *Managed Devices* and now contains the *Managed FortiSwitch* option.
- The *Switch Network* menu has been added, which contains the *Virtual Switch* option.

Diagnose command for 5000 series FortiGate units

A new diagnose command, `diagnose test application ipmc_sensord`, is available to view chassis IPMC status from a 5000 series blade installed in a chassis. The command can display:

- Power supply detection
- IPMC sensor status detection
- Comlog enable/disable/info/read/clear
- Smc time set/get
- AMC info
- Microswitch status detection
- HACO info

Because of this change, the following obsolete commands have been removed:

- `get system chassis`
- `get system blades`
- `get chassis status`
- `diag hardware fruinfo`
- `exec bladekvm`

New platforms for FortiGate-VM

FortiGate-VM is now supported for Microsoft Hyper-V and Kernel-based Virtual Machine (KVM).

Supported RFCs

The following RFCs are supported by the new features for FortiOS 5 Patch 5:

Table 1: Supported RFCs

Number	Title
2766	Network Address Translation - Protocol Translation (NAT-PT)

Table 1: Supported RFCs

Number	Title
4787	Network Address Translation (NAT) Behavioral Requirements for Unicast UDP
6691	TCP Options and Maximum Segment Size (MSS)

New features in FortiOS 5.0 Patch 4

This chapter provides a brief introduction to the following features that were added to Patch 4 of FortiOS 5.0. See the release notes for a complete list of new features in this release.

FortiSandbox

The new FortiSandbox unit can be used with a FortiGate unit for sandboxing suspicious files. Sandboxing can also be done using Cloud Sandbox, which was previously known as FortiGuard Analytics. For more information about this feature, see "FortiSandbox" on page 138.

Wireless Health Dashboard

The Wireless Health Dashboard provides an easy method for determining the health of your network's wireless infrastructure. The dashboard is used to display a variety of widgets, which show information such as AP status, client count over time and login failures.

The dashboard can be found by going to *WiFi Controller* > *Monitor* > *Wireless Health.*

Figure 7: The Wireless Health Dashboard

IPsec VPN

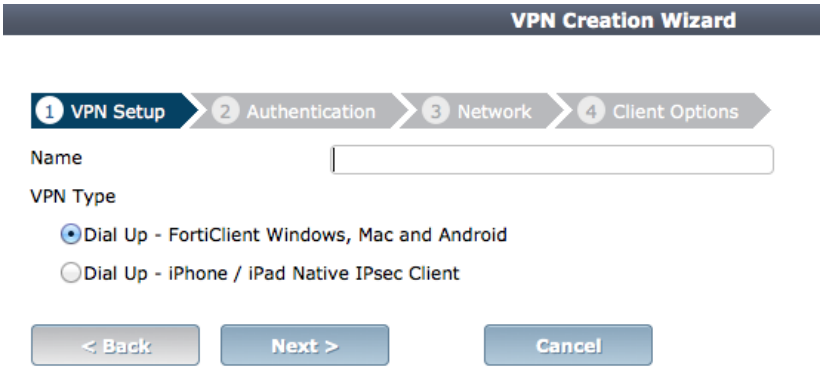
There have been several changes made to how IPsec VPN is configured.

Dial-up IPsec VPN Creation Wizard

A new wizard can be used to create Dial-up IPsec VPNs for FortiClient and Native iOS IPsec clients. The FortiClient configuration can be used for all platforms supported by FortiClient. Find the wizard by going to *VPN* > *IPsec* > *Auto Key (IKE)* and selecting *Create VPN Wizard*.

See http://docs.fortinet.com/sysadmin.html for more information about using the VPN Creation Wizard.

Figure 8: The VPN Creation Wizard



Show or Hide policy-based IPsec VPN

Policy-based IPsec VPN options have been added to the Feature Select options, which controls what features can be viewed and configured through the web-based manager. For more information on this feature, see “Feature Select” on page 243.

By default, policy-based IPsec VPN is hidden from the web-based manager and interface-based VPNs are easier to configure.

Managing FortiAP units

There have been several changes to how FortiAP units are managed by a FortiGate unit.

Units remain online when their WiFi Controller goes offline

FortiAP units can now remain online when their connection to the FortiGate unit's WiFi Controller goes offline. During such an outage, WiFi clients already associated with a bridge mode FortiAP unit continue to remain connected to their SSID and can communicate with other WiFi clients. Access to other network resources; however, is suspended until the FortiGate unit is back online.

The FortiAP unit can also continue to authenticate users if the SSID meets these conditions:

- Traffic Mode is Local bridge with FortiAP's Interface

  In this mode, the FortiAP unit does not send traffic back to the wireless controller.
- Security Mode is either WPA/WPA2-Personal or Open.

  These modes do not require the user database. In WPA/WPA2-Personal authentication, all clients use the same pre-shared key which is known to the FortiAP unit.
- Allow new client association when controller connection is down is enabled.

This field is available only if the other conditions have been met.

Assigning the same profile to multiple FortiAP units

The same profile can now be applied to multiple managed FortiAP units at the same time. To do this, do the following:

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAPs* to view the AP list.
2. Select all FortiAP units you wish to apply the profile to.
3. Right click on one of the selected FortiAPs and select *Assign Profile*.
4. Choose the profile you wish to apply.

Dynamic VLANs for SSIDs

Dynamic VLANs can now be used to divide a single SSID into several VLANs. In Patch 4, Dynamic VLANs are supported for both tunnel and bridge mode SSIDs.

VLAN assignment is based on the credentials supplied by the user. Dynamic VLANs allow individual users to be assigned different VLANs resulting in different levels of access even though all users are connecting to the same SSID.

The task of assigning users to a specific VLAN is handled by a RADIUS authentication server. When a client attempts to associate to a FortiAP registered with a controller, the FortiAP passes the credentials of the user to the RADIUS server for validation. Once the authentication is successful, the RADIUS server passes certain Internet Engineering Task Force (IETF) attributes to the user. These RADIUS attributes include the VLAN ID that should be assigned to the wireless client.

Dynamic VLANs are configured by doing the following:

1. Go to *User & Device* > *Authentication* > *RADIUS Servers* and create a new RADIUS server.
2. Go to *WiFi Controller* > *WiFi Network* > *SSID* and create a new SSID.
3. Enable Dynamic VLAN in the CLI, using the following command:

```
config wireless-controller vap
  edit <name>
    set dynamic-vlan enable
end
```

4. Go to *WiFi Controller* > *WiFi Network* > *Custom AP* and create a new radio 1 and radio 2 that use the new SSID.
5. Go to *System* > *Network* > *Interfaces* and create two or more VLAN interfaces that have DHCP server enabled.
6. Go to *Policy* > *Policy* > *Policy* and create policies that allow outbound traffic from the new VLANs.
7. Configure a policy on the RADIUS server for each VLAN.

When users scan for available SSIDs, they can connect to the new SSID and be assigned to one of the VLANs based on their credentials.

See http://docs.fortinet.com/supplement.html for some Dynamic VLAN examples.

NAT46 & NAT64

Policies and Virtual IPs for NAT46 and NAT64 can now be configured from the web-based manager. For these options to appear in the web-based manager, this feature must be enabled using Feature Select. For more information, see "Feature Select" on page 243.

To configure NAT64 policies go to *Policy* > *Policy* > *NAT64 Policy*.

To configure NAT46 policies go to *Policy* > *Policy* > *NAT46 Policy*.

Enhancements to Tables

Several enhancements have been made to the tables in the web-based manager to improve access to information.

Policy Table

The following enhancements have been made to the Policy Table:

- The Security Features column has been divided so that each feature has an individual menu, allowing the profile used to be easily visible.
- A pulldown menu will appear when a specific element is selected that displays the other options for the field, as well as showing the *Create New* option.
- The right-click menu has been simplified to show only the options related to the location that was selected. The menu will also change depending on whether a specific element name was selected or if the cell background was selected.

Member Display

The member columns for tables under *Firewall Objects* and *User & Device* have been improved to display members in a grid. When there is a high number of members in a single group, some members will be displayed in the grid, with the hidden members viewed via a dropdown menu.

The number of sub-columns displaying members, the width of sub-columns and the number of lines used to display members are all customizable by right-clicking on the header and selecting *Members Column Option*.

Fortinet Top Bar

In order to ensure that the Fortinet Top Bar appears in all browsers, port 8011 must be allowed in the firewall policy being used.

FortiAnalyzer and FortiManager log encryption

Logs sent to a FortiAnalyzer or FortiManager unit from a FortiGate unit can now be encrypted. Encryption is enabled by going to *Log & Report* > *Log Config* > *Log Settings*.

FortiToken Mobile

There have been several changes made to FortiToken Mobile:

- A QR code image will be attached to FortiToken activation emails.
- Softtoken polling requests have been extended to 5 minutes.
- The range for two factor FortiToken mobile expiry is now 1-168 hours.
- Notifications will be sent when a local user is created.

Load balancing for explicit web proxy forwarding server groups

Explicit web proxy traffic can now be load balanced among multiple forwarding servers in a forwarding server group.

To configure load balancing, add multiple forwarding servers to a forwarding server group and turn on load balancing for the server group. Then add the forwarding server group to a security policy.

The following example adds three forwarding servers to a forwarding server group. Start by creating the forwarding servers:

```
config web-proxy forward-server
  edit fwd-srv-1
    set ip 10.10.10.10
    set port 8080
  next
  edit fwd-srv-2
    set ip 10.10.10.20
    set port 8080
  next
  edit fwd-srv-3
    set ip 10.10.10.30
    set port 8080
  end
```

Then add the forwarding servers to a group:

```
config web-proxy forward-server-group
  edit fwd-srv-grp
    set affinity enable
    set ldb-method weighted
    set group-down-option block
      config server-list
        edit fwd-srv-1
          set weight 10
        next
        edit fwd-srv-2
          set weight 10
        next
        edit fwd-srv-3
          set weight 10
        end
  end
```

Then add the forwarding server group to a web-proxy security policy:

```
config firewall policy
  edit 0
    set srcintf web-proxy
    ...
    set webproxy-forward-server fwd-srv-grp
    ...
  end
```

Server load balancing enhancements

Server load balancing has been enhanced to alert administrators when a server fails and to improve handling of HTTP redirects.

SNMP traps

FortiGate units can now send SNMP traps when the FortiGate unit determines that one of the servers in a server load balance group has gone down. The OID for the trap is *.fgTrapServerLoadBalanceRealServerDown*.

You can use the following CLI command to enable this trap:

```
config system snmp community
  edit 0
    set events load-balance-real-server-down enable
end
```

HTTP redirects

Server load balancing now also supports checking HTTP redirects and setting the maximum number of redirects when 300-level return codes are received.

You can set `http-max-redirects` in the range 0 to 5. The default value is 0 which means do not check redirects, just assume they are available. This is how redirects functioned previously. When you set this option to 1 or more, the FortiGate unit will check up to 5 redirect URLs, until it finds one that is active. Traffic is then re-directed to the first active URL that is found.

Use the following command to check up to 3 redirects:

```
config firewall ldb=monitor
  edit 0
    set set type http
    set port 80
    set http-get "/index.php"
    set http-max-redirects 3
end
```

Additional filters for IPS and Application Control

New filters have been added for IPS and Application Control that will be shown when the *Advanced filter* option is selected on the sensor creation page. The new filters for IPS are Application and Protocol and the new filters for Application Control are Vendor and Protocol.

Blocking IPv6 packets by extension headers

FortiOS can now block IPv6 packets based on the extension headers, using the CLI syntax `config firewall ipv6-eh-filter`.

The following commands are now available:

`set hop-opt {disable | enable}`: Block packets with Hop-by-Hop Options header.

`set dest-opt {disable | enable}`: Block packets with Destination Options header.

`set hdopt-type <integar>`: Block specific Hop-by-Hop and/or Destination Option types (maximum 7 types, each between 0 and 255).

`set routing {disable | enable}`: Block packets with Routing header.

`set routing-type <integar>`: Block specific Routing header types (maximum 7 types, each between 0 and 255).

`set fragment {disable | enable}`: Block packets with Fragment header.

`set auth {disable | enable}`: Block packets with Authentication header.

`set no-next {disable | enable}`: Block packets with No Next header.

Distinguishing between HTTP GET and POST in DLP

Data Leak Prevention (DLP) can now distinguish between HTTP GET and POST protocols, allowing the protocols to be selected independently.

HTTP POST protocol can be examined by both message and file filters, while HTTP GET can only be used for file filters.

RADIUS Accounting

Accounting servers can now be configured in a RADIUS setting. For each RADIUS server, four more accounting servers can be created.

The following example adds an accounting server to a RADIUS server:

```
config user radius
  edit rad159
    set server 172.16.62.159
    set secret asdfasdf
    config accounting-server
      edit 1
        set status enable
        set server 175.18.5.36
        set secret asdfasdf
    end
end
```

H3C Compatibility

FortiOS now has H3C compatibility, allowing 802.1x authentication to be supported with two RADIUS attributes.

The following example enables H3C compatibility:

```
config user radius
  edit rad-jason
    set h3c-compability enable
end
```

Web filter administrative overrides

Administrative web filter overrides can now be configured by going to *Security Profiles* > *Web Filter* > *Web Overrides*. Overrides allow specific users to use an alternate web filter profile, in order to access sites that would normally be blocked.

Configurable idle timeout for console admin login sessions

An idle timeout has been added for FortiGate console sessions (admin sessions connecting to a FortiGate console port or USB port). By default the console timeout is set to 0 and console sessions will never timeout. You can enable a timeout in the range of 15-300 seconds from the CLI. Use the following command to set the timeout to 25 seconds:

```
config sys global
  set admin-console-timeout 25
end
```

Use the following command to disable the timeout.

```
config sys global
  unset admin-console-timeout
end
```

TCP reset

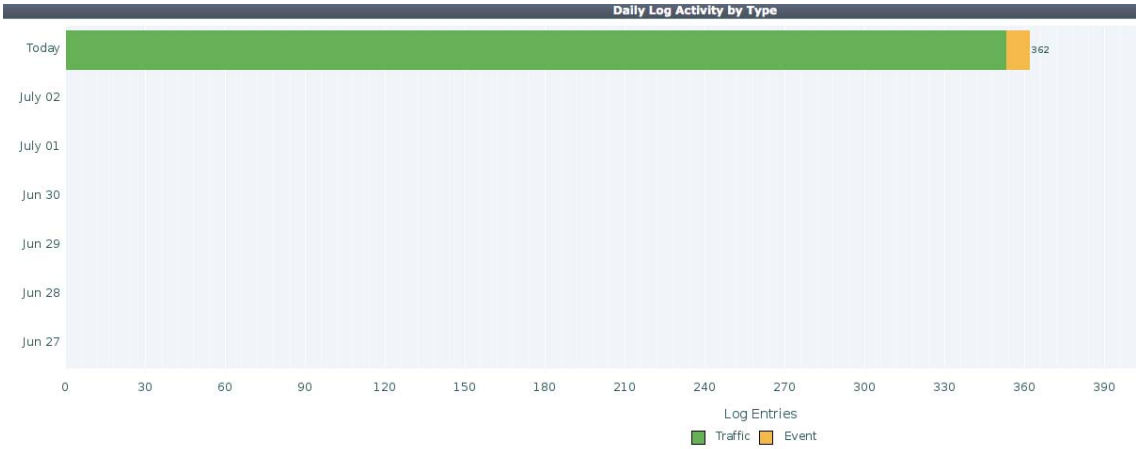
Security policies can now be configured to send a TCP reset when a specific application session times out. The following command is used to enable this function:

```
config firewall policy/policy6
  edit 0
    set timeout-send-rst enable
end
```

Log Volume Monitor

The Log Monitor has been renamed the Log Volume Monitor and has had several visual enhancements made. It can be found at *Log & Report* > *Monitor* > *Logging Volume Monitor*.

Figure 9: The Log Volume Monitor



Invalid Packet log

The Invalid Packet log has been merged with the Local Traffic and Forward Traffic logs. Denied traffic will now appear in either of these logs.

Server limits

The maximum number of virtual and real servers has been increased. The new maximum values vary by FortiGate model and are as follows:

- Desktop FGT: virtual servers, 128 globally; real servers, 4 per entry.
- 1U FGT: virtual servers, 512 globally; real servers, 8 per entry
- 2U FGT: virtual servers, 2048 globally; real servers, 32 per entry.

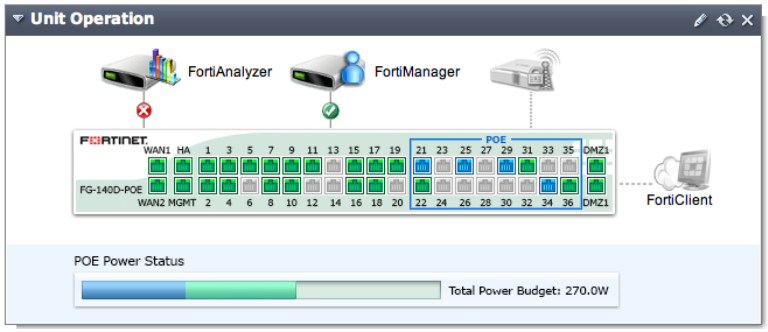
PoE Power Management display

This feature is only available on FortiGate 140D-POE models.

In the *Unit Operation* widget, the *POE Power Status* bar has been added to show the current power output for Power over Ethernet (POE). The bar displays both used power and reserved power.

The port display has also been changed so that the ports that are supplying power appear in blue.

Figure 10: The Unit Operation widget with the POE Power Status bar



Other new features

- Valgrind is now supported in urlfilter daemon, using the following commands:

```
diagnose debug urlfilter valgrind enable
diagnose debug urlfilter valgrind status
diagnose debug urlfilter valgrind memcheck
diagnose debug urlfilter valgrind log
```

- The default post-login banner now displays the time of the last successful and last failed administrator login.

New features in FortiOS 5.0 Patch 3

This chapter provides a brief introduction to the following features that were added to Patch 3 of FortiOS 5.0. See the release notes for a complete list of new features in this release.

Security Features

Features previously known as UTM Security Features are now known as Security Features. For more information about new Security Features in FortiOS 5.0, see “Security Features” on page 138.

Exempting IP addresses from IPS

IPS filters can be configured so that signatures are not applied to traffic from specific IP addresses. For more information about IPS exemptions, see “Exempting IP addresses from IPS” on page 144.

DLP Watermarking Client

The DLP watermarking client is now available for Windows as part of FortiExplorer. For more information about DLP watermarking, see “DLP watermarking” on page 153.

Predefined Device Groups

FortiOS now has Predefined Device Groups for Blackberry Playbook, Router/NAT Device and Windows Tablet. For more information about Predefined Device Groups, see “Device Groups” on page 175.

Client Reputation Configuration

Client Reputation configuration can be found at *Security Profiles* > *Client Reputation.* For more information about Client Reputation, see “Client Reputation” on page 181.

Feature Select

Feature Select replaces the *Display Options on GUI* feature to control which features can be configured and viewed on the web-based manager. For more information on this feature, see “Feature Select” on page 243.

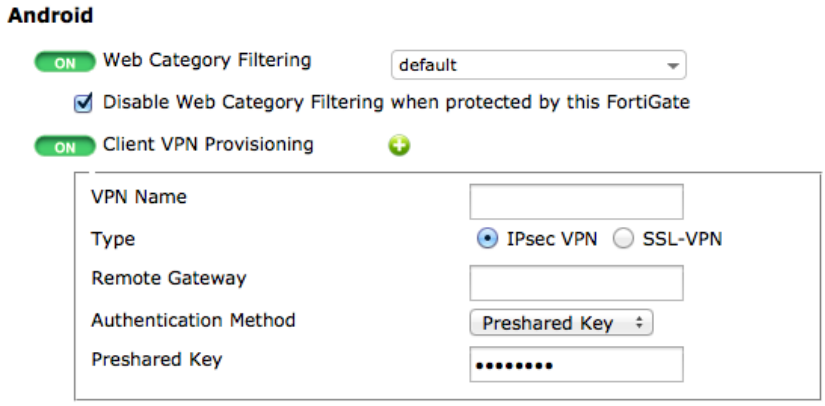
Changes to Endpoint Control

There have been several changes to Endpoint Control.

Endpoint control for Android

FortiOS now supports endpoint control for Android mobile devices. Endpoint profiles that include Android devices can be configured at *User & Device* > *Endpoint Protection* > *FortiClient Profiles.*

Figure 11: Endpoint control for Android



Assigning endpoint profiles to specific users and user groups

Endpoint profiles can now be assigned to specific users and user groups that have been defined on the FortiGate. This can be done from the CLI, using the following command:

```
config endpoint-control profile
  edit <profile-name>
    set users <user-name>
    set <user-groups> <user-group-name>
end
```

Endpoint profile portal pages

Custom endpoint profile portal pages can be configured. There are five different portals that can be used, depending on the operating system of the endpoint device. The five portals are: Android, Mac, iOS, Windows and other. To access the portal pages, go to *System* > *Config* > *Replacement Messages* and select *Extended View*.

Managing FortiAP units

There have been several changes to how FortiAP units are managed by a FortiGate unit.

Firmware Auto-detection

A FortiGate unit now auto-detects what the best firmware version is for the FortiAP units that it manages. If the FortiAP unit is not running the recommended firmware version you can download and install in from the FortiGate web-based manager.

Wireless Device Locating Service

A FortiAP unit can be configured to report all wireless devices that it locates, even if the device does not connect, or is unable to connect, to the FortiAP.

Locating service is enabled from the CLI, using the following command:

```
config wireless-controller wtp-profile
  edit "FAP220B-default"
    set ap-country JP
    config radio-1
      set station-locate enable
    end
    config radio-2
      set station-locate enable
    end
end
```

After this configuration is complete, the list of devices can be found using the following command:

```
diagnose wireless-controller wlac -c sta-locate
```

The command displays a list of currently located wireless devices. The list includes the MAC address of each device as well as wireless-related information about the device.

More Wireless Controller MIB Support

More fields related to wireless controller functionality has been added to the FortiGate MIB. Additions include the following:

- Asynchronous notifications from SNMP agent, including fgTrapWcApUp and fgTrapWcApDown.
- Objects defined for controller level information, for example: controller name and location, WTP capacity and count and station capacity and count.
- A set of objects that display a WLAN interface, for example: assigned SSID and security method.
- An object identifier for a list of tables pertaining to WTPs.
- A set of objects that display a custom WTP profile, for example: profile name, platform type, DTLS policy and country code.
- A set of objects that display a radio in a custom WTP profile, for example: radio mode, band and channel settings, power level and VAP configurations.
- A set of objects that display the configuration of a WTP, for example: WTP ID, name and assigned custom profile. If no custom profile is assigned, then a list of objects that supplement the automatic profile are defined.
- A set of objects that display wireless session information, for example: IP/MAC address, connection state, up time, profile name, WTP HW/SW information, WTP session statistics, CPU load and memory capacity and usage.
- A set of objects that display wireless session radio information, for example: radio mode, operating country code, operating channel, operating power level and client count.
- A set of objects that display a virtual access point (a WLAN allocated on a WTP radio), for example: client count and RX/TX byte counts.

A set of objects that display a wireless station, for example: WTP and radio it connects to, IP/MAC address, VCI/host information, signal/noise level, TX/RX bandwidth, channel, security type and on-line status.

Normal or Remote WTP mode parameter

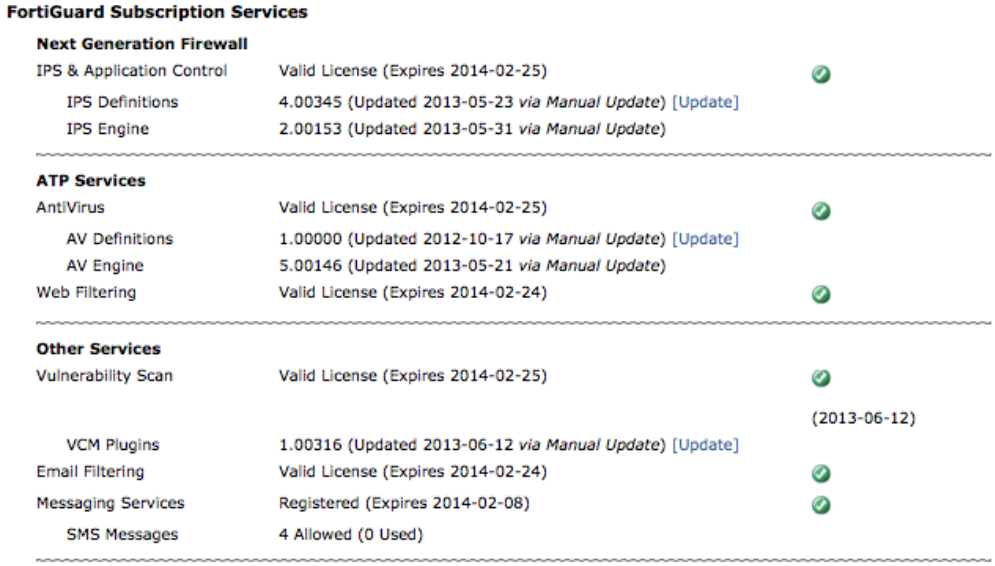
A new WTP mode parameter has been added in which FortiAP units are classified as either normal or remote. A FortiAP unit in normal mode uses SSID in tunneled mode while remote WTP mode uses only local bridge SSIDs.

This new mode has changed the maximum number of FortiAP units which can be managed by a FortiGate unit, with one value for the maximum number of normal FortiAPs and another for the maximum number of remote FortiAPs. For more information, see the Maximum Values Table for FortiOS 5.0.

FortiGuard Subscription Services

The FortiGuard Subscription Services have been reorganized into three categories: Next Generation Firewall, ATP Services and Other Services.

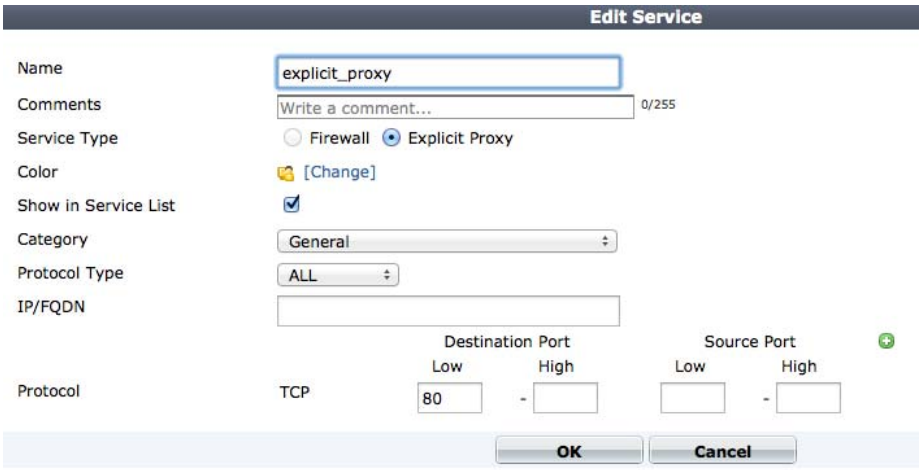
Figure 12: The FortiGuard Subscription Services



Adding Explicit Web Proxy services

Explicit proxy services can now be added and edited by going to *Firewall Objects* > *Service* > *Services* > *Create New* > *Custom Service* and selecting *Explicit Proxy*. Explicit web proxy services are used in security policies that control access to the explicit web proxy.

Figure 13: Editing an Explicit Web Proxy Service

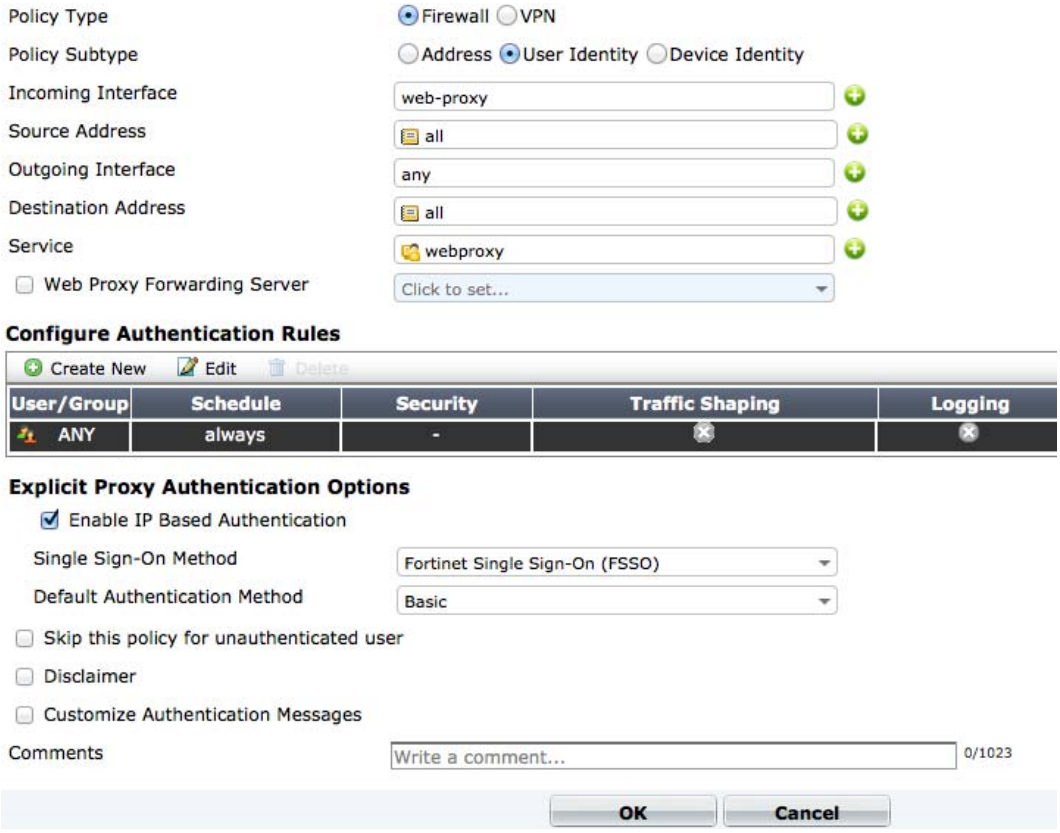


SSO Authentication failover for the Explicit Web Proxy

SSO authentication failover for the Explicit Web Proxy is now available, allowing two authentication methods to be configured. If the Single Sing-On Method fails, the FortiGate unit will use the *Default Authentication Method*.

To configure failover, the explicit web proxy must first be enabled.

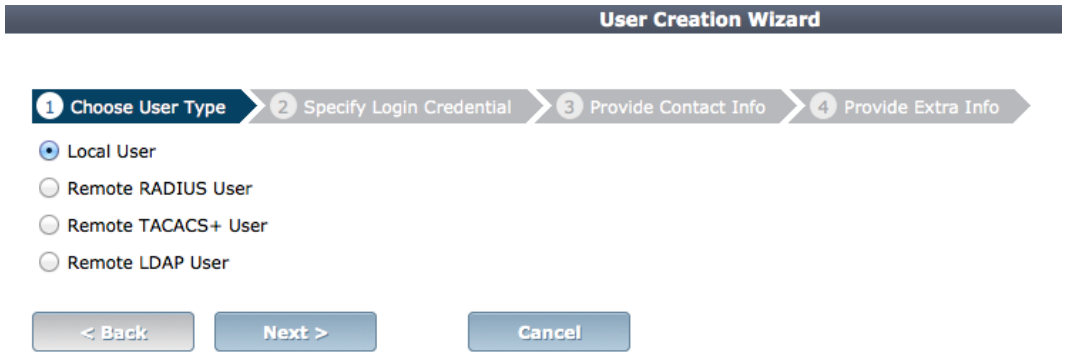
Figure 14: Configuring SSO authentication failover for the explicit web proxy



User Creation Wizard

The User Creation Wizard is used to create new users through a four step process. The four steps will vary depending on which type of user is being created (for example, when creating an LDAP user, step 3 requires choosing an LDAP filter).

Figure 15: The User Creation Wizard



The User Creation Wizard can be found at *User & Device* > *User* > *User Definition*.

FortiClient Registration

The FortiClient registration process has changed so that the initial confirmation message sent from FortiClient will be ignored by the FortiGate unit and applied only at the end of the registration process, to avoid the registration being rejected.

DSS and ECDSA Certificates for FortiGate SSL-related features

FortiOS now supports DSS and ECDSA certificates for the following features: HTTPS/SSL deep scanning, HTTPS/SSL server load balancing, HTTPS/SSL offloading and HTTPS over the explicit web proxy.

LDAP Servers

A Distinguished Name field and query button have been added to the LDAP Server creation page.

User Monitor

FSSO Logons are now shown in the user monitor, found at *User & Device* > *Monitor* > *Firewall*. In order for FSSO Logons to appear, *Show all FSSO Logons* must be enabled.

Web Filter Profiles

URL filters, used for website filtering, are now created as part of a Web Filter Profile. This can be done by going to *Security Profiles* > *Web Filter* > *Profiles* and selecting *Enable Web Site Filter*. A filter can then be enabled for all URLs you wish to block.

CAPWAP Administrative Access

CAPWAP Administrative Access can now be configured for all interfaces except Virtual Access Points (VAPs). CAPWAP must be used on any interface used to managed a FortiAP unit.

IPS Algorithms

There is a new algorithms for IPS, “super” mode, that improves performance for FortiGate units with more than 4GB of memory. Improvements have also been made for “low” mode, which is more efficient for FortiGate units with low memory.

The algorithm used for IPS can be changed from the CLI, using the following command:

```
config ips global
   set algorithm {engine-pick | high | low | super}
```

NAC-Quarantine Traffic Logs

Antivirus and DLP NAC-quarantine traffic logs now show whether the IP, user or interface has been banned. In the case of a virus, the name of the virus and the file in which the virus was found are also included.

New System Report Charts

The following charts have been added to the daily FortiGate System Report, based on data collected by event logs:

- VPN Usage
- Client Reputation Summary

Memory Logging

Memory logging is available on all FortiGate models. Logging can be enabled by going to *Log & Report* > *Log Config* > *Log Settings* and enabling *Disk*.

Logging to flash is also available for the FortiGate-60D and FortiWiFi-60D.

URL-based Web Proxy Forwarding

In order to configure URL-based web proxy forwarding, *WAN Opt. & Cache* must be enabled using Feature Setting. For more information, see “Feature Select” on page 243.

FortiOS now supports URL-based web proxy forwarded, which is required for explicit proxy installations using Threat Management Gateway or Blue Coat.

URL-based web proxy forwarding can be configured by going to *WAN Opt. & Cache* > *Cache* > *URL Match List*.

Changes to Routing

There following changes have occurred for FortiOS Routing:

- The OSPF summary address limit has decreased to 25 from 10.
- More routing community lists can be configured (limits vary by FortiGate model).

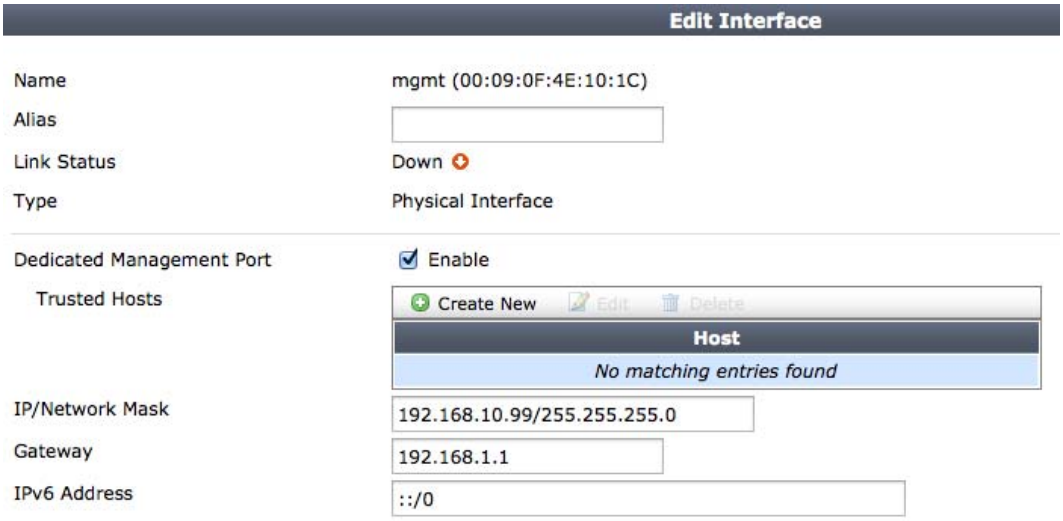
RADIUS Support for Dynamic VLANs

RADIUS authentication can be used to dynamically route authenticated user traffic to a VLAN. The name of this VLAN is then added to the user's RADIUS record.

Dedicated Management Port

The Management (MGMT) port can now be set as Dedicated to Management, in which case no firewall traffic will be allowed through this port.

Figure 16:MGMT port set to Dedicated to Management



URL Filtering

URL filtering has changed to allow certificate-based URL filtering for HTTPS traffic, which is used when deep-scan is disabled.

Certificate-based filtering extracts the hostname from the TLS handshake. If a valid hostname is found, it is used for the local or FortiGuard category query. If no hostname is found, HTTPS server CN web filtering will be used instead.

URL Source Tracking

URL source tracking has been added to transparent proxy and SSL deep-inspection proxy. There are three current URL source values: HTTP host head, subject CN in the certificate and server name field in the TLS handshake.

IPv6 Denial of Service Policies

Denial of Service (DoS) policies can now be configured by going to *Policy* > *Policy* > *IPv6 Dos Policy*.

Support for NAT46, VIP64 and VIP46

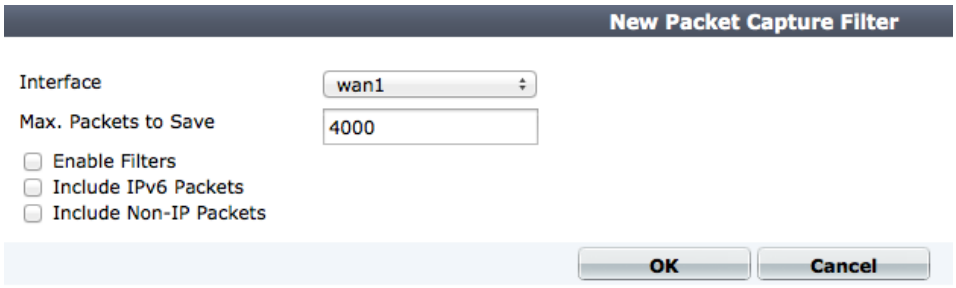
Security policies are now supported for NAT46, VIP64 and VIP46. They can be configured from the CLI, using the following commands:

```
config firewall policy46
config firewall vip64
config firewall vip46
```

Packet Capture Filters

Packet capture filters can be configured by going to *System* > *Network* > *Packet Capture*.

Figure 17: Configuring a packet capture filter



Configure hosts in an SNMP v1/2c community to send queries or receive traps

When you add a host to an SNMP v1/2c community you can now decide whether the FortiGate unit will accept queries from the host or whether the FortiGate unit will send traps to the host. You can also configure the host for both traps and queries.

Use the following command to add two hosts to an SNMP community:

- An IPv4 host that can send queries to the FortiGate unit
- An IPv6 host that the FortiGate unit will send traps to

```
config system snmp community
  config hosts
    edit 1
      set interface port1
      set ip 172.20.120.1
      set host-type query
    end
  config hosts6
    edit 1
      set interface port6
      set ip 2001:db8:0:2::30
      set host-type trap
    end
```

You can add up to 16 IPv4 hosts and up to 16 IPv6 hosts.

IP in IP tunneling support (RFC 1853)

FortiOS 5.0 MR3 supports RFC 1853 IP in IP Tunneling to provide for differential forwarding to packets. This tunneling mechanism is supported as an interface type and the FortiGate unit does not inspect the traffic in an IP in IP tunnel

To configure IP in IP tunneling:

```
config system ipip-tunnel
  edit tun0
    set interface <interface_name>
    set local-gw <local-gw-ip>
    set remote-gw <remote-gw-ip>
  end
end
```

GTP-u acceleration on FortiGate units with SP3 processors

FortiGate units with SP3 processors can offload GTP-u packet processing to their SP3 processor. The SP3 processor supports:

- GTP-u sanity packet check
- GTP-u rate limiting per gtp profile
- Encapsulated IP traffic filtering

New features in FortiOS 5.0 Patch 2

This chapter provides a brief introduction to the following features that were added to Patch 2 of FortiOS 5.0. See the release notes for a complete list of new features in this release.

Endpoint Profile Changes

A number of changes have been made to enhance Endpoint Profile functionality.

Client Reputation Changes

A number of changes have been made to enhance Client Reputation functionality. For information about how to configure and use Client Reputation, see “Client Reputation” on page 181.

Changes to logging in security policies

Instead of enabling or disabling traffic logging in security policies three Logging Options are now available:

- *No Log*, do not record log messages about traffic accepted by this security policy
- *Log UTM Events*, record traffic log messages when a UTM event occurs (such as when a virus is found by antivirus, a web page is blocked by web filtering, or the application responsible for a session is identified by application control).
- *Log all Sessions*, record traffic log messages for all sessions. For all sessions, a single traffic log message is recorded when the session ends. If you select this option, you can choose to record a traffic log message when a session starts as well. You can also choose to capture packets.

Enabling logging in a security policy can affect FortiGate performance because of the extra system resources required to record log messages. The performance hit can be reduced by selecting *Log UTM Events,* since fewer log messages will be recorded.

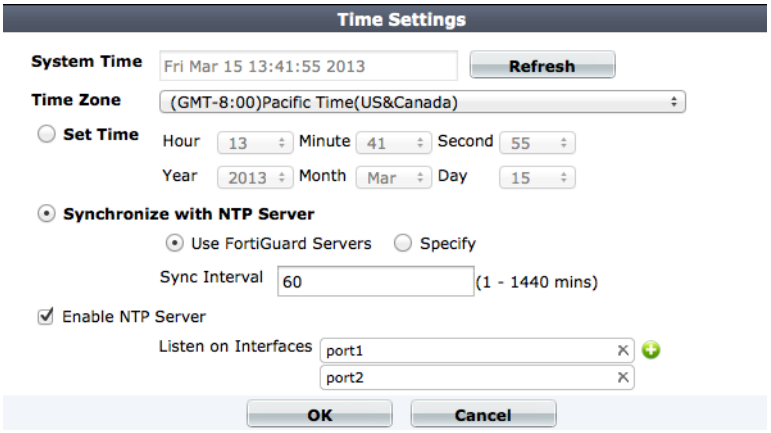
You can also enter the following command to write a log message when a session starts:

```
config firewall policy
  edit <policy-index>
    set logtraffic-start
  end
```

Configuring the FortiGate unit to be an NTP Server

When you configure system time from the System Information dashboard widget, you can configure the FortiGate unit to be an NTP server. As part of the NTP server configuration, you can select one or more interfaces on which to listen for NTP requests.

Figure 18: System time configuration: NTP server



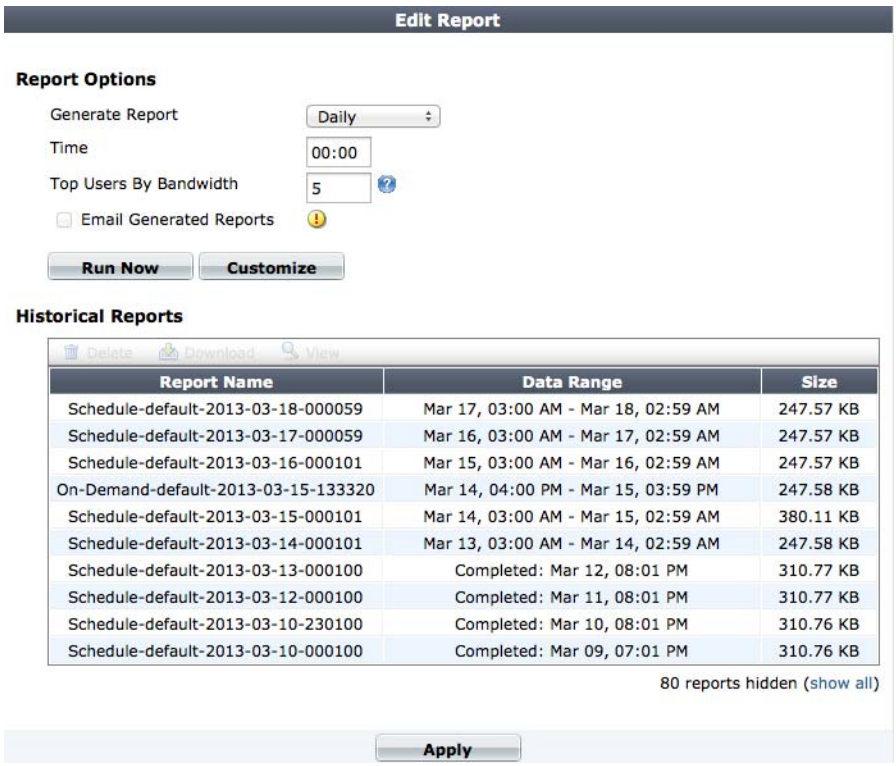
Customizing and viewing the local FortiGate UTM Security Analysis Report

In order for your FortiGate unit to create a Security Analysis Report, disk logging must be enabled. To enable disk logging, go to *Log & Report* > *Log Config* > *Log Settings* and under *Logging and Archiving* select *Disk* and *Enable Local Reports*.

You can go to *Log & Report* > *Report* > *Local* to view Local Reports created by the FortiGate unit. Local reports are saved as PDF files that you can view and download at any time.

By default, Local reports are produced every day. You customize how the FortiGate unit to produce reports daily, weekly, or on demand and you can set the day and time when the report is generated. You can control how many users appear in the Top Users by bandwidth summary part of the report. Each user gets a separate summary page. You can also configure the FortiGate unit to email the report to multiple email recipients.

Figure 19: Customizing the FortiGate report



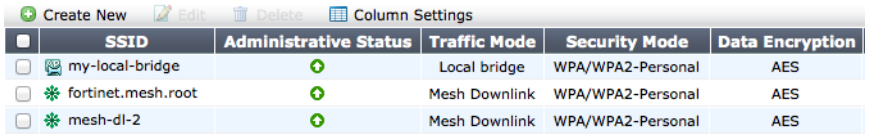
You can also select *Run Now* to run a report at any time. The report is created using current data.

You can select *Customize* to change the report layout. You can customize a report to add headings and text, divide a report into sections, add images, and add, remove, and rearrange the individual report charts.

Wireless changes: Custom mesh downlink SSIDs and new identifier for local bridge SSIDs

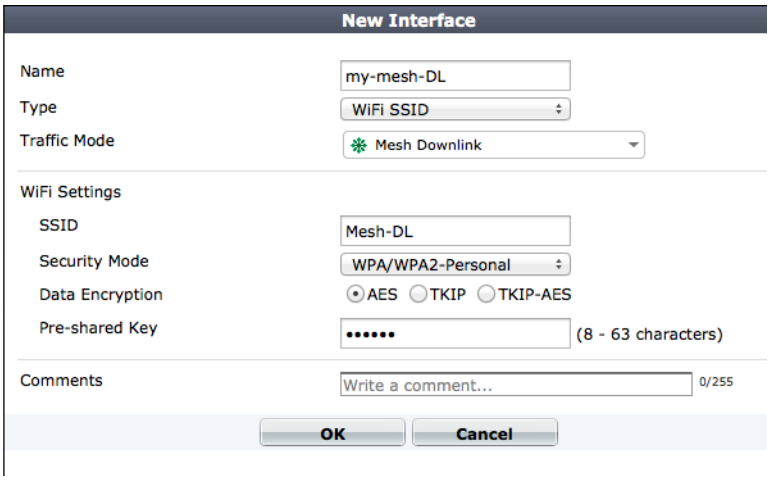
You can go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New* to add additional custom mesh downlink SSIDs.

Figure 20:SSID list showing a local-bridge SSID and two mesh downlink SSIDs



Configure a mesh downlink SSID by selecting *Create New,* setting the *Traffic Mode* to *Mesh Downlink* and entering an SSID.

Figure 21: Configuring a custom mesh downlink

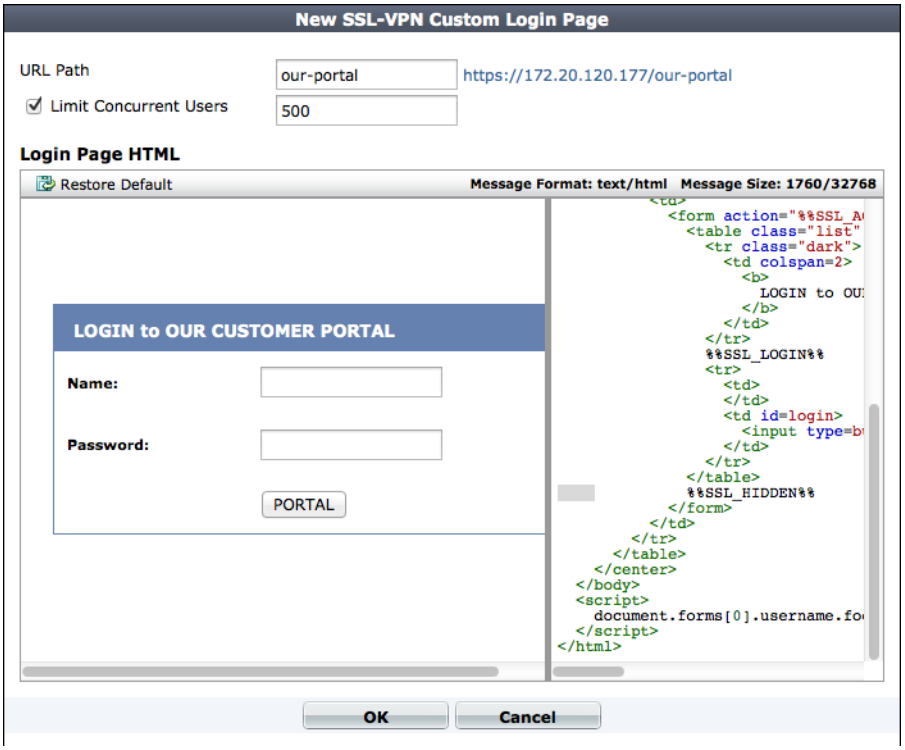


SSL-VPN Realm Support (multiple custom SSL VPN logins)

In order to create a custom login page using the web-based manager, this feature must be enabled using Feature Select. For more information, see “Feature Select” on page 243.

You configure a custom SSL VPN login by going to *VPN* > *SSL* > *Custom Login* and selecting *Create New*. Users access different portals depending on the URL they enter. The first option in the custom login page is to enter the path of the custom URL. This path is appended to the address of the FortiGate unit interface that SSL VPN users connect to. The actual path for the custom login page appears beside the URL path field. You can also limit the number of users that can access the custom login at any one time. Finally you can use HTML code to customize the appearance of the login page.

Figure 22: Custom SSL VPN login



After adding the custom login, you must associate it with the users that will access the custom login. Do this by going to *Policy* > *Policy* > *Policy* and creating an SSL VPN policy. Add an *Authentication Rule* to the policy and select the users and user groups who should access the custom login page. Select *Custom Login* and select the custom login page that you created.

Figure 23: Associating a custom SSL VPN login with a user group

Automatically add devices found by device identification to the vulnerability scanner configuration

When you go to *System* > *Network* > *Interfaces* to configure an interface to detect and identify devices you can also select *Add New Devices to Vulnerability Scan List*. As devices are found, they are added to the Asset Definitions list of the Vulnerability scanner. You can choose to run a scan of all of the devices on the list or of selected items, including devices found using FortiGate device identification.

The SIP ALG can receive SIP traffic on multiple TCP and UDP ports

You also configure the SIP ALG to listen in two different TCP ports and two different UDP ports for SIP sessions. For example, if you receive SIP TCP traffic on port 5060 and 5064 and UDP traffic on ports 5061 and 5065, you can enter the following command to receive the SIP traffic on all of these ports:

```
config system settings
   set sip-tcp-port 5060 5064
   set sip-udp-port 5061 5065
end
```

IPv6 PIM sparse mode multicast routing

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with RFC 4601: Protocol Independent Multicast - Sparse Mode (PIM-SM). You can use the following command to configure IPv6 PIM sparse multicast routing.

```
config router multicast6
  set multicast-routing {enable | disable}
    config interface
      edit <interface-name>
        set hello-interval <1-65535 seconds>
        set hello-holdtime <1-65535 seconds>
    end
    config pim-sm-global
      config rp-address
        edit <index>
          set ipv6-address <ipv6-address>
    end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

Wireless RADIUS-Based MAC Authentication

Wireless clients can be supplementally authenticated by MAC address. A RADIUS server stores the allowed MAC address for each client and the wireless controller checks the MAC address independently of other authentication methods.

MAC-based authentication must be configured in the CLI. In the following example, MAC-based authentication is added to an existing access point *vap1* to use a RADIUS server at 192.168.1.95:

```
config wireless-controller vap
  edit vap1
    set radius-mac-auth enable
    set radius-mac-auth-server 192.168.1.95
end
```

Security Features

Features previously known as UTM Security Features are now known as Security Features.

In order to create new profiles for the Security Features, Multiple Security Profiles must be enabled using Feature Select. For more information, see “Feature Select” on page 243.

New Security Features in FortiOS 5.0 include:

- FortiSandbox
- Botnet and phishing protection
- Windows file sharing (CIFS) flow-based antivirus scanning
- Advanced Application Control and IPS sensor creation
- Custom Application Control signatures and IPS signatures
- Flow-based inspection improvements
- Configuring SSL inspection for flow-based and proxy protection
- Explicit web Proxy Extensions – SSL inspection, IPS, Application Control, and flow-based antivirus, web filtering and DLP
- Replacement messages for flow-based web filtering of HTTPS traffic
- DNS web filtering
- FortiGuard Web Filter quotas can be set based on traffic volume
- Customizing the authentication replacement message for a FortiGuard web filter category
- YouTube Education Filter implemented in Web Filtering Profiles
- IPS hardware acceleration
- New SIP ALG features
- DLP watermarking
- SSH inspection
- Optimizing SSL encryption/decryption performance

FortiSandbox

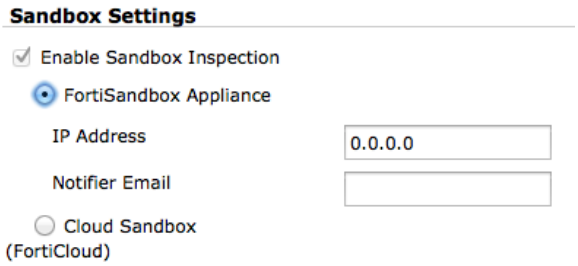
The new FortiSandbox unit is used for automated sample tracking, or sandboxing, for files from a FortiGate unit. This allows suspicious files to be sent to be inspected without risking network security. If the file exhibits risky behavior, or is found to contain a virus, a new virus signature is created and added to the FortiGuard antivirus signature database.

Cloud Sandbox, formerly known as FortiGuard Analytics, can also be used for sandboxing if you have an active FortiCloud subscription.

Configuration

FortiSandbox is configured by going to *System* > *Config* > *FortiSandbox*. After enabling FortiSandbox, select either: *FortiSandbox Appliance* or *Cloud Sandbox (FortiCloud)*.

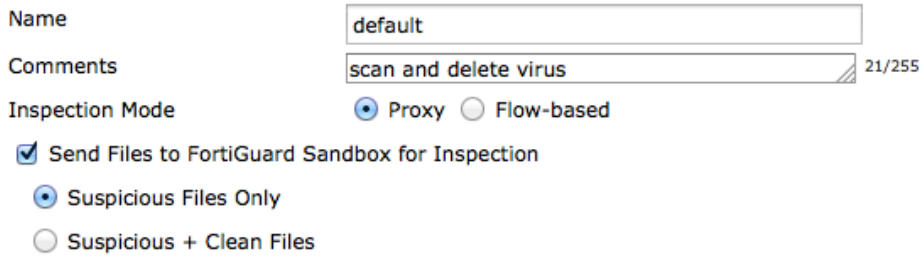
Figure 24: FortiSandbox Configuration



Sending files to FortiSandbox

An anti-virus profile can be set up to send files to FortiSandbox. To do this, edit the profile being used and enable *Send Files to FortiSandbox for Inspection*.

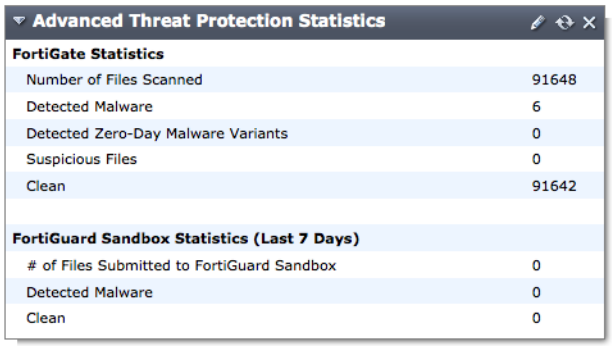
Figure 25: An anti-virus profile using FortiSandbox



Tracking submitted files

The *Advanced Threat Protection Statistics* widget shows the number of files that have been submitted to FortiSandbox and the inspection results.

Figure 26: The Advanced Threat Protection Statistics widget

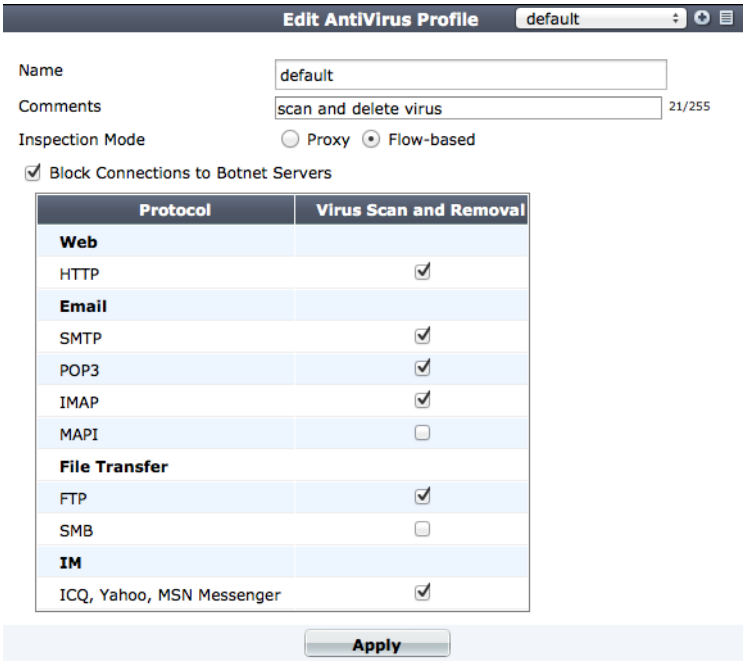


Botnet and phishing protection

In a proxy or flow-based antivirus profile, you can configure the FortiGate unit to detect and block botnet server connection attempts. This feature also blocks attempted access to phishing URLs. The antivirus database is constantly updated with the addresses of known command and control (C&C) sites that Botnet clients attempt to connect to as well as phishing URLs.

To enable Botnet and phishing protection in either a proxy or flow-based antivirus profile, select *Block Connections to Botnet Servers*.

Figure 27: Adding Botnet and phishing protection to a flow-based antivirus profile

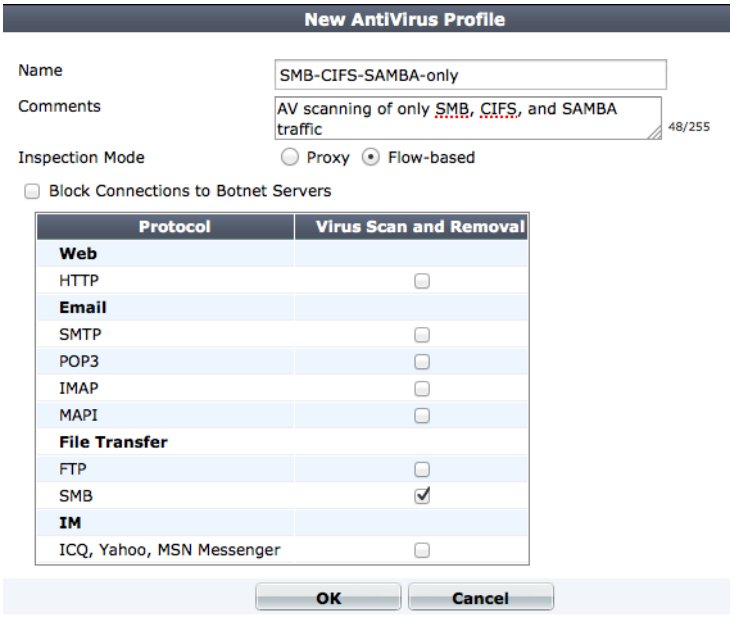


Windows file sharing (CIFS) flow-based antivirus scanning

FortiOS 5.0 now supports virus scanning of Windows file sharing traffic. This includes CIFS, SMB and SAMBA traffic. This feature is applied by enabling SMB scanning in an antivirus profile and then adding this profile to a security policy that accepts CIFS traffic. CIFS virus scanning is available only through flow-based antivirus scanning.

FortiOS 5.0 flow-based virus scanning can detect the same number of viruses in CIFS/SMB/SAMBA traffic as it can for all supported content protocols.

Figure 28: Configuring CIFS/SMB/SAMBA virus scanning



Use the following command to enable CIFS/SMB/SAMBA virus scanning in an antivirus profile:

```
config antivirus profile
  edit smb-profile
    config smb
      set options scan
      set avdb flow-based
    end
```

Then add this antivirus profile to a security policy that accepts the traffic to be virus scanned. In the security policy the service can be set to ANY, SAMBA, or SMB.

```
config firewall policy
  edit 0
    set service ANY
    ...
    set utm-status enable
    set av-profile smb-profile
  end
```

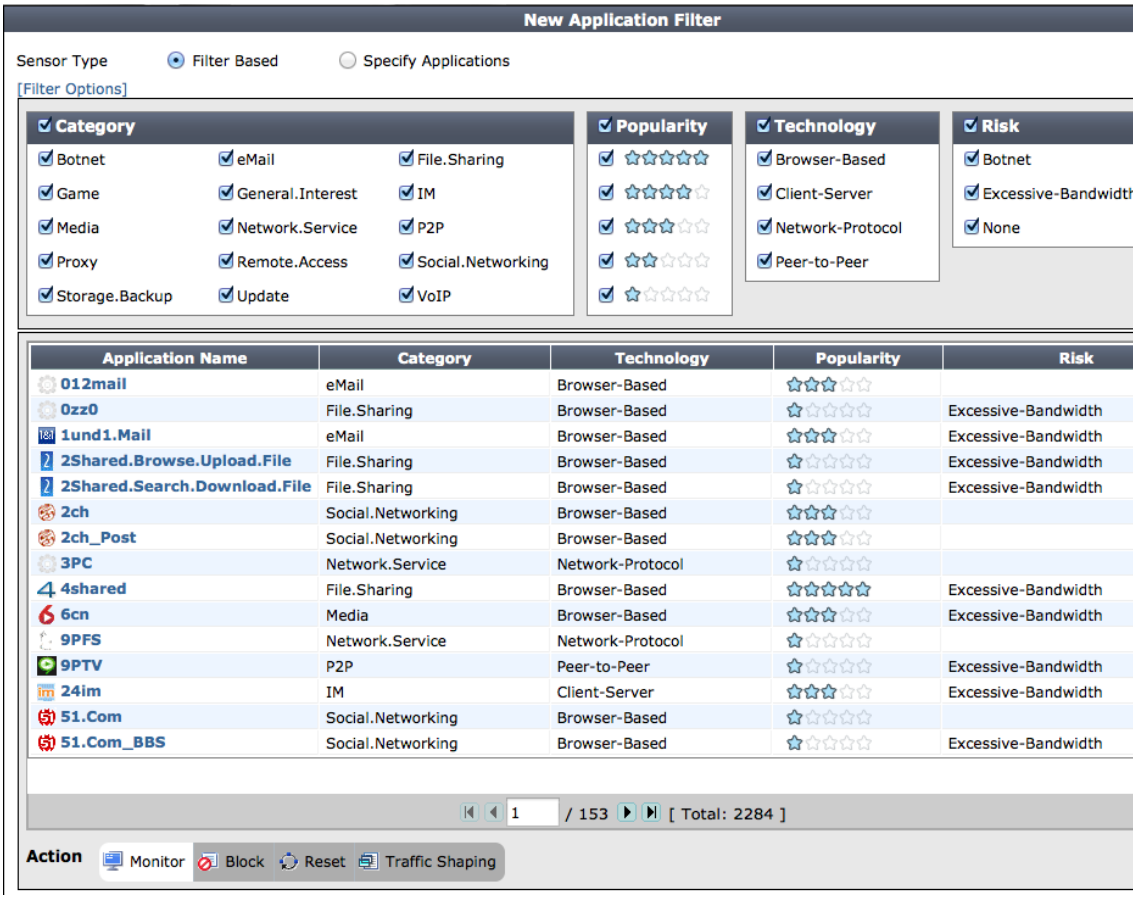
Note the following about CFIS/SMB/SAMBA virus scanning:

- Some newer version of SAMBA clients and SMB2 can spread one file across multiple sessions, preventing some viruses from being detected.
- Enabling CIFS/SMB/SAMBA virus scanning can affect FortiGate performance.
- SMB2 is a new version of SMB that was first partially implemented in Windows Vista. Currently SMB2 is supported by Windows Vista or later, partly supported by Samba 3.5 and fully support by Samba 3.6.
- The latest version of SMB2.2 will be introduced with Windows 8.
- Most clients still use SMB as default setting.

Advanced Application Control and IPS sensor creation

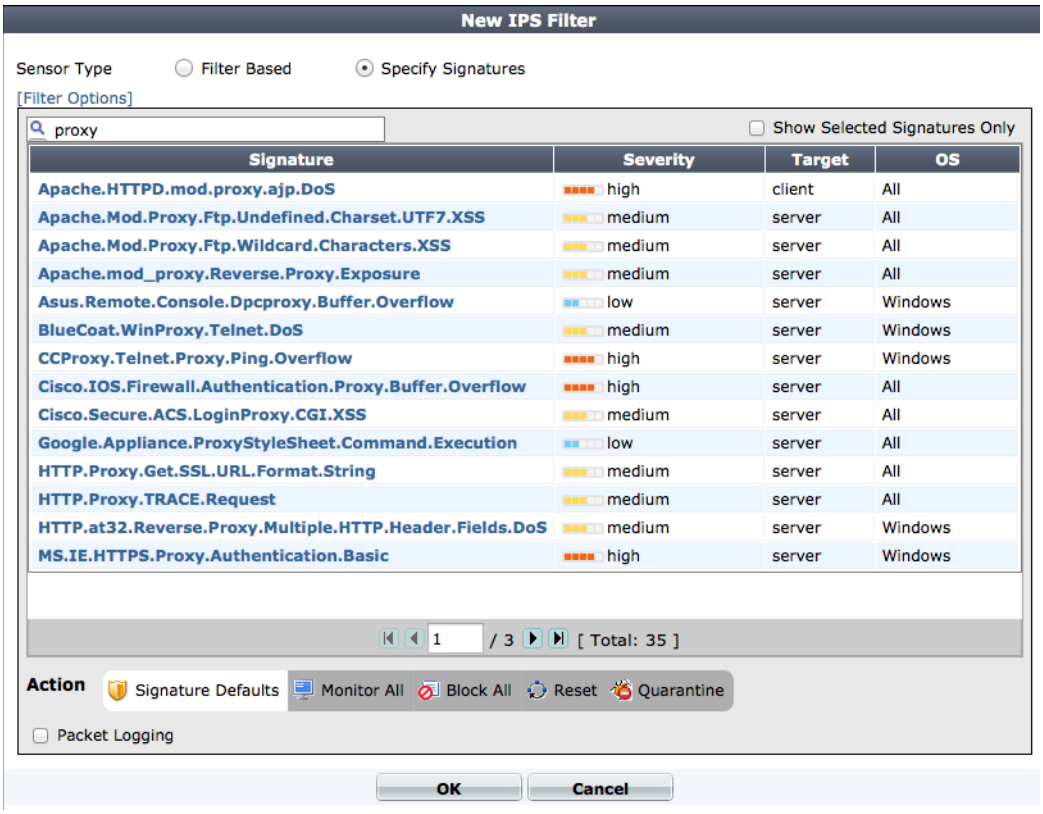
In FortiOS 5.0, it is much easier to sort through Fortinet's thousands of application definitions and IPS signatures to find the ones that you want to add to Application Control and IPS sensors. The creation pages for both of these features include filters for severity, category, popularity, technology and risk.

Figure 29: Application list filtering



You can also search through the application or signature list by name.

Figure 30:IPS signatures search example



Custom Application Control signatures and IPS signatures

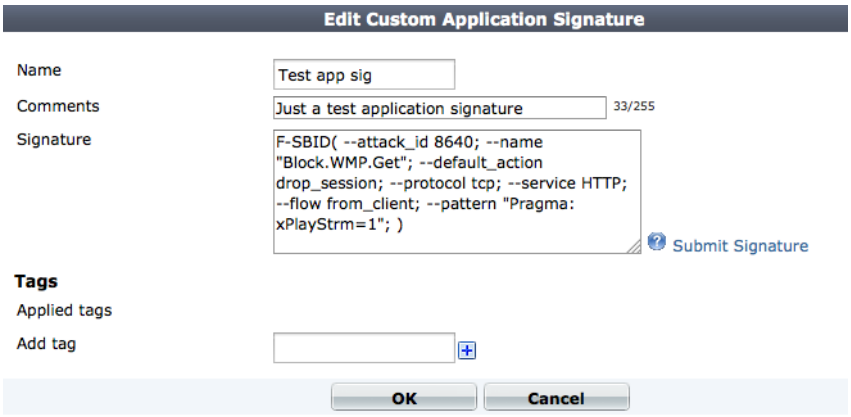
The application control and IPS signatures provide coverage for most applications and network vulnerabilities. You can extend the coverage by adding custom application signatures and custom IPS signatures.

You add custom application signatures by going to *Security Policies* > *Application Control* > *Application List* and selecting *Create New*.

You add custom IPS signatures by going to *Security Policies* > *Intrusion Protection* > *IPS Signatures* and selecting *Create New*.

Custom application signatures and custom IPS signatures use the same syntax. See the *UTM Guide* for a description the signature syntax.

Figure 31: Example custom application signature



Use the following command to add a custom application control signature.

```
config application custom
  edit New-custom-sig
    set signature F-SBID( --attack_id 8640; --name "Block.WMP.Get";
        --default_action drop_session; --protocol tcp; --service
        HTTP; --flow from_client; --pattern "Pragma: xPlayStrm=1";
        )
    end
```

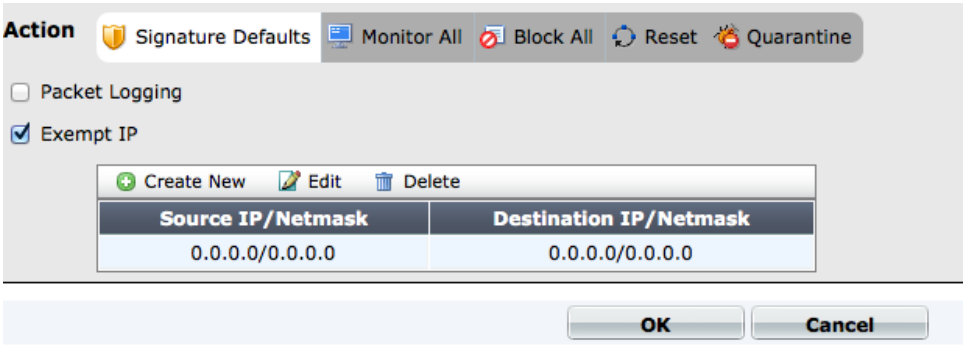
Use the following command to add a custom IPS signature.

```
config ips custom
  edit New-custom-sig
    set signature F-SBID( --attack_id 8640; --name "Block.WMP.Get";
        --default_action drop_session; --protocol tcp; --service
        HTTP; --flow from_client; --pattern "Pragma: xPlayStrm=1";
        )
    end
```

Exempting IP addresses from IPS

IPS filters can be configured so that signatures are not applied to traffic from specific IP addresses. To exempt an IP address, a filter must be created with the *Sensor Type* set to *Specify Signatures*. *Exempt IP* can then be enabled and the necessary exemptions configured using Source and Destination IPs.

Figure 32: Exempting IP addresses from IPS



Flow-based inspection improvements

If your FortiGate unit supports flow-based scanning, you can choose to select flow-based instead of proxy scanning. Flow-based scanning uses the FortiGate IPS engine to examine network traffic as it passes through the FortiGate unit without using a proxy to buffer and potentially change packets.

In FortiOS 5.0, flow-based inspection has been extended to email filtering. The following sections contain information about additional flow-based scanning improvements.

Configuring SSL inspection for flow-based and proxy protection

FortiOS 5.0 fully supports flow-based inspection of SSL sessions. This means that HTTPS, IMAPS, POP3S, SMTPS and FTPS traffic can now be decrypted and inspected by IPS and application control and flow-based antivirus, web filtering and email filtering.

FortiOS 5.0 continues to fully support proxy inspection of SSL sessions. In FortiOS 5.0, configuring proxy SSL inspection has changed as described below.

To enable proxy or flow-based inspection of SSL sessions, you must add an SSL/SSH Inspection profile to a security policy. You can configure SSL/SSH inspection profiles to inspect HTTPS, SMTPS, POP3S, IMAPS and FTPS traffic, as well as SSH traffic. You can configure the profile to control which SSL protocols to inspect, the ports to inspect for each protocol and the certificate to use with SSL sessions.

To apply proxy virus scanning and web filtering to HTTPS, IMAPS, POP3S, SMTPS and FTPS sessions

1. Go to *Policy* > *Policy* > *SSL/SSH Inspection* and create or edit an SSL/SSH inspection profile.
2. Under *SSL Inspection Options* select the CA certificate to use for SSL sessions. You can import a new certificate or use one already imported into the FortiGate unit.
3. Under enable the SSL protocols that you want to inspect and set the ports to inspect for each protocol.
4. Configure other settings as required and select *Apply* to save your changes.
5. Go to *Policy* > *Policy* > *Policy* and create a new or edit a policy that accepts the SSL traffic to be inspected.
6. Under *Security Profiles,* turn on *AntiVirus* and *Web Filter* and select profiles for them.
7. Turn on *SSL/SSH Inspection* and select the SSL/SSH inspection profile that you configured.
8. Select OK.

To apply flow-based virus scanning and web filtering and application control to HTTPS, and POP3S sessions

This example describes adding factory default antivirus, web filtering, application control and SSL/SSL profiles to a security policy that accepts HTTPS and POP3S traffic to apply flow-based virus scanning, web filtering and application control to the HTTPS and POP3S traffic accepted by the security policy.

1. Go to *Policy* > *Policy* > *Policy* and create or edit a policy that accepts the HTTPS and POP3S traffic to be inspected.
2. Under *Security Profiles,* turn on *AntiVirus* and select the *AV-flow* profile.
3. Turn on *Web Filter* and select the *web-filter-flow* profile.
4. Turn on *Application Control* and select the *default* profile.
5. Turn on *SSL/SSH Inspection* and select the *default* profile.
6. Select *OK*.

Explicit web Proxy Extensions – SSL inspection, IPS, Application Control, and flow-based antivirus, web filtering and DLP

FortiOS 5.0 fully supports SSL inspection of explicit web proxy traffic. This means that HTTPS traffic accepted by the explicit web proxy can now be subject to deep inspection for antivirus, web filtering and DLP.

FortiOS 5.0 also fully supports flow-based inspection of explicit web proxy traffic. This includes full support for IPS and application control, as well as flow-based virus scanning and web filtering for HTTP, HTTPS and FTP over HTTP traffic.

SSL content inspection and flow-based inspection are added to explicit web proxy sessions by enabling Security Profiles in a security policy that accepts web-proxy traffic and then selecting profiles that implement flow-based inspection for the features you need.

The explicit FTP proxy and the IPv6 explicit web proxy do not support SSL inspection or IPS, application control, and flow-based antivirus, web filtering and DLP.

Replacement messages for flow-based web filtering of HTTPS traffic

FortiOS 5.0 now supports replacement messages for flow-based HTTPS web filtering. Flow-based HTTP and HTTPS web filtering send the same replacement message as proxy web filtering. For FortiGuard web filtering, the replacement message is the *FortiGuard Block Page* and for URL web filtering, the replacement message is the *URL Block Page*. To edit replacement messages, go to *System* > *Config* > *Replacement Messages*.

DNS web filtering

A DNS request is typically the first part of any new session to a new website. DNS web filtering takes advantage of this by including the web site category in DNS responses. When a FortiGate unit resolves a URL, it receives a rating in addition to the IP address of the website.

DNS Web filtering uses the same categories as FortiGuard Web Filtering and requires you to configure your FortiGate unit to use FortiGuard DNS as its DNS Server. DNS web filtering is lightweight in terms of resource usage because it doesn't involve any actual content inspection.

DNS web filtering includes reduced functionality compared to proxy and flow-based web filtering. DNS web filtering does not support:

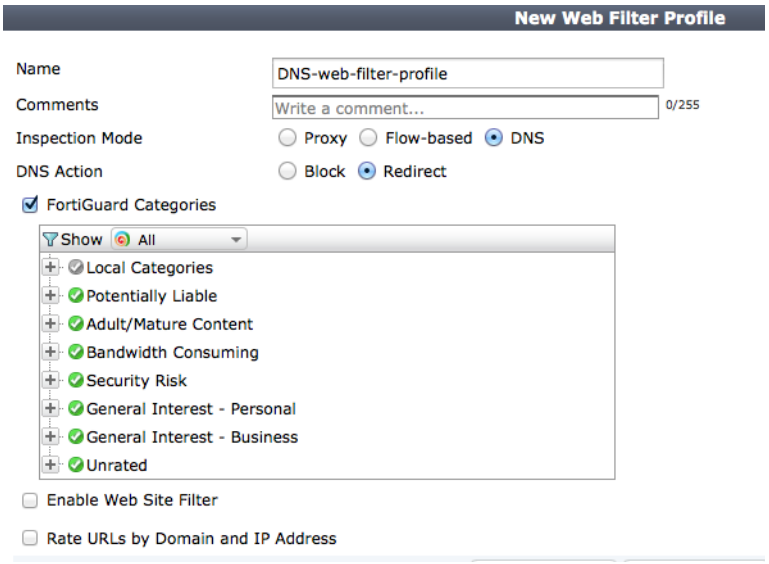
- Quotas
- Setting web filter categories to Warning or Authenticate (Allow, Monitor and Block are supported)
- Safe Search
- URL only scanning for HTTPS
- Advanced filtering options such as web content filtering, web resume download blocking, blocking invalid URLs, HTTP post action options, Java applet filtering, ActiveX filtering, cookie filtering, image rating, allowing websites when a rating error occurs and blocking HTTP redirects by rating

To configure your FortiGate unit to use DNS web filtering, start by going to *System* > *Network* > *DNS* and under *DNS Settings*, make sure *Use FortiGuard Servers* is selected and select *Apply*.

Go to *Security Profiles* > *Web Filter* > *Profiles* and edit a web filtering profile or create a new one. Set *Inspection Mode* to DNS. Then you can set *DNS action* to *Block* or *Redirect*. If you select *Redirect*, every time a web page is blocked by DNS web filtering the URL is re-directed to a web page on the FortiGuard network that displays a block message. If you select *Block,* the page is blocked and the user's web browsers display an error message or the connection attempt will time out.

Set the FortiGuard web filtering categories as required. You can configure DNS web filtering to block, allow and monitor web pages in each FortiGuard category. Select *Apply* to save the profile.

Figure 33:DNS web filtering profile



Go to *Policy* > *Policy* > *Policy* and create or edit a security policy, enable web filtering and select the web filtering profile that you configured for DNS web filtering.

All traffic HTTP accepted by the policy will be inspected by DNS web filtering.

FortiGuard Web Filter quotas can be set based on traffic volume

In FortiOS 5.0, FortiGuard web filter quotas can now set based on the amount of traffic as well as time.

You can add traffic quotas to a web filter profile from the CLI. The following command shows how to add a quota of 20 GB for bandwidth consuming web sites. These command assumes you have already set up the profile to monitor, warn or require authentication for bandwidth consuming web sites (category g04).

```
config webfilter profile
  edit default
    config ftgd-wf
      config quota
        edit 0
          set category g04
          set type traffic
          set unit GB
          set value 20
      end
    end
end
```

Customizing the authentication replacement message for a FortiGuard web filter category

FortiOS 5.0 allows you to customize the replacement message that appears for a specific FortiGuard Web Filtering category. You do this by editing a Web Filter profile, right clicking on a FortiGuard Web Filtering category, selecting *Authenticate* and selecting a user group. Then right-click on the category again and select *Customize*.

A blank customize replacement message window appears and you can create the custom replacement message. Select *Save* and close the replacement message editor. The selected category has an Authenticate icon next to it. You can select this icon to edit the replacement message.

Saving the message creates a custom replacement message group. If you go to *System* > *Config* > *Replacement Messages Group* and open the replacement message group called *web-filter-default* you can find a *Custom Messages* category that contains the new replacement message.

YouTube Education Filter implemented in Web Filtering Profiles

You can add your organization's YouTube education filter to a web filtering profile. The Educational filter will be implemented on all YouTube sessions accepted by the security policy that the web filter profile is added to. This makes it easier to allow your users to only access educational YouTube content while blocking content not considered educational.

To add a YouTube eduction filter

1 Go to *Security Profiles* > *Web Filter* > *Profiles* and edit a web filter profile.

2 Select *Enable Safe Search* > *YouTube Education Filter* and enter the YouTube education filter code.

3 Select Apply to save the changes to the web filter profile.

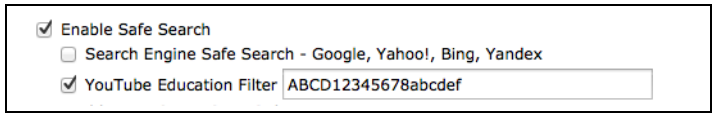
4 Go to *Policy* > *Policy* > *Policy* and edit the security policy that allows users to access the Internet.

5 Select Security Profiles.

6 Select *Enable Web Filter* and select the web filter profile that includes the YouTube education filter.

7 Select OK to save the security policy.

Figure 34: Adding a YouTube education filter code to a web filter profile



Use the following CLI command to add a YouTube education code to a web filter profile:

```
config webfilter profile
  edit youtube-EDU
    config web
      set safe-search youtube-edu
      set youtube-edu-filter-id "ABCD1234567890abcdef"
    end
  end
```

IPS hardware acceleration

FortiGate units with CPx and NPx processes can accelerate IPS performance by offloading pattern matching to the CPx or NPx processor. If your FortiGate hardware supports this feature the following CLI command will be available:

```
config ips global
  set hardware-accel-mode {engine-pick | none | CP-only | NP-only |
      NP+CP}
end
```

Where:

- `engine-pick`, let the IPS engine pick the best mode.
- `none`, hardware acceleration disabled.
- `CP-Only`, accelerate with content processors only.
- `NP-only`, accelerate with network processor only.
- `NP+CP`, accelerate with both network and content processors.

New SIP ALG features

FortiOS 5.0 includes the following new SIP ALG features:

- Inspecting SIP over SSL/TLS (secure SIP)
- Opening and closing SIP via and record-route pinholes
- Adding the original IP address and port to the SIP header after NAT

Inspecting SIP over SSL/TLS (secure SIP)

Some SIP phones and SIP servers can communicate using SSL or TLS to encrypt the SIP signalling traffic. To allow SIP over SSL/TLS calls to pass through the FortiGate unit, the encrypted signalling traffic has to be unencrypted and inspected. To do this, the FortiGate SIP ALG intercepts, unencrypts and inspects the SIP packets. The packets are then re-encrypted and forwarded to their destination.

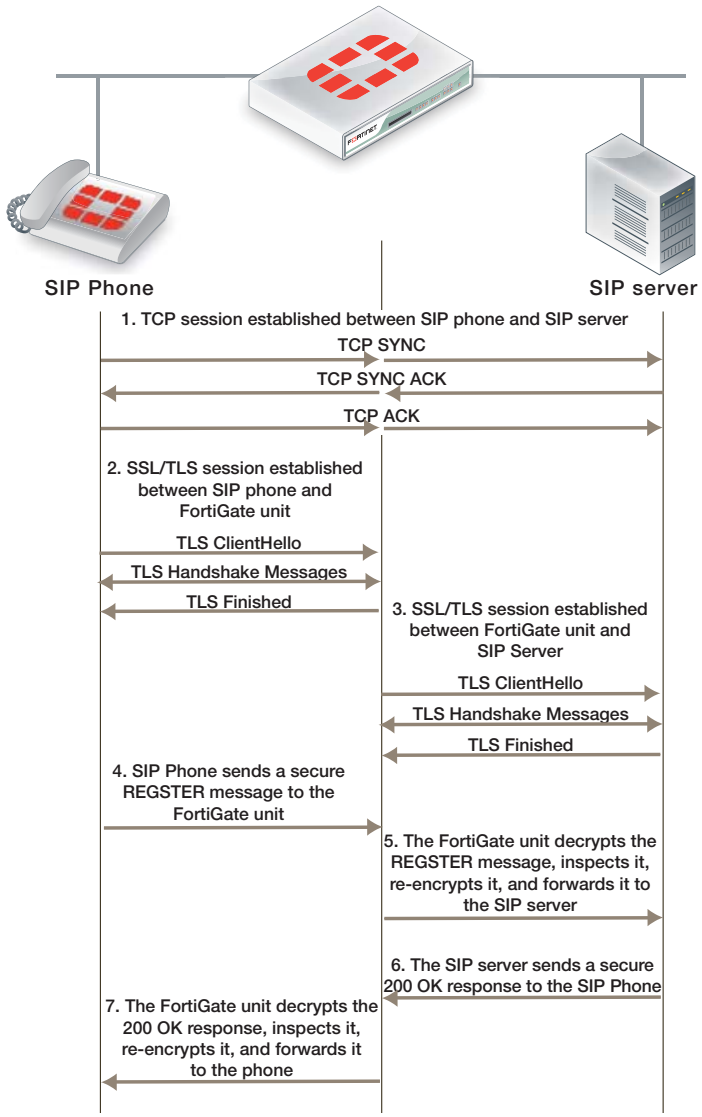
Normally SIP over SSL/TLS uses port 5061. You can use the following command to change the port that the FortiGate listens on for SIP over SSL/TLS sessions to port 5066:

```
config system settings
  set sip-ssl-port 5066
end
```

The SIP ALG supports full mode SSL/TLS only. Traffic between SIP phones and the FortiGate unit and between the FortiGate unit and the SIP server is always encrypted.

You enable SSL/TLS SIP communication by enabling SSL mode in a VoIP profile. You also need to install the SIP server and client certificates on your FortiGate unit and add them to the SSL configuration in the VoIP profile.

Figure 35:SIP over SSL/TLS between a SIP phone and a SIP server



Other than enabling SSL mode and making sure the security policies accept the encrypted traffic, the FortiGate configuration for SSL/TLS SIP is the same as any SIP configuration.

SIP over SSL/TLS is supported for all supported SIP configurations.

Adding the SIP server and client certificates

A VoIP profile that supports SSL/TLS SIP requires one certification for the SIP server and one certificate that is used by all of the clients. Use the following steps to add these certificates to the FortiGate unit. Before you start, make sure the client and server certificate files and their key files are accessible from the management computer.

1. Go to *System* > *Certificates* > *Local Certificates* and select *Import.*
2. Set *Type* to *Certificate*.
3. Browse to the *Certificate file* and the *Key file* and select *OK*.
4. Enter a password for the certificate and select *OK*.

   The certificate and key are uploaded to the FortiGate unit and added to the *Local Certificates* List.
5. Repeat to upload the other certificate.

The certificates are added to the list of Local Certificates as the filenames you uploaded. You can add comments to make it clear where the certificate is from and how it is intended to be used.

Adding SIP over SSL/TLS support to a VoIP profile

Use the following commands to add SIP over SSL/TLS support to the default VoIP profile. The following command enables SSL mode and adds the client and server certificates and passwords (the same ones you entered when you imported the certificates):

```
config voip profile
  edit default
    config sip
      set ssl-mode full
      set ssl-client-certificate "Client_cert"
      set ssl-server-certificate "Server_cert"
      set ssl-auth-client "check-server"
      set ssl-auth-server "check-server-group"
  end
end
```

Other SSL mode options are also available:

`ssl-send-empty-frags {disable | enable}`	Enable to send empty fragments to avoid CBC IV attacks. Compatible with SSL 3.0 and TLS 1.0 only. Default is `enable`.
`ssl-client-renegotiation {allow | deny | secure}`	Control how the ALG responds when a client attempts to renegotiate the SSL session. You can allow renegotiation or block sessions when the client attempts to renegotiate. You can also select `secure` to reject an SSL connection that does not support RFC 5746 secure renegotiation indication. Default is `allow`.

`ssl-algorithm {high | low | medium}`	Select the relative strength of the algorithms that can be selected. You can select `high`, the default, to allow only AES or 3DES, `medium`, to allow AES, 3DES, or RC4 or `low`, to allow AES, 3DES, RC4, or DES.
`ssl-pfs {allow | deny | regqure}`	Select whether to `allow`, `deny`, or `require` perfect forward secrecy (PFS). Default is `allow`.
`ssl-min-version {ssl-3.0 | tls-1.0 | tls-1.1}`	Select the minimum level of SSL support to allow. The default is `ssl-3.0`.
`ssl-max-version {ssl-3.0 | tls-1.0 | tls-1.1}`	Select the maximum level of SSL support to allow. The default is `tls-1.1`.

Opening and closing SIP via and record-route pinholes

If `open-via-pinhole` is disabled (the default setting), the FortiGate unit does not open pinholes for Via messages. You can enable `open-via-pinhole` so that the FortiGate unit opens pinholes for Via messages. In previous versions of FortiOS, this option was `reg-diff-port`.

If `open-record-route-pinhole` is enabled (the default setting), the FortiGate unit opens pinholes for Record-Route messages. You can disable `open-record-route-pinhole` so that the FortiGate unit does not open pinholes for Record-Route messages.

Usually you would want to open these pinholes. Keeping them closed may prevent SIP from functioning properly through the FortiGate unit. However, they can be disabled for interconnect scenarios (where all SIP traffic is between proxies and traveling over a single session). In some cases, these settings can also be disabled in access scenarios if it is known that all users will be registering regularly so that their contact information can be learned from the register request.

You may also want to prevent pinholes from being opened to avoid creating a pinhole for every register or non-register request. Each pinhole uses additional system memory, which can affect system performance if there are hundreds or thousands of users, and requires refreshing that can take a relatively long amount of time if there are thousands of active calls.

Adding the original IP address and port to the SIP header after NAT

In some cases, your SIP configuration may require that the original IP address and port from the SIP contact request is kept after NAT. For example, the original SIP contact request could include the following:

```
Contact: <sip:0150302438@172.20.120.110:5060>;
```

After the packet goes through the FortiGate unit and NAT is performed, the contact request could look like the following (the IP address translated to a different IP address and the port to a different port):

```
Contact: <sip:0150302438@10.10.10.21:33608>;
```

You can enable `register-contact-trace` in a VoIP profile to have the SIP ALG add the original IP address and port in the following format:

```
Contact: <sip:0150302438@<nated-ip>:<nated-port>;o=<original-ip>:
    <original-port>>;
```

So the contact line after NAT could look like the following:

```
Contact: <sip:0150302438@10.10.10.21:33608;o=172.20.120.110:5060>;
```

Enter the following command to enable keeping the original IP address and port:

```
config voip profile
  edit Profile_name
    config sip
      set register-contract-trace enable
  end
```

DLP watermarking

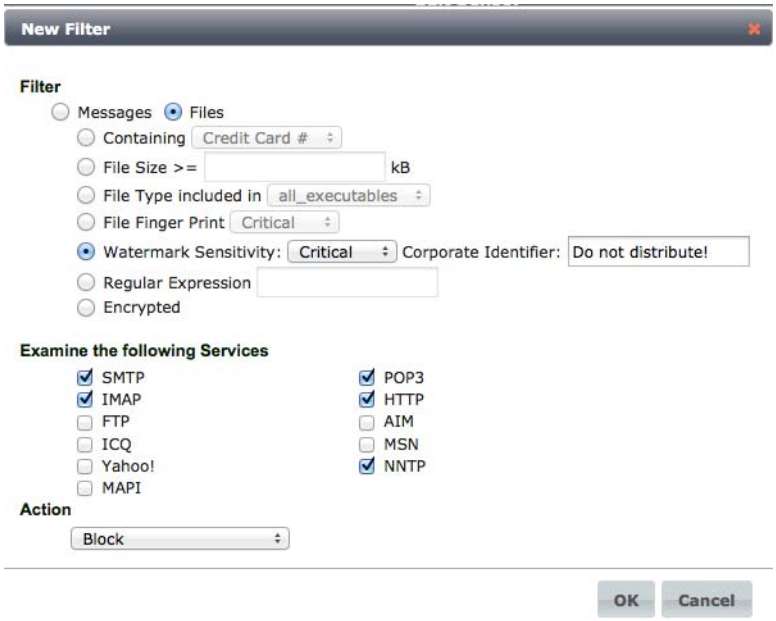
DLP watermarking involves using DLP to filter files that pass through the FortiGate unit and contain a corporate identifier (a text string) and a sensitivity level (Critical, Private and Warning) hidden in a watermark. Watermarked files have this information applied in a way that is not visible to the user. DLP watermarking requires a FortiGate unit with a hard disk or flash disk.

You must use the Fortinet watermarking client to apply a watermark to a file. Files should be watermarked before they are distributed. Then, with DLP watermarking enabled, your FortiGate unit can track and optionally block watermarked files that pass through it.

To configure DLP to filter for watermarked files, go to *Security Profiles* > *Data Leak Prevention* > *Sensors* and create or edit a DLP sensor. Add a filter to the sensor and set *Filter* to *Files*. Then select *Watermark Sensitivity* and select *Critical*, *Private* or *Warning*. Then enter the *Corporate Identifier*. The corporate identifier is a case-sensitive text string that must exactly match the corporate identifier text string added by the watermarking client.

Select the services in which to look for watermarked files. Usually you would choose all of the email protocols active on your network and HTTP. Then set the action for the watermark filter. When DLP finds a file with a watermark that matches the filter, the action selected in the filter is performed. Actions include writing a log message, blocking the file or quarantining the user, IP address or interface.

Figure 36:DLP filter configuration using a watermark



Files can have multiple watermarks in them. The FortiGate unit only has to find one match in a file for DLP watermarking to match it and it will ignore watermarks that don't match. Files without watermarks are ignored by DLP watermarking.

Fortinet watermarking utility

Watermarking uses a digital pattern to mark a file as being proprietary to a specific company. Fortinet has a utility that will apply a digital watermark to any file except a .txt file. The utility adds a small (around 100 bytes) pattern to the file that is recognized by the DLP Watermark filter. This pattern is invisible to the end user.

Currently, FortiGate DLP only works with Fortinet's watermarking client. When watermarking a file, it should be verified that the pattern matches up to a DLP category. Before planning to use watermarking software, it is always best to verify that the software will work with your OS and file types. At the time of writing this document the utility was only available with the current version of FortiExplorer for Windows or through using the CLI for Linux.

Installation of the watermarking client on Linux

Add the watermark file to a location on the system that is in the $PATH

To see what the path is use the command

```
~$ echo $PATH
```

Example results:

```
/usr/local/sbin:/usr/local/bin:/usr/sbin:/usr/bin:/sbin:/bin:/usr/ga
     mes
```

for example you could move or copy the file to the :/bin directory.

Permissions on the watermark file

Check the existing permissions:

The command in Linux for listing file along with the permissions is:

```
ls -l
```

Run the check to see if the permission status. The results may be something along these lines:

```
-rw-r--r-- 1 root root 2053868 Jan 10 11:44
     fortinet-watermark-linux.out
```

You will see that in this case it has no executable permissions

To change the permissions on the watermark file:

It will be assume for this command that the utility is in the bin directory and that you have ownership level access.

```
/bin# chmod o+x /bin/ fortinet-watermark-linux.out
```

To verify the change:

```
/bin# ls -l wa*
-rw-r--r-x 1 root root 2053868 Jan 10 11:44
     fortinet-watermark-linux.out
```

You can see how the x for executable has been added to the permissions for the others group.

Syntax of the watermarking client on Linux

The tool is executed in a Linux environment by passing in files or directories of files to insert a watermark.

USAGE:

```
fortinet-watermark-linux.out <options> -f <file name> -i <identifier>
     -l <sensitivity level>
fortinet-watermark-linux.out <options> -d <directory> -i <identifier>
     -l <sensitivity level>
```

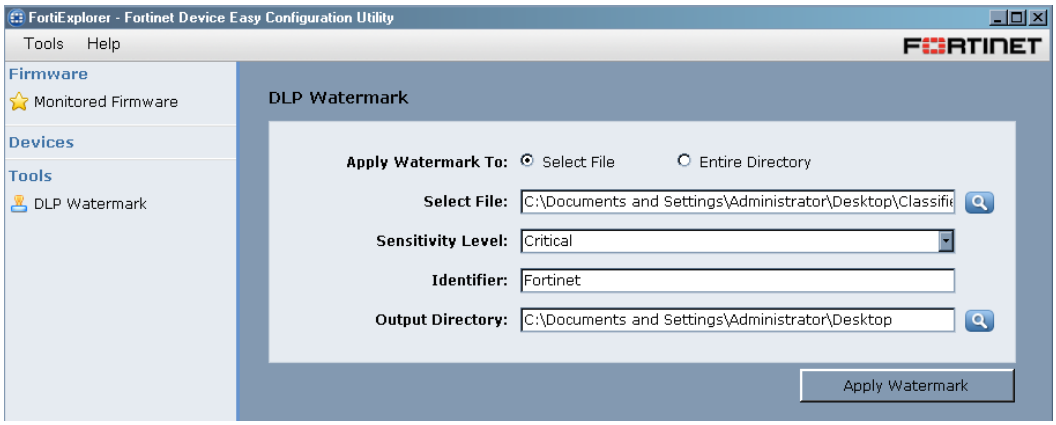
Options:

```
-h print help
-v verbose information
-I inplace watermarking (don't copy file)
-o output directory
-e encode <to non-readable>
-a add additional watermark (by default replaces watermarks existing
    watermarks)
-D delete all watermarks
```

Using the watermarking client with Windows

The watermarking client is now part of FortiExplorer in Windows, appearing in the Tools menu. Using the client, you can apply a watermark to any files you wish to track and possibly block using DLP.

Figure 37: The Fortinet watermarking client in Windows



Using the watermarking client with Linux

If you are in your home directory and you want to watermark a file in the Documents directory, you could plan out the command like this:

watermark [because that is the executable to be used]

-v [so that you can get as much feedback as possible]

-I [because you don't want a new file you just want to watermark the existing one]

-f [because you only want to change the one file not the entire directory]

filename.pdf [the name of the file]

-i 123456 [to set the identifier to 123456 - this is a required setting

-l Private [to set the sensitivity level to "Private"]

Now at the command prompt enter all of these components in order:

```
~/Documents$ fortinet-watermark-linux.out -v -I -f filename.pdf -i
     12345 -l Private
Creating watermark.  Pattern:
=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=identifier=12345
     sensitivity=Private=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=-=
Watermarking file: 'filename.pdf'
Inserted watermark size 148
<command prompt>:~/Documents$
```

SSH inspection

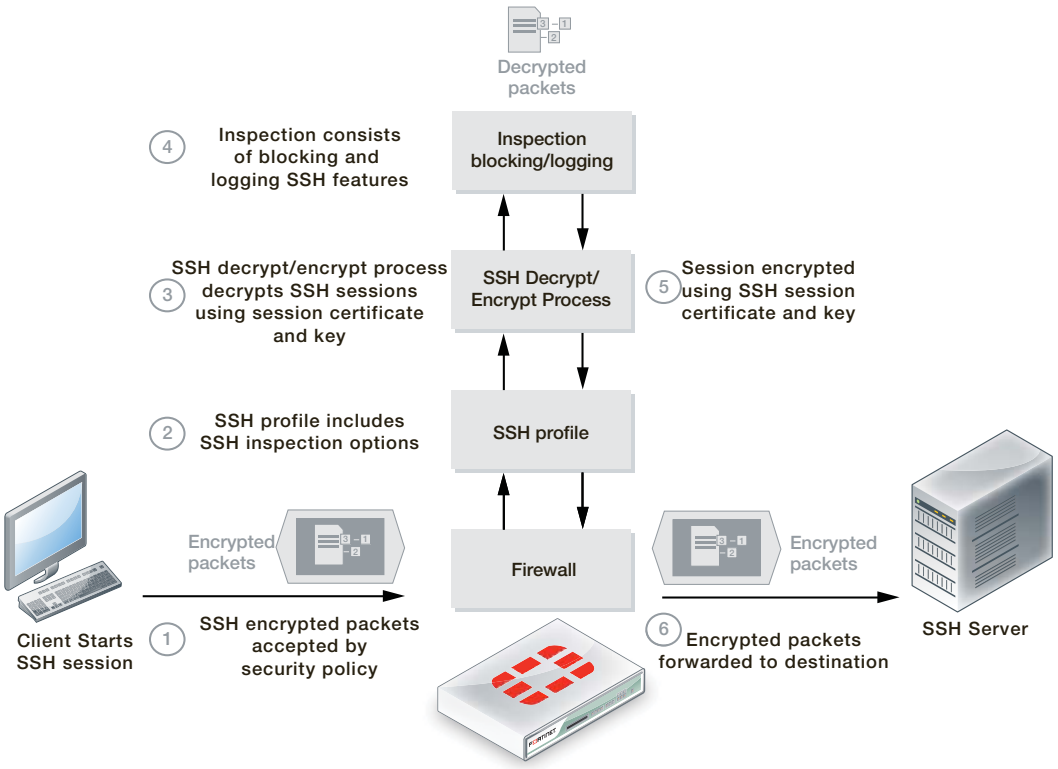
FortiOS 5.0 includes a new SSH proxy, available on selected models, that supports decrypting and inspecting SSH sessions to block or log the following:

- SSH remote execution
- Port forwarding
- SSH remote shell
- x11 server forwarding

Similar to SSL content inspection, the SSH proxy intercepts the SSH key exchange between the SSH client and server when an SSH session is being set up. All traffic that is part of the SSH session is decrypted by the SSH proxy and SSH inspection features are applied according to the SSH profile in the security policy that accepts the SSH traffic. After inspection, the session is re-encrypted and forwarded to the recipient.

SSH inspection is enabled by default in a SSL/SSH inspection profile.

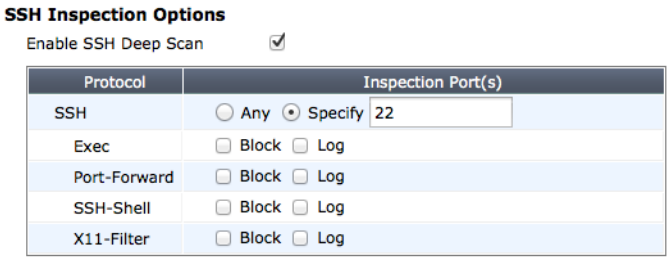
Figure 38:SSH inspection



To configure SSH inspection, go to *Policy* > *Policy* > *SSL/SSH Inspection* and create or edit an SSL/SSH Inspection profile and ensure that *SSH Inspection Options* are enabled. Then configure the port or ports to look for SSH traffic on. The default port is 22 but you can add more. You can then block or log Exec commands, port-forwarding, SSH shells, and X11 FIlters.

Then add this profile to security policy that accepts SSH traffic. Enable the required Security Profiles in the policy.

Figure 39: Configuring SSL Inspection Options



From the CLI:

```
config firewall profile-protocol-options
  edit new-profile
    config ssh
      set port <number> <number> ... (default is port 22)
      set inspect-all {enable | disable}
      set options {allow-invalid-server-cert | ssl-ca-list }
      set oversize-limit <size>
      set block {exe | port-forward | ssh-shell | x11-filter}
    end
```

Optimizing SSL encryption/decryption performance

By default, FortiGate units handle SSL decryption/encryption using the SSL functionality built into their FortiASIC processors. In situations where the FortiGate unit processes large amounts of SSL traffic and has more than 4 CPUs, you may be able to optimize SSL encryption/decryption performance by changing how SSL processing is distributed to the CPUs. You can also use the following command to specify the number of CPUs to use for SSL processing (in the command, CPU is called an SSL worker):

```
config system global
  set optimize-ssl {enable | disable}
  set ssl-worker-count <worker-count>
end
```

The `<worker-count>` is the number of CPUs. The range depends on the number of CPUs in the FortiGate model (this feature only works for FortiGate units with 4 or more CPUs).

You can use the following command to display information about each CPU running in your FortiGate unit:

```
get hardware cpu
```

The command output numbers the CPUs starting at 0. For example, a FortiGate-5001B contains 8 CPUs and the command output for this model contains information about all 8 CPUs numbered 0 to 7. Here is the first few output lines for CPU 7:

```
...
processor       : 7
vendor_id       : GenuineIntel
cpu family      : 6
model           : 14
model name      : Intel(R) Xeon(R) CPU           C5528  @ 2.13GHz
stepping        : 4
cpu MHz         : 2128.072
...
```

If your FortiGate unit includes multiple CPUs and you want to improve SSL performance, use the following command to begin distributing SSL decryption/encryption to 4 CPUs:

```
config system global
  set optimize-ssl enable
  set ssl-worker-count 4
end
```

Monitor FortiGate performance and if SSL performance improves without affecting other performance, you can either maintain this configuration or add another CPU to the configuration (if one is available). Continue in this manner until you achieve optimum performance for your FortiGate unit.

Continue monitoring performance in case you have to change this setting due changes in your network traffic patterns.

Authentication: users and devices

The FortiGate authentication umbrella has been expanded from just user authentication (or user identity) to encompass device identification and client reputation. As well, endpoint control and the vulnerability scanner have become part of FortiOS 5.0 user and device detection, identification and authentication.

Endpoint control and vulnerability scanner changes are described in this chapter. For information about device identification, see "FortiOS and BYOD" on page 173. For information about client reputation, see "Client Reputation" on page 181.

New authentication features described in this chapter include:

- User authentication menu changes
- User identity policy changes
- Authentication-based routing
- Secondary and tertiary RADIUS, LDAP, and TACAS+ servers
- FortiToken two-factor authentication and FortiToken Mobile
- SSO using a FortiAuthenticator unit
- SSO with Windows AD or Novell
- Citrix Agent support for Single Sign On
- Configuring guest access
- Vulnerability Scanning

User authentication menu changes

The user authentication part of FortiOS is seeing major changes for FortiOS 5.0. To begin, the *User* section of the web-based manager has been renamed *User & Device*. All previously available user authentication features are still available but the menu structure has changed to include device identification, the vulnerability scanner, endpoint control, and client reputation:

- Go to *User & Device* > *User* to configure users, user groups, and guest users ("Configuring guest access" on page 167)
- Go to *User & Device* > *Authentication* to configure single sign-on and add RADIUS, LDAP, and TACACS+ servers
- Go to *User & Device* > *Two-factor Authentication* to configure support for two-factor authentication using FortiToken ("FortiToken two-factor authentication and FortiToken Mobile" on page 162)
- Go to *User & Device* > *Vulnerability Scan* to configure and operate the FortiGate vulnerability scanner ("Vulnerability Scanning" on page 170)
- Go to *User & Device* > *Monitor* to view the firewall and banned user authentication lists

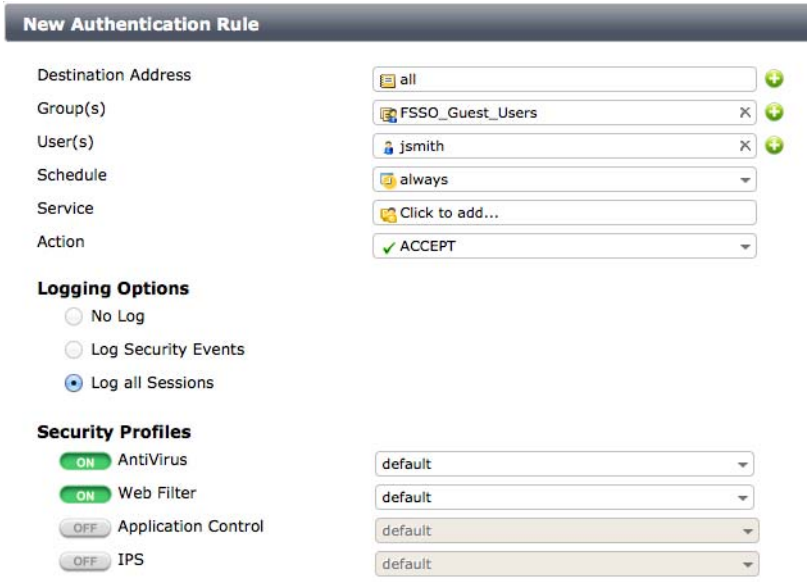
User identity policy changes

The steps for adding user identity-based policies have changed. To add a user identity based policy go to *Policy* > *Policy* > *Policy* and create a new security policy. Select the *Firewall* policy type and the *User Identity* subtype. Select the incoming and outgoing interfaces and source addresses. Configure other features such as NAT and so on.

Then select *Create New* to add user authentication rules to the policy. User authentication rules include the destination addresses, user groups and or individual users, schedule, service, action, logging, and UTM security profiles.

You select the destination address separately for each authentication rule. This means that you can apply different features to different user groups depending on the destination address.

Figure 40: Adding a user authentication rule



Authentication-based routing

FortiOS 5.0 supports authentication-based routing by creating an identity-based route that associates a user group with one or more routes. This identity-based route is then added to a security policy and all traffic from users authenticated by this user group is routed to the gateway. This feature is configured from the CLI and can be useful for MSSPs who need to route users from different organizations to different Internet gateways.

Enter the following command to add an identity-based route that routes all traffic from users in the company1-user-group and the company2-user-group user groups out the wan1 interface to a next-hop router with IP address 172.20.120.2:

```
config firewall identity-based-route
  edit new-id-route
    config rule
      edit 1
        set gateway 172.20.120.2
        set device wan1
        set groups company1-user-group company2-user-group
      end
    end
```

Enter the following command to add the identity-based route to a security policy:

```
config firewall policy
  edit 1
    ...
    set identity-based enable
    set identity-based-route new-id-route
    ...
  end
```

Secondary and tertiary RADIUS, LDAP, and TACAS+ servers

You can now add secondary and tertiary servers to RADIUS, LDAP, and TACAS+ remote authentication server configurations. When you add a secondary server, the FortiGate unit will contact the secondary server only if the primary server is unreachable. The FortiGate unit will only contact the tertiary server if the both the primary and secondary servers are unreachable.

Enter the following command to add up to three servers to a RADIUS server configuration. Specify a domain name or IP address for each server as well as the server secret. In the following example, the RADIUS servers are at IP addresses 172.20.120.10, 172.20.120.20, and 172.20.120.30:

```
config user radius
  edit new-radius-server
    set server 172.20.120.10
    set secret 1st-secret
    set secondary-server 172.20.120.20
    set secondary-secret 2nd-secret
    set tertiary-server 172.20.120.30
    set tertiary-secret 3rd-secret
  end
```

Enter the following command to add up to three servers to an LDAP server configuration. Specify a domain name or IP address for each server. Other than the domain name or password, the secondary and tertiary servers must use the same port and LDAP settings such as the cnid and username. In the following example, the LDAP servers are at IP addresses 192.168.10.10, 192.168.10.20, and 192.168.10.30:

```
config user ldap
  edit "test-ldap"
    set server "192.168.10.10"
    set cnid "exAccountName"
    set dn "dc=americas,dc=example,dc=net"
    set port 3268
    set type regular
    set username "CN=example,OU=Service
         Accounts,OU=Admins,DC=example,DC=csplc,DC=net"
    set password ENC AAAEAOZh5R5/oqYeUVkO2OOKh9QV6DAVZoAjbv0sonh
    set member-attr "ASCCGKraftFortinetVPNInternalUsers"
    set secondary-server "192.168.10.20"
    set tertiary-server "192.168.10.30"
  end
```

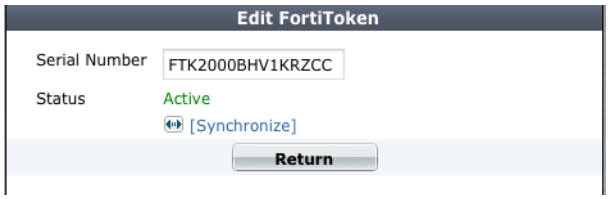
Enter the following command to add up to three servers to an TACAS+ server configuration. Specify a domain name or IP address and key for each server. In the following example, the TACAS+ servers are at IP addresses 10.10.10.10, 10.10.10.20, and 10.10.10.30:

```
config user tacacs+
  edit "test-tacacs"
    set server "10.10.10.10"
    set key ENC
         2OG/F6wocz2/CpE3eHIJs/Qt8gZsXgeNkQCuTxPWPeBk6BXDu8luM
    set secondary-server "10.10.10.20"
    set secondary-key ENC 2OG/F6wocz2/CpE3eHIJs/Qt8gZ
    set tertiary-server "10.10.10.30"
    set tertiary-key ENC 2OG/F6wocz2/CpE3eHIJs/Qt8gZ
    next
  end
```

FortiToken two-factor authentication and FortiToken Mobile

The web-based manager provides improved management of FortiToken devices. The status of each current FortiToken device is listed under *User & Device* > *Two-factor Authentication* > *Fortitokens*. You can also resynchronize FortiToken devices that have gone out of sync. You can also enter new FortiToken devices individually or by importing a list of FortiToken serial numbers in a text file.

Figure 41: View status and synchronize a FortiToken



Configuring FortiToken mobile soft token support

FortiOS 5.0 adds support for FortiToken Mobile, a Fortinet application that enables you to generate One Time Passwords (OTPs) on a mobile device for FortiGate two factor authentication. The user's mobile device and the FortiGate unit must be connected to the Internet to activate FortiToken mobile. Once activated, users can generate OTPs on their mobile device without having network access.

FortiToken Mobile is available for iOS and Android devices from their respective Application stores. No cellular network is required for activation.

The latest FortiToken Mobile documentation is available from the FortiToken page of the Fortinet Technical Documentation website.

To use FortiToken Mobile, a user needs to install the application on their mobile device and then activate a token. After the token is activated, the user can begin to generate OTPs on their mobile device.

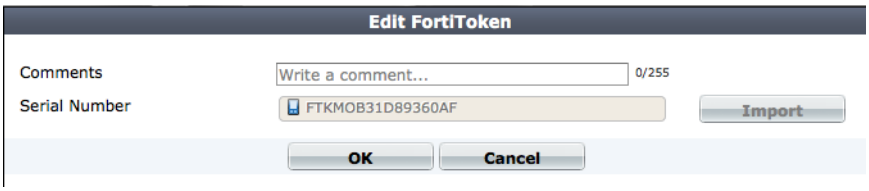
Two free trial tokens are included with every registered FortiGate unit. Additional tokens can be purchased from your reseller or from Fortinet.

You can generate the two free tokens from the FortiGate CLI by entering the following command:

```
execute fortitoken-mobile import 0000-0000-0000-0000-0000
```

This command adds two FortiToken mobile entries to the FortiGate configuration. To view them, go to *User & Device* > *Two-factor Authentication* > *Fortitokens* and open the *MobileToken* list and edit one of the entries.

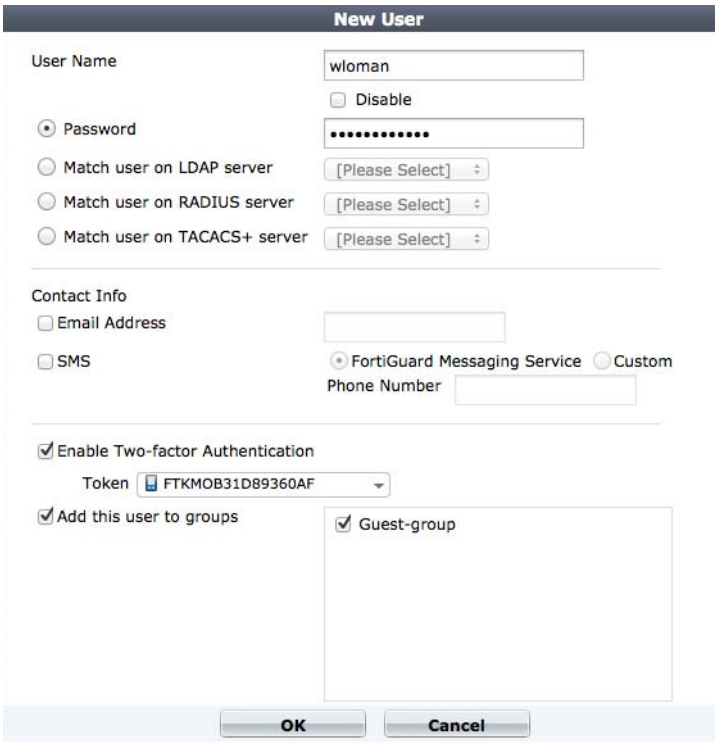
Figure 42: Example free FortiToken Mobile token



To assign a token to a user, go to *User & Device* > *User* > *User Definition* and either add a new user or select the user to assign the token to. Configure the user as required and select *Enable Two-factor Authentication*. Select the token to associate with the user.

Select *OK* to assign the token to the user. If you have added the user's email address or configured SMS settings and configured your FortiGate unit to send email or send SMS messages, the FortiGate unit sends the user an activation code. (To configure your FortiGate unit to send email or SMS messages go to *System* > *Config* > *Messaging Servers*.)

Figure 43: Assigning a FortiToken Mobile token to a user



If for some reason you cannot send the activation code to the user through email or an SMS message, or would rather send the activation code by other means specific to your operation, you can view the activation code from the CLI. For example, for a token with serial number of FTKMOB28E0CA6018 you can enter the following commands:

```
config user fortitoken
  edit FTKMOB28E0CA6018
  get
  serial-number        : FTKMOB28E0CA6018
  activation-code      : 8F41F304
  activation-expire    : 604800
  comments             :
  license              : FTMTRIAL00001088
  status               : active
```

Send the activation-code (in this example, `8F41F304`) to the user. Following the instructions in the *FortiToken Mobile User Guide,* the user can activate their FortiToken Mobile application using this activation code.

The user's mobile device, as well as the FortiGate unit, must be connected to the Internet to complete the activation. When the activation is complete, the *Status* of the FortiToken Mobile token changes to *Provisioned* on the FortiGate unit.

SSO using a FortiAuthenticator unit

If you use a FortiAuthenticator unit in your network as a single sign-on agent:

- Users can authenticate through a web portal on the FortiAuthenticator unit.
- Users with FortiClient Endpoint Security installed can be automatically authenticated by the FortiAuthenticator unit through the FortiClient SSO Mobility Agent.

The FortiAuthenticator unit can integrate with external network authentication systems such as Windows Active Directory, Novell e-Directory, RADIUS and LDAP to gather user logon information and send it to the FortiGate unit.

User's view of FortiAuthenticator SSO authentication

There are two different ways users can authenticate through a FortiAuthenticator unit.

Users without FortiClient Endpoint Security - SSO widget

To log onto the network, the user accesses the organization's web page with a web browser. Embedded on that page is a simple logon widget. The SSO widget sets a cookie on the user's browser. When the user browses to a page containing the login widget, the FortiAuthenticator unit recognizes the user and updates its database if the user's IP address has changed. The user will not need to re-authenticate until the login expires, which can take up to 30 days.

Users with FortiClient Endpoint Security - FortiClient SSO Mobility Agent

All authentication is performed transparently with no request for credentials. IP address changes, such as those due to WiFi roaming, are automatically sent to the FortiAuthenticator unit. When the user logs off or otherwise disconnects from the network, the FortiAuthenticator unit is aware of this and deauthenticates the user.

The FortiClient SSO Mobility Agent, a feature of FortiClient Endpoint Security v5.0, must be configured to communicate with the appropriate FortiAuthenticator unit. After that, the agent automatically provides user name and IP address information to the FortiAuthenticator unit for transparent authentication.

Administrator's view of FortiAuthenticator SSO authentication

You can configure either or both of these authentication types on your network.

SSO widget

You need to configure the Single Sign-On portal on the FortiAuthenticator unit. Go to *SSO & Dynamic Polices* > *SSO* > *Login Portal* to do this. Copy the *Embeddable login widget* code for use on your organization's home page. Identity-based security policies on the FortiGate unit determine which users or groups of users can access which network resources.

FortiClient SSO Mobility Agent

Your users must be running FortiClient Endpoint Security v5.0 to make use of this type of authentication.

On the FortiAuthenticator unit, you need to enable *FortiClient Service* when you define the unit's secret key. Go to *SSO & Dynamic Policies* > *SSO* > *Options*. You need to provide your users the FortiAuthenticator IP address and secret key so that they can configure the FortiClient SSO Mobility Agent on their computers.

SSO with Windows AD or Novell

The FortiGate unit can authenticate users transparently based on their Windows Active Directory (AD) or Novell eDirectory privileges. This means that users who have logged on to the network are not asked again for their credentials to access network resources through the FortiGate unit, hence the term "Single Sign-On".

FSSO Collector agent and DC agent have been tested on Windows Server 2003, 2008 and 2012.

On a Microsoft Windows or Novell network, users authenticate with the Microsoft AD or Novell eDirectory at logon. It would be inconvenient if users then had to enter another username and password for network access through the FortiGate unit. FSSO agents installed on the network provide user information, such as IP address and user group memberships, to the FortiGate unit. Security policies on the FortiGate unit allow network access based on the user groups to which the user belongs.

There are several mechanisms for passing user authentication information to the FortiGate unit:

- FSSO Collector agent software installed on a Windows AD network monitors user logons and sends the required information to the FortiGate unit. The FSSO software can obtain this information by polling the AD domain controllers or by using an FSSO agent on each AD domain controller that monitors user logons in real time. New in FortiOS 5.0, a FortiGate unit can obtain group information directly from AD using Lightweight Directory Access Protocol (LDAP).
- On a Windows AD network, the FSSO software can also serve NT LAN Manager (NTLM) requests coming from client browsers (forwarded by the FortiGate unit) with only one or more Controller agents installed.
- FSSO eDirectory agent software installed on a Novell network monitors user logons and sends the required information to the FortiGate unit. The agent can obtain information from the Novell eDirectory using either the Novell API or LDAP.
- A FortiAuthenticator server can act as a replacement for the Collector agent in polling mode in a Windows AD network. FortiAuthenticator can also be configured with internal or external LDAP and RADIUS servers. For more information, see the *FortiAuthenticator Administration Guide*.

Citrix Agent support for Single Sign On

FortiOS 5.0 supports single sign on authentication for Citrix environments by installing a Citrix FSSO polling agent on the Citrix server, installing an FSSO collector on the network, and then configuring the FortiGate unit to get user credentials from the Citrix FSSO polling agent.

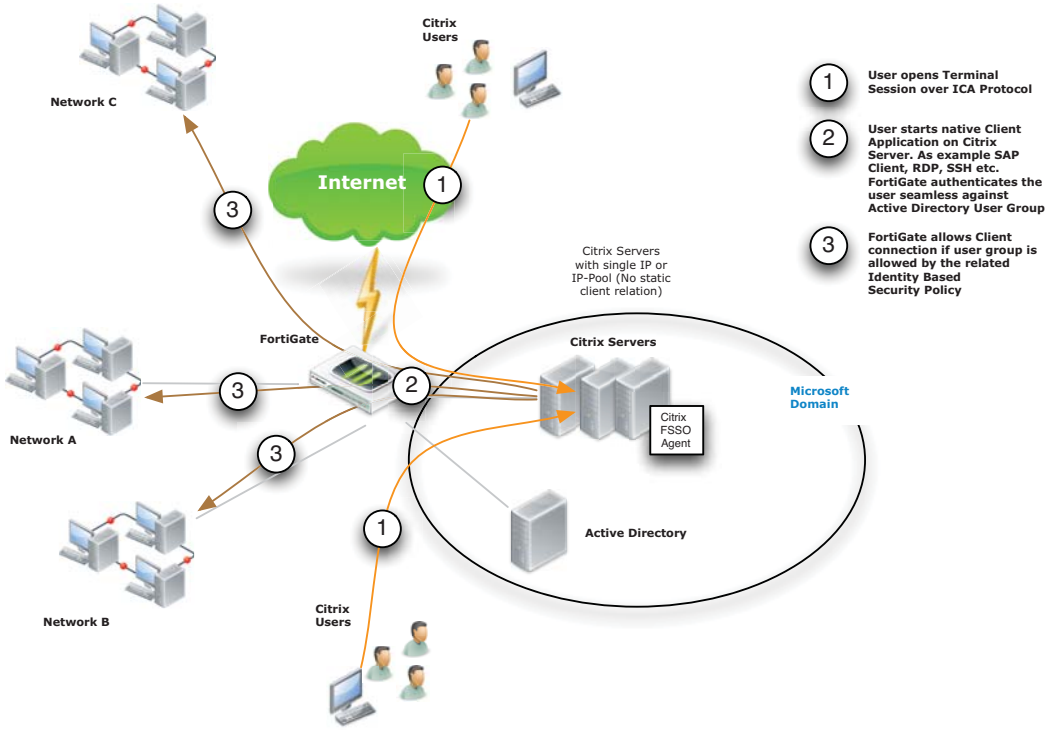
TSAgent running on the Citrix server XenAPP server version 6 has been tested with FSSO build0129 running Windows Server 2008.

Configuration steps include:

- Install the Fortinet Citrix FSSO agent on the Citrix server.
- Install the Fortinet FSSO collector on a server on the network.
- Add the Citrix FSSO agent to the FortiGate Single-sign-On configuration.
- Add Citrix FSSO groups and users to an FSSO user group.
- Add an FSSO identity-based security policy that includes the Citrix FSSO user groups.

After this configuration is complete, Citrix users credentials are made available to the FortiGate unit by the Citrix FFSO agent when a Citrix Terminal Session is started.When the user starts a client application (such as a web browser, SAP client, and so on), the user's session through the FortiGate unit is automatically authenticated and allowed by the FSSO identity-based security policy.

Figure 44: Example Citrix single sign on with FSSO network topology



Installing Citrix/Terminal Service Support Agent (TS Agent)

Install the Citrix/terminal service support agent on the Citrix terminal server, or other terminal, in the same was a you would install the FSSO agent on any platform.

1. Log into the server with an account that has administrator privileges and a password that does not expire.
2. Start the FSSO agent installer.

3. Following the installation wizard prompts.

   During the installation process:

   - the *Host IP Address* is The local IP of the Citrix or Terminal service server.
   - The *Fortinet SSO collector IP and port* is the IP and port of the FSSO collector.

4. Make sure that Launch DC Agent Install Wizard is selected and then select Finish to end the installation.

Installing the FSSO collector

There are no special requirements for installing the FSSO collector.

To enable single sign-on using polling mode

1. Go to *User & Device* > *Authentication* > *Single Sign-On* and select *Create New* to add a single sign-on server.
2. Select *Fortinet Single-Sign-On Agent*.
3. Enter the Name and the IP address or Name and password for the Citrix server.
4. Select *OK* to save the configuration.

Verifying the configuration

You can use the following diagnose commands to verify the configuration:

```
diagnose debug authd fsso list
diagnose debug application authd -1
diagnose firewall auth list
```

Configuring guest access

You can create many guest accounts at once using randomly-generated User IDs and passwords. This reduces administrator workload for large events.

User's view of guest access

1. The user receives an email, SMS message or printout from a FortiGate administrator listing a User ID and password.
2. The user logs onto the network with the provided credentials.
3. After the expiry time, the credentials are no longer valid.

Administrator's view of guest access

1. Create one or more guest user groups.

   All members of the group have the same characteristics: type of User ID, type of password, information fields used, type and time of expiry.

2. Create guest accounts using Guest Management.
3. Use captive portal authentication and select the appropriate guest group.

Creating guest management administrators

The guest management administrator can be a regular FortiGate administrator. Optionally, you can create administrator accounts that can perform only guest management. This type of administrator is also limited to specific guest user groups.

To create a guest management administrator

1. Go to *System* > *Admin* > *Administrators* and create a regular administrator account.
   For detailed information see the System Administration chapter.
2. Select *Restrict to Provision Guest Accounts*.
3. In *Guest Groups*, add the guest groups that this administrator manages.

Creating guest user groups

The guest group configuration determines the fields that are provided when you create a guest user account.

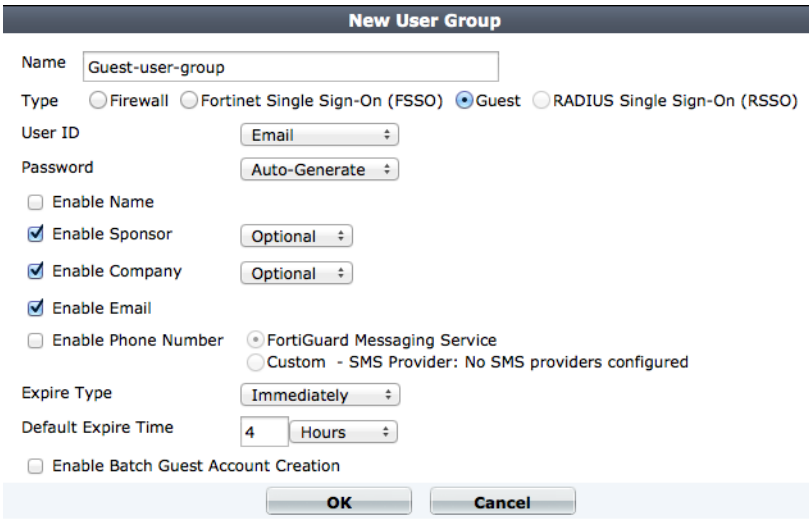
To create a guest user group

1. Go to *User & Device* > *User* > *User Group* and select *Create New*.
2. Configure the guest user group:

Name	Enter a name for the group.
Type	Guest
User ID	Select one of: • Email — User's email address • Specify — Administrator assigns user ID • Auto-Generate — FortiGate unit creates a random user ID
Password	Select one of: • Specify — Administrator assigns user ID • Auto-Generate — FortiGate unit creates a random password • Disable — no password
Enable Name	If enabled, user must provide a name.
Enable Sponsor	If enabled, user form has Sponsor field. Select *Required* or *Optional*.
Enable Company	If enabled, user form has Company field. Select *Required* or *Optional*.
Enable Email	If enabled, user is notified by email.
Enable Phone Number	If enabled, user is notified by SMS. Select whether FortiGuard Messaging Service or a another SMS provider is used. You can add SMS providers in *System* > *Config* > *Messaging Servers*.
Expire Type	Choose one of: Immediately —expiry time is counted from creation of account After first login — expiry time is counted from user's first login

Default Expire Time	Set the expire time. The administrator can change this for individual users.
Enable Batch Guest Account Creation	Create multiple accounts automatically. When this is enabled: • *User ID* and *Password* are set to *Auto-Generate*. • The user accounts have only *User ID, Password*, and *Expiration* fields. Only the *Expiration* field is editable. If the expiry time is a duration, such as “8 hours”, this is the time after first login. • You can print the account information. Users do not receive email or SMS notification.

Figure 45: Adding a Guest user group



Creating guest user accounts

Guest user accounts are not the same as local user accounts created in *User & Device* > *User* > *User Definition*. Guest accounts are not permanent; they expire after a defined time period. You create guest accounts in *User & Device* > *User* > *Guest Management*.

To create a guest user account

1. Go to *User & Device* > *User* > *Guest Management.*
2. In *Guest Groups*, select the guest group to manage.
3. Select *Create New* and fill in the fields in the *New User* form.

   Fields marked Optional can be left blank. The guest group configuration determines the fields that are available.
4. Select *OK*.
5. Select to print the temporary user account information or to email it to the email address of the account.
6. Select *Return*.

Guest Management Account List

Go to *User & Device* > *User* > *Guest Management* to create, view, edit or delete guest user accounts.

Create New	Creates a new guest user account.
Edit	Edit the selected guest user account.
Delete	Delete the selected guest user account.
Purge	Remove all accounts from the list.
Print	Print all of the user accounts in the group. You can print one or 3 accounts per page.
Send	Send the user account information to the guest. Depending on the group settings and user information, the information can be sent to the user by email or SMS.
Refresh	Update the list.
Guest Groups	Select the guest group to list. New accounts are added to this group.
User ID	The user ID. Depending on the guest group settings, this can be the user's email address, an ID that the administrator specified, or a randomly-generated ID.
Expires	Indicates a duration such as "3 hours". A duration on its own is relative to the present time. Or, the duration is listed as "after first login."

Batch guest account creation

You can use the guest user group auto generate options and guest user management options to quickly create any number of guest user accounts in just a few steps. Use the following steps to create 50 users with randomly generated usernames and passwords.

1. Go to *User & Device* > *User* > *User Groups* and select *Create New* to add a new user group.
2. Give the group a name, and set *Type* to *Guest*.
3. Select *Enable Batch Guest Account Creation* and select *OK*.
4. Go to *User & Device* > *User* > *Guest Management* and in the *Guest Groups* field select the guest user group that you just created.
5. *Select Create New* > *Multiple Users.*
6. Set the number of accounts to 50, set the expiry date, and select *OK*.

You can edit the individual accounts after they are created to send them to the user. You can also change the user name, password, and expiration time.

Vulnerability Scanning

The network vulnerability scanner helps you to protect your network assets (servers and workstations) by scanning them for security weaknesses. Configuration and operation of the vulnerability scanner has been simplified and the feature has been moved to *User & Device* > *Vulnerability Scan*.

This section describes how to configure a single FortiGate unit for network scanning and how to view the results of the scan.

Running and configuring scans and viewing scan results

You can configure regular network scans on a daily, weekly, or monthly basis.

To run a vulnerability scan

1. Go to *User & Device* > *Vulnerability Scan* > *Scan Definition* and select *Start Scan*.

   The vulnerability starts a scan using the current scanner settings. When the scan is running you can pause or stop it at any time. You can also watch the progress of the scan.
2. When the scan is complete go to *User & Device* > *Vulnerability Scan* > *Vulnerability Result* to view the results of the scan.

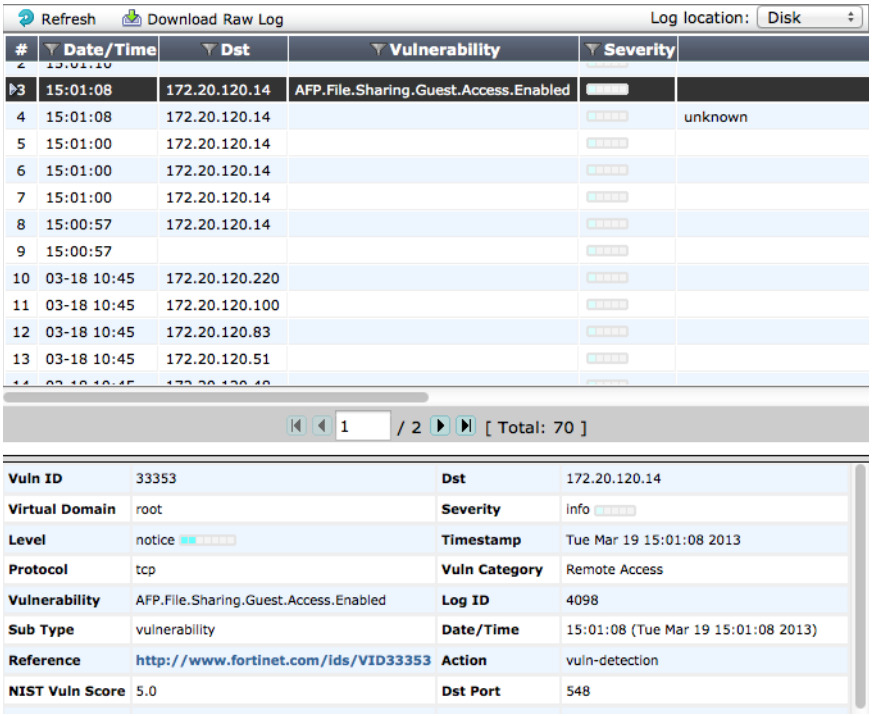
To run a vulnerability scan of one device or selected devices

1. Go to *User & Device* > *Vulnerability Scan* > *Scan Definition*.
2. Select the devices to scan from the *Asset Definitions* list.

   You can shift-click to select more than one device.
3. Select *Start*.

   The vulnerability starts a scan of the selected devices using the current scanner settings. When the scan is running you can pause or stop it at any time. You can also watch the progress of the scan.
4. When the scan is complete go to *User & Device* > *Vulnerability Scan* > *Vulnerability Result* to view the results of the scan. Select any log entry to view log details.

Figure 46: Example vulnerability scan results



To configure scanning

1. Go to *User & Device* > *Vulnerability Scan* > *Scan Definition*.

2. Beside *Schedule* select *Change* to set the scan schedule and mode:

Recurrence	Select *Daily*, *Weekly*, or *Monthly* and configure the details for the option you have selected.
Suspend Scan between	Set a time during which the scan should be paused if its running.
Vulnerability Scan Mode	**Quick** — check only the most commonly used ports **Standard** — check the ports used by most known applications **Full** — check all TCP and UDP ports

3. Select *Apply* to save the schedule and scan type.
4. Select *Create New* under *Asset Definitions* to select the devices on the network to scan.
5. Enter the following information and select *OK*:

Name	Enter a name for this asset.
Type	Select *IP Address* to add a single IP address. Select *Range* to add a range of IP addresses to scan.
IP Address	Enter the IP address of the asset. (*Type* is *IP Address*.)
Range	Enter the start and end of the IP address range. (*Type* is *Range*.)
Enable Scheduled Vulnerability Scanning	Select to allow this asset to be scanned according to the schedule. Otherwise the asset is not scanned during a scheduled vulnerability scan.
Windows Authentication	Select to use authentication on a Windows operating system. Enter the username and password in the fields provided.
Unix Authentication	Select to use authentication on a Unix operating system. Enter the username and password in the fields provided.

6. Select *Apply* to save the configuration.

FortiOS and BYOD

FortiOS can control network access for different types of personal mobile devices that your employees bring onto your premises. This is done by:

- Identifying and monitoring the types of devices connecting to your networks, wireless or wired
- Using MAC address based access control to allow or deny individual devices
- Creating policies based on device type
- Enforcing endpoint control on devices that can run FortiClient Endpoint Control software

This section describes:

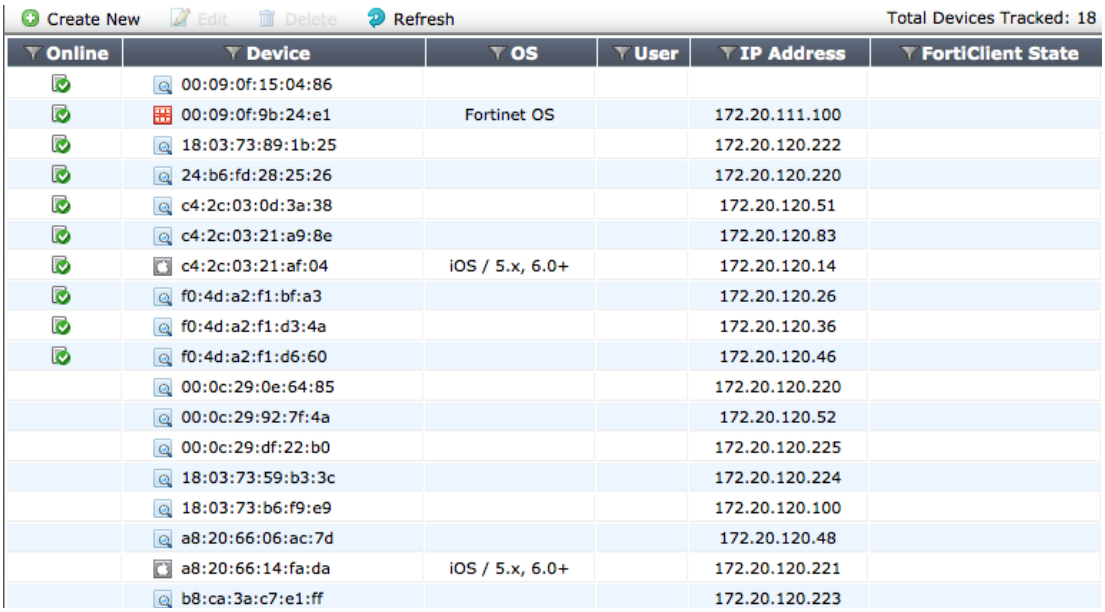
Device monitoring

The FortiGate unit can monitor your networks and gather information about the devices operating on those networks. Collected information includes:

- Whether the device is currently online
- MAC address
- IP address
- Operating system
- Hostname
- User
- How long ago the device was detected and on which FortiGate interface
- Whether FortiClient is installed on the device

You can go to *User & Device* > *Device* > *Device Definitions* to view this information.

Figure 47: The Device List



Online	Device	OS	User	IP Address	FortiClient State
✓	00:09:0f:15:04:86				
✓	00:09:0f:9b:24:e1	Fortinet OS		172.20.111.100	
✓	18:03:73:89:1b:25			172.20.120.222	
✓	24:b6:fd:28:25:26			172.20.120.220	
✓	c4:2c:03:0d:3a:38			172.20.120.51	
✓	c4:2c:03:21:a9:8e			172.20.120.83	
✓	c4:2c:03:21:af:04	iOS / 5.x, 6.0+		172.20.120.14	
✓	f0:4d:a2:f1:bf:a3			172.20.120.26	
✓	f0:4d:a2:f1:d3:4a			172.20.120.36	
✓	f0:4d:a2:f1:d6:60			172.20.120.46	
	00:0c:29:0e:64:85			172.20.120.220	
	00:0c:29:92:7f:4a			172.20.120.52	
	00:0c:29:df:22:b0			172.20.120.225	
	18:03:73:59:b3:3c			172.20.120.224	
	18:03:73:b6:f9:e9			172.20.120.100	
	a8:20:66:06:ac:7d			172.20.120.48	
	a8:20:66:14:fa:da	iOS / 5.x, 6.0+		172.20.120.221	
	b8:ca:3a:c7:e1:ff			172.20.120.223	

Device monitoring is enabled separately on each interface.

To configure device monitoring

1. Go to *System* > *Network* > *Interfaces* and edit a FortiGate interface to use for device monitoring.
2. Under *Device Management* select *Detect and Identify Devices*.
3. If you plan to use the Vulnerability scanner to scan discovered devices for vulnerabilities, select *Add New Devices to Vulnerability Scan List.*
4. Select *OK*.
5. Repeat for all interfaces to use for device monitoring.

To edit device information

1. Go to *User & Device* > *Device* > *Device Definitions* and double-click the entry to edit it.
2. Enter an *Alias* to identify the device.

   This is step is compulsory. The alias replaces the MAC address in the device list.
3. If the device can have more than on MAC address, add them to the device.
4. Optionally add the device to a custom device group.
5. Change other information as needed.
6. Select *OK*.

To add a device manually

1. Go to *User & Device* > *Device* > *Device Definitions* and select *Create New*.
2. Enter the following information.
   - Alias (required)
   - MAC address
   - Device Type
3. Optionally, add additional MAC addresses, select a *Custom Group* and enter *Comments*.
4. Select *OK*.

Device Groups

Device Groups are used in device policies to specify which devices match the policy. FortiOS automatically adds detected devices of well-known device types to predefined device groups. You can also create custom device groups so that you can create a different policy for specific, known devices.

Table 2: Predefined Device Groups

Group	Devices
Android Phone	Android-based phones.
Android Tablet	Android-based Tablets.
BlackBerry Phone	BlackBerry-based phones.
BlackBerry Playbook	BlackBerry-based tablets.
Collected Emails	All devices from which FortiOS has collected a user email address.
Fortinet Device	FortiGate, FortiManager, FortiAnalyzer, FortiMail, etc.
Gaming Console	All Gaming consoles listed in the Device Visibility database. This includes Xbox, PS2, PS3, Wii, PSP.
iPad	IOS-based tablets.
iPhone	IOS-based phones.
IP Phone	IP phones.
Linux PC	Linux-based PCs.
Mac	Apple Macintosh computers.
Media Streaming	Media streaming devices such as Apple TV.
Router/NAT Device	Routers and other gateway devices.
Windows Phone	Windows OS based phones.
Windows PC	Windows-based PCs.
Windows Tablet	Windows-based tablets.
Other Network Device	All other network devices not categorized under any other group.
All	All devices.

Creating a custom device group

The predefined device groups are automatically populated. When you create a custom device group, you choose the members. Adding a device that the FortiGate unit has already detected is easiest. But you can also add a device that has not yet been detected if you know its MAC address.

To create the custom device group

1. Go to *User & Device* > *Device* > *Device Groups* and select *Create New*.

2. Enter a name for the group.
3. Add devices to the group.
4. Select *OK*.

Controlling access with a MAC Address Access Control List

A MAC Address Access Control List is best used to handle exceptions. If you want to limit network access to a larger group, such as your employees, it is better to create a custom device group and specify that group in your device-based security policies.

A MAC Address Access Control List functions as either a list of blocked devices or a list of allowed devices. This is determined by the *Unknown MAC Address* entry.

- By default, unknown MAC addresses are allowed: *Action* is *Assign IP*. You add an entry for each MAC address that you want to block and set its *Action* to *Block*.
- If you want to restrict access to a limited set of devices, you set the *Unknown MAC Address* entry to *Block* and add an entry for each allowed MAC address with *Action* set to *Assign IP.*

To create a MAC Address Access Control List

1. In the SSID or other interface configuration, select *Enable DHCP Server*.
2. Enter the required *Address Range* and *Netmask*.
3. Expand *MAC Address Access Control List*.
4. Select *Create New* and enter the device's *MAC Address*.
5. Select *Assign IP* to allow the device or *Block* to block the device and then select *OK*.
6. Repeat Steps 4 and 5 for each additional MAC address entry.

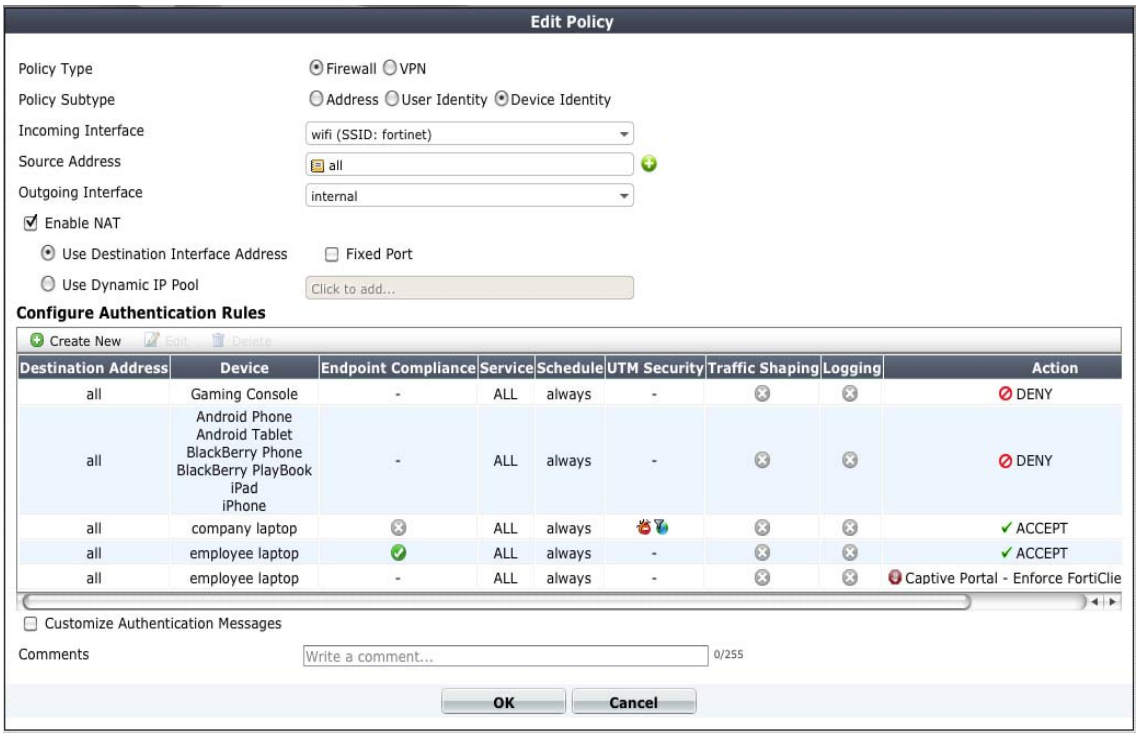
Device policies

Policies based on device identity enable you to implement policies according to device type. For example:

- Gaming consoles cannot connect to the company network or the Internet.
- Personal tablet and phone devices can connect to the Internet but not to company servers.
- Company-issued laptop computers can connect to the Internet and company servers. Web filtering and antivirus are applied.
- Employee laptop computers can connect to the Internet, but web filtering is applied. They can also connect to company networks, but only if FortiClient Endpoint Security is installed to protect against viruses.

Figure 48 shows these policies implemented for WiFi to the company network.

Figure 48: Device policies for WiFi access to the company network



Device-based security policies are similar to policies based on user identity:

- The policy enables traffic to flow from one network interface to another.
- NAT can be enabled.
- Authentication rules can allow or deny specific devices or device groups.
- UTM protection can be applied.

To create a device identity policy

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. In *Policy Subtype*, select *Device Identity*.
3. Choose *Incoming Interface*, *Source Address*, and *Outgoing Interface* as you would for any security policy.
4. Select *Enable NAT* if appropriate.

   You are now ready to create authentication rules.

To create an authentication rule

1. Select *Create New.*
2. Enter *Destination*, *Schedule*, and *Service* as you would for any security policy.
3. In *Device*, select the devices or device groups to which this policy applies.

   You can select multiple devices or groups.
4. Select *Compliant with Endpoint Profile* if you want to enforce use of FortiClient Endpoint Security by the client devices. This is available here only if Action is ACCEPT. See “Adding endpoint control” next.
5. Select one of the following for Action:
   - ACCEPT
   - DENY

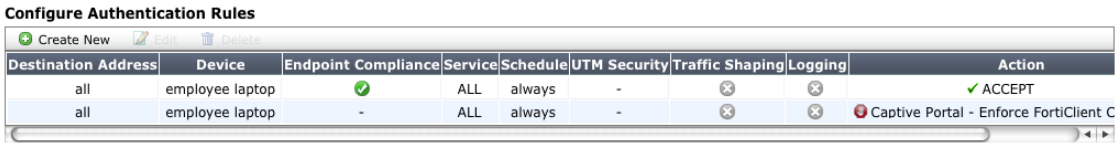
6. Configure *UTM Security Profiles* as you would for any security policy.
7. Select *OK*.
8. Select *OK* again to complete creation of the security policy.

Adding endpoint control

Optionally, you can require that user's devices have FortiClient Endpoint Security software installed. The software provides FortiOS more detailed information about the applications being used. FortiOS pushes its endpoint profile to the FortiClient software, configuring network protection such as antivirus, application control, and web category filtering. Devices without an up-to-date installation of FortiClient software are restricted to a captive portal that provides links from which the user can download a FortiClient installer.

If you have already created an ACCEPT rule for particular device groups, you simply edit this rule and enable *Compliant with Endpoint Profile*. Then you add a second rule that sends the same devices to the Enforce FortiClient Compliance captive portal. Devices lacking the required FortiClient software arrive at this policy because they do not match the preceding policy.

Figure 49: Endpoint compliance rule and captive portal rule



Device policy portal options

The following portal options are available when configuring a device policy:

- Attempt to detect all Unknown device types before implicit deny
- Redirect all non-compliant/unregistered FortiClient compatible devices to a captive portal

  Custom portals are available for Windows, Mac OS, iPhone/iPad and Android devices. These portals acts as a quarantine for devices that are not protected by FortiClient Endpoint Security. The portal provides links to obtain the FortiClient software. The user can retry connecting after installing the FortiClient software.
- Prompt E-mail Collection Portal for all devices

  This portal is used to collect an email address as a means of identifying the device user. When the email address has been verified, the device is added to the Collected Emails device group.

Creating the WiFi SSID

In order to create a WiFi SSID using the web-based manager, the WiFi Controller (called WiFi & Switch Controller on FortiGate models 100D, 200D, 240D, 600C, 800C, and 1000C) feature must be enabled using Feature Select. For more information, see "Feature Select" on page 243.

Both guest and employee devices will need an SSID (WiFi network) with open security. This means that no passphrase is required to join the SSID. Device policies will determine who gets access to network resources. By default, open security is not available in the WiFi SSID configuration.

To configure the SSID

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.
2. Enter the following information and select OK:

Name	byod-example
IP/Netmask	10.10.110.1/24
Administrative Access	Ping (to assist with testing)
Enable DHCP Server	Enable
Address Range	10.10.110.2 - 10.10.110.199
Netmask	255.255.255.0
Default Gateway	Same As Interface IP
SSID	byod-guest
Security Mode	Open
Block Intra-SSID Traffic	Select.
Leave other settings at their default values.	

For detailed information about creating a WiFi SSID, see the Deploying Wireless Networks chapter of the FortiOS Handbook.

Configuring Internet access for guests with mobile devices

Guest devices have access only to the Internet. You need a device policy that allows traffic to flow from the WiFi SSID to the Internet interface. Within that policy, you need an authentication rules to allow access for the various types of devices.

To create the device policy

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Enter the following information:

Policy Type	Firewall
Policy Subtype	Device Identity
Incoming Interface	byod-example
Source Address	all
Outgoing Interface	wan1
Enable NAT	Enable.

You are now ready to create the authentication rule.

To create the authentication rule

1. In *Configure Authentication Rules*, select *Create New* and enter:

Destination Address	all
Device	Device or Device Group
Compliant with Endpoint Profile	not selected
Schedule	always
Service	ALL
Action	ACCEPT

2. Select *OK*.
3. If asked, confirm that you accept FortiOS will enable device identification on the source interface.

   The rule is now configured.
4. Select *OK* to complete configuration of the security policy.

Client Reputation

The Security scan types available on FortiGate units are varied and tailored to detect specific attacks. However, sometimes user/client behavior can increase the risk of attack or infection. For example, if one of your network clients receives email viruses on a daily basis while no other clients receive these attachments, extra measures may be required to protect the client, or a discussion with the user about this issue may be worthwhile.

Before you can decide on a course of action, you need to know the problem is occurring. Client reputation can provide this information by tracking client behavior and reporting on activities that you determine are risky or otherwise noteworthy.

Activities you can track include:

- Bad Connection Attempts: A typical BOT behavior is to connect to some hosts that do not exist on the Internet. This is because the BOT home needs to constantly change itself to dodge legislative enforcement or to hide from AV vendors. Bad connection attempts are tracked by:
  - Look ups for a DNS name that does not exist.
  - Connection attempts to an IP address that has no route.
  - HTTP 404 errors
- Packets that are blocked by security policies.
- Intrusion protection: Attack detected. The effect on reputation increases with severity of attack. A subscription to FortiGuard IPS updates is required.
- Malware protection: Malware detected. This requires a subscription to FortiGuard Antivirus updates.
- Web activity: Visit to web site in risky categories, including Potentially Liable, Adult/Mature Content, Bandwidth Consuming and Security Risk. A subscription to FortiGuard Web Filtering is required.
- Application protection: Client uses software in risky categories, including Botnet, P2P, Proxy, and Games applications. A subscription to FortiGuard IPS updates is required.
- Geographical locations that clients are communicating with. Access to the FortiGuard geographic database and a valid Fortinet support contract is required.

You can configure how severely each type of tracked activity will impact the reputation of the client in a sliding scale of Low, Medium, High or Critical. You can also choose to ignore an activity by setting it to Off. When an activity is turned off, it will have no effect on reputation.

You can enable client reputation tracking for your FortiGate unit by going to *Security Profiles* > *Client Reputation* > *Threat Level Definition*. Turning on client reputation tracking turns on traffic logging for all security policies, for all DoS policies and for all sniffer policies. While client reputation is enabled, logging cannot be turned off for these policies. Traffic logging must be enabled for data to be added to the client reputation database.

Client reputation only highlights risky activity and does not include tools to stop it. Instead, client reputation is a tool that exposes risky behavior. When you uncover risky behavior that you are concerned about, you can take additional action to stop it. That action could include adding more restrictive security policies to block the activity or increase UTM protection. You can also taking other measures outside your FortiGate unit to stop the activity.

To support client reputation your FortiGate unit must be registered, have a valid support contract and be licensed for FortiGuard antivirus, IPS and Web Filtering.

After client reputation is turned on, the FortiGate unit tracks recent behavior using a sliding window and displays current data for this window. The client reputation monitor displays clients and their activities in charts ordered according to how risky the behavior exhibited by the client is.

Client Reputation data is stored in traffic log messages in the newly added client reputation fields (crscore and craction). When you enable client reputation *Log UTM Events* or *Log all Sessions* is enabled in all security policies. *Log UTM Events* records traffic log messages for UTM sessions and *Log all Sessions* records traffic logs for all sessions. When Client Reputation is enabled you cannot select *No Log* in a security policy. Using client reputation data in log messages, you can configure FortiAnalyzer to produce a client reputation report.

Enabling client reputation can affect system performance if you had not been using traffic logging.

This chapter describes:

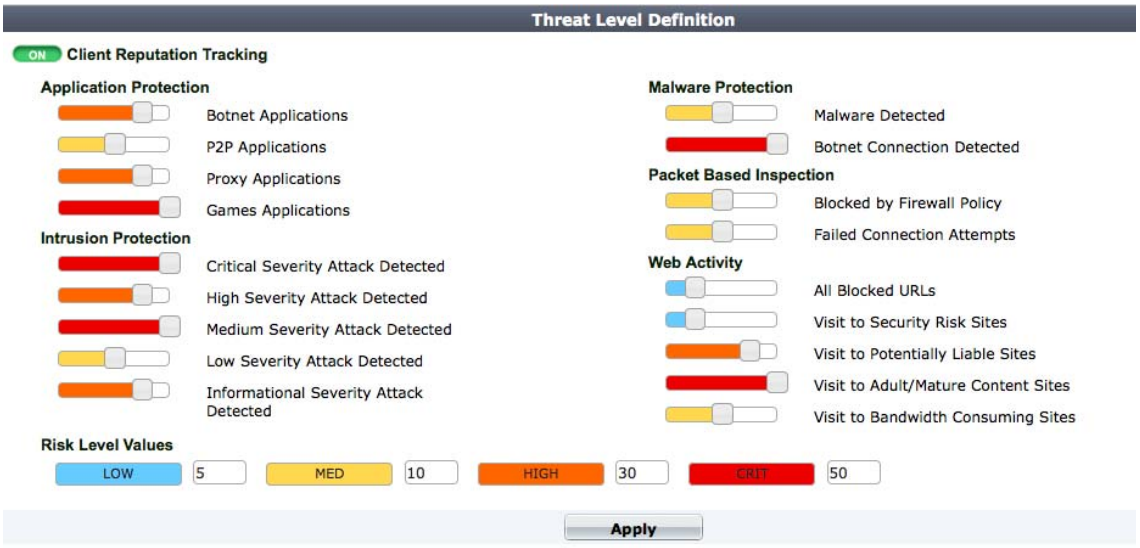
Setting the client reputation profile/definition

Configure the client reputation profile by going to *Security Profiles* > *Client Reputation* > *Threat Level Definition*. You configure one client reputation profile for all of the activity monitored by the FortiGate unit. The profile sets the risk levels for the types of behavior that client reputation monitors. You can set the risk to off, low, medium, high and critical for the following types of behavior:

- Application Protection
  - Botnet applications
  - P2P applications
  - Proxy applications
  - Games applications
- Intrusion protection (IPS)
  - Critical severity attack detected
  - High severity attack detected
  - Medium severity attack detected
  - Low severity attack detected
  - Informational severity attack detected
- Malware Protection
  - Malware detected
  - Botnet connection detected
- Packet based inspection
  - Blocked by firewall policy
  - Failed connection attempts

- Web Activity
  - All blocked URLs
  - Visit to security risk sites
  - Visit to potentially liable sites
  - Visit to adult/mature content sites
  - Visit to bandwidth consuming sites

Figure 50: Default client reputation profile



To configure the profile, decide how risky or dangerous each of the types of behavior are to your network and rate them accordingly. The higher you rate a type of behavior, the more visible clients engaging in this behavior will become in the client reputation monitor and the more easily you can detect this behavior.

For example, if you consider malware a high risk for your network, you can set the client reputation profile for malware to high or critical (as it is in the default client reputation profile). Then, whenever any amount of malware is detected, clients that originated the malware will be very visible in the client reputation monitor.

Set the risk to off for types of activity that you do not want client reputation to report on. This does not reduce the performance requirements or the amount of data gathered by client reputation, just the report output.

You can change a profile setting at any time and data that has already been collected will be used.

It is normally not necessary to change the *Risk Level Values* but it can be done if you need to alter the relative importance of the risk settings.

Applying client reputation monitoring to your network

Client reputation monitoring is applied to network traffic by going to *Security Profiles* > *Client Reputation* > *Threat Level Definition* turning on *Client Reputation Tracking* and selecting *Apply*.

You can then either change the client reputation profile used by your FortiGate unit or you can accept the default profile. The client reputation profile indicates how risky you consider different types of client behavior to be. See “Expanding client reputation to include more types of behavior” on page 184 for details.

Viewing client reputation results

Client reputation results can be viewed in the *Threat History* widget, which is found at *System* > *Dashboard* > *Threat History.*

The *Threat History* widget displays threat severity over time. Specific time periods can be selected, at which point drilldown menus are available to view more information about the threats, including information about threat types and the sources of each incident.

Figure 51: The *Threat History* widget

Expanding client reputation to include more types of behavior

You can use the following command to change the client reputation profile from the CLI to include client reputation reporting about more settings:

```
config client-reputation profile
```

In addition to the settings configurable from the web-based manager, you can also set the following options:

- `geolocation` to enable reporting on connections to and from different countries (geographical locations). For example, use the following command to indicate that you consider communication with Aruba to be medium risk:

```
config client-reputation profile
  config geolocation
    edit 0
      set country AW
      set level medium
    end
  end
```

- `url-block-detected` to report on connections blocked by web filtering. Use the following command to enable reporting about blocked URLs and set the risk level to medium:

```
config client-reputation profile
  set url-block-detected medium
end
```

From the CLI you can configure client reputation to report more FortiGuard web filtering categories and more types of applications. For example, to report on social network activity (application control category 23):

```
config client-reputation-profile
  config application
    edit 0
      set category 23
      set level medium
    end
  end
```

To report on the local web filtering category (category 22):

```
config client-reputation-profile
  config web
    edit 0
      set group 22
      set level medium
    end
  end
```

Client reputation execute commands

The `execute client-reputation` command includes the following options:

- `erase`, deletes all client reputation data.
- `host-count`, lists the clients that started sessions recorded by client reputation
- `host-detail`, for a specified client's IP address, displays the client reputation traffic log messages saved for that client.
- `host-summary`, for a specified client's IP address, displays the client's IP address, total entries, and total score.
- `purge`, deletes all data from the client reputation database.
- `topN`, display the top N clients identified by client reputation.

Client reputation diagnose commands

The `diagnose client-reputation` command includes the following options

- `convert-timestamp` convert a client reputation database timestamp to date and time
- `test-all` adds log messages from multiple sources to the client reputation database for testing
- `test-app` adds application control log messages to the client reputation database for testing
- `test-ips` adds Intrusion Protection log messages to the client reputation database for testing
- `test-webfilter` adds webfilter log messages to the client reputation database for testing

Wireless

New wireless features include:

- Wireless IDS
- WiFi performance improvements
- FortiAP web-based manager and CLI
- WiFi guest access provisioning
- FortiAP local bridging (Private Cloud-Managed AP)
- WiFi data channel encryption
- Wireless client load balancing for high-density deployments
- Bridge SSID to FortiGate wired network

Wireless IDS

FortiGate wireless IDS monitors wireless traffic for a wide range of security threats by detecting and reporting on possible intrusion attempts. When an attack is detected, the FortiGate unit records a log message.

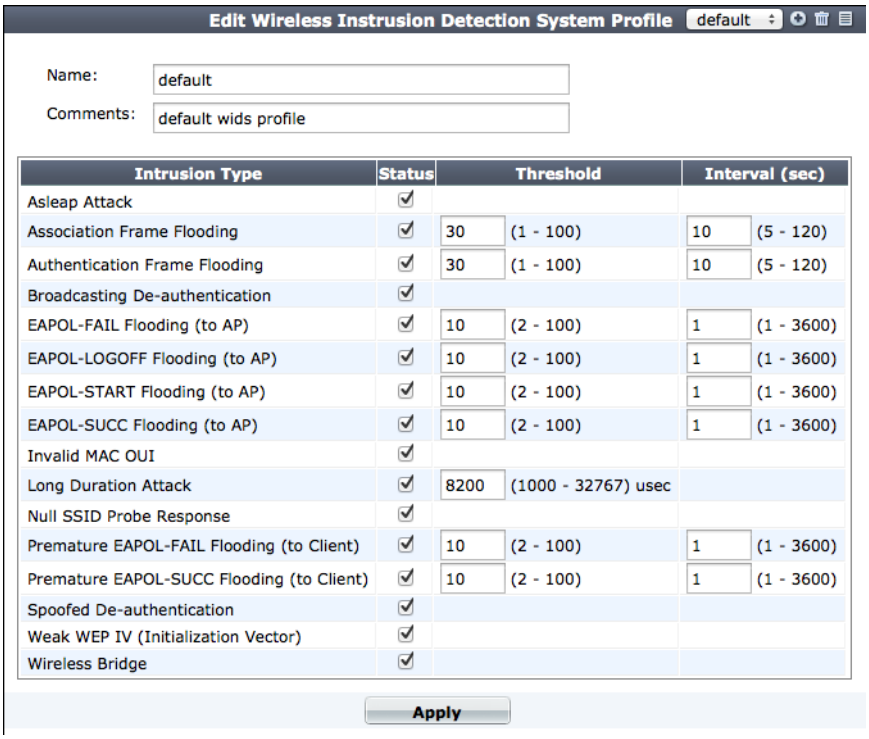
You can create a WIDS profile to enable the following types of intrusion detection among others:

- Unauthorized Device Detection
- Rogue/Interfering AP Detection
- Adhoc Network Detection and Containment
- Wireless Bridge Detection
- Misconfigured AP Detection
- Weak WEP Detection
- Multi Tenancy Protection
- MAC OUI Checking

You can enable wireless IDS by going to *WiFi Controller* > *WiFi Network* > *Custom AP Profiles* and editing an access point profile or creating a new one.

Inside the profile, set *WIDS Profile* to the name of a wireless IDS profile to apply wireless IDS protection to the access points that uses the profile. FortiGate units include a *default* wireless IDS profile. You can customize this profile or create additional profiles by going to WiFi *Controller* > *WiFi Network* > *WIDS Profiles.*

Figure 52: Configuring a WIDS profile



You can also use the `config wireless-controller wids-profile` command to configure Wireless Intrusion Detection (WIDS) profiles.

Syntax

```
config wireless-controller wids-profile
  edit <wids-profile_name>
    set comment <comment_str>
    set asleap-attack {enable | disable}
    set assoc-frame-flood {enable | disable}
    set auth-frame-flood {enable | disable}
    set deauth-broadcast {enable | disable}
    set eapol-fail-flood {enable | disable}
    set eapol-fail-intv <int>
    set eapol-fail-thres <int>
    set eapol-logoff-flood {enable | disable}
    set eapol-logoff-intv <int>
    set eapol-logoff-thres <int>
    set eapol-pre-fail-flood {enable | disable}
    set eapol-pre-fail-intv <int>
    set eapol-pre-fail-thres <int>
    set eapol-pre-succ-flood {enable | disable}
    set eapol-pre-succ-intv <int>
    set eapol-pre-succ-thres <int>
    set eapol-start-flood {enable | disable}
    set eapol-start-intv <int>
```

```
        set eapol-start-thres <int>
        set eapol-succ-flood {enable | disable}
        set eapol-succ-intv <int>
        set eapol-succ-thres <int>
        set invalid-mac-oui {enable | disable}
        set long-duration-attack {enable | disable}
        set long-duration-thresh <int>
        set null-ssid-probe-resp {enable | disable}
        set spoofed-deauth {enable | disable}
        set weak-wep-iv {enable | disable}
        set wireless-bridge {enable | disable}
    end
```

Variable	Description	Default
`<wids-profile_name>`	Enter a name for this WIDS profile.	No default.
`comment <comment_str>`	Optionally, enter a descriptive comment.	No default.
`asleap-attack {enable | disable}`	Enable to detect asleap attack (attempt to crack LEAP security).	disable
`assoc-frame-flood {enable | disable}`	Enable to detect association frame flood attack.	disable
`auth-frame-flood {enable | disable}`	Enable to detect authentication frame flood attack.	disable
`deauth-broadcast {enable | disable}`	Enable to detect deauthentication broadcasts which can disrupt wireless services to multiple clients.	disable
`eapol-fail-flood {enable | disable}`	Enable to detect EAP FAIL flood attack.	disable
`eapol-fail-intv <int>`	Set EAP FAIL detection interval.	1
`eapol-fail-thres <int>`	Set EAP FAIL detection threshold.	10
`eapol-logoff-flood {enable | disable}`	Enable to detect EAP LOGOFF flood attack.	disable
`eapol-logoff-intv <int>`	Set EAP LOGOFF detection interval.	1
`eapol-logoff-thres <int>`	Set EAP LOGOFF detection threshold.	10
`eapol-pre-fail-flood {enable | disable}`	Enable to detect EAP premature FAIL flood attack.	disable
`eapol-pre-fail-intv <int>`	Set EAP premature FAIL detection interval.	1
`eapol-pre-fail-thres <int>`	Set EAP premature FAIL detection threshold.	10
`eapol-pre-succ-flood {enable | disable}`	Enable to detect EAP premature SUCC flood attack.	disable
`eapol-pre-succ-intv <int>`	Set EAP premature SUCC detection interval.	1
`eapol-pre-succ-thres <int>`	Set EAP premature SUCC detection threshold.	10

Variable	Description	Default
`eapol-start-flood {enable | disable}`	Enable to detect EAP START flood attack.	disable
`eapol-start-intv <int>`	Set EAP START detection interval.	1
`eapol-start-thres <int>`	Set EAP START detection threshold.	10
`eapol-succ-flood {enable | disable}`	Enable to detect EAP SUCC flood attack.	disable
`eapol-succ-intv <int>`	Set EAP SUCC detection interval.	1
`eapol-succ-thres <int>`	Set EAP SUCC detection threshold.	10
`invalid-mac-oui {enable | disable}`	Enable to detect use of spoofed MAC addresses. (The first three bytes should indicate a known manufacturer.)	disable
`long-duration-attack {enable | disable}`	Enable for long duration attack detection based on long-duration-thresh.	disable
`long-duration-thresh <int>`	Enter the duration in usec for long-duration attack detection. This is available when long-duration-attack is enable.	8200
`null-ssid-probe-resp {enable | disable}`	Detect attacks that include an incorrectly formed response packets that include a null SSID. This attack can cause wireless clients to crash.	disable
`spoofed-deauth {enable | disable}`	Enable to detect spoofed deathentication packets.	disable
`weak-wep-iv {enable | disable}`	Enable to detect APs using weak WEP encryption.	disable
`wireless-bridge {enable | disable}`	Enable to detect wireless bridge operation, which is suspicious if your network doesn't use a wireless bridge.	disable

WiFi performance improvements

FortiOS 5.0 improves performance for WiFi users connecting to the wifi network on a FortiWiFi unit or remotely on FortiAP units. WiFi traffic is now handled in the FortiOS kernel like other network traffic, rather than in a separate application.

FortiAP web-based manager and CLI

You can now log into a FortiAP web-based manager to view FortiAP status as well as view and change the FortiAP configuration. Logging into the FortiAP web-based manager is similar to logging into the FortiGate web-based manager.

The FortiAP CLI now includes more configuration commands and a complete set of diagnose commands.

Configuration commands include the following

`cfg -h`	Display help for all commands.
`cfg -r var`	Remove variables.
`cfg -e`	Export variables.
`cfg -s`	List variables.
`cfg -x`	Reset to factory defaults.
`cfg -c`	Commit the change to flash.
`cfg -a var=value`	Add or change variables.

Diagnose commands include:

`cw_diag help`	Display help for all diagnose commands.
`cw_diag uptime`	Show daemon uptime.
`cw_diag --tlog <on|off>`	Turn on/off telnet log message.
`cw_diag --clog <on|off>`	Turn on/off console log message.
`cw_diag baudrate [9600 | 19200 | 38400 | 57600 | 115200]`	Set the console baud rate.
`cw_diag plain-ctl [0|1]`	Show or change current plain control setting.
`cw_diag sniff-cfg ip port`	Set sniff server ip and port.
`cw_diag sniff [0|1|2]`	Enable/disable sniff packet.
`cw_diag stats wl_intf`	Show wl_intf status.
`cw_diag admin-timeout [30]`	Set shell idle timeout in minutes.
`cw_diag -c wtp-cfg`	Show current wtp config parameters in control plane.
`cw_diag -c radio-cfg`	Show current radio config parameters in control plane.
`cw_diag -c vap-cfg`	Show current vaps in control plane.
`cw_diag -c ap-rogue`	Show rogue APs pushed by AC for on-wire scan.
`cw_diag -c sta-rogue`	Show rogue STAs pushed by AC for on-wire scan.
`cw_diag -c arp-req`	Show scanned arp requests.
`cw_diag -c ap-scan`	Show scanned APs.
`cw_diag -c sta-scan`	Show scanned STAs.
`cw_diag -c sta-cap`	Show scanned STA capabilities.
`cw_diag -c wids`	Show scanned WIDS detections.

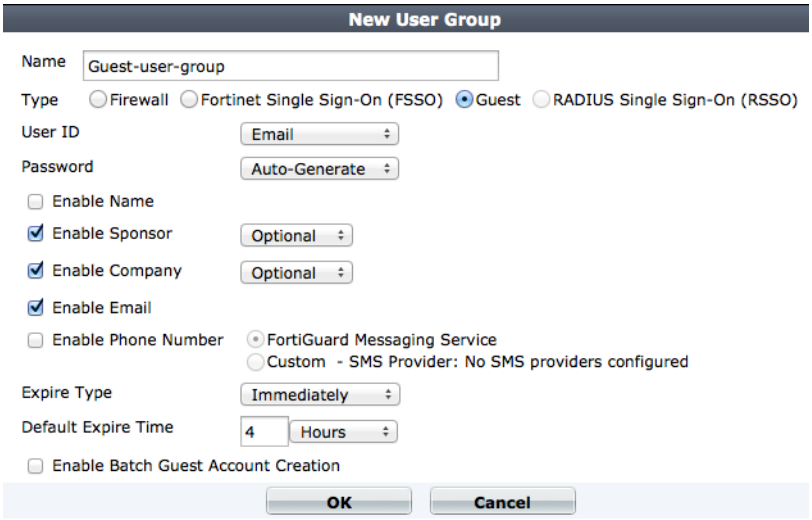
`cw_diag -c darrp`	Show darrp radio channel.
`cw_diag -c mesh`	Show mesh status.
`cw_diag -c mesh-veth-acinfo`	Show mesh veth ac info, and mesh ether type.
`cw_diag -c mesh-veth-vap`	Show mesh veth vap.
`cw_diag -c mesh-veth-host`	Show mesh veth host.
`cw_diag -c mesh-ap`	Show mesh ap candidates.
`cw_diag -c scan-clr-all`	Flush all scanned AP/STA/ARPs.
`cw_diag -c ap-suppress`	Show suppressed APs.
`cw_diag -c sta-deauth`	Ee-authenticate an STA.

WiFi guest access provisioning

Guest access provisioning allows you to easily add guest accounts to your FortiGate unit. These accounts are mainly used to authenticate guest WiFi users for temporary access to a WiFi network managed by a FortiGate unit.

Guest access configuration begins by going to *User & Device* > *User Definition* > *User Group* and adding one or more guest user groups.

Figure 53: Adding a Guest user group



Many guest account options are available including:

- Email address or user name to identify the guest account
- Requiring a password or no password to log in
- Require a sponsor or company name
- Sending the user's account information to them using email, FortiGuard Messaging Service, or SMS messages
- Configurable account expiry time, starting immediately or after the first login
- Batch guest account creation using auto-generated user IDs and passwords

Guest users are added, removed and managed from *User & Device* > *User* > *Guest Management*. From this page, you select the guest user group to change, then add users to it, edit users that have been added or purge all users. When you add the user, you can customize the account expiration date and time.

To provide guest users with their account information, you can select the account from this Guest Management page and select *Send* to print the guest account credentials or send them to the user as an email or SMS message.

Adding guest access to a WiFi network

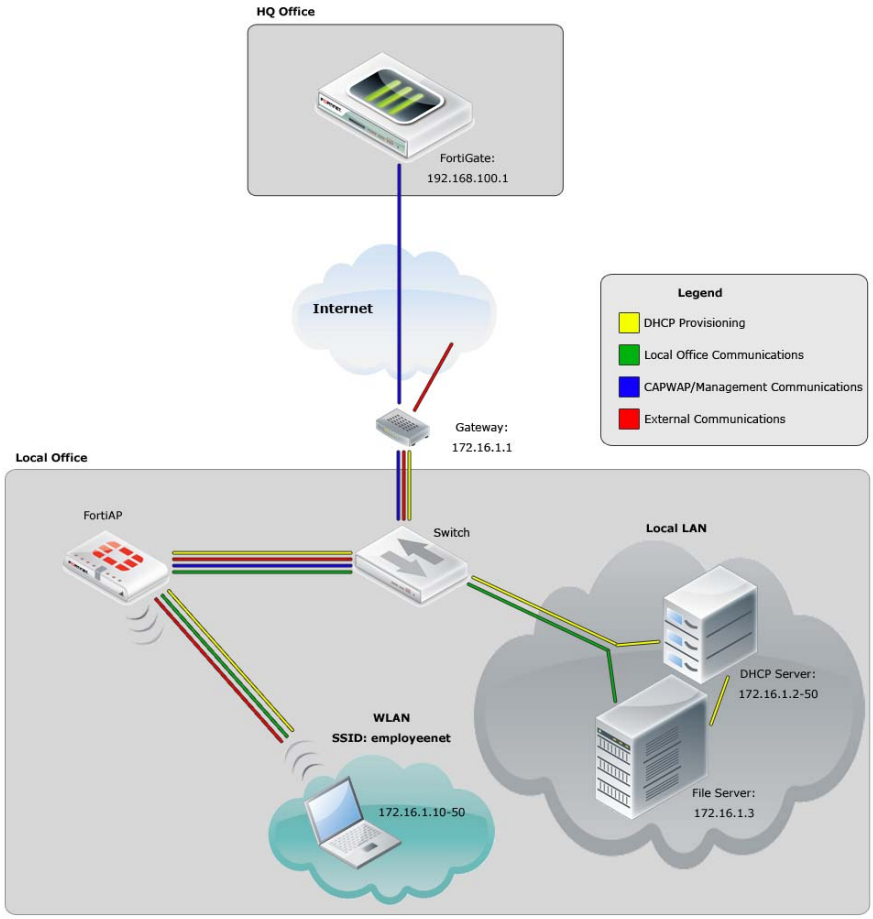
To apply guest access provisioning to a Wifi network, set the *Security Mode* of an SSID to *Captive Portal* and select one or more guest user groups. Guest users can then log into the portal using their guest account.

FortiAP local bridging (Private Cloud-Managed AP)

A FortiAP unit can provide WiFi access to a LAN, even when the wireless controller is located remotely. This configuration is useful for the following situations:

- Installations where the WiFi controller is remote and most of the traffic is local or uses the local Internet gateway
- Wireless-PCI compliance with remote WiFi controller
- Telecommuting, where the FortiAP unit has the WiFi controller IP address pre-configured and broadcasts the office SSID in the user's home or hotel room. In this case, data is sent in the wireless tunnel across the Internet to the office and should have encryption using DTLS enabled.

Figure 54: Remotely-managed FortiAP providing WiFi access to local network



On the remote FortiGate wireless controller, the WiFi SSID is created with the *Traffic Mode* set to *Local Bridge with FortiAP's Interface*. In this mode, no IP addresses are configured. The FortiAP unit's WiFi and Ethernet interfaces behave like a switch. WiFi client devices obtain IP addresses from the same DHCP server as wired devices on the LAN.

There can be only one Bridge mode SSID per FortiAP unit. The Local Bridge feature cannot be used in conjunction with Wireless Mesh features.

To configure a FortiAP local bridge - web-based manager

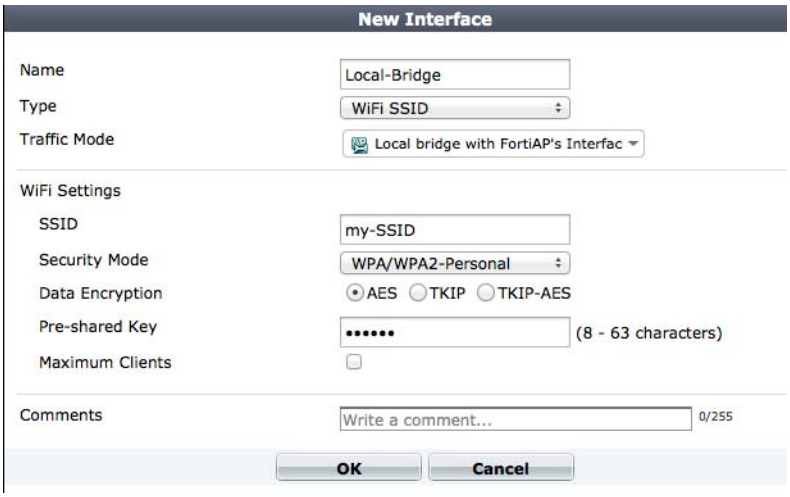
1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.
2. Enter:

Interface name	A name for the new WiFi interface.
Traffic Mode	Local bridge with FortiAP's Interface

SSID	The SSID visible to users.
Security Mode **Data Encryption** **Preshared Key**	Configure security as you would for a regular WiFi network.

3. Select OK.
4. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP,* select the FortiAP unit for editing.
5. Authorize the FortiAP unit.
6. The FortiAP unit can carry regular SSIDs in addition to the Bridge SSID.

Figure 55:SSID configured for Local Bridge operation



To configure a FortiAP local bridge - CLI

This example creates a WiFi interface “branchbridge” with SSID “LANbridge” using WPA-Personal security, passphrase “Fortinet1”.

```
config wireless-controller vap
  edit "branchbridge"
    set vdom "root"
    set ssid "LANbridge"
    set local-bridging enable
    set security wpa-personal
    set passphrase "Fortinet1"
  end
config wireless-controller wtp
  edit FAP22B3U11005354
    set admin enable
    set vaps "branchbridge"
  end
```

WiFi data channel encryption

You can enhance the security of communication between a FortiGate wireless controller and a FortiAP unit by applying DTLS encryption to the data channel.

There are data channel encryption settings on both the FortiGate unit and the FortiAP unit. At both ends, you can enable Clear Text, DTLS encryption or both. The settings must agree or the FortiAP unit will not be able to join the WiFi network. By default, both Clear Text and DTLS-encrypted communication are enabled on the FortiAP unit, allowing the FortiGate setting to determine whether data channel encryption is used. If the FortiGate unit also enables both Clear Text and DTLS, Clear Text is used.

Data channel encryption settings are located in the Custom AP profile. If you use Automatic profile, only Clear Text is supported.

Data channel encryption is software-based and can affect performance. Verify that the system meets your performance requirements with encryption enabled.

Configuring DTLS on the FortiGate unit

To enable DTLS for the FAP320B-default profile, enter:

```
config wireless-controller wtp-profile
  edit FAP320B-default
    set dtls-policy dtls-enabled
  end
```

Configuring encryption on the FortiAP unit

The FortiAP unit has its own settings for data channel encryption.

Enabling CAPWAP encryption - FortiAP web-based manager

1 On the *System Information* page, in *WTP Configuration* > *AC Data Channel Security*, select one of:
- Clear Text
- DTLS Enabled
- Clear Text or DTLS Enabled (default)

2 Select *Apply*.

Enabling encryption - FortiAP CLI

You can set the data channel encryption using the AC_DATA_CHAN_SEC variable:

- 0 is Clear Text
- 1 is DTLS Enabled
- 2 is Clear Text or DTLS Enabled (default)

For example, to set security to DTLS and then save the setting, enter

```
cfg -a AC_DATA_CHAN_SEC=1
cfg -c
```

Wireless client load balancing for high-density deployments

Wireless load balancing allows your wireless network to distribute wireless traffic more efficiently among wireless access points and available frequency bands. FortiGate wireless controllers support the following types of client load balancing:

- Access Point Hand-off - the wireless controller signals a client to switch to another access point.
- Frequency Hand-off - the wireless controller monitors the usage of 2.4GHz and 5GHz bands, and signals clients to switch to the lesser-used frequency.

Load balancing is not applied to roaming clients.

Access point hand-off

Access point handoff wireless load balancing involves the following:

- If the load on an access point (ap1) exceeds a threshold (for example, 30 clients) then the client with the weakest signal will be signaled by the wireless controller to drop off and join another nearby access point (ap2).
- When one or more access points are overloaded (more than 30 clients) and a new client attempts to join a wireless network, the wireless controller selects the least busy access point that is closest to the new client and this access point is the one that responds to the client and the one that the client joins.

Frequency hand-off or band-steering

Encouraging clients to use the 5GHz WiFi band if possible enables those clients to benefit from faster interference-free 5GHz communication. The remaining 2.4GHz clients benefit from reduced interference.

The WiFi controller probes clients to determine their WiFi band capability. It also records the RSSI (signal strength) for each client on each band.

If a new client attempts to join the network, the controller looks up that client's MAC address in its wireless device table and determines if it's a dual band device. If it is not a dual band device, then its allowed to join. If it is a dual band device, then its RSSI on 5GHz is used to determine whether the device is close enough to an access point to benefit from movement to 5GHz frequency.

If both conditions of 1) dual band device and 2) RSSI value is strong, then the wireless controller does not reply to the join request of the client. This forces the client to retry a few more times and then timeout and attempt to join the same SSID on 5GHz. Once the controller see this new request on 5GHz, the RSSI is again measured and the client is allowed to join. If the RSSI is below threshold, then the device table is updated and the controller forces the client to timeout again. A client's second attempt to connect on 2.4GHz will be accepted.

Configuration

From the web-based manager, edit a custom AP profile and select *Frequency Handoff* and *AP Handoff* as required for each radio on the AP.

From the CLI, you configure wireless client load balancing thresholds for each custom AP profile. Enable access point hand-off and frequency hand-off separately for each radio in the custom AP profile.

```
config wireless-controller wtp-profile
  edit new-ap-profile
    set handoff-rssi <rssi_int>
    set handoff-sta-thresh <clients_int>
    config radio-1
      set frequency-handoff {disable | enable}
      set ap-handoff {disable | enable}
    end
    config radio-2
      set frequency-handoff {disable | enable}
      set ap-handoff {disable | enable}
    end
  end
```

Where:

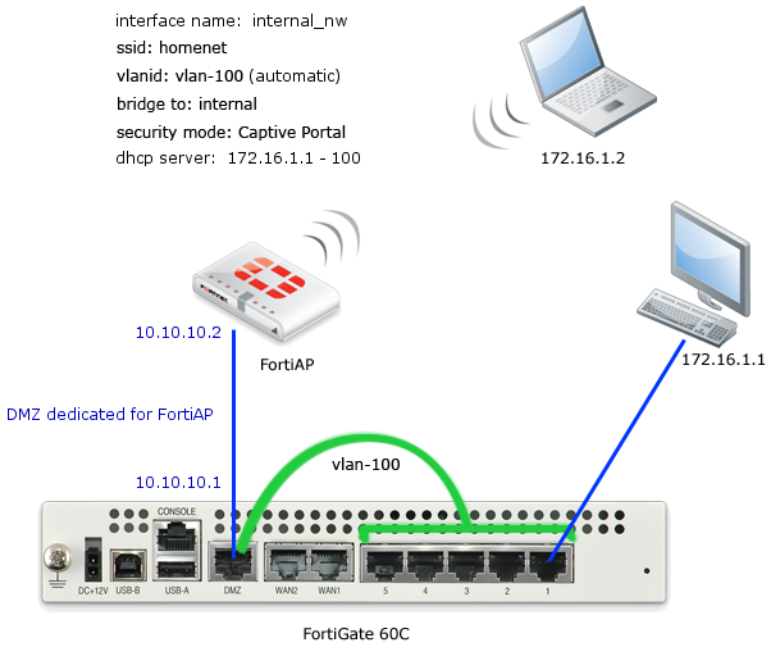
- `handoff-rssi` is the RSSI threshold. Clients with a 5 Ghz RSSI threshold over this value are load balanced to the 5GHz frequency band. Default is 25. Range is 20 to 30.
- `handoff-sta-thresh` is the access point handoff threshold. If the access point has more clients than this threshold it is considered busy and clients are changed to another access point. Default is 30, range is 5 to 25.
- `frequency-handoff` enable or disable frequency handoff load balancing for this radio. Disabled by default.
- `ap-handoff` enable or disable access point handoff load balancing for this radio. Disabled by default.

Frequency handoff must be enabled on the 5GHz radio to learn client capability.

Bridge SSID to FortiGate wired network

A WiFi network can be combined with a wired LAN so that WiFi and wired clients are on the same subnet. This is a convenient configuration for users.

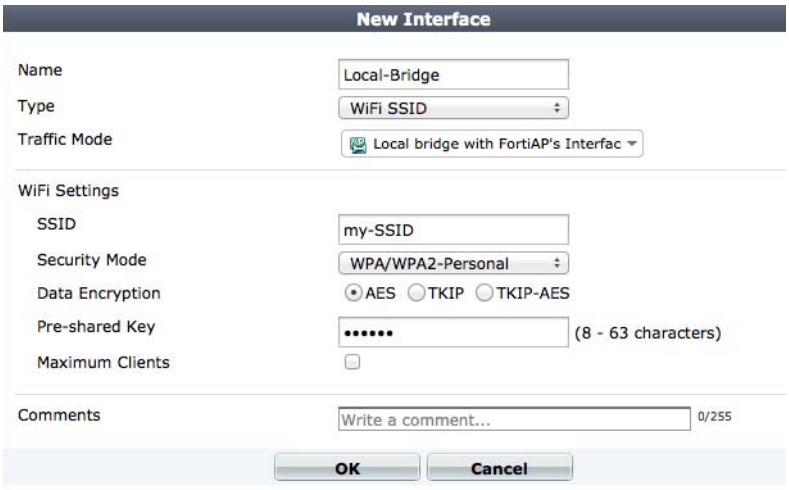
Figure 56:A FortiAP unit bridged with the internal network



This configuration cannot be used in conjunction with Wireless Mesh features because it enables the FortiAP Local Bridge option.

To create the bridged WiFi and wired LAN configuration, you need to configure the SSID with the Local Bridge option so that traffic is sent directly over the FortiAP unit's Ethernet interface to the FortiGate unit, instead of being tunneled to the WiFi controller.

Figure 57:SSID configured with Local Bridge option



Enter the following command from the CLI:

```
config wireless-controller vap
  edit "homenet_if"
    set vdom "root"
    set ssid "homenet"
    set local-bridging enable
    set security wpa-personal
    set passphrase "Fortinet1"
  end
config wireless-controller wtp
  edit FAP22B3U11005354
    set admin enable
    set vaps "homenet_if"
  end
```

IPv6

In order to configure IPv6 features using the web-based manager, IPv6 must be enabled using Feature Select. For more information, see “Feature Select” on page 243.

The following new IPv6 features are available from the FortiOS 5.0 web-based manager:

- IPv6 Policy routing
- IPv6 security policies
- IPv6 Explicit web proxy
- IPv6 NAT – NAT64, DNS64, NAT66
- IPv6 Forwarding Policies - IPS, Application Control, and flow-based antivirus, web filtering and DLP
- New Fortinet FortiGate IPv6 MIB fields
- IPv6 Per-IP traffic shaper
- DHCPv6 relay
- FortiGate interfaces can get IPv6 addresses from an IPv6 DHCP server

IPv6 Policy routing

IPv6 policy routing functions in the same was as IPv4 policy routing. To add an IPv6 policy route, go to *Router* > *Static* > *Policy Routes* and select *Create New* > *IPv6 Policy Route*.

Figure 58:IPv6 policy route

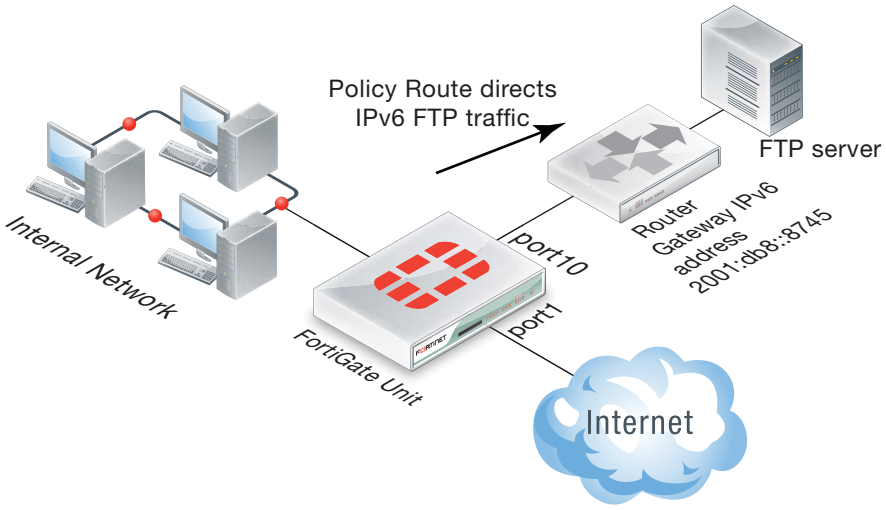


Figure 59: Adding an IPv6 Policy route

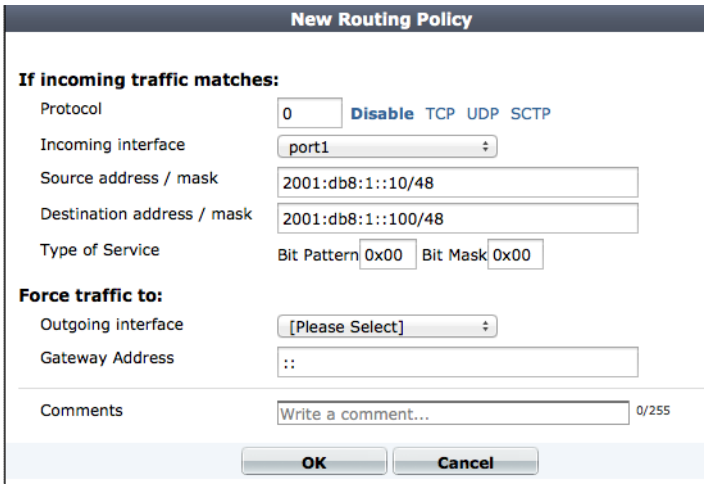


You can also use the following command to add IPv6 policy routes:

```
config router policy6
  edit 0
    set input-device <interface>
    set src <ipv6_ip>
    set dst <ipv6_ip>
    set protocol <0-255>
    set gateway <ipv6_ip>
    set output-device <interface>
    set tos <bit_pattern>
    set tos-mask <bit_mask>
  end
```

IPv6 security policies

IPv6 security policies now support all the features supported by IPv4 security policies. The following new features were added in FortiOS 5.0:

- Policy types and subtypes.
- NAT support including using the destination interface IP address, fixed port, and dynamic IP pools.
- All security features (antivirus, web filtering, application control, IPS, email filtering, DLP, VoIP and ICAP).
- All traffic shaping options, including shared traffic shaping, reverse shared traffic shaping and per-IP traffic shaping.
- All user and device authentication options.

IPv6 Explicit web proxy

With FortiOS 5.0, you can use the explicit web proxy for IPv6 traffic. To do this you need to:

- Enable the Explicit Proxy from the System Information dashboard widget.
- Enable the IPv6 explicit web proxy from the CLI.
- Enable the explicit web proxy for one or more FortiGate interfaces. These interfaces also need IPv6 addresses.
- Add IPv6 web proxy security policies to allow the explicit web proxy to accept IPv6 traffic.

Use the following steps to set up a FortiGate unit to accept IPv6 traffic for the explicit web proxy at the Internal interface and forward IPv6 explicit proxy traffic out the wan1 interface to the Internet.

1. Enter the following CLI command to enable the IPv6 explicit web proxy:

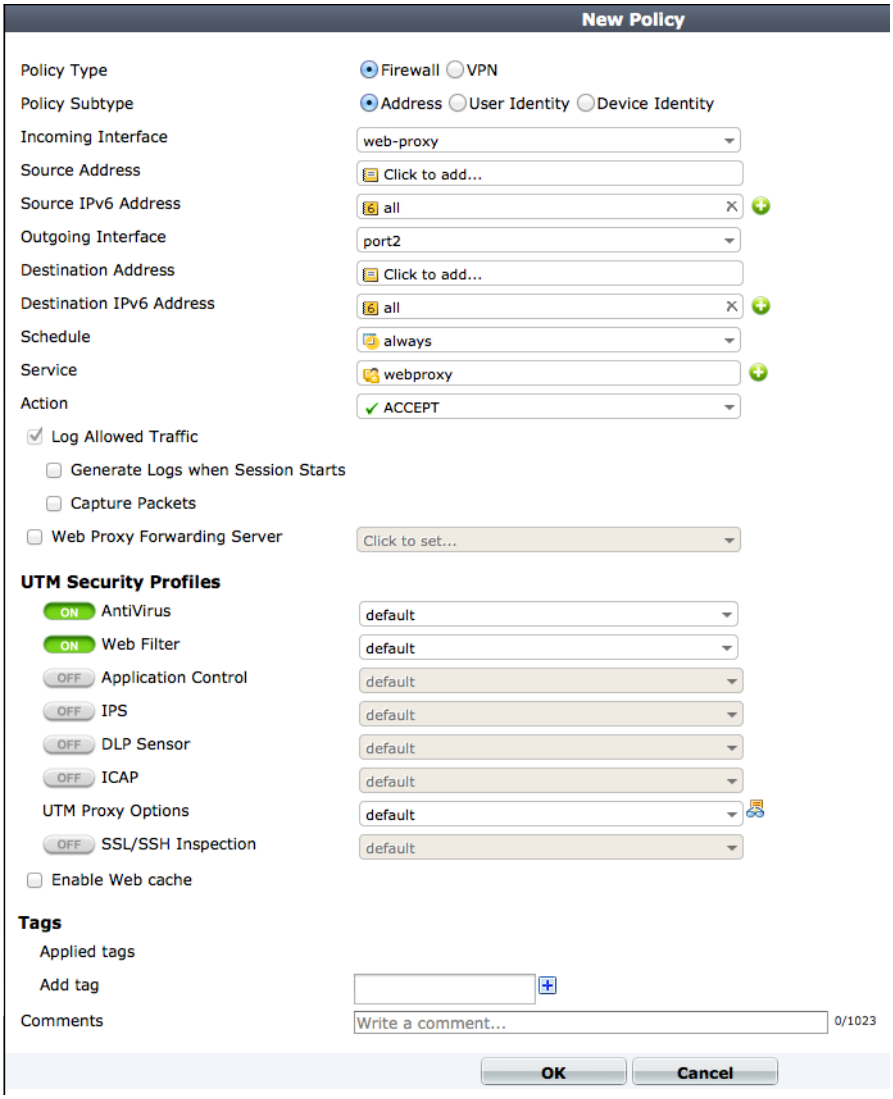
```
config web-proxy explicit
  set status enable
  set ipv6-status enable
end
```

2. Go to *System* > *Network* > *Interfaces* and edit the *internal* interface, select *Enable Explicit Web Proxy* and select *OK*.
3. Go to *Policy* > *Policy* > *IPv6 Policy* and select *Create New* to add an IPv6 explicit web proxy security policy with the following settings shown in Figure 60.

   This IPv6 explicit web proxy policy allows traffic from all IPv6 IP addresses to connect through the explicit web proxy and through the wan1 interface to any IPv6 addresses that are accessible from the wan1 interface.

If you have enabled both the IPv4 and the IPv6 explicit web proxy you can combine IPv4 and IPv6 addresses in a single explicit web proxy policy to allow both IPv4 and IPv6 traffic through the proxy.

Figure 60: Example IPv6 Explicit Web Proxy security policy



Restricting the IP address of the explicit IPv6 web proxy

You can use the following command to restrict access to the IPv6 explicit web proxy using only one IPv6 IP address. The IPv6 address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit web proxy is enabled on an interface with multiple IPv6 addresses.

For example, to require uses to connect to the IPv6 address 2001:db8:0:2::30 to connect to the explicit IPv6 HTTP proxy:

```
config web-proxy explicit
  set incoming-ipv6 2001:db8:0:2::30
end
```

Restricting the outgoing source IP address of the IPv6 explicit web proxy

You can use the following command to restrict the source address of outgoing web proxy packets to a single IPv6 address. The IP address that you specify must be the IPv6 address of an interface that the explicit HTTP proxy is enabled on. You might want to use this option if the explicit HTTP proxy is enabled on an interface with multiple IPv6 addresses.

For example, to restrict the outgoing packet source address to 2001:db8:0:2::50:

```
config http-proxy explicit
  set outgoing-ip6 2001:db8:0:2::50
end
```

IPv6 NAT – NAT64, DNS64, NAT66

NAT66, NAT64 and DNS64 are now supported for IPv6. These options provide IPv6 NAT and DNS capabilities IPv6-IPv4 tunnelling or dual stack configurations. These are available only in the CLI.

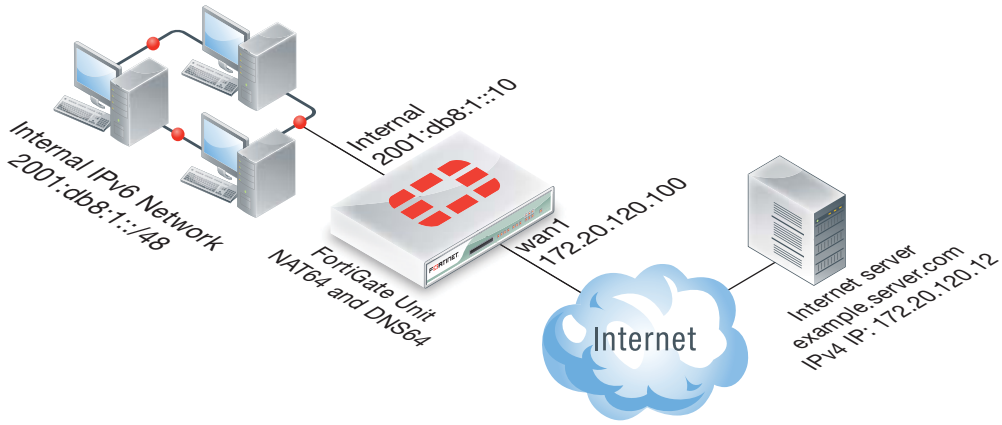
Fortinet supports all features described in RFC 6146. However, for DNS64 there is no support for handling Domain Name System Security Extensions (DNSSEC). DNSSEC is for securing types of information that are provided by the DNS as used on an IP network or networks. You can find more information about DNS64 in RFC 6147.

NAT64 and DNS64

NAT64 is used to translate IPv6 addresses to IPv4 addresses so that a client on an IPv6 network can communicate transparently with a server on an IPv4 network. NAT64 is usually implemented in combination with DNS64. DNS64 synthesizes AAAA records from A records and is used to synthesize IPv6 addresses for hosts that only have IPv4 addresses.

With a NAT64 and DNS64 configuration in place on a FortiGate unit, clients on an IPv6 network can transparently connect to addresses on an IPv4 network. NAT64 and DNS64 perform IPv4 to IPv6 transition, allowing clients that have already switched to IPv6 addresses to continue communicating with servers that still use IPv4 addresses.

Figure 61: Example NAT64 configuration



To configure NAT64 to allow a host on the IPv6 network to connect to the Internet server

In this example the Internal IPv6 network address is 2001:db8:1::/48 and the external IPv4 network address is 172.20.120.0/24. NAT64 is configured to allow a user on the internal network to connect to the server at IPv4 address 172.20.120.12. In this configuration, sessions exiting the wan1 interface must have their source address changed to and IPv4 address in the range 172.20.120.200 to 172.20.120.210.

1. Enter the following command to enable NAT64.

```
config system nat64
  set status enable
end
```

Enabling NAT64 with the `config system nat64` command means that all IPv6 traffic received by the current VDOM can be subject to NAT64 if the source and destination address matches an NAT64 security policy.

By default, the setting `always-senthetize-aaaa-record` is not enabled. With this setting disabled, the DNS proxy will attempt to find an AAAA records for queries to domain names and therefore resolve the host names to IPv6 addresses. If the DNS proxy cannot find an AAAA record, it synthesizes one by adding the NAT64 prefix to the A record.

By using the `nat64-prefix` option of the `config system nat64` command to change the default nat64 prefix (the default is the well known prefix 64:ff9b::/96) and setting `always-senthetize-aaaa-record` to enable, the DNS proxy does not check for AAAA records and always synthesizes AAAA records.

As an alternative to the above entry, there is the optional configuration that would allow the resolution of CNAME queries.

```
config system nat64
  set status enable
  set nat64-prefix 64:ff9b::/96
  set always-synthesize-aaaa-record enable
end
```

2. Enter the following command to add an IPv6 firewall address for the internal network:

```
config firewall address6
  edit internal-net6
    set ip6 2001:db8::/48
  end
```

3. Enter the following command to add an IPv4 firewall address for the external network:

```
config firewall address
  edit external-net4
    set subnet 172.20.120.0/24
    set associated-interface wan1
  end
```

4. Enter the following command to add an IP pool containing the IPv4 address that the should become the source address of the packets exiting the wan1 interface:

```
config firewall ippool
  edit exit-pool4
    set startip 172.20.120.200
    set endip 172.20.120.210
  end
```

5. Enter the following command to add a NAT64 policy that allows connections from the internal IPv6 network to the external IPv4 network:

```
config firewall policy64
  edit 0
    set srcintf internal
    set srcaddr internal-net6
    set dstintf wan1
    set dstaddr external-net4
    set action accept
    set schedule always
    set service ANY
    set logtraffic enable
    set ippool enable
    set poolname exit-pool4
  end
```

The `srcaddr` can be any IPv6 firewall address and the `dstaddr` can be any IPv4 firewall address.

Other NAT64 policy options include `fixedport`, that can be used to prevent NAT64 from changing the destination port. You can also configure traffic shaping for NAT64 policies.

How a host on the internal IPv6 network communicates with example.server.com that only has IPv4 address on the Internet

1. The host on the internal network does a DNS lookup for example.server.com by sending a DNS query for an AAAA record for example.server.com.
2. The DNS query is intercepted by the FortiGate DNS proxy.
3. The DNS proxy attempts to resolve the query with a DNS server on the Internet and discovers that there are no AAAA records for example.server.com.

The previous step is skipped if `always-senthetize-aaaa-record` is enabled.

4. The DNS proxy performs an A-record query for example.server.com and gets back an RRSet containing a single A record with the IPv4 address 172.20.120.12.
5. The DNS proxy then synthesizes an AAAA record. The IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits and the received IPv4 address in the lower 32 bits. By default, the resulting IPv6 address is 64:ff9b::172.20.120.12.
6. The host on the internal network receives the synthetic AAAA record and sends a packet to the destination address 64:ff9b::172.20.120.12.
7. The packet is routed to the FortiGate internal interface where it is accepted by the NAT64 security policy.
8. The FortiGate unit translates the destination address of the packets from IPv6 address 64:ff9b::172.20.120.12 to IPv4 address 172.20.120.12 and translates the source address of the packets to 172.20.120.200 (or another address in the IP pool range) and forwards the packets out the wan1 interface to the Internet.

NAT66

NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. NAT66 is not as common or as important as IPv4 NAT, as many IPv6 IP addresses do not need NAT66 as much as IPv4 NAT. However, NAT66 can be useful for a number of reasons. For example, you may have changed the IP addresses of some devices on your network but want traffic to still appear to be coming from their old addresses. You can use NAT66 to translate the source addresses of packets from the devices to their old source addresses.

In FortiOS 5.0, NAT66 options can be added to an IPv6 security policy from the CLI.

Configuring NAT66 is very similar to configuring NAT in an IPv4 security policy. For example, use the following command to add an IPv6 security policy that translates the source address of IPv6 packets to the address of the destination interface (similar to IPv4 source NAT:

```
config firewall policy6
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr internal_net
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
  end
```

Its also can be useful to translate one IPv6 source address to another address that is not the same as the address of the exiting interface. You can do this using IP pools. For example, enter the following command to add an IPv6 IP pool containing one IPv6 IP address:

```
configure firewall ippool6
  edit example_6_pool
    set startip 2001:db8::
    set endip 2001:db8::
  end
```

Enter the following command to add an IPv6 firewall address that contains a single IPv6 IP address.

```
configure firewall address6
  edit device_address
    set ip6 2001:db8::132/128
  end
```

Enter the following command to add an IPv6 security policy that accepts packets from a device with IP address 2001:db8::132 and translates the source address to 2001:db8::.

```
config firewall policy6
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr device_address
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
    set nat enable
    set ippool enable
    set poolname example_6_pool
  end
```

NAT66 destination address translation

NAT66 can also be used to translate destination addresses. This is done in an IPv6 policy by using IPv6 virtual IPs. For example, enter the following command to add an IPv6 virtual IP that maps destination address 2001:db8::dd to 2001:db8::ee

```
configure firewall vip6
  edit example-vip6
    set extip 2001:db8::dd
    set mappedip 2001:db8::ee
  end
```

Enter the following command to add an IPv6 security policy that accepts packets with a destination address 2001:db8::dd and translates that destination address to 2001:db8::ee

```
config firewall policy6
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr all
    set dstaddr example-vip6
    set action accept
    set schedule always
    set service ANY
  end
```

IPv6 Forwarding Policies - IPS, Application Control, and flow-based antivirus, web filtering and DLP

FortiOS 5.0 fully supports flow-based inspection of IPv6 traffic. This includes full support for IPS, application control, as well as flow-based virus scanning, and web filtering.

To add flow-based inspection to IPv6 traffic go to *Policy* > *Policy* > *IPv6 Policy* and select *Create New* to add an IPv6 Security Policy. Configure the policy to accept the traffic to be scanned. Select UTM and select the UTM profiles to apply to the traffic. To apply flow-based

inspection you can select an IPS and an application control profile. You can also select antivirus or web filtering profiles in which flow-based inspection has been selected.

New Fortinet FortiGate IPv6 MIB fields

The following IPv6 MIB fields have been added to the Fortinet FortiGate MIB. These MIS entries can be used to display IPv6 session and policy statistics.

- IPv6 Session Counters:
  `fgSysSes6Count`
  `fgSysSes6Rate1`
  `fgSysSes6Rate10`
  `fgSysSes6Rate30`
  `fgSysSes6Rate60`
- IPv6 Policy Statistics:
  `fgFwPol6StatsTable`
  `fgFwPol6StatsEntry`
  `FgFwPol6StatsEntry`
  `fgFwPol6ID`
  `fgFwPol6PktCount`
  `fgFwPol6ByteCount`
- IPv6 Session Statistics:
  `fgIp6SessStatsTable`
  `fgIp6SessStatsEntry`
  `FgIp6SessStatsEntry`
  `fgIp6SessNumber`

The fgSysSesCount and fgSysSesRateX MIBs report statistics for IPv4 plus IPv6 sessions combined. This behavior was not changed.

New OIDs

The following OIDs have been added:

```
FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgSystem.fgSystemInfo
.fgSysSes6Count   1.3.6.1.4.1.12356.101.4.1.15
.fgSysSesRate1    1.3.6.1.4.1.12356.101.4.1.16
.fgSysSesRate10   1.3.6.1.4.1.12356.101.4.1.17
.fgSysSesRate30   1.3.6.1.4.1.12356.101.4.1.18
.fgSysSesRate60   1.3.6.1.4.1.12356.101.4.1.19

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgFirewall.fgFwPolicies
     .fgFwPolTables
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ID   1.3.6.1.4.1.12356.
     101.5.1.2.2.1.1
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6PktCount   1.3.6.1.4.1.
     12356.101.5.1.2.2.1.2
.fgFwPol6StatsTable.fgFwPol6StatsEntry.fgFwPol6ByteCount   1.3.6.1.4.1
     .12356.101.5.1.2.2.1.3

FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgInetProto.fgInetProto
     Tables
.fgIp6SessStatsTable.fgIp6SessStatsEntry.fgIp6SessNumber
     1.3.6.1.4.1.12356.101.11.2.3.1.1
```

EXAMPLE SNMP get/walk output

```
// Session6 stats excerpt from sysinfo:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.4
FORTINET-FORTIGATE-MIB::fgSysSes6Count.0 = Gauge32: 203
FORTINET-FORTIGATE-MIB::fgSysSes6Rate1.0 = Gauge32: 10 Sessions Per
    Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate10.0 = Gauge32: 2 Sessions Per
    Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate30.0 = Gauge32: 1 Sessions Per
    Second
FORTINET-FORTIGATE-MIB::fgSysSes6Rate60.0 = Gauge32: 0 Sessions Per
    Second

// FwPolicy6 table:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.5.1.2.2
FORTINET-FORTIGATE-MIB::fgFwPol6ID.1.3 = INTEGER: 3
FORTINET-FORTIGATE-MIB::fgFwPol6ID.1.4 = INTEGER: 4
FORTINET-FORTIGATE-MIB::fgFwPol6PktCount.1.3 = Counter64: 4329
FORTINET-FORTIGATE-MIB::fgFwPol6PktCount.1.4 = Counter64: 0

FORTINET-FORTIGATE-MIB::fgFwPol6ByteCount.1.4 = Counter64: 0

// IP6SessNumber:
snmpwalk -v2c -cpublic 192.168.1.111 1.3.6.1.4.1.12356.101.11.2.3.1
FORTINET-FORTIGATE-MIB::fgIp6SessNumber.1 = Counter32: 89
```

IPv6 Per-IP traffic shaper

You can add any Per-IP traffic shaper to an IPv6 security policy using the following command:

```
config firewall policy6
  edit 0
    set per-ip-shaper 'new-perip-shaper'
  end
```

DHCPv6 relay

You can use the following command to configure a FortiGate interface to relay DHCPv6 queries and responses from one network to a network with a DHCPv6 server and back. The command enables DHCPv6 relay and includes adding the IPv6 address of the DHCP server that the FortiGate unit relays DHCPv6 requests to:

```
config system interface
  edit internal
    config ipv6
      set dhcp6-relay-service enable
      set dhcp6-relay-type regular
      set dhcp6-relay-ip 2001:db8:0:2::30
  end
```

FortiGate interfaces can get IPv6 addresses from an IPv6 DHCP server

From the CLI you can configure any FortiGate interface to get an IPv6 address from an IPv6 DHCP server. For example, to configure the wan2 interface to get an IPv6 address from an IPv6 DHCP server enter the following command:

```
config system interface
  edit wan2
    config ipv6
      set ip6-mode dhcp
    end
end
```

Logging and reporting

New logging and reporting features include:

- Log message reorganization
- Log Viewer Improvements
- The FortiGate Security Analysis Report
- Converting compact log format

FortiCloud, the new logging and reporting feature that replaces FAMS, is described in FortiOS 5.0 *Installation and System Administration*.

Log message reorganization

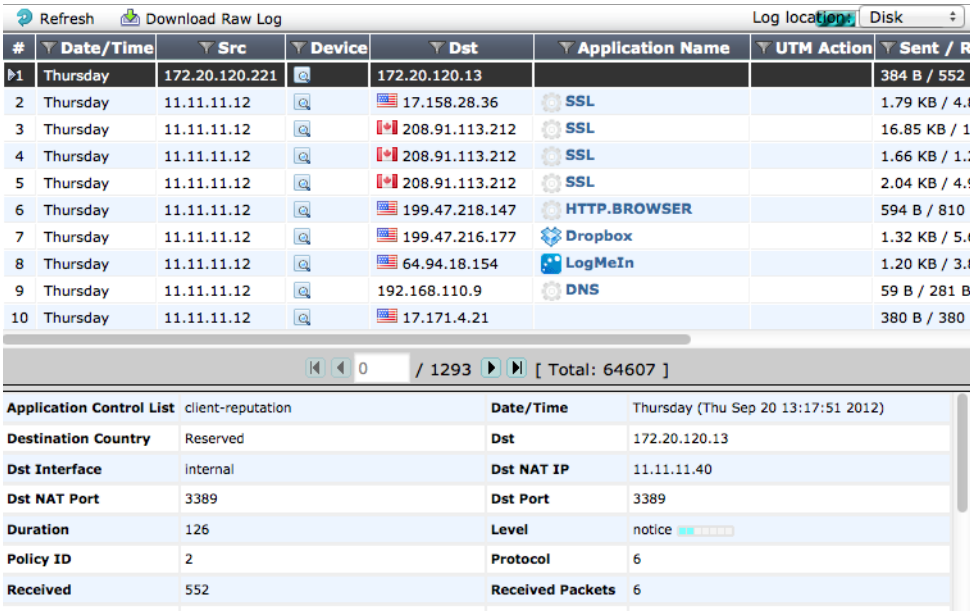
FortiOS 5.0 log messages have been re-organized. The new log message format will be described in the FortiOS 5.0 *Logging and Reporting Guide* and *Log Message Reference*.

Log Viewer Improvements

In FortiOS 5.0, the Log & Report menu provides access to the following types of log messages:

- Traffic log
  - Forward Traffic - log messages for traffic passing through the FortiGate unit. Includes traffic log messages as well as Security log messages so that you can view messages about Security events (such as a message indicating that a virus was found) in the same location as the traffic log messages that recorded the current traffic at the time. From the forward traffic log viewer, you can also view content logs and quarantined files. Forward traffic log messages also include log messages created when you enable logging for the IPv4 and IPv6 security policy implicit security policies.
  - Local Traffic - Log messages for traffic terminating at the FortiGate unit. All traffic terminating at the FortiGate unit is allowed or denied by a local in policy. To view local in policies go to *Policy* > *Policy* > *Local In Policy*. You can enable and disable logging for local in traffic from here as well.
  - Multicast Traffic - Log messages for multicast traffic passing through the FortiGate unit and allowed by multicast traffic policies
  - Invalid Packets - Log messages recorded when the FortiGate unit receives invalid packets.
- Event log - Event log messages organized into the following categories:
  - System
  - Router
  - VPN
  - User
  - WAN Opt. & Cache
  - WiFi

Figure 62: Example Forward Traffic log display showing some Security log messages



From each of these log message viewers, you can download raw log messages, adjust the column settings to display the ones you are most interested in, filter the messages according to a wide range of criteria and display detailed information for a selected log message. In addition, you can control the source of the log messages that are displayed. For example, setting the log location source can be the disk, if your FortiGate unit has available internal storage.

Other logging improvements include:

- New event log types including event logs for FortiClient usage.
- Traffic log messages for packets blocked by the implicit policies that appear at the bottom of IPv4 and IPv6 policy lists. You can enable logging for these policies by editing them and selecting *Log Violation Traffic*.
- When you enable logging on a security policy and a session begins, the FortiGate unit logs that session as well as logging when that session closes. These traffic logs contain the log fields status=start, when a session has started, and status=close, when the session ends.
- Email filter log messages now contain a new field, the cc field, which provides all the email addresses that were copied (or cc'd) to the original email message.
- There are two new event logs that contain information about the FSSO polling daemon: one event log is recorded when a logged on user adds or replaces an old user; the second event log is recorded when an old user is logged off because of inactivity or when replaced.

From the CLI, all of these and some other options are available from the new `config log setting` command. This command configures traffic logging settings per VDOM.

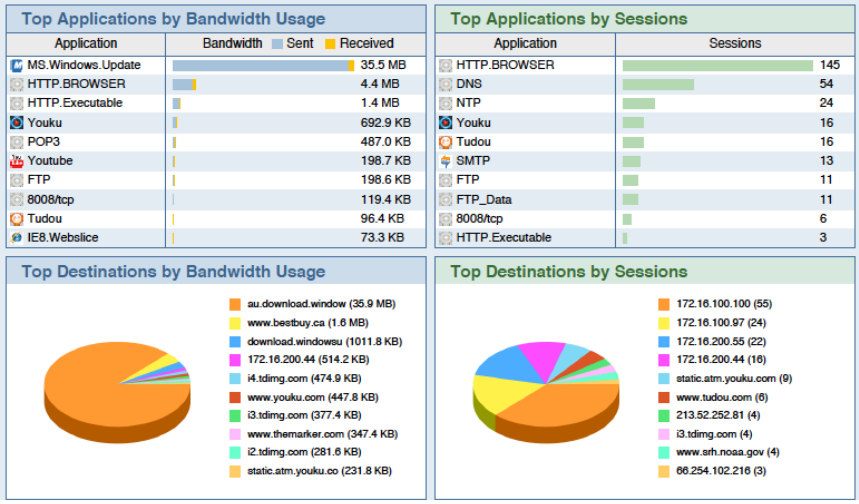
The FortiGate Security Analysis Report

In order for your FortiGate unit to create a Security Analysis Report, disk logging must be enabled. To enable disk logging, go to *Log & Report* > *Log Config* > *Log Settings* and under *Logging and Archiving* select *Disk* and *Enable Local Reports*.

Viewing the current report

You can go to *Log & Report* > *Report* > *Local* and select *Run Now* to view the latest FortiGate Security Analysis Report. This report is constantly updated so you can go here any time to get the current report. The Multi-page report provides wide range of data including bandwidth and application use, users, destinations, streaming usage, email traffic, and so on.

Figure 63: Extract from a sample report



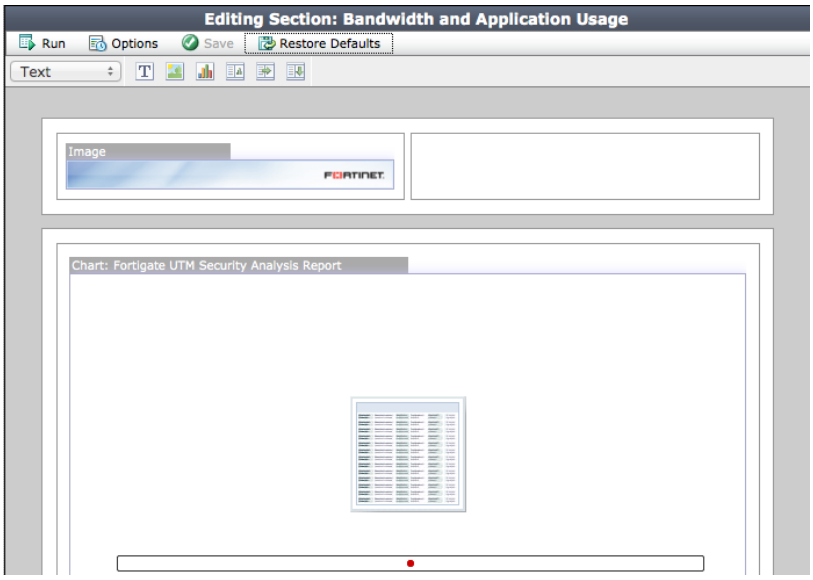
Viewing the saved (historical) security analysis reports

You can go to *Log & Report* > *Report* > *Local* to select saved reports to view.

Customizing the security analysis report

You can go to *Log & Report* > *Report* > *Local* and select *Customize* to customize the look and content of the report. You can also change the report schedule and other options.

Figure 64: Customizing report look and content



Select *Options* to change the report schedule to Daily, Weekly or On Demand. You can also change the time of day at which an old report is saved and a new one started.

Converting compact log format

To convert your compact logs to the new FortiOS 5 format, use the following CLI command:

```
execute log convert-oldlogs
```

This command is available only if you have upgraded from an earlier version of FortiOS and have old compact logs on your system.

Firewall

New firewall features include:

- Choosing the policy type
- Reorganized Firewall Services
- Local in policies
- Multicast Policies
- Adding DoS Anomaly protection to a FortiGate interface
- Changes to security proxy options
- SSL and SSH inspection

Choosing the policy type

Creating and editing security policies has been enhanced make creating different types of security policies easier to understand. Now the first step in creating a security policy, after going to *Policy* > *Policy* > *Policy* and selecting *Create New* is to select the *Policy Type* (Firewall or VPN) and *Policy Subtype*. The policy subtype selections depend on the policy type:

- If you select *Firewall* you can also select
  - *Address* to create a basic security policy
  - *User Identity* to create a policy that identifies users (user authentication)
  - *Device Identity* to create a policy that identifies devices (device authentication or BYOD)
- If you select *VPN* you can also select
  - *IPsec* to create IPsec VPN policies
  - *SSL-VPN* to create SSL VPN policies

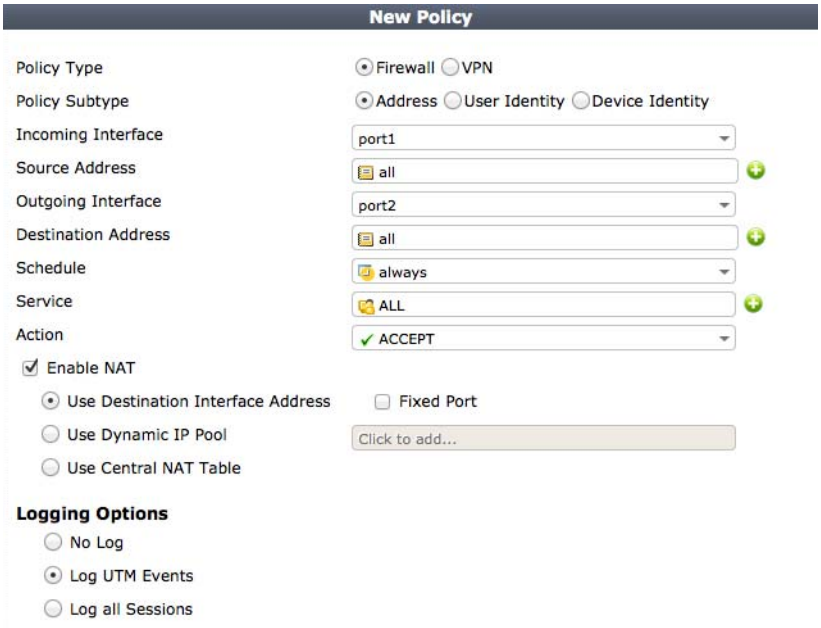
This section describes:

- Creating a basic security policy
- Creating a security policy to authenticate users
- Creating a security policy to authenticate devices for BYOD
- Creating a policy-based IPsec VPN security policy
- Creating a route-based IPsec VPN security policy
- Creating an SSL VPN security policy

Creating a basic security policy

Use the default policy type settings to create a basic security policy. Select incoming and outgoing interfaces, source and destination addresses, the schedule, services and the action. Select other features such as NAT, logging, Security Features and so on.

Figure 65: Creating a basic security policy



Creating a security policy to authenticate users

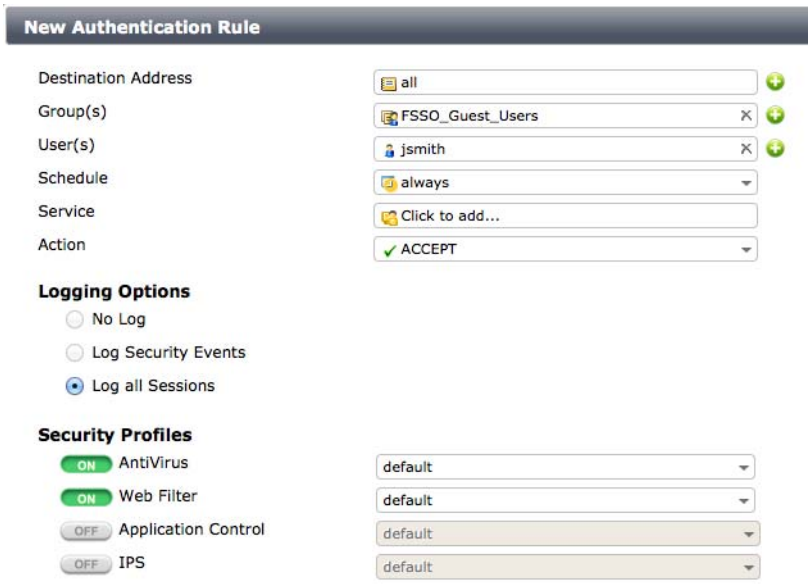
Select the *Firewall* policy type and the *User Identity* subtype. Select incoming and outgoing interfaces, source addresses, and other features. Then select *Create New* to add a user authentication rule to the policy.

User authentication rules include destination addresses, user groups and or individual users, a schedule, services, the action, logging settings, and UTM security profiles.

You select the destination address separately for each authentication rule. This means that you can apply different features to different user groups depending on their destination addresses.

You can also now add individual users to authentication rules instead of just user groups.

Figure 66: Adding a user authentication rule

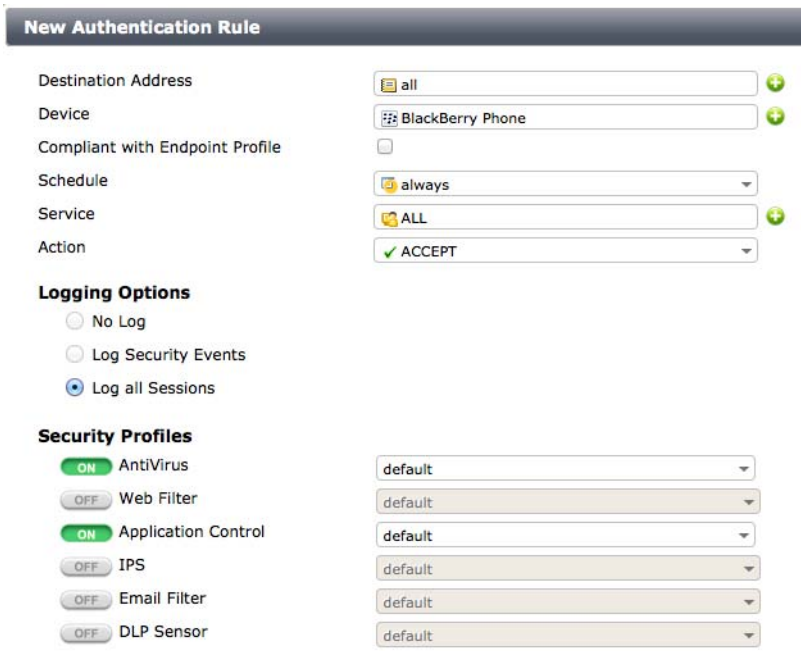


Creating a security policy to authenticate devices for BYOD

Select the *Firewall* policy type and the *Device Identity* subtype. Select incoming and outgoing interfaces, source addresses, and other features. Then select *Create New* to add device authentication rules to the policy.

Device authentication rules include the destination address, user groups and or individual users, schedule, service, action, logging, and UTM security profiles.

Figure 67: Adding a device authentication rule



Creating a policy-based IPsec VPN security policy

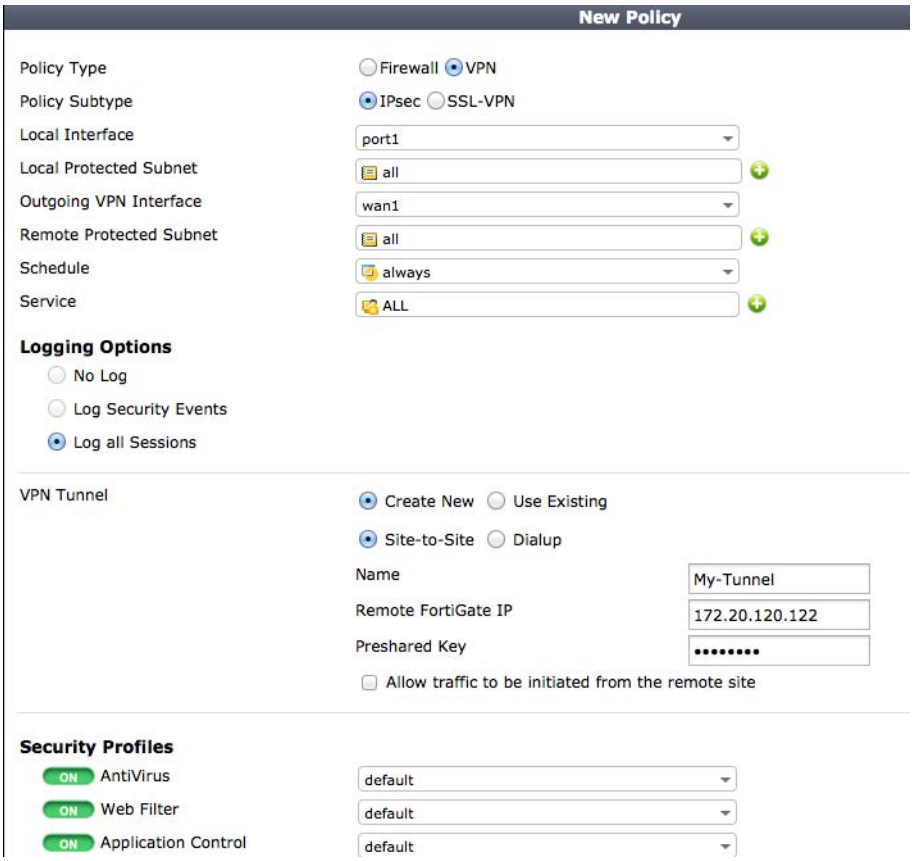
Select the *VPN* policy type and the *IPsec* subtype. Select the local and outgoing VPN interfaces, local protected subnet and remote protected subnet addresses, the schedule, services, and the action.

You have two options to configure the *VPN Tunnel* used by the policy.

- You can use a tunnel that has already been added. Select *Use Existing* and select the tunnel to use.
- You can add a new tunnel. Select *Create New* and select either *Site to Site* or *Dialup*. Add a *Name* for the tunnel, the IP address of the remote FortiGate unit (not required for Dialup) and the Preshared Key to be used by the tunnel.

You can also apply Security Profiles and Client Reputation to IPsec VPN traffic.

Figure 68: Creating a policy-based IPsec VPN policy

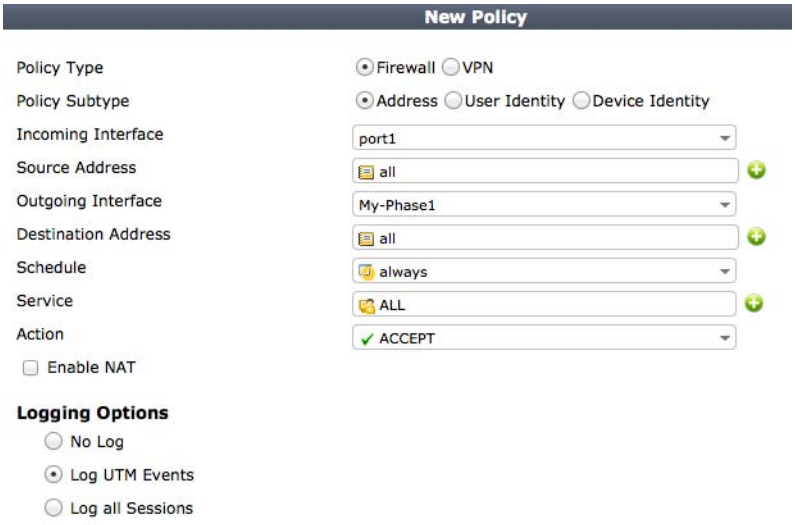


Creating a route-based IPsec VPN security policy

You configure route-based IPsec VPN by first adding a Phase 1 and selecting *Enable IPsec Interface Mode*. This adds an IPsec interface with the same name as the Phase 1.

A security policy for this VPN is a standard security policy that allows traffic between the IPsec interface and another FortiGate unit interface. Create a new policy, select the *Firewall* policy type and the *Address* policy subtype. To allow traffic from the internal network to connect to the VPN, set the incoming interface to internal and the outgoing interface to the IPsec interface. Otherwise configure the security policy like any basic security policy.

Figure 69: Creating a route-based IPsec VPN policy



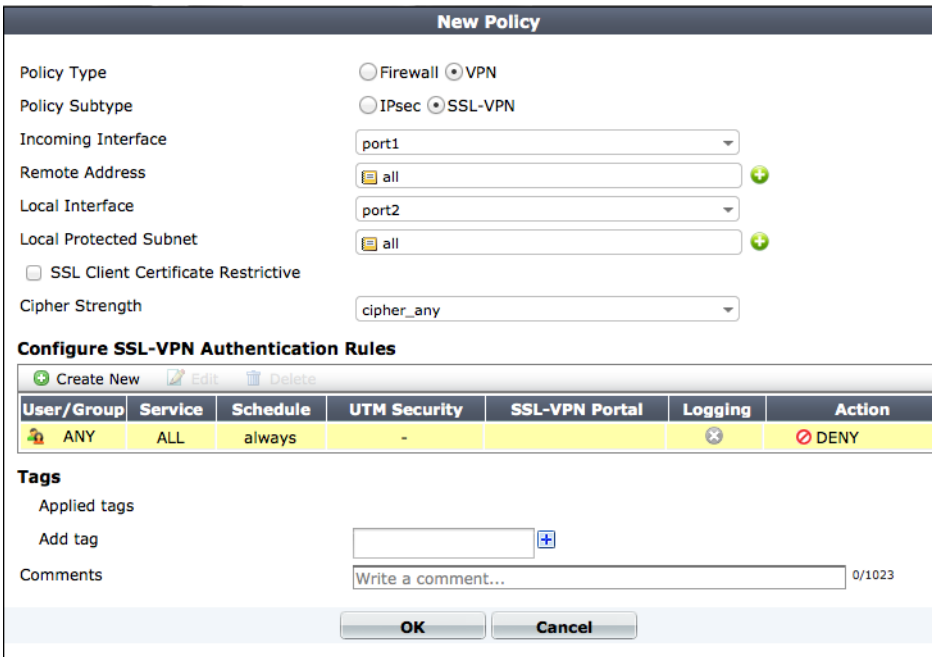
Creating an SSL VPN security policy

Select the *VPN* policy type and the *SSL-VPN* subtype. Select the incoming interface, the remote address, the local interface, and the address for the local protected subnet. Then select *Create New* to add SSL VPN authentication rules to the policy.

SSL authentication rules include user groups, individual users, schedule, service, SSL VPN portal, action, logging, and UTM security profiles.

FortiOS 5.0 no longer includes SSL VPN users or user groups. Any type of user group can be added to an SSL VPN authentication rule.

Figure 70: Creating an SSL VPN policy

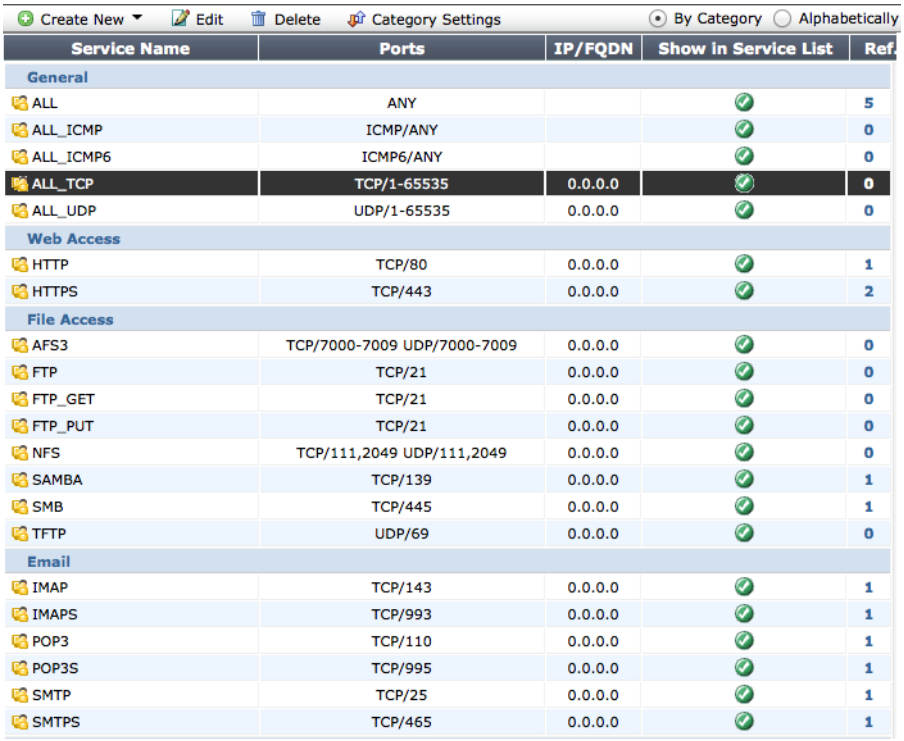


Reorganized Firewall Services

To make Firewall services easier to use and more customizable, the former predefined services list and custom services have been merged into one list and the list has been organized into categories. You can go to *Firewall Objects* > *Service* > *Services* to see the new service list.

The order that the categories and services in the services list is maintained when you add a service to another configuration object, such as a security policy. You can add categories, change the category that a service is in and rearrange the order of categories in the list.

Figure 71: Firewall Services list



The single *ANY* service has been replaced with five *ALL* services that match all services or all services of a specific type (ICMP, ICMP6, TCP and UDP). Otherwise, all of the familiar pre-defined services can be found in the new services list.

By default, the list is organized by categories. You can select *Category Settings* to change the order of the categories in the list. You can also choose to organize the list alphabetically by service name.

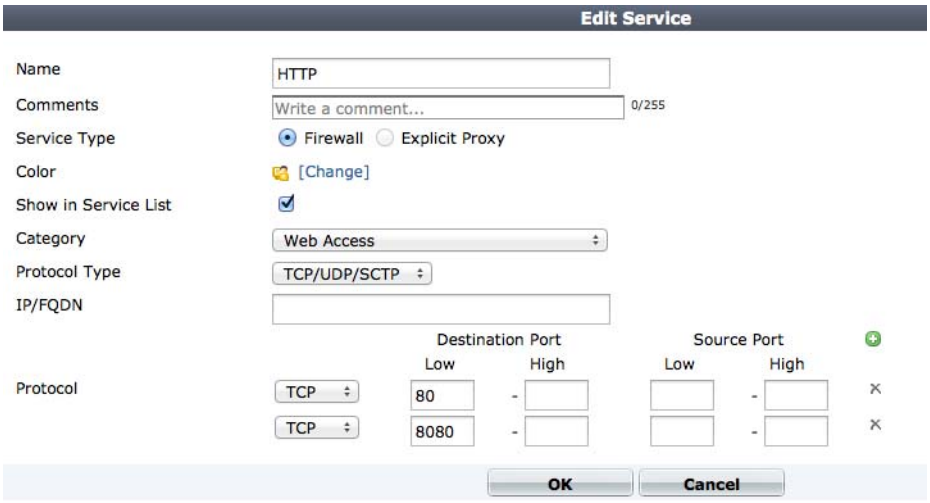
Editing and deleting services

You can edit and delete any of the services in the list; however, use caution when deleting any services. Normally you would only delete a custom service that you have created.

You can edit any service to change its name, add a comment, change its icon color, add or remove it from the list, change its category, change its protocol type, add an IP address or fully qualified domain name (FQDN) and change the source and destination ports for the service.

In most cases, you should not need to edit predefined services. Instead you would add custom services. However, in some cases editing pre-defined services can simplify your configuration. For example, if all of you HTTP traffic uses port 8080, you could edit the HTTP service and change its destination port to 8080. Alternatively, if your network uses port 80 and 8080 for HTTP traffic, you could edit the HTTP service and add port 8080.

Figure 72:HTTP service customized to include port 80 and port 8080



Adding an address to a service

Services now include a IP/FQDN field into which you can add an IP address or a fully qualified domain name. Use this field if you want to restrict the network address that the FortiGate unit will accept connections to this service from.

Adding a new service

To add a new service, go to the service list and select *Create New* > *Service*. Configure the custom service as shown in Figure 72 and select *OK* to save it.

Adding a new service category

If you have a group of services that you use often, you can group them into your own service category to make them easy to find in the list. To add a new service category, go to the service list and select *Create New* > *Category*, add a name for the custom service and select *OK*.

Then select Category Settings and change the order in which the services appear in the list. To make your custom category easy to find, move it to the top of the list.

To add services to your category, edit them and set *Category* to the name of your custom category.

Local in policies

Read-only local in policies show you all the types of traffic that can connect to or terminate at the FortiGate unit. For the FortiGate unit to receive local traffic a policy to receive the traffic must be in the local in policy list. The FortiGate unit needs to be able to receive traffic for a number of reasons. Among them:

- Central management connections from FortiManager
- Networking and routing connections, for example accepting or relaying DHCP requests, accepting routing communication from other routers (for example, OSPF, RIP, VRRP)
- Administrative access to FortiGate interfaces over ICMP, HTTP, HTTPS, and so on.

The local-in policy list includes an action column that shows whether the FortiGate unit accepts or drops sessions identified by the individual local in policies. As you change some

configuration settings those changes are reflected in the local in policies. For example, Administrative Access local in policies change depending on the administrative access settings of your FortiGate interfaces.

From the local in policy page (*Firewall* > *Policy* > *Local In Policy)*, you can enable or disable logging for local in allowed and denied traffic and for local out traffic.

In addition to the pre-defined local in policies, you can add your own using the following command:

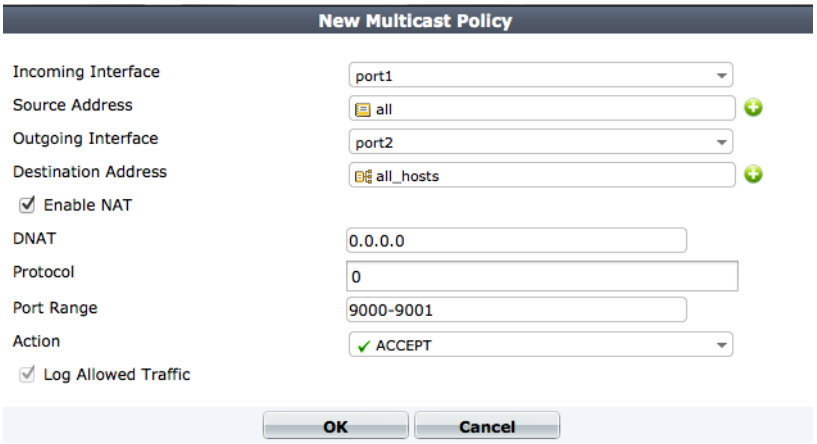
```
config firewall {local-in-policy | local-in-policy6}
  edit 0
    set srcaddr all
    set dstaddr all
    set action {deny | allow}
    set service ALL
    set schedule always
    set auto-asic-offload {disable | enable}
  end
```

Multicast Policies

A number of popular services use multicast protocols. Examples include the Bonjour service used for finding devices on a network, EIGRP and OSPF. To make it easier to allow multicast traffic through the FortiGate unit, you can now add multicast policies from the web-based manager by going to *Policy* > *Policy* > *Multicast Policy* and selecting *Create New*.

Similar to a regular security policy, you configure a multicast policy by selecting incoming and outgoing interfaces, source and destination addresses, enabling NAT, and selecting an action.

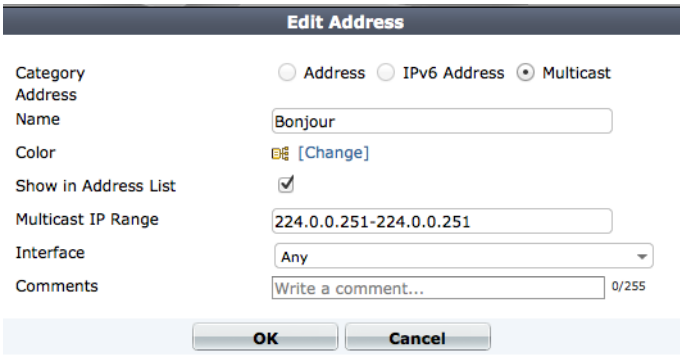
Figure 73: Adding a multicast policy



Specific to multicast policies, you can also specify a destination NAT (DNAT) address and select a multicast protocol (options include ANY, ICMP, IGMP, TCP, UDP, OSPF and other). You cannot add or edit these protocols but, if you select *Other,* you can add a protocol number.

The destination address of a multicast policy must be a multicast address firewall object. Multicast addresses are added by going to *Firewall Objects* > *Address* > *Addresses* and selecting *Create New* > *Multicast Address*. The FortiGate default configuration includes some commonly used multicast addresses. Figure 74 shows the configuration of the default Bonjour multicast address.

Figure 74: Default Bonjour multicast firewall address



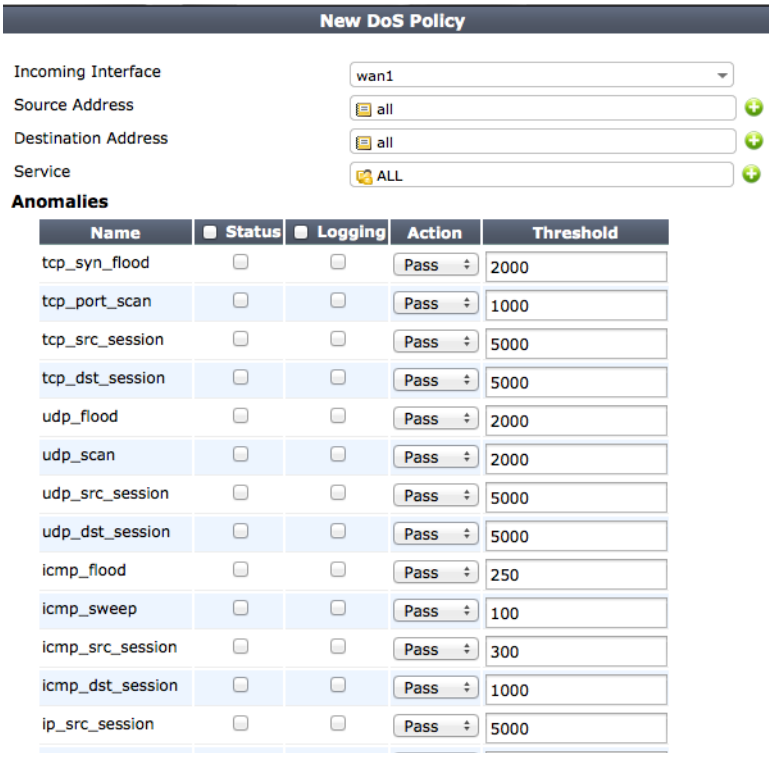
Adding DoS Anomaly protection to a FortiGate interface

New DoS policies allow you to apply DoS anomalies to all traffic that hits a FortiGate interface. This is the only way to apply DoS anomaly protection.

To add a DoS policy go to *Policy* > *Policy* > *DoS Policy* and select Create New to add a new DoS policy. Select the FortiGate interface to add the policy to and select the source and destination addresses and services that will match the packets that you want to apply DoS anomalies to.

Enable one or more DoS anomalies. For each anomaly you can enable logging, set the action to pass or block and change the threshold.

Figure 75: DoS policy



Use the following command to add a DoS policy from the CLI that adds syn flood protection for all traffic hitting the wan2 interface:

```
config firewall DoS-policy
  edit 1
    set interface wan2
    set srcaddr all
    set dstaddr all
    set service ALL
        config anomaly
          edit tcp_syn_flood
            set status enable
            set log enable
            set action block
          end
  end
```

DoS sensors no longer available. DoS policies are the most common method for applying DoS anomalies in FortiOS 5.0.

You can also use the following command to apply DoS anomalies to a one-arm sniffer configuration.

```
config firewall sniffer
```

Interface policies are still available in FortiOS 5.0 from the CLI using the following commands:

```
config firewall interface-policy
config firewall interface-policy6
```

You can use interface policies to apply application control, intrusion protection, virus scanning, web filtering, email filtering and data leak protection to traffic received by an interface.

The following commands are also available for adding sniffer interface policies, which are similar to interface policies:

```
config firewall sniff-interface-policy
config firewall sniff-interface-policy6
```

All of these command have similar syntax for applying Security Features to traffic connecting to or sniffed by a FortiGate interface.

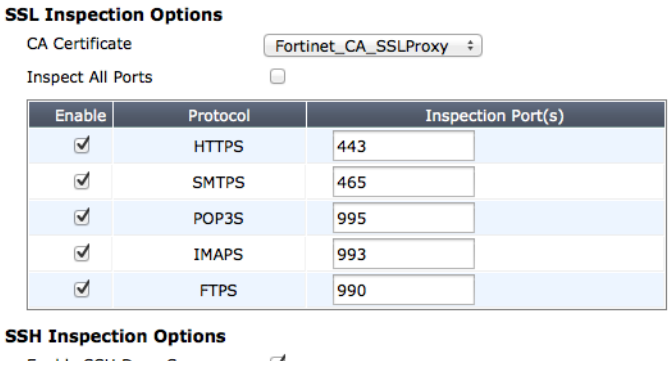
Changes to security proxy options

Security proxy profile options are now configured by feature instead of by protocol. Also, SSL and SSH inspection options have been moved to the new SSL/SSH inspection options profiles.

Protocol port mapping

For all content protocols, you can configure protocol port mapping to set the ports on which the FortiGate unit looks for the protocols. The FortiGate unit can inspect each kind of traffic on any port or you can specify one or more ports.

Figure 76: Configuring Protocol Port Mapping



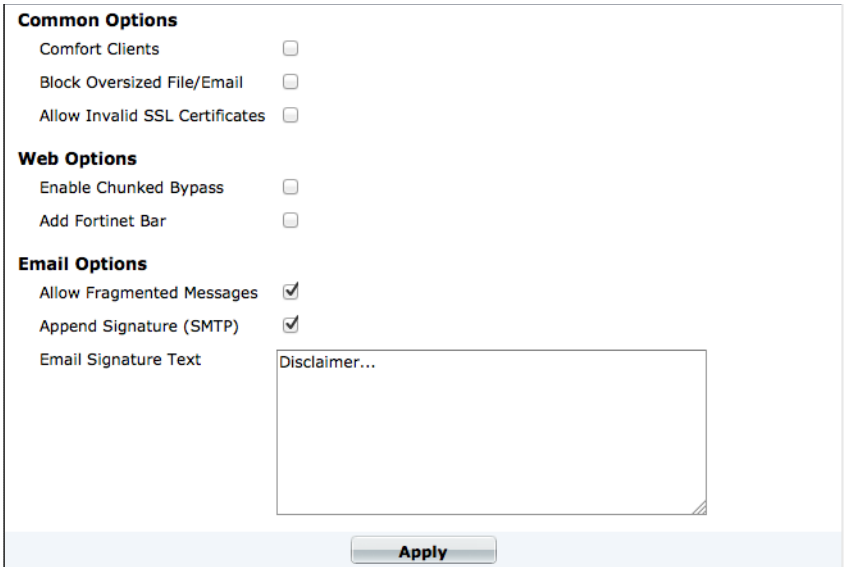
Common options, web options and email options

Here you can configure client comforting, whether to block oversized files or email, and whether or not to allow invalid SSL certificates.

Web options include enabling chunked by pass and adding the Fortinet bar (see "Fortinet Top Bar" on page 245).

Email options include allowing fragmented messages and appending a signature to all SMTP email messages.

Figure 77: Configuring common options, web options and email options



SSL and SSH inspection

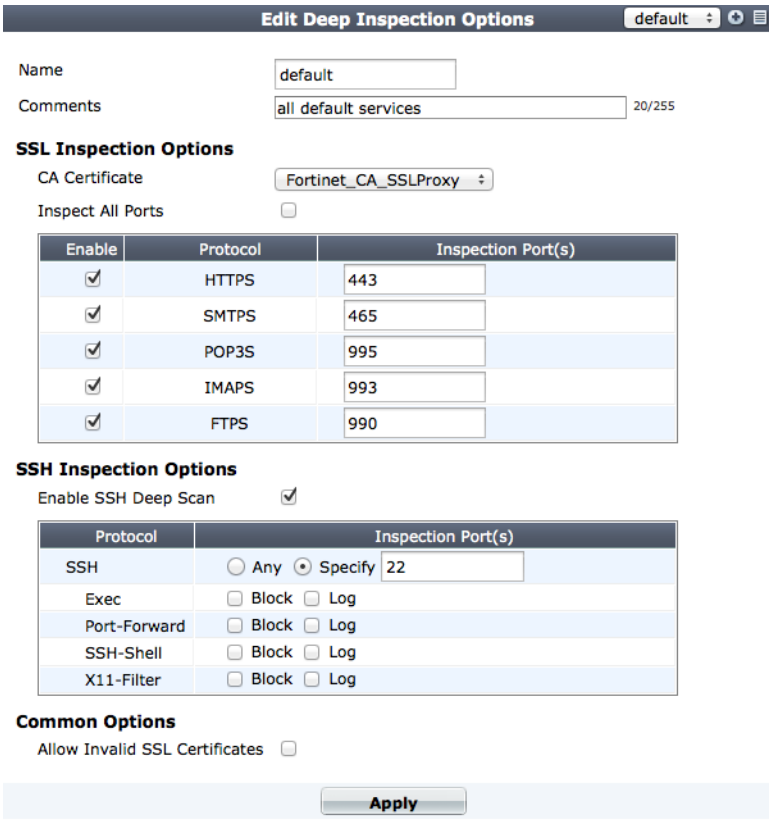
To configure how encrypted SSL or SSH traffic is inspected in security policy that accepts the SSL or SSH traffic to be inspected, turn on *SSL/SSH Inspection* and select an SSL/SSH inspection profile.

You can go to *Policy* > *Policy* > *SSL/SSH Inspection* to change the default SSL and SSH inspection profile or you can create new profiles.

SSL inspection options

For SSL traffic, you can select the certificate to use for this traffic and enable inspection of SSL traffic on all ports. You can also select individual SSL protocols and configure the inspection ports and port ranges for them. You can also choose to block or allow invalid SSL certificates.

Figure 78: Configuring SSL and SSH Inspection



SSH inspection options

For SSH traffic, you can enable SSH deep scanning, inspect all ports or specified ports for SSH traffic. You can also block or log all Exec, Port-Forward, SSH-Shell and X-11 SSH activity.

WAN optimization and Web Caching

In FortiOS 5.0, WAN optimization is enabled in security policies and WAN optimization rules are no longer required. Instead of adding a security policy that accepts traffic to be optimized and then creating WAN optimization rules to apply WAN optimization, in FortiOS 5.0 you create security policies that accept traffic to be optimized and enable WAN optimization in those policies. WAN optimization is applied by WAN optimization profiles which are created separately and added to the required security policies.

Because of this change, you can now apply all Security features to WAN optimization traffic without having to use a configuration that requires two VDOMS (one for applying Security features and one for applying WAN optimization). Instead, you can enable Security features in the security policies that accept WAN optimization traffic.

WAN optimization in policies requires you to add extra security policies with the incoming interface set to the new *wanopt* interface.

In FortiOS 4.3, you could create web caching only WAN optimization rules while in FortiOS 5.0 you cannot create web caching only WAN optimization profiles. Instead, you simply enable web caching in security policies, including WAN optimization policies. You can enable web caching for any WAN optimization policy. You can also enable HTTPS web caching and SSL offloading from the CLI for any security policy.

This chapter describes:

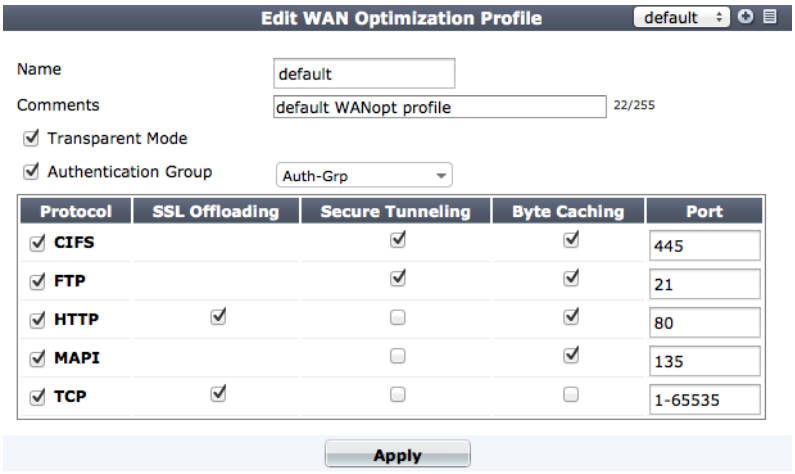
Configuring WAN optimization profiles

Use WAN optimization profiles to apply WAN optimization techniques to traffic to be optimized. In a WAN optimization profile, you can select the protocols to be optimized and for each protocol you can enable SSL offloading, secure tunneling, byte caching and set the port the protocol uses. You can also enable transparent mode and select an authentication group. You can edit the default WAN optimization profile or create new ones.

In order to configure WAN optimization profiles using the web-based manager, this feature must be enabled using Feature Select. For more information, see “Feature Select” on page 243.

To configure a WAN optimization profile go to *WAN Opt & Cache* > *WAN Opt. Profile* > *Profile* and edit a profile or create a new one.

Figure 79: Configuring a WAN optimization profile



From the CLI you can use the following command to configure a WAN optimization profile to optimize HTTP traffic.

```
config wanopt profile
  edit new-profile
    config http
      set status enable
  end
```

Enter the following command to view WAN optimization profile CLI options:

```
tree wanopt profile
-- [profile] --*name (36)
             |- transparent
             |- comments
             |- auth-group (36)
             |- <http> -- status
                       |- secure-tunnel
                       |- byte-caching
                       |- prefer-chunking
                       |- tunnel-sharing
                       |- log-traffic
                       |- port
                       |- ssl
                       |- ssl-port
                       |- unknown-http-version
                       +- tunnel-non-http
             |- <cifs> -- status
                       |- secure-tunnel
                       |- byte-caching
                       |- prefer-chunking
                       |- tunnel-sharing
                       |- log-traffic
                       +- port
             |- <mapi> -- status
                       |- secure-tunnel
                       |- byte-caching
                       |- tunnel-sharing
                       |- log-traffic
                       +- port
             |- <ftp> -- status
                       |- secure-tunnel
                       |- byte-caching
                       |- prefer-chunking
                       |- tunnel-sharing
                       |- log-traffic
                       +- port
             +- <tcp> -- status
                       |- secure-tunnel
                       |- byte-caching
                       |- byte-caching-opt
                       |- tunnel-sharing
                       |- log-traffic
                       |- port
                       |- ssl
                       +- ssl-port
```

Dynamic data chunking for WAN optimization byte caching

Dynamic data chunking helps to detect persistent data chunks in a changed files or in data embedded in traffic using an unknown protocol. For example, Lotus notes uses a private protocol to transfer email attachments in crafted messages. Dynamic data chunking performs byte caching of data in Lotus notes traffic. Dynamic data chunking is available for HTTP, CIFS and FTP.

Use the following command to enable dynamic data chunking for HTTP in the default WAN optimization profile.

```
config wanopt profile
  edit default
       config http
          set prefer-chunking dynamic
    end
```

By default, dynamic data chunking is disabled and `prefer-chunking` is set to `fix`.

Policy-based WAN optimization configuration changes summary

This section summarizes how basic WAN optimization configurations work in FortiOS 5.0, now that WAN optimization is enabled in security policies.

On the client side

New features:

- WAN optimization rules are removed and WAN optimization profiles are added. Profiles are configured in the client side.
- New options in firewall policies: `wanopt`, `wanopt-detection`, `wanopt-profile` and `wanopt-peer`. `wanopt-peer` is used only on the client side for manual mode (`wanopt-detection` is `off`).
- You can add Security features inspection to security policies that accept WAN optimization traffic.

On the server side

New features:

- New wanopt interface which represents the WAN optimization tunnel.
- Add a firewall policy with incoming (source) interface set to the wanopt interface to accept WAN optimization tunnel sessions (only required on the server side).
- For active/passive WAN optimization, set the server side to *passive*.
- For manual mode no WAN optimization policy required.
- WAN optimization profiles inherited by the server side.
- You can add Security feature inspection to security policies that accept WAN optimization traffic.

Client side configuration summary

WAN optimization profile

```
config wanopt profile
  edit "default"
    set comments "default WANopt profile"
      config http
        set status enable
        set prefer-chunking fix
    end
    config cifs
        set status enable
        set prefer-chunking fix
    end
        config mapi
        set status enable
    end
    config ftp
        set status enable
        set prefer-chunking fix
    end
    config tcp
        set status enable
        set byte-caching-opt mem-disk
    end
end
```

Local host ID and peer settings

```
config wanopt settings
  set host-id "client"
end
config wanopt peer
  edit "server"
  set ip 10.10.2.82
end
```

Security policies

Two client side WAN optimization security policy configurations are possible: one for active-passive WAN optimization and one for manual WAN optimization.

Active/passive mode on the client side

```
config firewall policy
  edit 2
    set srcintf "internal"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable <<< enable UTM
    set av-profile default <<< select an antivirus profile
    set profile-protocol-options default
    set wanopt enable <<< enable WAN optimization
    set wanopt-detection active <<< set the mode to active/passive
    set wanopt-profile "default" <<< select the wanopt profile
  next
end
```

Manual mode on the client side

```
config firewall policy
  edit 2
    set srcintf "internal"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable <<< enable UTM
    set av-profile default <<< select an antivirus profile
    set profile-protocol-options default
    set wanopt enable <<< enable WAN optimization
    set wanopt-detection off <<< sets the mode to manual
    set wanopt-profile "default" <<< select the wanopt profile
    set wanopt-peer "server" <<< set the only peer to do wanopt with
                                 (required for manual mode)
  next
end
```

Server Side configuration summary

Local host ID and peer settings

```
config wanopt settings
  set host-id "server"
end
config wanopt peer
  edit "client"
    set ip 10.10.2.81
end
```

Security policies

Two server side WAN optimization security policy configurations are possible: one for active-passive WAN optimization and one for manual WAN optimization.

Active/passive mode on server side

```
config firewall policy
   edit 2 <<< the passive mode policy
     set srcintf "wan1"
     set dstintf "internal"
     set srcaddr "all"
     set dstaddr "all"
     set action accept
     set schedule "always"
     set service "ANY"
     set utm-status enable <<< enable UTM
     set av-profile default <<< select an antivirus profile
     set profile-protocol-options default
     set wanopt enable
     set wanopt-detection passive
     set wanopt-passive-opt transparent
  next
  edit 3 <<< policy that accepts wanopt tunnel connections from the
            server
     set srcintf "wanopt" <<< wanopt tunnel interface
     set dstintf "internal"
     set srcaddr "all"
     set dstaddr "all"
     set action accept
     set schedule "always"
     set service "ANY"
  next
end
```

Manual mode on server side

```
configure firewall policy
  edit 3 <<< wanopt tunnel policy
    set srcintf "wanopt" <<< wanopt tunnel interface
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set utm-status enable <<< enable UTM
    set av-profile default <<< select an antivirus profile
    set profile-protocol-options default
  next
end
```

Combining web caching for HTTP traffic with WAN optimization

Web caching can be applied to any HTTP or HTTPS traffic by enabling web caching in a security policy that accepts the traffic. This includes WAN optimization and explicit web proxy traffic. Web caching caches all HTTP traffic accepted by a policy on TCP port 80.

You can add web caching to a WAN optimization security policy to combine web caching with WAN optimization for any WAN optimization security policy. This includes manual, active and passive WAN optimization policies and WAN optimization tunnel policies. You can enable web caching on both the client-side and the server-side FortiGate units or on just one or the other. For optimum performance, you can enable web caching on both the client-side and server-side FortiGate units. In this way, only uncached content is transmitted through the WAN optimization tunnel. All cached content is access locally by clients from the client side FortiGate unit.

Turning on web caching and SSL offloading for HTTPS traffic

Web caching can cache the content of HTTPS traffic on TCP port 443. With HTTPS web caching, the FortiGate unit receives the HTTPS traffic on behalf of the client, opens up the encrypted traffic and extracts content to be cached. Then FortiGate unit re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack. You enable HTTPS web caching from the CLI in a security policy that accepts the traffic to be cached using `webcache-https`:

```
config firewall policy
  edit 0
    .
    .
    .
    set webcache enable
    set webcache-https any
    .
    .
    .
  end
```

The `any` setting causes the FortiGate unit to re-encrypt the traffic with the FortiGate unit's certificate rather than the original certificate. This configuration can cause errors for HTTPS clients because the name on the certificate does not match the name on the web site.

You can stop these errors from happening by configuring HTTPS web caching to use the web server's certificate by setting `webcache-https` to `ssl-server`:

```
config firewall policy
  edit 0
    .
    .
    .
    set webcache enable
    set webcache-https ssl-server
    .
    .
    .
  end
```

The `ssl-server` option causes the FortiGate unit to re-encrypt the traffic with the certificate that you imported into the FortiGate unit. The certificate is added to an SSL server configuration using the following command:

```
config wanopt ssl-server
  edit example_server
    set ip <Web-Server-IP>
    set port 443
    set ssl-mode { full | half}
    set ssl-cert <Web-Server-Cert>
  end
```

Where:

`Web-Server-IP` is the web server's IP address.

`Web-Server-Cert` is the original web server certificate imported into the FortiGate unit.

The SSL server configuration also determines whether the SSL server is operating in half or full mode and the port used for the HTTPS traffic.

Using the SSL server configuration, web caching also supports SSL offloading that uses the FortiGate unit's FortiASIC SSL encryption/decryption engine to accelerate SSL performance.

Changing the ports on which to look for HTTP and HTTPS traffic to cache

By default, FortiOS assumes HTTP traffic uses TCP port 80 and HTTPS traffic uses port 443 and so web caching is configured for all HTTP traffic accepted by a policy on TCP port 80 and all HTTPS traffic on TCP port 443. If you want to cache HTTP or HTTPS traffic on other ports, you can enable Security features for the security policy and add an SSL/SSH inspection profile that looks for HTTP and HTTPS traffic on other TCP ports.

Setting the HTTP port to *Any* in the an SSL/SSH inspection profile is not compatible with web caching. If you set the HTTP port to any, web caching only caches HTTP traffic on port 80.

Web proxy URL debugging

You can use the following CLI commands to get debugging information that shows how the web cache is handling specific URLs. You can debug web caching for a single web page (such as docs.fortinet.com/fgt40mr3.html) or for all requests to a URL pattern (such as docs.fortinet.com to debug all connections to any page on docs.fortinet.com). Wildcard characters and regular expressions are not supported.

Normally you would use this feature if the web cache was not caching specific pages and sites. It makes it easier to get debug information just for the pages causing the problem. This feature works for web caching enabled in any security policy including web proxy and WAN optimization security policies.

Debugging caching of a specific web page

Start by adding the URL to the configuration:

```
config web-proxy debug-url
  edit docs-url
    set url-pattern "docs.fortinet.com/fgt40mr3.html"
    set status enable
    set exact enable
  end
```

Then enter the following commands to enable debugging:

```
diagnose debug application wad 0
diagnose wad debug-url enable
diagnose debug enable
```

The CLI then displays debug information as the `wad` application processes sessions. However, the `diagnose wad debug-url enable` command isolates and formats the debug output for sessions to and from docs.fortinet.cm/fgt40mr3.html.

Example output when a user browses to docs.fortinet.cm/fgt40mr3.html with Firefox. You may have to scroll through other debug output to find this, but its should be easy to find because its formatted differently than the other web cache diagnose output.

```
[0x40d977d0] Received request from client: 10.31.101.20:54932

GET /fgt40mr3.html HTTP/1.1

Connection: close
Content-Type: text/html

[0x40d977d0] Forward response from sever:

HTTP/1.1 200 OK
Server: Microsoft-IIS/5.0
Date: Fri, 10 Feb 2012 17:05:15 GMT
X-Powered-By: ASP.NET
Content-Type: text/html
Connection: close
```

Debugging caching of multiple web pages

Use the following commands to get URL debugging output when any docs.fortinet.com and www.fortinet.com web page is cached. In this configuration, just the high-level URLs are added to the configuration and `exact` is set to disable:

```
config web-proxy debug-url
  edit docs-url
    set url-pattern "docs.fortinet.com"
    set status enable
    set exact disable
  next
  edit docs-url
    set url-pattern "www.fortinet.com"
    set status enable
    set exact disable
  next
end
```

Then enter the following commands to enable debugging:

```
diagnose debug application wad 0
diagnose wad debug-url enable
diagnose debug enable
```

The CLI then displays debug information as the `wad` application processes sessions, highlighting all connections to docs.fortinet.com and www.fortinet.com.

FortiOS Web Caching now caches Windows/MS-Office software updates

FortiOS web caching is not always able to cache Windows and MS-Office updates because they are downloaded using HTTP in multipart or chunked mode and typically run through multiple TCP connections. To resolve this issue in FortiOS 5.0, the first request for Windows or MS-Office updates (to download.windowsupdate.com) causes the cache process to download the new update file in the background.

Once the new update file has been downloaded to the cache, it is available to web cache users and all subsequent requests for this update will be downloaded from the cache. Because the update file will not be available in the web cache until it has completely downloaded, the first update request will not be able to get it from the web cache and neither will any updates requested while the file is downloading in the background.

Usability enhancements

FortiOS 5.0 introduces usability enhancements to make configuration easier and management more effective and efficient.

New usability features include:

- Feature Select
- Improved list editing
- Dynamic comment fields
- Setup Wizard enhancements
- Fortinet Top Bar
- VDOM Mode GUI changes
- Enhanced Top Sessions dashboard widget
- Improved CLI syntax for multi-value fields

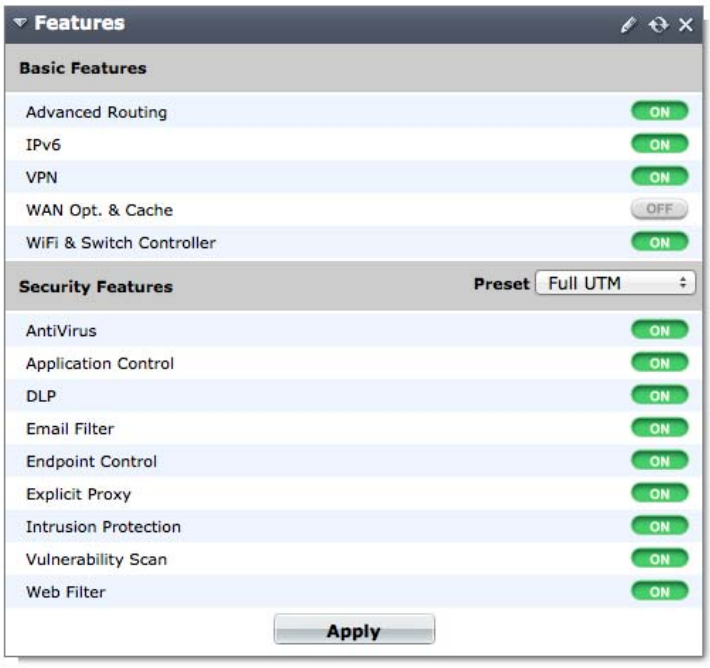
Feature Select

Feature Select is used to disable features which are not required for network administration. Disabling features also removes all related configuration options from the web-based manager.

This feature replaces the previous GUI display options control.

Feature Select can be managed using the *Features* widget on the *Status* page. They can also be found at *System* > *Config* > *Features*, where additional features are also available by selecting *Show More*.

Figure 80: The Features widget



If a feature, such as IPv6, has been configured before being removed from the web-based manager, this configuration will still exist as part of the network, even though it is no longer visible using the web-based manager.

Security Features Presets

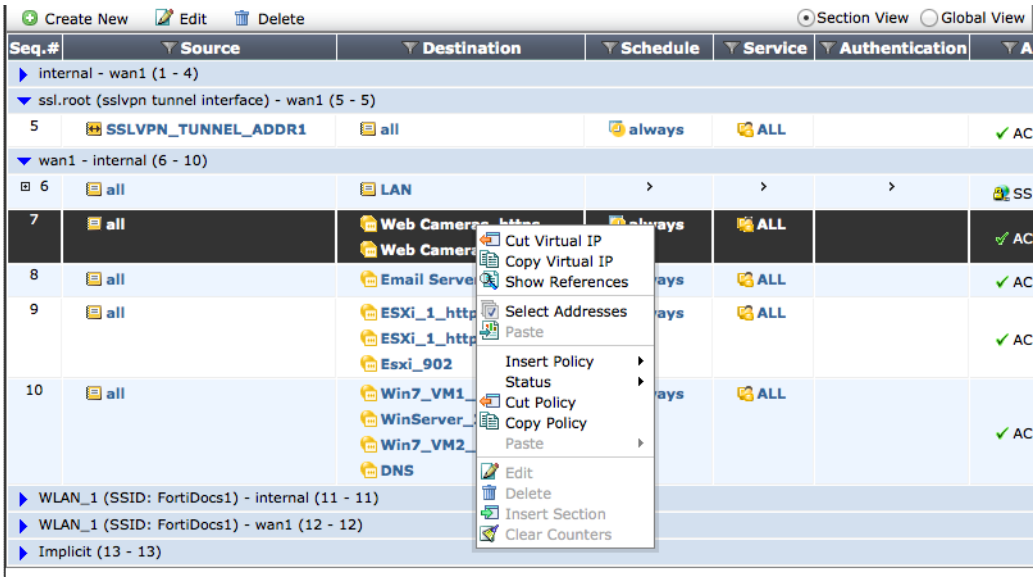
The main Security Features can be turned off individually or the five system presets can be used:

- *UTM* should be chosen for networks that require full protection from FortiOS. UTM is the default setting.
- *WF* should be chosen for networks that require web filtering.
- *ATP* should be chosen for networks that require protection from viruses and other external threats.
- *NGFW* should be chosen for networks that require application control and protection from external attacks.
- *NGFW + ATP* should be chosen for networks that require protection from external threats and attacks.

Improved list editing

List editing has been enhanced on most lists of configuration items on the FortiOS 5.0 web-based manager. On most list items, you can click on any item to display a list of options. The options available depend on the item and context.

Figure 81: Example security policy list address menu



Dynamic comment fields

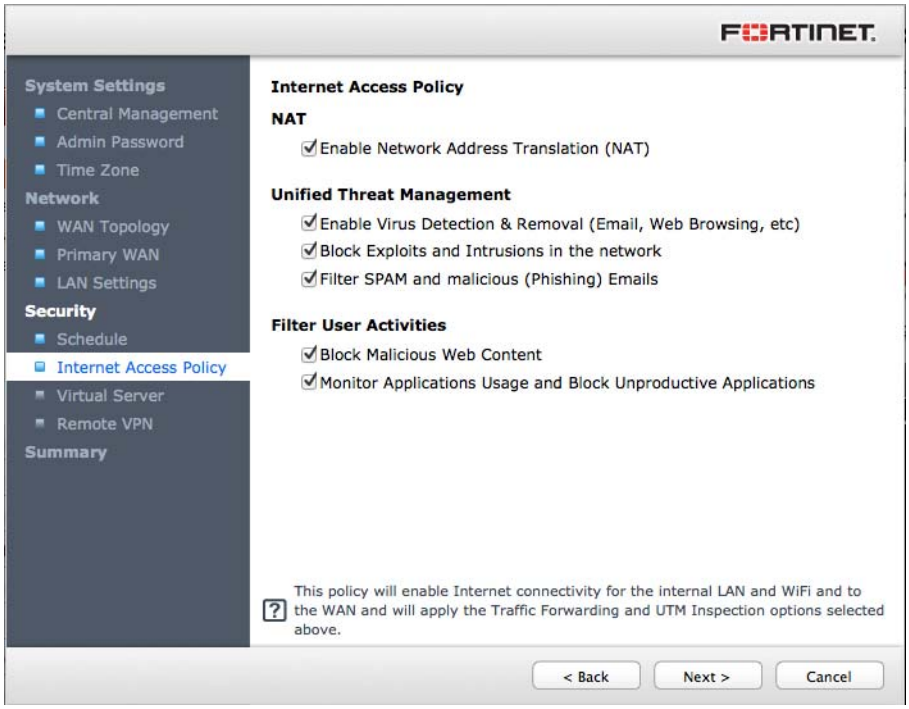
Most comment fields available from the web-based manager and CLI have been extended to a maximum of 255 characters and others to a maximum of 1023 characters. To save system memory, the amount of storage space for comment fields is dynamically allocated based on the size of the comment.

Setup Wizard enhancements

The Setup Wizard is now available for all FortiGate units. On individual models the wizard can include advanced or model-specific configuration options, such as load balancing, 3G/4G modem, virtual servers, remote VPN and the opportunity to configure all available interfaces.

The Setup Wizard also allows you to enable central management. When this option is selected, much of the Wizard is bypassed because a FortiManager unit supplies the configuration information. The WAN Topology and Primary WAN wizard pages are still presented for configuration because the FortiGate unit must be able to connect to its network before FortiManager can contact it.

Figure 82: Setup wizard - Internet access policy setup



Fortinet Top Bar

You can configure the FortiGate unit to overlay a Fortinet status bar on your user's web pages by going to *Policy* > *Policy* > *Proxy Options* and selecting *Add Fortinet Bar* and then by adding this Proxy Options profile to a security policy. Whenever a user accesses a web page through this policy, the Fortinet Top Bar is displayed overlaying the upper right corder of the web page.

The top bar can display a user ID if the user has authenticated with the FortiGate unit (in the example the user ID is bdickie). You can select the user icon to sign out of the FortiGate unit.

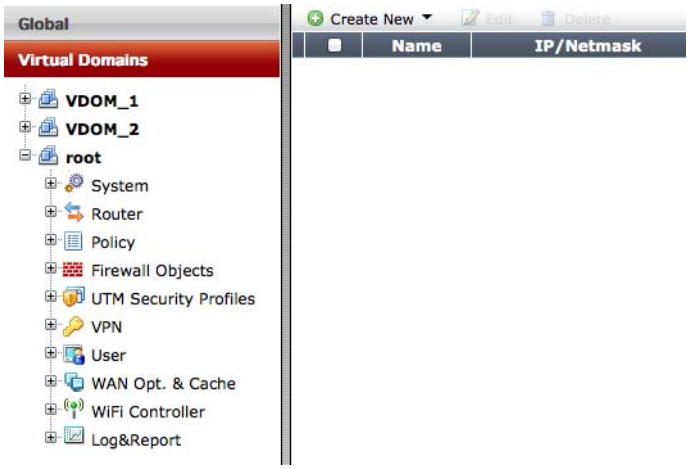
The top bar can also display other information such as:

- Application control violations
- Endpoint control enforcement
- Your web browsing quota
- User ID if the user has authenticated
- SSL VPN status and bookmarks

VDOM Mode GUI changes

When operating a FortiGate unit with VDOMs enabled, when you log in as a system administrator who can access multiple VDOMs, the VDOMs you can access appear under Virtual Domains in the left web-based manager menu. Figure 83 shows an example VDOM menu for a FortiGate unit with three virtual domains.

Figure 83:VDOM menu



Enhanced Top Sessions dashboard widget

The Top Sessions dashboard widget has been enhanced to allow you to display information about sessions according to their source address, destination address and the application creating the sessions. To demonstrate this new functionality, by default the web-based manager includes three new dashboards.

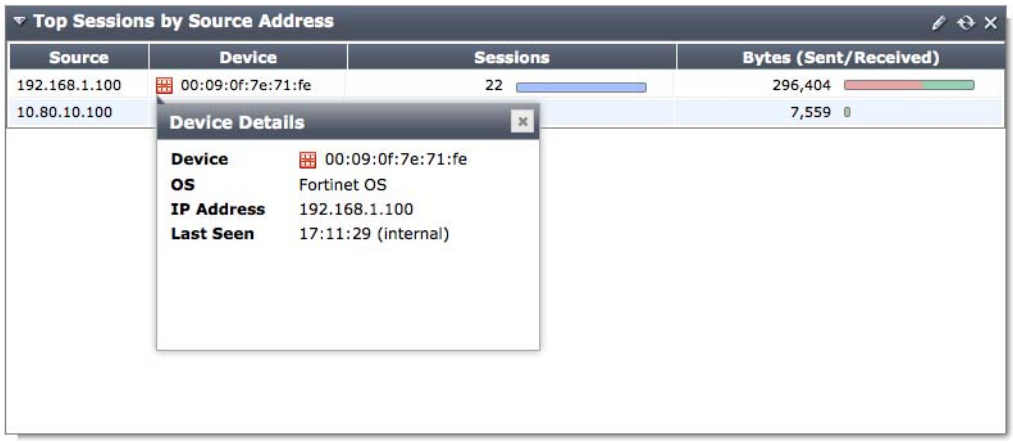
You may need to reset your dashboard if these dashboard widgets are not appearing. To reset the dashboard, select *Reset Dashboards* from the *Dashboard* menu.

Top Sources

Top sources displays the top 25 source addresses. For each source address, the widget displays device information, host name, the number of active sessions and the amount of data sent/received by the device. You can hover over the device icon to get more information about

the device. You can also select an entry to see all of the individual sessions from that source address. The session table includes the destination address, security policy, application name and amount of data sent and received by the session.

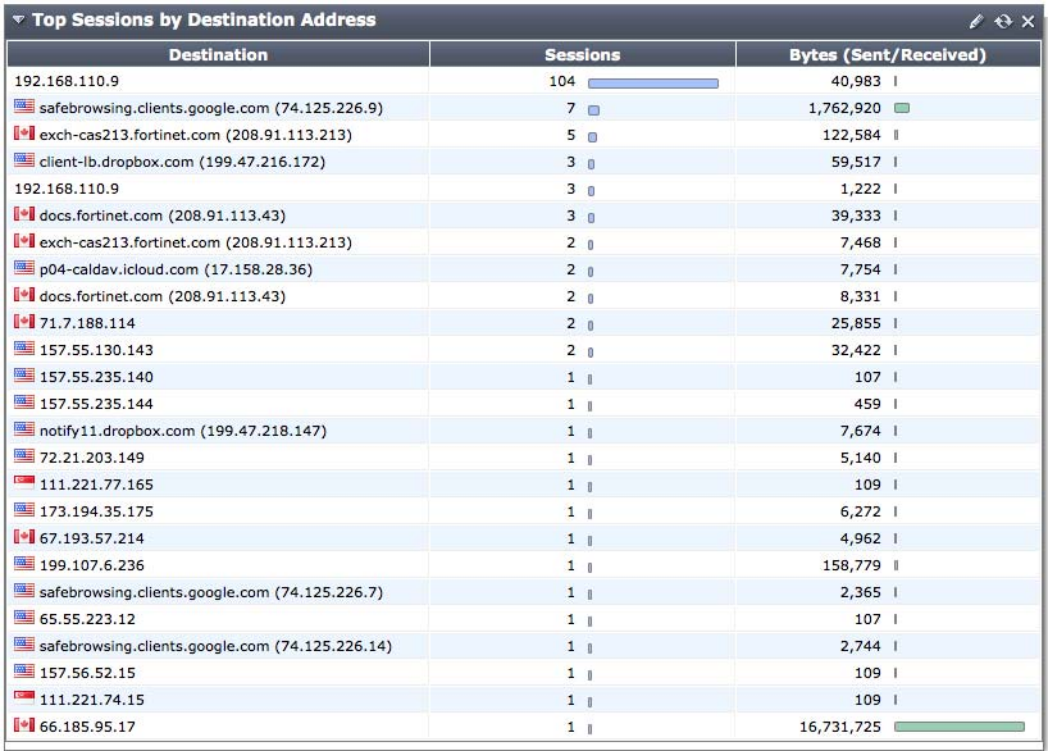
Figure 84: Top Sessions by Source Address



Top Destinations

Top destinations displays the top 25 destination addresses. For each destination address, the widget displays the destination host name and country, the number of sessions going to the destination and the amount of data in bytes sent and received by the destination. You can select an entry to see the individual sessions to that destination address. The session table includes the source address, security policy, application name and amount of data sent received by the session.

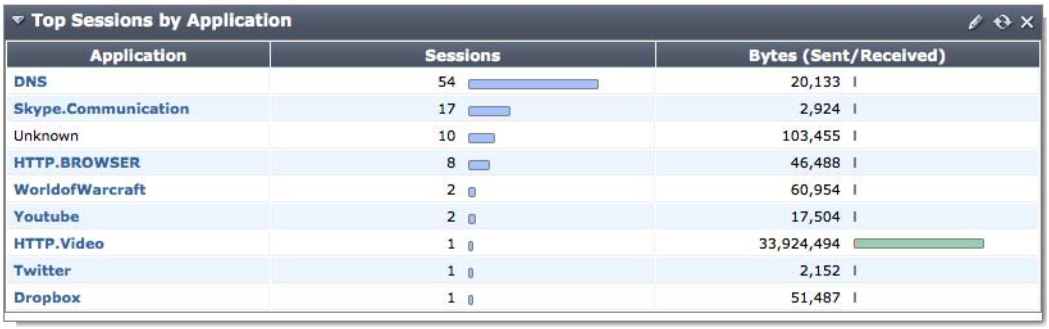
Figure 85: Top Sessions by Destination Address



Top Applications

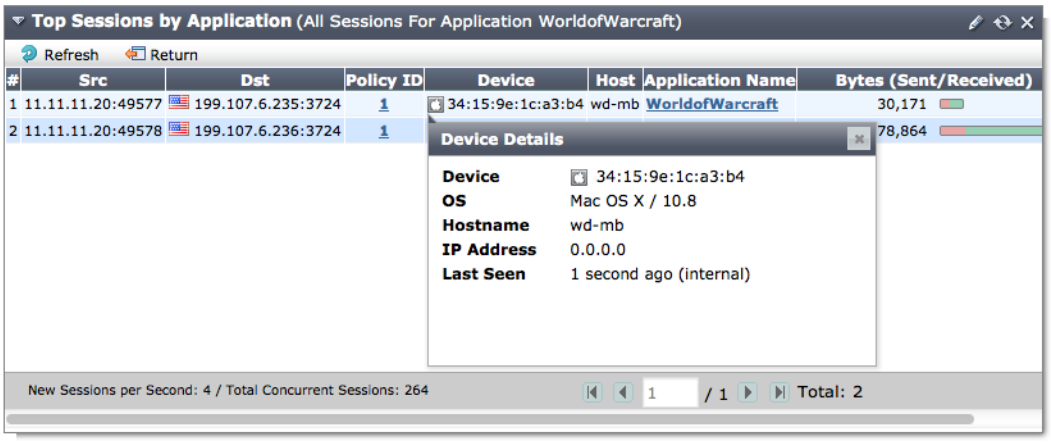
Top applications displays the top 25 applications sending traffic through the FortiGate unit. For this widget to show data, you must enable application control for security policies that allow traffic through the FortiGate unit.

Figure 86: Top Sessions by Application



For each application, the widget displays the application name, the number of sessions and the amount of data in bytes sent and received. You can select the application name to get more information about the application. You can select an entry to see the individual sessions for that application. The session table includes the source address, destination address, security policy, application name and amount of data sent received by the session.

Figure 87: Details about the sessions for an application



Identifying Skype sessions

If Skype is in use on your network, Skype sessions may appear on the *Top Sessions By Application* list with the *Application Name* displayed as *unknown*. You can help the FortiGate unit identify Skype sessions by using the following command to add the public IP address of your network to the FortiGate configuration.

For example, if the IP address of the FortiGate interface connected to the Internet is 172.20.120.14 and if the security policies for connections to the Internet have source NAT enabled, enter the following command to add the public IP address of your network which is the public address used by Skype sessions:

```
config ips global
  set skype-client-public-ipaddr 172.20.120.14
end
```

You can add multiple IP addresses with this command. This can be useful if your network or your Skype sessions have more than one public IP address. For example, you may have multiple Internet connections each with a different IP address. Also, if the external IP address is set using DHCP or PPPoE it may change and you can add multiple IP addresses to help account for this. Use the following command to add multiple public IP addresses (separate the addresses with a comma and no spaces).

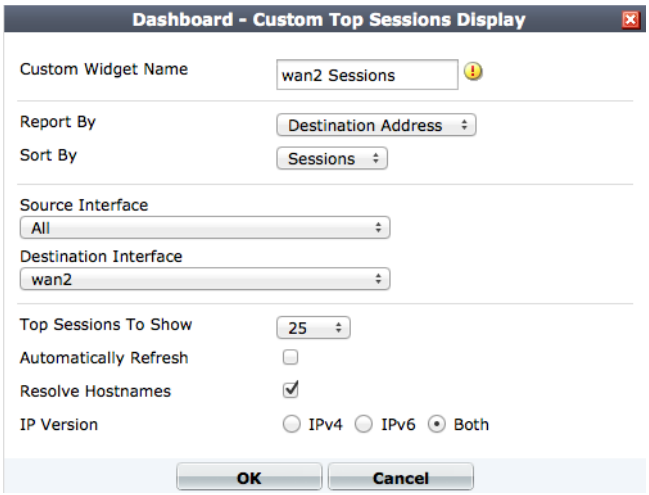
```
config ips global
  set skype-client-public-ipaddr 172.20.120.14,10.10.10.20
end
```

You may not have direct knowledge of your network's public IP address. This can happen for a number of reasons, depending on your network configuration. For example, your FortiGate unit may not be connected directly to the Internet. To make sure you are adding the right IP addresses you can use free services such as WhatIsMyIP.com to verify your network's public IP address.

Customizing the Top Sessions dashboard widget

You can create multiple top sessions dashboard widgets that report sessions by source address, destination address or application. You can customize the widgets with a custom widget name, control the source and destination interfaces of the sessions and determine whether to sort the sessions by bytes or by number of sessions.

Figure 88: Customizing the Top Sessions dashboard widget



Improved CLI syntax for multi-value fields

Several new subcommands simplify editing of CLI fields that accept multiple values. This eliminates re-typing of lists of options, IP addresses, and so on, saving time and avoiding errors. You can simply add or remove individual items from the list.

Table 3: CLI subcommands for multi-value fields

`append <field_name> <list>`	Add one or more values to the list.
`unselect <field_name> <list>`	Remove one or more values from the list.

`select <field_name> <list>`	Select one or more values. This is the same as the `set` subcommand.
`clear <field_name>`	Reset the multi-value field to its default value. This is the same as the `unset` subcommand.

You can continue to use the `set` and `unset` subcommands on multi-value fields.

The new subcommands support command completion. For example, in the `config system interface` command, if you enter select ?, the response shows only the multi-value fields:

```
dhcp-relay-ip    dhcp relay ip address
allowaccess      Allow management access to the interface
```

Example

Prior to FortiOS 5.0, to add SSH administrative access to an interface that currently allows HTTPS, FGFM and PING access, you would enter:

```
set allowaccess https fgfm ping ssh
```

In FortiOS 5.0, you can do this:

```
append allowaccess ssh
```

Similarly, to remove `ping` from the list, you would enter:

```
unselect allowaccess ping
```

To reset `allowaccess` to its default, you would enter:

```
clear allowaccess
```

SSL VPN

New SSL VPN features include:

- New default SSL VPN portals
- SSL VPN user groups no longer required
- SSL VPN policy interface name change
- Support SSL VPN push configuration of DNS suffix

New default SSL VPN portals

FortiOS 5.0 includes 3 new default SSL VPN portal configurations:

- full-access is a general use portal that includes tunnel mode and web mode and supports all possible supported applications over the SSL VPN. Split tunneling and including the FortiClient download is not enabled.
- tunnel-access only includes support for tunnel mode (and not web mode). Split tunneling is enabled and remote users are prompted to download FortiClient.
- web-access only includes support for web mode. The connection tool and FortiClient download options are disabled.

SSL VPN user groups no longer required

The distinction between SSL VPN user groups and firewall user groups has been removed. Any use group can be used for SSL VPN authentication, except FSSO user groups.

SSL VPN policy interface name change

The former SSL.root interface used in SSL VPN security policies as the source or destination interface for SSL VPN traffic has been renamed to *sslvpn tunnel interface*.

Support SSL VPN push configuration of DNS suffix

You can now assign one or more DNS suffixes to the FortiGate SSL VPN configuration so that SSL VPN clients do not need to use full-qualified host names to connect to internal resources. If you add one suffix, it is always attached to DNS queries.

If you add more than one suffix the FortiGate unit will attempt a DNS lookup by adding each suffix and use the first one that can be found in the DNS database. Multiple suffixes should be added in the proper search order. You can use up to 253 characters to add one or more DNS suffixes. Separate the suffixes with a space.

For example, if an organization requires DNS suffixes for example.com and example.org and you want DNS queries to try example.com first, you can use the following command to add these suffixes to the SSL VPN configuration:

Use the following command to add a DNS suffix that is used for SSL VPN sessions:

```
config vpn ssl settings
  set dns-suffix ”example.com example.org”
end
```

Other new features

This chapter provides a brief introduction to the following new features:

New FortiGuard features

The following FortiGuard services are available for any FortiGate unit free of charge:

- System time from FortiGuard NTP servers
- Default DNS configuration uses FortiGuard DNS servers

With a valid support contract, the following FortiGuard services are also available:

- Antivirus database updates
- IPS signature updates
- Vulnerability scan signature updates
- FortiGuard Web Filtering lookups
  - DNS-based Web Filtering; the FortiGuard DNS server network returns web filter ratings. DNS web filtering uses less CPU time, system memory and network bandwidth than proxy or flow-based FortiGuard web filtering, resulting in better performance.
  - IP address reputation scores from the FortiGuard DNS server network.
- FortiGuard Email filtering lookups
- Geographic address database for geographic firewall addressing
- BYOD device signature updates
- USB Modem Updates

FortiGate Auto-config using DHCP

FortiOS 5.0 supports uploading a configuration file from a TFTP server to the FortiGate unit to automatically configure the FortiGate unit with one simple step. Similar to an auto-configuration feature used for VoIP phones, you can store the domain name or IP address of a TFTP server and a configuration file name in your DHCP server configuration.

- DHCP option 66 is used for the TFTP server domain name (RFC 2132)
- DHCP option 67 is used for the configuration file name (RFC 2132)

For example, to use auto-configuration to configure a FortiGate unit, add the TFTP server information and configuration file name to your DHCP server. Make sure the TFTP server is running and includes the configuration file. Then, from the CLI of the FortiGate unit to be auto-configured, enter the following command (assuming the FortiGate internal interface is connected to the same network as the TFTP server).

```
execute restore config dhcp internal
```

The FortiGate unit gets the information it needs from the DHCP server, downloads and installs the configuration file from the TFTP server and restarts running its new configuration.

If the TFTP server is only available on a VLAN network (for example, VLAN id 224), you can use the following command to access the TFTP server on the VLAN network:

```
execute restore config dhcp internal 224
```

FortiGate Session Life Support Protocol (FGSP)

In a network that already includes load balancing (either with load balancers or routers) for traffic redundancy, two FortiGate units can be integrated into the load balancing configuration using the FortiGate Session Life Support Protocol (FGSP). The external load balancers or routers can distribute IPv4 and IPv6 TCP, UDP, ICMP and expectation, and NAT sessions among the FortiGate units and the FGSP performs ***session synchronization*** to keep the session tables of both FortiGate units synchronized.

If one of the FortiGate units fails, session failover occurs and active sessions fail over to the unit that is still operating. This failover occurs without any loss of data. As well, the external load balancers or routers detect the failover and re-distribute all sessions to the unit that is still operating.

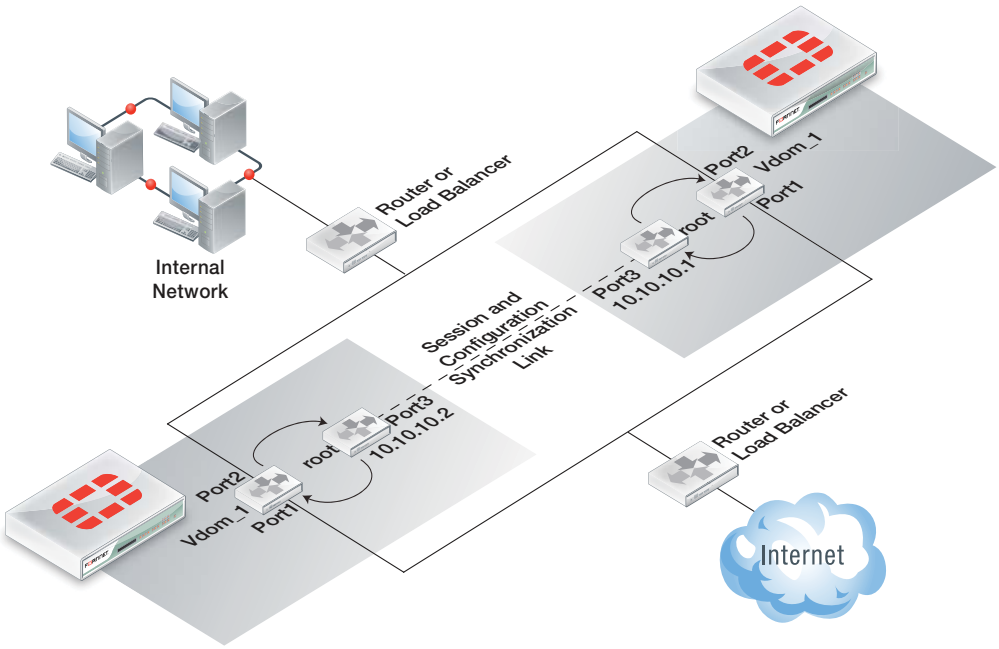
Load balancing and session failover is done by external routers or load balancers and not by the FGSP. The FortiGate units perform session synchronization which allows session failover to occur without packet loss.

The FGSP also includes ***configuration synchronization***, allowing you to make configuration changes at once for both FortiGate units, instead of requiring duplicate configuration changes on each unit.

Settings that identify the FortiGate unit to the network, for example, interface IP addresses and BGP neighbor settings, are not synchronized so that each FortiGate unit maintains its identity on the network. These settings must be configured separately for each FortiGate unit.

In previous versions of FortiOS, the FGSP was called TCP session synchronization or standalone session synchronization. However, the FGSP has been expanded to include configuration synchronization and session synchronization of connectionless sessions, expectation sessions, and NAT sessions.

Figure 89: Example FGSP HA configuration



HA failover supports more features

FortiOS 5.0 HA and the FortiGate Clustering Protocol (FGCP) support the following new types of failover:

- IPv6 session failover: if session pickup is enabled, IPv6 sessions are synchronized between cluster members and, after an HA failover, IPv6 sessions will resume with only minimal interruption.
- NAT64 session failover: if session pickup is enabled, NAT64 sessions are synchronized between cluster members and, after an HA failover, NAT64 sessions will resume with only minimal interruption.
- Full support for NAT 66 session failover: if session pickup is enabled, after an HA failover, NAT66 sessions will resume with only minimal interruption.
- SSL VPN authentication failover support: if session pick is enabled, SSL VPN sessions will resume after a failover without requiring SSL VPN users to re-authenticate.
- Device identification and management (BYOD).

New HA mode: Fortinet redundant UTM protocol (FRUP)

FortiOS 5.0 includes an extension to the FotiGate Clustering Protocol that combines Switching HA and Firewall HA into a single unified design. This feature is initially available on the FortiGate-100D and will be considered for other models in future releases.

A FRUPS setup consists of 2 (and only 2) identical FortiGate-100D units. The setup supports dual redundant HA links between the units for sharing session and configuration data.

To see a FRUP example, please refer to Cookbook Beta - FortiGate Redundant UTM Protocol.

ICAP and the explicit web proxy

Internet Content Adaptation Protocol (ICAP) profiles can be added to explicit web proxy security policies. ICAP is a light-weight response/request protocol that allows the FortiGate unit to offload explicit web proxy traffic to external servers for different kinds of processing. ICAP is often used for offloading virus scanning and web filtering but has many other applications.

If you enable ICAP in a web proxy security policy, HTTP traffic intercepted by the explicit web proxy is transferred to an ICAP server in the ICAP profile added to the policy. Responses from the ICAP server are returned to the FortiGate unit which forwards them to their destination.

You can offload HTTP responses or HTTP requests (or both) to the same or different ICAP servers. You can also enable streaming media bypass.

Example ICAP sequence for an ICAP server performing web URL filtering on web proxy HTTP requests

1 A user opens a web browser and sends an HTTP request to connect to a web server.

2 The FortiGate unit intercepts the HTTP request and forwards it to an ICAP server.

3 The ICAP server receives the request and determines if the request is for URL that should be blocked or allowed.

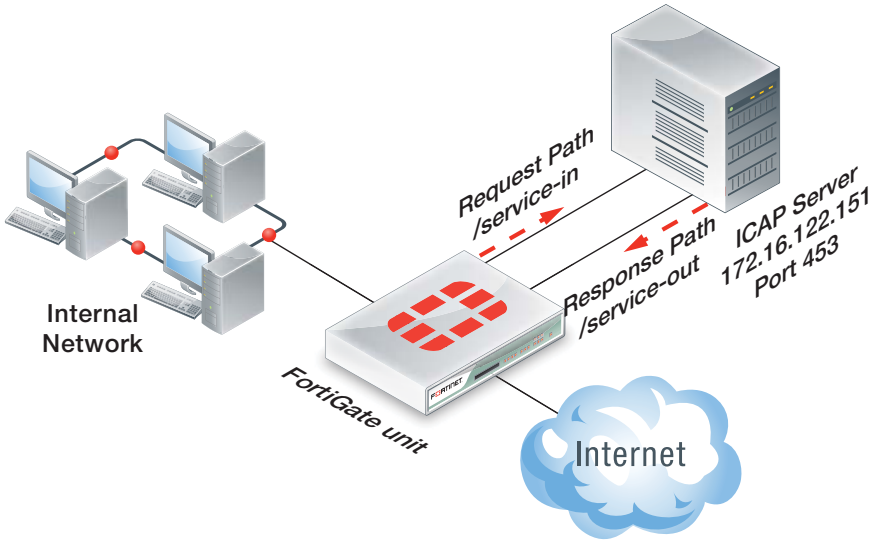
- If the URL should be blocked, the ICAP server sends a response to the FortiGate unit. The FortiGate unit returns this response to the user's web browser. This response could be a message informing the user that their request was blocked.
- If the URL should be allowed, the ICAP server sends a request to the FortiGate unit. The FortiGate unit forwards the request to the web server that the user originally attempted to connect to.

When configuring ICAP on the FortiGate unit, you must configure an ICAP profile that contains the ICAP server information; this profile is then applied to a security policy.

Example ICAP configuration

The following example shows how to configure the FortiGate unit to offload processing to an ICAP server. The ICAP server IP address is 172.16.122.151 and port it is listening on is 453. The ICAP server request path /service-in and its response path is /service-out.

Figure 90: Example ICAP network configuration



Adding ICAP to a web proxy security policy - web-based manager

In order to configure ICAP using the web-based manager, this feature must be enabled using Feature Select. For more information, see “Feature Select” on page 243.

The following is an example of configuring the ICAP feature on the FortiGate unit and applying an ICAP profile to an existing web proxy security policy.

1 Go to *Security Profiles* > *ICAP* > *Servers* and select *Create New* to add the following ICAP server:

Name	New ICAP Server
IP Type	IPv4
IP Address	172.16.122.151
Port	453

2 Go to *Security Profiles* > *ICAP* > *Profiles* and select *Create New* to add an ICAP profile names *New ICAP Profile.*

3 Select *Enable Request Processing* and configure the following:

Server	New ICAP Server
Path	/service-in
On Failure	Error

4 Select *Enable Response Processing* and configure the following:

Server	New ICAP Server
Path	/service-out
On Failure	Error

5 Select *Enable Streaming Media Bypass* and select *OK*.

6 Go to *Policy* > *Policy* > *Policy* and edit the security policy that accepts the traffic to be processed by the ICAP server.

7 Under *Security Policies*, select *Enable ICAP* and set *New ICAP Server*.

8 Select *OK*.

Adding ICAP to a web proxy security policy - CLI

The following is an example of configuring the ICAP feature on the FortiGate unit and applying an ICAP profile to an existing web proxy security policy.

1 Log in to the CLI.

2 Enter the following to configure the ICAP server:

```
config icap server
  edit “New ICAP Server”
    set ip-address 172.16.122.151
    set ip-version 4
    set max-connections 100
    set port 453
  end
```

3 Enter the following to configure the ICAP profile to then apply to a security policy:

```
config icap profile
  edit "New ICAP Profile"
    set request enable
    set request-failure error
    set request-path "/service-in"
    set request-server icap_server
    set response enable
    set response-failure error
    set response-path "/service-out"
    set response-server "New ICAP Server"
    set streaming-content-bypass enable
  end
```

4 In the `config firewall policy` command, apply the ICAP profile to a security policy:

```
config firewall policy
  edit 0
    set srcintf web-proxy
    ...
    set utm-status enable
    set icap-profile "New ICAP Profile"
  end
```

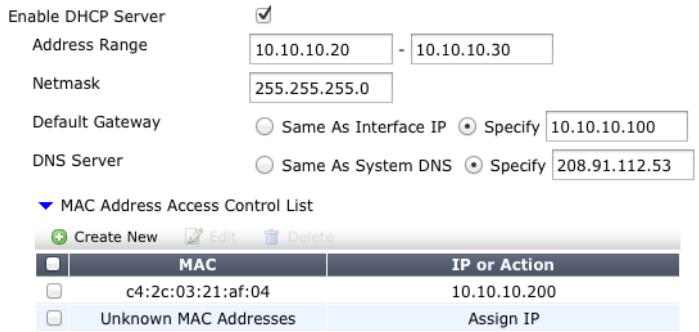
New interface features - DHCP server and authentication

You can add a DHCP server and authentication to any FortiGate interface. This includes physical interfaces, WiFi interfaces (SSIDs), switch interfaces (software and hardware switch interfaces), aggregate interfaces, redundant interfaces, loopback interfaces and VLAN interfaces.

Adding a DHCP server to an interface

To add a DHCP server to an interface, edit the interface and select *Enable DHCP Server*. Then you can specify the address range, netmask, default gateway and DNS servers provided by the DHCP server. An interface must have a static IP address to add a DHCP server to it.

Figure 91: Adding a DHCP server to a FortiGate interface

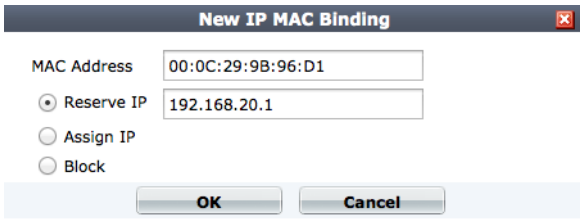


Reserving, assigning and blocking MAC addresses

While adding a DHCP server to an interface you can select *MAC Address Control list* and select *Create New* to configure the DHCP server to:

- Always assign the same IP address to a device according to its MAC address (*Reserved IP* address)
- *Block* access to a device according to its MAC address (MAC address filtering)
- The default action is to *Assign* an IP address to a device.

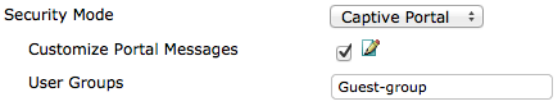
Figure 92: Reserving an IP address for a device with a specific MAC address



Authentication - Captive Portal

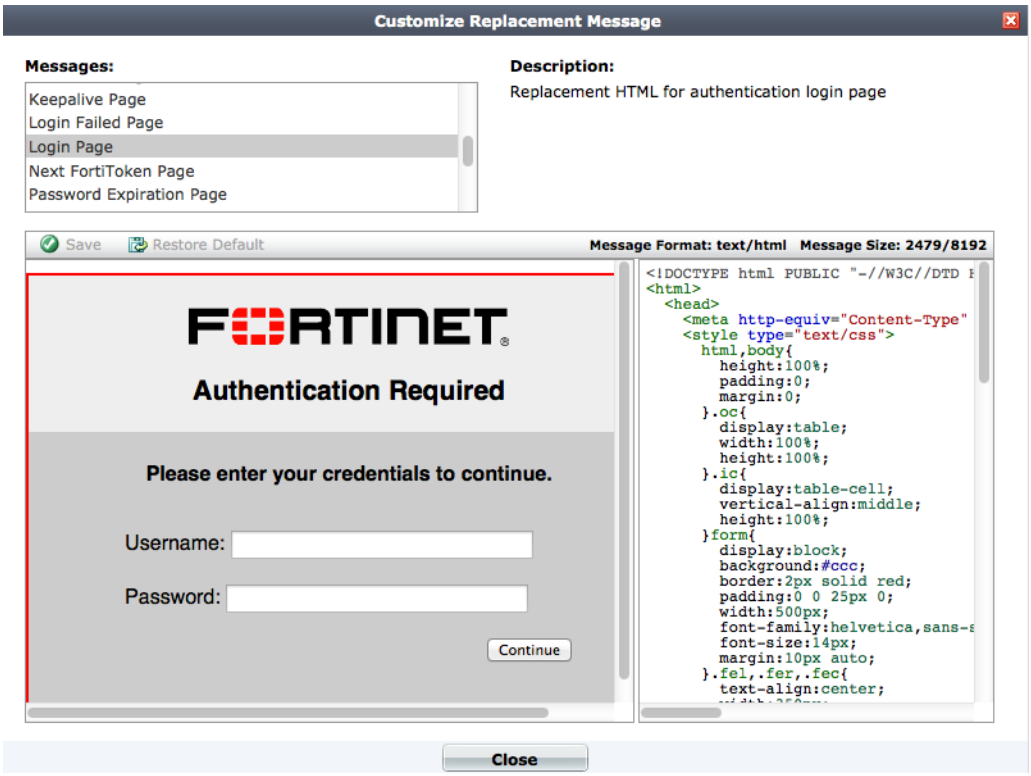
To add authentication to an interface, edit an interface and set *Security Mode* to *Captive Portal*. Then select one or more *User Groups*. Users who attempt to connect through the interface must first use HTTP or HTTPS to connect to a captive portal and enter a user name and password.

Figure 93: Reserving an IP address for a device with a specific MAC address



You can customize the captive portal for each interface or select from a saved portal.

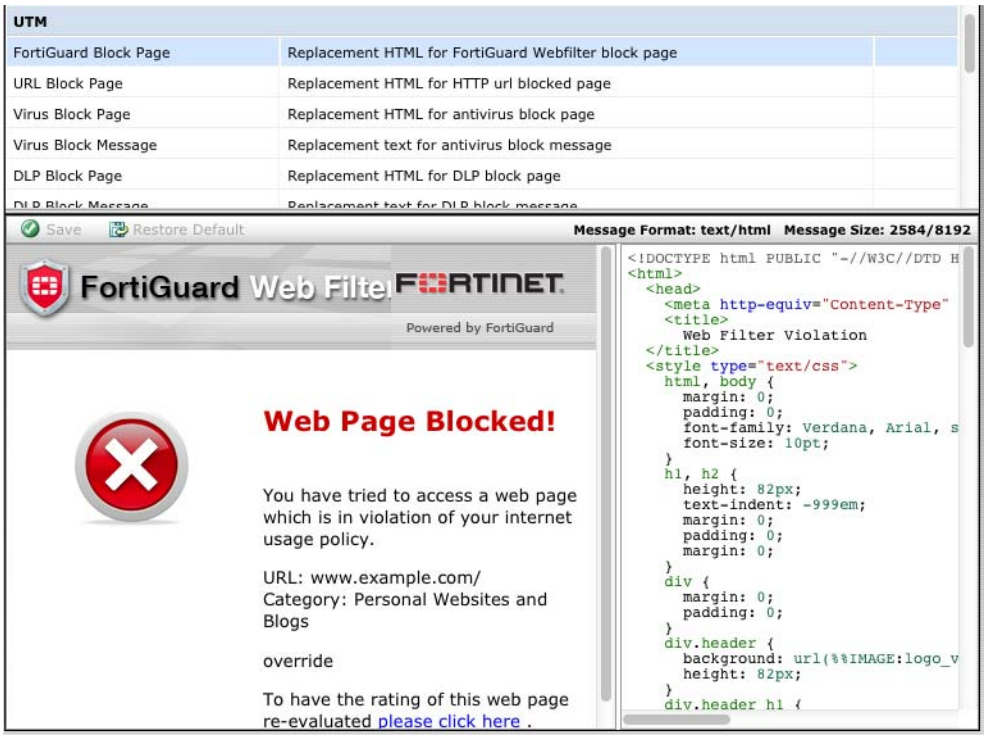
Figure 94: Customizing the captive portal



Replacement Message Improvements

Go to *System* > *Config* > *Replacement Messages* to edit replacement messages. Editing replacement messages has been enhanced with a new editor that you can use to select and edit replacement messages and view your changes in real time as you make them.

Figure 95: Editing replacement messages



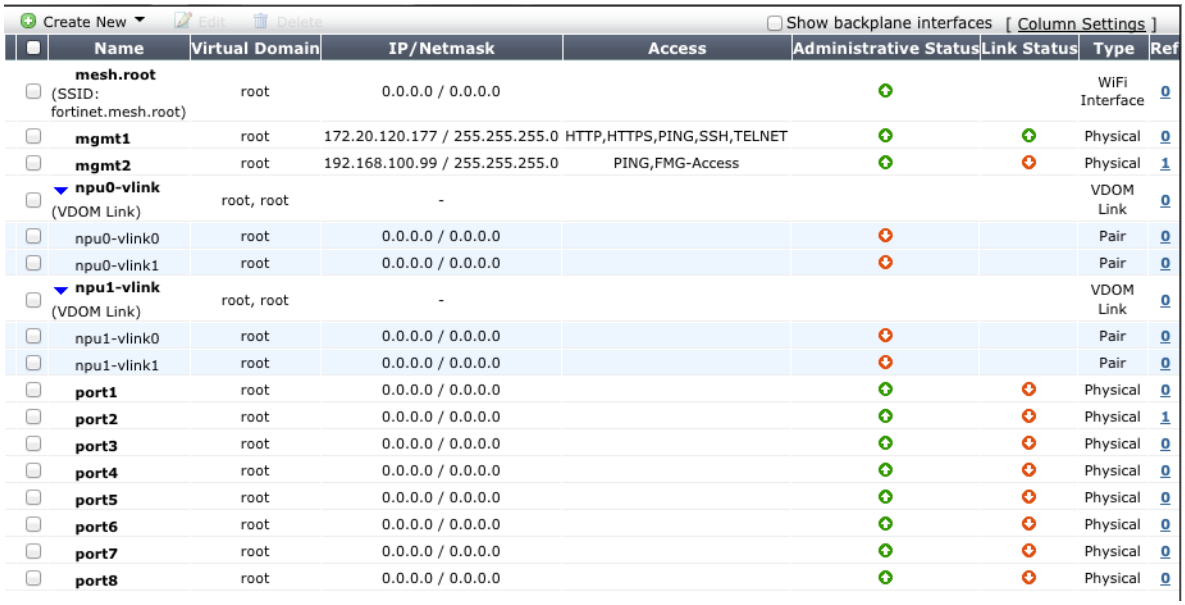
In addition, more replacement messages are available and the replacement message editor includes simple and extended view. The simple view includes the most commonly edited replacement messages while the extended view includes all of them.

Acceleration of Inter-VDOM Traffic (by NP4)

On high-end FortiGate units that include NP4 processors, you can add inter-VDOM links where the traffic is accelerated by NP4 processors. This means enhanced performance for traffic passing between VDOMs that will improve the overall performance and capacity of many multiple VDOM implementations.

If your FortiGate unit supports accelerated inter-VDOM links, when it is operating in multiple VDOM mode, the interface list includes interfaces with names such as npu0-vlink0, npu1-vlink and so on (see Figure 96).

Figure 96: FortiGate-5001B interface list showing NP4 accelerated inter-VDOM links



By default, all of these links are associated with the root VDOM. However, you can edit each interface in the link and add it another VDOM, creating an inter-VDOM link between 2 VDOMs

Virtual Hardware Switch

In previous versions of FortiOS, you can use the software switch feature to group independent interfaces into a single logical switch. In this virtual software switch, all of the interfaces share the same IP address and be connected to the same subnet and traffic would pass between them as if they were switch ports, with no firewall or other FortiGate features applied to the traffic. However, the virtual software switch feature just simulates a switch and, since the FortiGate CPU must process the switch traffic, performance can be affected if the FortiGate unit becomes busy processing a lot of traffic.

In FortiOS 5.0, for FortiGate models that have internal hardware switches, you can use the following command to group interfaces in the hardware switch into virtual hardware switches in which all traffic between the switch ports is processed on the switch itself and the FortiGate CPU is not involved resulting in improved performance.

Recent FortiGate models with internal hardware switches support this feature.

Use the following command to create a virtual hardware switch using ports p1, p2, p3, and p4:

```
config system virtual-switch
  edit virt-sw-1
    set physical-switch sw0
      config port
        edit 1
          set port p1
          set speed <speed>
          set duplex { up | down}
        next
        edit 2
          set port p2
          set speed <speed>
          set duplex { up | down}
        end
        edit 3
          set port p3
          set speed <speed>
          set duplex { up | down}
        next
        edit 4
          set port p4
          set speed <speed>
          set duplex { up | down}
        end
```

FortiExplorer for iOS devices

You can use FortiExplorer for iOS to manage most FortiGate models running FortiOS 5.0 firmware from an iOS device (iPhone, iPad, or iPod Touch running iOS 5.0 or later). FortiExplorer is a free download from the Apple iOS App Store (App Store Link).

Connecting to and logging into a FortiGate unit

Use FortiExplorer for iOS by connecting your iOS device to any FortiGate USB port, using the USB cable that came with your iOS device. (Connect to any FortiGate USB-A port. There is no need to connect to the USB-B port required for the PC or Mac OS versions of FortiExplorer).

Start FortiExplorer on your iOS device and select *Setup* and log into the FortiGate unit using any administrator account user name and password.

After logging in, you can use FortiExplorer to change the firmware running on the FortiGate unit, configure network settings, and change general system settings. You also have one-step access to the configuration of each FortiGate interface.

Updating firmware and configuring network settings

Usually you would use FortiExplorer to upgrade firmware and configure network and basic settings. Then log into the web-based manager for more advanced configuration. However, you can select *Web* to connect directly to the FortiGate unit's web-based manager from your iOS device.

You can also select *Firmware* to view the available firmware versions for any FortiGate model and download new firmware and install it on your FortiGate unit.

Inter-VDOM links between NAT mode and Transparent mode VDOMs

FortiOS 5.0 supports inter-VDOM links between NAT and Transparent mode VDOMs. No special configuration is required and you can create an inter-VDOM link between NAT and Transparent mode VDOMs in the same way as creating an inter-VDOM link between two NAT mode VDOMs.

About inter-VDOM links between NAT and Transparent mode VDOMs

Inter-VDOM links between NAT and Transparent mode VDOMS can be useful for configurations where the NAT based VDOMs that share a common Internet service route, which can be routed through a Transparent VDOM that provides additional functionality, like common Security inspection, WAN optimization, explicit proxying and so on.

Other examples include:

- Performing SSL offloading in the Transparent mode VDOM and providing Internet access through a NAT mode VDOM.
- Applying WAN optimization in a Transparent mode VDOM and other security features in the NAT mode VDOM.
- Using a dedicated Transparent mode VDOM for the explicit web proxy in front of a NAT mode VDOM that applies other security features.
- An ISP configuration with multiple per-tenant NAT mode VDOMs all sharing a single Internet connection but where the ISP only presents a single routed subnet. Each tenant can then be assigned an IP from the subnet for their respective VDOM link interface while using a single physical port to connect to the ISP router.

Sniffer modes: one-armed and normal

FortiGate units can operate in one-arm sniffer mode or as a regular traffic sniffer. When the FortiGate unit has an interface dedicated to its exclusive use (one-arm sniffer mode), all traffic entering the interface is processed by the sniffer. The traffic is compared to the configured filters and data that doesn't match the filters is discarded. The selected Security profiles process the remaining traffic and log their findings. At the same time, the packets triggering the configured Security features are saved for later examination. After all examination of the traffic is complete, it is discarded. This continues until the configured maximum number of packets are saved, when the sniffer stops.

When the sniffer does not have an interface dedicated to its exclusive use, the traffic is examined by the sniffer, then processed normally by the FortiGate unit. That is, traffic is sniffed and can then leave the FortiGate unit depending on how it is configured. The sniffed interface traffic is examined for traffic matching the sniffer filters and matching packets are saved. Security features can not be used to limit the traffic the sniffer examines when not in one-armed mode. When the configured maximum number of packets is saved, the sniffer stops. The FortiGate unit continues to process network traffic as normal.

Configuring an interface to operate as a one-arm sniffer

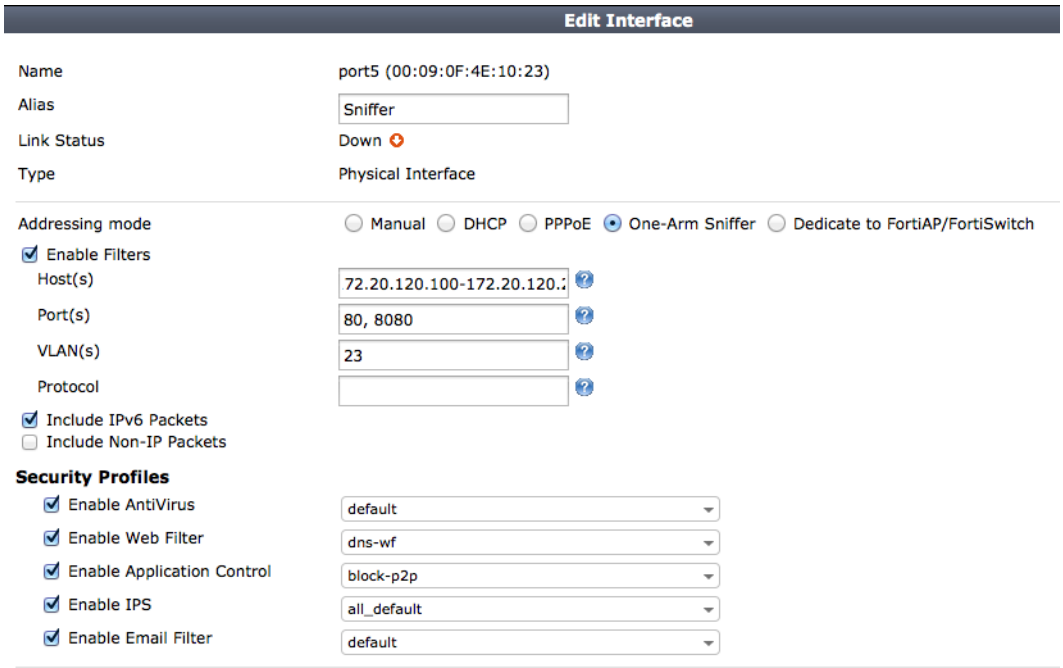
Connect the interface to the network to be analyzed. Go to *System* > *Network* > *Interfaces* and edit the interface and select *One-Arm Sniffer* and select *Apply*.

Configure the sniffer by selecting *Enable Filters* to filter traffic by IP address (host), address range, port number, VLANs and protocols. You can also configure the sniffer to *Include IPv6 Packets* and to *Include Non-IP Packets*.

Finally, under *Security Profiles* you can select Security profiles to apply to the sniffer.

Select *Apply* to save your changes.

Figure 97: Example one-arm sniffer configuration



Integrated switch fabric (ISF) access control list (ACL) short-cut path

On FortiGate models that include NP4 and XLR ports and an integrated switch fabric (for example, the FortiGate-3x40 and 3950/1 models), you can create an ISF ACL security policy that allows some traffic (for example, multicast traffic) to bypass security inspection, resulting in reduced CPN and NP4 processor load.

This feature is only available in Transparent mode and only between port pairs.

Traffic accepted and forwarded by an ISF policy is not subject to security inspection. Normally, you should only create ISF policies for traffic that you consider very low risk.

Use the following command to add an ISF ACL shortcut policy:

```
config firewall isf-acl
  config port-pair-1
    edit 1
      set type binary
      set ingressport <port1 | port2>
      set offset
      set length
      set matchpattern <patter in hex>
      set action <bypass|block>
    edit 2
      set type 5-tuple
      set srcaddr: a.b.c.d/32
      set dstaddr 239.A.A.a/32
      set proto UDP
      set port XXX
      set action <bypass|block>
  end
```

Generalized TTL Security Mechanism (GTSM) support

Generalized TTL Security Mechanism (GTSM), defined in RFC 5082, prevents attacks based on forged protocol packets sent from outside the network.

In IP packets, the TTL (time-to-live) value sets the maximum number of routers the packet can pass through to reach its destination. Each router decrements the TTL value and the packet is discarded if TTL reaches zero before the packet reaches its destination. In IPv6, TTL is called Hop Limit.

Most protocol-related packets pass between adjacent routers, so the TTL value at the destination is within a predictable range. TTL is difficult to spoof, especially the value of 255 which occurs if the sender is directly connected to the destination router.

On the FortiGate firewall, you can define TTL policies that specify the acceptable TTL range for a particular packet source, destination and service. You do this using the new `config firewall ttl-policy` command.

Use the following command to add a TTL policy that sets the TTL range to from 20 to 30:

```
config firewall ttl-policy
  edit 0
    set srcintf port1
    set srcaddr example_net
    set service ALL
    set schedule always
    set ttl 20-30
  end
```

Firewall services

The CLI command `get firewall service predefined` command has been removed. All predefined services have been moved to `{get | set} firewall service custom`.

Chapter 2 Advanced Routing for FortiOS 5.0

This chapter describes advanced static routing concepts and how to implement dynamic routing on FortiGate units.

This FortiOS Handbook chapter contains the following sections:

Advanced Static Routing explains universal and static routing concepts, equal cost multipath (ECMP) and load balancing, policy routing, and routing in transparent mode.

Dynamic Routing Overview provides an overview of dynamic routing, compares static and dynamic routing, and helps you decide which dynamic routing protocol is best for you.

Routing Information Protocol (RIP) describes a distance-vector routing protocol intended for small, relatively homogeneous networks.

Border Gateway Protocol (BGP) describes classless inter-domain routing, and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol.

Open Shortest Path First (OSPF) provides background on the specific protocol explaining terms used and how the protocol works, as well as providing some troubleshooting information and examples on configuring the protocols in different situations.

Intermediate System to Intermediate System Protocol (IS-IS), which describes the link state protocol, is well-suited to smaller networks and with near universal support on routing hardware. The section also provides troubleshooting information and configuration examples.

Advanced Static Routing

Advanced static routing includes features and concepts that are used in more complex networks. Dynamic routing is not addressed in this section.

This section includes:

Routing concepts

Many routing concepts apply to static routing. However without first understanding these basic concepts, it is difficult to understand the more complex dynamic routing.

This section includes:

Routing in VDOMs

Routing on FortiGate units is configured per-VDOM. This means if VDOMs are enabled, you must enter a VDOM to do any routing configuration. This allows each VDOM to operate independently, with its own default routes and routing configuration.

In this guide, the procedures assume your FortiGate unit has VDOMs disabled. This is stated in the assumptions for the examples. If you have VDOMs enabled you will need to perform the following steps in addition to the procedure's steps.

To route in VDOMs - web-based manager

Select the VDOM that you want to view or configure at the bottom of the main menu.

To route in VDOMs - CLI

Before following any CLI routing procedures with VDOMs enabled, enter the following commands. For this example, it is assumed you will be working in the root VDOM. Change root to the name of your selected VDOM as needed.

```
config vdom
  edit root
```

Following these commands, you can enter any routing CLI commands as normal.

Default route

The default route is used if either there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

All routers, including FortiGate units, are shipped with default routes in place. This allows customers to set up and become operational more quickly. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

FortiGate units come with a default static route with an IPv4 address of 0.0.0.0, an administration distance of 10, and a gateway IPv4 address.

Adding a static route

To add or edit a static route, go to *Router* > *Static* > *Static Routes* and select *Create New*.

Destination IP / Mask	Enter the destination IP address and netmask. A value of `0.0.0.0/0.0.0.0` is universal.
Device	Select the name of the interface which the static route will connect through.
Gateway	Enter the gateway IP address.
Distance	Enter the distance value, which will affect which routes are selected first by different protocols for route management or load balancing. The default is 10.
Priority	Enter the priority if desired, which will artificially weight the route during route selection. The higher the number, the less likely the route is to be selected over others. The default is 0.

Routing table

When two computers are directly connected, there is no need for routing because each computer knows exactly where to find the other computer. They communicate directly.

Networking computers allows many computers to communicate with each other. This requires each computer to have an IP address to identify its location to the other computers. This is much like a mailing address - you will not receive your postal mail at home if you do not have an address for people to send mail to. The routing table on a computer is much like an address book used to mail letters to people in that the routing table maintains a list of how to reach computers. Routing tables may also include information about the quality of service (QoS) of the route, and the interface associated with the route if the device has multiple interfaces.

Looking at routing as delivering letters is more simple than reality. In reality, routers loose power or have bad cabling, network equipment is moved without warning, and other such events happen that prevent static routes from reaching their destinations. When any changes such as these happen along a static route, traffic can no longer reach the destination — the route goes down. Dynamic routing can address these changes to ensure traffic still reaches its destination. The process of realizing there is a problem, backtracking and finding a route that is operational is called convergence. If there is fast convergence in a network, users won't even know that re-routing is taking place.

The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes—the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Routing tables are also used in unicast reverse path forwarding (uRPF). In uRPF, the router not only looks up the destination information, but also the source information to ensure that it exists. If there is no source to be found, then that packet is dropped because the router assumes it to be an error or an attack on the network.

The routing table is used to store routes that are learned. The routing table for any device on the network has a limited size. For this reason, routes that aren't used are replaced by new routes. This method ensures the routing table is always populated with the most current and most used routes — the routes that have the best chance of being reused. Another method used to maintain the routing table's size is if a route in the table and a new route are to the same destination, one of the routes is selected as the best route to that destination and the other route is discarded.

Some actions you can perform on the routing table include:

- Viewing the routing table in the web-based manager
- Viewing the routing table in the CLI
- Searching the routing table

Viewing the routing table in the web-based manager

VDOM

By default, all routes are displayed in the Routing Monitor list. The default static route is defined as 0.0.0.0/0, which matches the destination IP address of "any/all" packets.

To display the routes in the routing table, go to *Router* > *Monitor* > *Routing Monitor*.

Figure 98 shows the Routing Monitor list belonging to a FortiGate unit that has interfaces named "port1", "port4", and "lan". The names of the interfaces on your FortiGate unit may be different.

Figure 99 shows the Routing Monitor list when IPv6 has been selected. Note that the information available for IPv6 is limited.

Figure 98: Routing Monitor list - IPv4

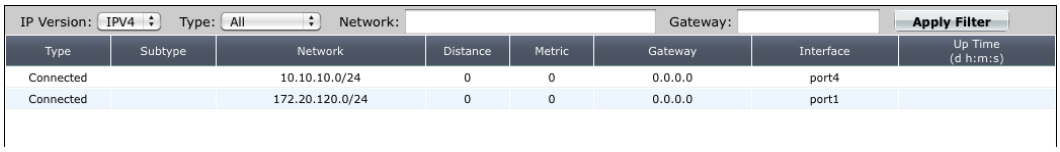


Figure 99: Routing Monitor list - IPv6

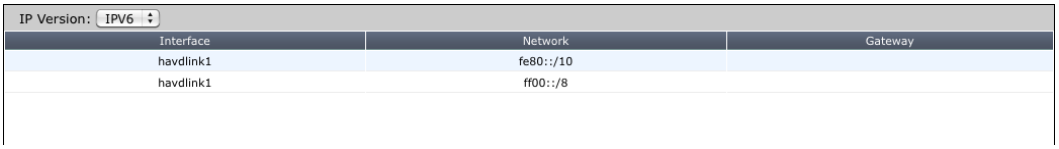

IP version:	Select IPv4 or IPv6. This is available only when IPv6 is enabled in the web-based manager. The fields displayed in the table depend on which IP version is selected.
Type:	Select one of the following route types to search the routing table and display routes of the selected type only: *All* — all routes recorded in the routing table. *Connected* — all routes associated with direct connections to FortiGate unit interfaces. *Static* — the static routes that have been added to the routing table manually. *RIP* — all routes learned through RIP. For more information see "Routing Information Protocol (RIP)" on page 319. *RIPNG* — all routes learned through RIP version 6 (which enables the sharing of routes through IPv6 networks). *BGP* — all routes learned through BGP. For more information see "Border Gateway Protocol (BGP)" on page 358. *OSPF* — all routes learned through OSPF. For more information see "Open Shortest Path First (OSPF)" on page 396. *OSPF6* — all routes learned through OSPF version 6 (which enables the sharing of routes through IPv6 networks). *IS-IS* — all routes learned through IS-IS. For more information see "Intermediate System to Intermediate System Protocol (IS-IS)" on page 438. *HA* — RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you are viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster. Not displayed when IP version IPv6 is selected. For details about HA routing synchronization, see the FortiGate HA User Guide.
Network:	Enter an IP address and netmask (for example, `172.16.14.0/24`) to search the routing table and display routes that match the specified network.
Gateway:	Enter an IP address and netmask (for example, `192.168.12.1/32`) to search the routing table and display routes that match the specified gateway.
Apply Filter	Select to search the entries in the routing table based on the specified search criteria and display any matching routes. Not displayed when IP version IPv6 is selected.
Type	The type values assigned to FortiGate unit routes (Static, Connected, RIP, OSPF, or BGP). Not displayed when IP version IPv6 is selected.

Subtype	If applicable, the subtype classification assigned to OSPF routes. An empty string implies an intra-area route. The destination is in an area to which the FortiGate unit is connected. *OSPF inter area* — the destination is in the OSPF AS, but the FortiGate unit is not connected to that area. *External 1* — the destination is outside the OSPF AS. This is known as OSPF E1 type. The metric of a redistributed route is calculated by adding the external cost and the OSPF cost together. *External 2* — the destination is outside the OSPF AS. This is known as OSPF E2 type. In this case, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. *OSPF NSSA 1* — same as External 1, but the route was received through a not-so-stubby area (NSSA). *OSPF NSSA 2* — same as External 2, but the route was received through a not-so-stubby area. For more information on OSPF subtypes, see "OSPF Background and concepts" on page 396. Not displayed when IP version 6 is selected.
Network	The IP addresses and network masks of destination networks that the FortiGate unit can reach.
Distance	The administrative distance associated with the route. A value of 0 means the route is preferable compared to other routes to the same destination, and the FortiGate unit may routinely use the route to communicate with neighboring routers and access servers. Modifying this distance for dynamic routes is route distribution. See "Redistributing and blocking routes in BGP" on page 389 Not displayed when IP version 6 is selected.
Metric	The metric associated with the route type. The metric of a route influences how the FortiGate unit dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to. *Hop count* — routes learned through RIP. *Relative cost* — routes learned through OSPF. *Multi-Exit Discriminator (MED)* — routes learned through BGP. However, several attributes in addition to MED determine the best path to a destination network. For more information on BGP attributes, see "BGP attributes" on page 364. By default, the MED value associated with a BGP route is zero. However, the MED value can be modified dynamically. If the value was changed from the default, the Metric column will display a non-zero value. Not displayed when IP version 6 is selected.
Gateway	The IP addresses of gateways to the destination networks.

Interface	The interface through which packets are forwarded to the gateway of the destination network.
Up Time	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable. Not displayed when IP version IPv6 is selected.

Viewing the routing table in the CLI

In the CLI, you can easily view the static routing table just as in the web-based manager or you can view the full routing table.

When viewing the list of static routes using the CLI command `get route static`, it is the configured static routes that are displayed. When viewing the routing table using the CLI command `get router info routing-table all`, it is the entire routing table information that is displayed including configured and learned routes of all types. The two are different information in different formats.

If VDOMs are enabled on your FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

To view the routing table

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter
    area
* - candidate default

S*      0.0.0.0/0 [10/0] via 192.168.183.254, port2
S       1.0.0.0/8 [10/0] via 192.168.183.254, port2
S       2.0.0.0/8 [10/0] via 192.168.183.254, port2
C       10.142.0.0/23 is directly connected, port3
B       10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C       192.168.182.0/23 is directly connected, port2
```

Examining an entry:

```
B       10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route including netmask.
[20/0]	20 indicates and administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
10.142.0.74	The gateway, or next hop.
port3	The interface used by this route.
2d18h02m	How old this route is, in this case almost three days old.

To view the kernel routing table

```
# get router info kernel

tab=254 vf=0 scope=253 type=1 proto=2 prio=0
     0.0.0.0/0.0.0.0/0->10.11.201.0/24 pref=10.11.201.4 gwy=0.0.0.0
     dev=5(external1)

tab=254 vf=0 scope=253 type=1 proto=2 prio=0
     0.0.0.0/0.0.0.0/0->172.20.120.0/24 pref=172.20.120.146 gwy=0.0.0.0
     dev=6(internal)
```

The parts of the routing table entry are:

tab	table number. This will be either 254 (unicast) or 255 (multicast).
vf	virtual domain of the firewall. This is the vdom index number. If vdoms are not enabled, this number will be 0.
type	type of routing connection. Valid values include: 0 - unspecific 1 - unicast 2 - local 3 - broadcast 4 - anycast 5 - multicast 6 - blackhole 7 - unreachable 8 - prohibited

proto	type of installation. This indicates where the route came from. Valid values include: 0 - unspecific 2 - kernel 11 - ZebOS routing module 14 - FortiOS 15 - HA 16 - authentication based 17 - HA1
prio	priority of the route. Lower priorities are preferred.
->10.11.201.0/24 (->x.x.x.x/mask)	the IP address and subnet mask of the destination
pref	preferred next hop along this route
gwy	gateway - the address of the gateway this route will use
dev	outgoing interface index. This number is associated with the interface for this route, and if VDOMs are enabled the VDOM will be included here as well. If an interface alias is set for this interface it will also be displayed here.

Searching the routing table

You can apply a filter to search the routing table and display certain routes only. For example, you can display one or more static routes, connected routes, routes learned through RIP, OSPF, or BGP, and routes associated with the network or gateway that you specify.

If you want to search the routing table by route type and further limit the display according to network or gateway, all of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed — an implicit AND condition is applied to all of the search parameters you specify.

For example, if the FortiGate unit is connected to network 172.16.14.0/24 and you want to display all directly connected routes to network 172.16.14.0/24, you must select *Connected* from the *Type* list, type `172.16.14.0/24` in the *Network* field, and then select *Apply Filter* to display the associated routing table entry or entries. Any entry that contains the word "Connected" in its *Type* field and the specified value in the *Gateway* field will be displayed.

In this example, you will apply a filter to search for an entry for static route to 10.10.10.10/24

To search the FortiGate unit routing table in the web-based manager

1. Go to *Router* > *Monitor* > *Routing Monitor*.
2. From the *Type* list, select the type of route to display. In our example, select *Static*.
3. If you want to display routes to a specific network, type the IP address and netmask of the network in the Networks field. In our example, enter `10.10.10.10/24`.
4. If you want to display routes to a specific gateway, type the IP address of the gateway in the *Gateway* field.

5. Select *Apply Filter*.

All of the values that you specify as search criteria must match corresponding values in the same routing table entry in order for that entry to be displayed.

To search the FortiGate unit routing table in the CLI

```
FGT # get router info routing-table details 10.10.10.10
Routing entry for 10.10.10.10/24
  Known via "static", distance 10, metric 0, best
```

If there are multiple routes that match your filter, they will all be listed, with the best match at the top of the list as indicated by the word best.

Building the routing table

In the factory default configuration, the FortiGate unit routing table contains a single static default route. You can add routing information to the routing table by defining additional static routes.

It is possible that the routing table is faced with several different routes to the same destination—the IP addresses of the next-hop router specified in those routes or the FortiGate interfaces associated with those routes may vary. In this situation, the “best” route is selected from the table.

The FortiGate unit selects the “best” route for a packet by evaluating the information in the routing table. The “best” route to a destination is typically associated with the shortest distance between the FortiGate unit and the closest gateway, also known as a next-hop router. In some cases, the next best route may be selected if the best route is unavailable.

The FortiGate unit installs the best available routes in the unit’s forwarding table, which is a subset of the unit’s routing table. Packets are forwarded according to the information in the forwarding table.

Static routing security

Securing the information on your company network is a top priority for network administrators. Security is also required as the routing protocols used are internationally known standards that typically provide little or no inherent security by themselves.

The two reasons for securing your network are the sensitive and proprietary information on your network, and also your external bandwidth. Hackers not only can steal your information, but they can also steal your bandwidth. Routing is a good low level way to secure your network, even before UTM features are applied.

Routing provides security to your network in a number of ways including obscuring internal network addresses with NAT and blackhole routing, using RPF to validate traffic sources, and maintaining an access control list (ACL) to limit access to the network.

This section includes:

- Network Address Translation (NAT)
- Access Control List (ACL)
- Blackhole Route
- Reverse path lookup

Network Address Translation (NAT)

Network address translation (NAT) is a method of changing the address traffic appears to originate from. This practice is used to hide the IP address on company's internal networks, and helps prevent malicious attacks that use those specific addresses.

This is accomplished by the router connected to that local network changing all the IP addresses to its externally connected IP address before sending the traffic out to the other networks, such as the Internet. Incoming traffic uses the established sessions to determine which traffic goes to which internal IP address. This also has the benefit of requiring only the router to be very secure against external attacks, instead of the whole internal network as would be the case without NAT. Securing one computer is much cheaper and easier to maintain.

Configuring NAT on your FortiGate unit includes the following steps.

1. Configure your internal network. For example use the `10.11.101.0` subnet.
2. Connect your internal subnet to an interface on your FortiGate unit. For example use `port1`.
3. Connect your external connection, for example an ISP gateway of `172.20.120.2`, to another interface on your Fortigate unit, for example `port2`.
4. Configure security policies to allow traffic between port1 and port2 on your FortiGate unit, ensuring that the NAT feature is enabled.

The above steps show that traffic from your internal network will originate on the 10.11.101.0 subnet and pass on to the 172.20.120.0 network. The FortiGate unit moves the traffic to the proper subnet. In doing that, the traffic appears to originate from the FortiGate unit interface on that subnet — it does not appear to originate from where it actually came from.

NAT "hides" the internal network from the external network. This provides security through obscurity. If a hacker tries to directly access your network, they will find the Fortigate unit, but will not know about your internal network. The hacker would have to get past the security-hardened FortiGate unit to gain access to your internal network. NAT will not prevent hacking attempts that piggy back on valid connections between the internal network and the outside world. However other UTM security measures can deal with these attempts.

Another security aspect of NAT is that many programs and services have problems with NAT. Consider if someone on the Internet tries to initiate a chat with someone on the internal network. The outsider only can access the FortiGate unit's external interface unless the security policy allows the traffic through to the internal network. If allowed in, the proper internal user would respond to the chat. However if its not allowed, the request to chat will be refused or time-out. This is accomplished in the security policy by allowing or denying different protocols.

Access Control List (ACL)

An access control list (ACL) is a table of addresses that have permission to send and receive data over a router's interface or interfaces. The router maintains an ACL, and when traffic comes in on a particular interface it is buffered, while the router looks up in the ACL if that traffic is allowed over that port or not. If it is allowed on that incoming interface, then the next step is to check the ACL for the destination interface. If the traffic passes that check as well the buffered traffic is delivered to its accentuation. If either of those steps fail the ACL check, the traffic is dropped and an error message may be sent to the sender. The ACL ensures that traffic follows expected paths, and any unexpected traffic is not delivered. This stops many network attacks. However, to be effective the ACL must be kept up to date —when employees or computers are removed from the internal network their IP addresses must also be removed from the ACL. For more information on the ACL, see the router chapter of the FortiGate CLI Reference.

Blackhole Route

A blackhole route is a route that drops all traffic sent to it. It is very much like /dev/null in Linux programming.

Blackhole routes are used to dispose of packets instead of responding to suspicious inquiries. This provides added security since the originator will not discover any information from the target network.

Blackhole routes can also limit traffic on a subnet. If some subnet addresses are not in use, traffic to those addresses (traffic which may be valid or malicious) can be directed to a blackhole for added security and to reduce traffic on the subnet.

The loopback interface, a virtual interface that does not forward traffic, was added to enable easier configuration of blackhole routing. Similar to a normal interface, this loopback interface has fewer parameters to configure, and all traffic sent to it stops there. Since it cannot have hardware connection or link status problems, it is always available, making it useful for other dynamic routing roles. Once configured, you can use a loopback interface in security policies, routing, and other places that refer to interfaces. You configure this feature only from the CLI. For more information, see the system chapter of the *FortiGate CLI Reference*.

Reverse path lookup

Whenever a packet arrives at one of the FortiGate unit's interfaces, the unit determines whether the packet was received on a legitimate interface by doing a reverse lookup using the source IP address in the packet header. This is also called anti-spoofing. If the FortiGate unit cannot communicate with the computer at the source IP address through the interface on which the packet was received, the FortiGate unit drops the packet as it is likely a hacking attempt.

If the destination address can be matched to a local address (and the local configuration permits delivery), the FortiGate unit delivers the packet to the local network. If the packet is destined for another network, the Fortigate unit forwards the packet to a next-hop router according to a policy route and the information stored in the FortiGate forwarding table.

Multipath routing and determining the best route

Multipath routing occurs when more than one entry to the same destination is present in the routing table. When multipath routing happens, the FortiGate unit may have several possible destinations for an incoming packet, forcing the FortiGate unit to decide which next-hop is the best one.

It should be noted that some IP addresses will be rejected by routing protocols. These are called Martian addresses. They are typically IP addresses that are invalid and not routable because they have been assigned an address by a misconfigured system, or are spoofed addresses.

Two methods to manually resolve multiple routes to the same destination are to lower the administrative distance of one route or to set the priority of both routes. For the FortiGate unit to select a primary (preferred) route, manually lower the administrative distance associated with one of the possible routes. Setting the priority on the routes is a FortiGate unit feature and may not be supported by non-Fortinet routers.

Administrative distance is based on the expected reliability of a given route. It is determined through a combination of the number of hops from the source and the protocol used. A hop is when traffic moves from one router to the next. More hops from the source means more possible points of failure. The administrative distance can be from 1 to 255, with lower numbers being preferred. A distance of 255 is seen as infinite and will not be installed in the routing table.

Here is an example to illustrate how administration distance works — if there are two possible routes traffic can take between two destinations with administration distances of 5 (always up) and 31 (sometimes not available), the traffic will use the route with an administrative distance of 5. If for some reasons the preferred route (admin distance of 5) is not available, the other route will be used as a backup.

Different routing protocols have different default administrative distances. These different administrative distances are based on a number of factors of each protocol such as reliability,

speed, and so on. The default administrative distances for any of these routing protocols are configurable.

Table 4: Default administrative distances for routing protocols and connections

Routing protocol	Default administrative distance
Direct physical connection	1
Static	10
EBGP	20
OSPF	110
IS-IS	115
RIP	120
IBGP	200

Another method to determine the best route is to manually change the priority of both routes in question. If the next-hop administrative distances of two routes on the FortiGate unit are equal, it may not be clear which route the packet will take. Manually configuring the priority for each of those routes will make it clear which next-hop will be used in the case of a tie. The priority for a route be set in the CLI, or when editing a specific static route, as described in the next section. Lower priority routes are preferred. Priority is a Fortinet value that may or may not be present in other brands of routers.

All entries in the routing table are associated with an administrative distance. If the routing table contains several entries that point to the same destination (the entries may have different gateways or interface associations), the FortiGate unit compares the administrative distances of those entries first, selects the entries having the lowest distances, and installs them as routes in the FortiGate unit forwarding table. As a result, the FortiGate unit forwarding table contains only those routes having the lowest distances to every possible destination. While only static routing uses administrative distance as its routing metric, other routing protocols such as RIP can use metrics that are similar to administrative distance.

Route priority

After the FortiGate unit selects static routes for the forwarding table based on their administrative distances, the priority field of those routes determines routing preference. Priority is a Fortinet value that may or may not be present in other brands of routers.

You can configure the priority field through the CLI or the web-based manager. Priority values can range from 0 to 4 294 967 295. The route with the lowest value in the priority field is considered the best route. It is also the primary route.

To change the priority of a route - web-based manager

1. Go to *Router* > *Static* > *Static Routes*.
2. Select the route entry, and select *Edit*.
3. Select *Advanced*.
4. Enter the *Priority* value.
5. Select *OK*.

To change the priority of a route - CLI

The following command changes the priority to 5 for a route to the address `10.10.10.1` on the `port1` interface.

```
config router static
  edit 1
    set device port1
    set gateway 10.10.10.10
    set dst 10.10.10.1
    set priority 5
  end
```

If there are other routes set to priority 10, the route set to priority 5 will be preferred. If there are routes set to priorities less than 5, those other routes will be preferred instead.

In summary, because you can use the CLI to specify which sequence numbers or priority field settings to use when defining static routes, you can prioritize routes to the same destination according to their priority field settings. For a static route to be the preferred route, you must create the route using the `config router static` CLI command and specify a low priority for the route. If two routes have the same administrative distance and the same priority, then they are equal cost multipath (ECMP) routes.

Since this means there is more than one route to the same destination, it can be confusing which route or routes to install and use. However, if you have enabled load balancing with ECMP routes, then different sessions will resolve this problem by using different routes to the same address.

Troubleshooting static routing

When there are problems with your network that you believe to be static routing related, there are a few basic tools available to locate the problem.

These tools include:

- Ping
- Traceroute
- Examine routing table contents

Ping

Beyond the basic connectivity information, ping can tell you the amount of packet loss (if any), how long it takes the packet to make the round trip, and the variation in that time from packet to packet.

If there is no packet loss detected, your basic network connectivity is OK.

If there is some packet loss detected, you should investigate:

- possible ECMP, split horizon, network loops
- cabling to ensure no loose connections

If there is total packet loss, you should investigate:

- hardware - ensure cabling is correct, and all equipment between the two locations is accounted for
- addresses and routes - ensure all IP addresses and routing information along the route is configured as expected
- firewalls - ensure all firewalls are set to allow PING to pass through

To ping from a Windows PC

1. Go to a DOS prompt. Typically you go to *Start* > *Run*, enter `cmd` and select OK.
2. Enter `ping 10.11.101.100` to ping the default internal interface of the FortiGate unit with four packets.

To ping from an Apple computer

1. Open the Terminal.
2. Enter `ping 10.11.101.100`.
3. If the ping fails, it will stop after a set number of attempts. If it succeeds, it will continue to ping repeatedly. Press `Control+C` to end the attempt and see gathered data.

To ping from a Linux PC

1. Go to a command line prompt.
2. Enter `"/bin/etc/ping 10.11.101.101"`.

Traceroute

Where ping will only tell you if it reached its destination and came back successfully, traceroute will show each step of its journey to its destination and how long each step takes. If ping finds an outage between two points, traceroute can be used to locate exactly where the problem is.

To use traceroute on an Windows PC

1. Go to a DOS prompt. Typically you go to *Start* > *Run*, enter "`cmd`" and select OK.
2. Enter "`tracert fortinet.com`" to trace the route from the PC to the Fortinet website.

To use traceroute from an Apple computer

1. Open the Terminal.
2. Enter `traceroute fortinet.com`.
3. The terminal will list the number of steps made. Upon reaching the destination, it will list three asterisks per line. Press `Control+C` to end the attempt.

To use traceroute on a Linux PC

1. Go to a command line prompt.
2. Enter `"/bin/etc/traceroute fortinet.com"`.

   The Linux traceroute output is very similar to the MS Windows traceroute output.

Examine routing table contents

The first place to look for information is the routing table.

The routing table is where all the currently used routes are stored for both static and dynamic protocols. If a route is in the routing table, it saves the time and resources of a lookup. If a route isn't used for a while and a new route needs to be added, the oldest least used route is bumped if the routing table is full. This ensures the most recently used routes stay in the table. Note that if your FortiGate unit is in Transparent mode, you are unable to perform this step.

If the FortiGate is running in NAT mode, verify that all desired routes are in the routing table: local subnets, default routes, specific static routes, and dynamic routing protocols.

To check the routing table in the web-based manager, use the Routing Monitor — go to *Router* > *Monitor* > *Routing Monitor*. In the CLI, use the command `get router info routing-table all`.

Static routing tips

When your network goes beyond basic static routing, here are some tips to help you plan and manage your static routing.

Always configure a default route

The first thing configured on a router on your network should be the default route. And where possible the default routes should point to either one or very few gateways. This makes it easier to locate and correct problems in the network. By comparison, if one router uses a second router as its gateway which uses a fourth for its gateway and so on, one failure in that chain will appear as an outage for all the devices downstream. By using one or very few addresses as gateways, if there is an outage on the network it will either be very localized or network-wide — either is easy to troubleshoot.

Have an updated network plan

A network plan lists different subnets, user groups, and different servers. Essentially is puts all your resources on the network, and shows how the parts of your network are connected. Keeping your plan updated will also help you troubleshoot problems more quickly when they arise.

A network plan helps your static routing by eliminating potential bottlenecks, and helping troubleshoot any routing problems that come up. Also you can use it to plan for the future and act on any changes to your needs or resources more quickly.

Plan for expansion

No network remains the same size. At some time, all networks grow. If you take future growth into account, there will be less disruption to your existing network when that growth happens. For example allocating a block of addresses for servers can easily prevent having to re-assign IP addresses to multiple servers due to a new server.

With static routing, if you group parts of your network properly you can easily use network masks to address each part of your network separately. This will reduce the amount of administration required both to maintain the routing, and to troubleshoot any problems.

Configure as much security as possible

Securing your network through static routing methods is a good low level method to defend both your important information and your network bandwidth.

- Implement NAT to obscure your IP address is an excellent first step.
- Implement black hole routing to hide which IP addresses are in use or not on your local network.
- Configure and use access control list (ACL) to help ensure you know only valid users are using the network.

All three features limit access to the people who should be using your network, and obscure your network information from the outside world and potential hackers.

Policy routing

Policy routing enables you to redirect traffic away from a static route. This can be useful if you want to route certain types of network traffic differently. You can use incoming traffic's protocol, source address or interface, destination address, or port number to determine where to send the traffic. For example, generally network traffic would go to the router of a subnet, but you might want to direct SMTP or POP3 traffic directly to the mail server on that subnet.

If you have configured the FortiGate unit with routing policies and a packet arrives at the FortiGate unit, the FortiGate unit starts at the top of the Policy Route list and attempts to match the packet with a policy. If a match is found and the policy contains enough information to route the packet (a minimum of the IP address of the next-hop router and the FortiGate interface for forwarding packets to it), the FortiGate unit routes the packet using the information in the policy. If no policy route matches the packet, the FortiGate unit routes the packet using the routing table.

Most policy settings are optional, so a matching policy alone might not provide enough information for forwarding the packet. The FortiGate unit may refer to the routing table in an attempt to match the information in the packet header with a route in the routing table. For example, if the outgoing interface is the only item in the policy, the FortiGate unit looks up the IP address of the next-hop router in the routing table. This situation could happen when the interfaces are dynamic (such as DHCP or PPPoE) and you do not want or are unable to specify the IP address of the next-hop router.

Policy route options define which attributes of a incoming packet cause policy routing to occur. If the attributes of a packet match all the specified conditions, the FortiGate unit routes the packet through the specified interface to the specified gateway.

To view policy routes go to *Router* > *Static* > *Policy Routes*.

Create New	Add a policy route. See "Adding a policy route" on page 285.
Delete icon	Delete the selected policy route.
Edit icon	Edit the selected policy route.
Move To icon	Move the selected policy route. Enter the new position and select OK. For more information, see "Moving a policy route" on page 287.
#	The ID numbers of configured route policies. These numbers are sequential unless policies have been moved within the table.
Incoming	The interfaces on which packets subjected to route policies are received.
Outgoing	The interfaces through which policy routed packets are routed.
Source	The IP source addresses and network masks that cause policy routing to occur.
Destination	The IP destination addresses and network masks that cause policy routing to occur.

Adding a policy route

To add a policy route, go to *Router* > *Static* > *Policy Route* and select *Create New*.

Protocol	Enter the protocol number to match. The Internet Protocol Number is found in the IP packet header. RFC 5237 describes protocol numbers and you can find a list of the assigned protocol numbers here. The range is from 0 to 255. A value of `0` disables the feature. Commonly used *Protocol* settings include 6 for TCP sessions, 17 for UDP sessions, 1 for ICMP sessions, 47 for GRE sessions, and 92 for multicast sessions.
Incoming Interface	Select the name of the interface through which incoming packets subjected to the policy are received.
Source Address / Mask	To perform policy routing based on IP source address, type the source address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination Address / Mask	To perform policy routing based on the IP destination address of the packet, type the destination address and network mask to match. A value of `0.0.0.0/0.0.0.0` disables the feature.
Destination Ports	To perform policy routing based on the port on which the packet is received, type the same port number in the From and To fields. To apply policy routing to a range of ports, type the starting port number in the From field and the ending port number in the To field. A value of 0 disables this feature. The Destination Ports fields are only used for TCP and UDP protocols. The ports are skipped over for all other protocols.
Type of Service	Use a two digit hexadecimal bit pattern to match the service, or use a two digit hexadecimal bit mask to mask out. For more information, see "Type of Service" on page 286.
Outgoing Interface	Select the name of the interface through which packets affected by the policy will be routed.
Gateway Address	Type the IP address of the next-hop router that the FortiGate unit can access through the specified interface.

Example policy route

Configure the following policy route to send all FTP traffic received at `port1` out the `port10` interface and to a next hop router at IP address `172.20.120.23`. To route FTP traffic set protocol to 6 (for TCP) and set both of the destination ports to 21, the FTP port.

Protocol	6
Incoming interface	port1
Source address / mask	0.0.0.0/0.0.0.0
Destination address / mask	0.0.0.0/0.0.0.0

Destination Ports	From 21 to 21
Type of Service	bit pattern: 00 (hex) bit mask: 00 (hex)
Outgoing interface	port10
Gateway Address	172.20.120.23

Type of Service

Type of service (TOS) is an 8-bit field in the IP header that enables you to determine how the IP datagram should be delivered, with such qualities as delay, priority, reliability, and minimum cost.

Each quality helps gateways determine the best way to route datagrams. A router maintains a ToS value for each route in its routing table. The lowest priority TOS is 0, the highest is 7 - when bits 3, 4, and 5 are all set to 1. The router tries to match the TOS of the datagram to the TOS on one of the possible routes to the destination. If there is no match, the datagram is sent over a zero TOS route.

Using increased quality may increase the cost of delivery because better performance may consume limited network resources. For more information, see RFC 791 and RFC 1349.

Table 5: The role of each bit in the IP header TOS 8-bit field

bits 0, 1, 2	**Precedence**	Some networks treat high precedence traffic as more important traffic. Precedence should only be used within a network, and can be used differently in each network. Typically you do not care about these bits.
bit 3	**Delay**	When set to 1, this bit indicates low delay is a priority. This is useful for such services as VoIP where delays degrade the quality of the sound.
bit 4	**Throughput**	When set to 1, this bit indicates high throughput is a priority. This is useful for services that require lots of bandwidth such as video conferencing.
bit 5	**Reliability**	When set to 1, this bit indicates high reliability is a priority. This is useful when a service must always be available such as with DNS servers.
bit 6	**Cost**	When set to 1, this bit indicates low cost is a priority. Generally there is a higher delivery cost associated with enabling bits 3,4, or 5, and bit 6 indicates to use the lowest cost route.
bit 7	**Reserved for future use**	Not used at this time.

For example, if you want to assign low delay, and high reliability, say for a VoIP application where delays are unacceptable, you would use a bit pattern of xxx1x1xx where an ‘x’ indicates that bit can be any value. Since all bits are not set, this is a good use for the bit mask; if the mask is set to 0x14, it will match any TOS packets that are set to low delay and high reliability.

Moving a policy route

A routing policy is added to the bottom of the routing table when it is created. If you prefer to use one policy over another, you may want to move it to a different location in the routing policy table.

The option to use one of two routes happens when both routes are a match, for example `172.20.0.0/255.255.0.0` and `172.20.120.0/255.255.255.0`. If both of these routes are in the policy table, both can match a route to `172.20.120.112` but you consider the second one as a better match. In that case the best match route should be positioned before the other route in the policy table.

To change the position of a policy route in the table, go to *Router* > *Static* > *Policy Routes* and select *Move To* for the policy route you want to move.

Before/After	Select Before to place the selected Policy Route before the indicated route. Select After to place it following the indicated route.
Policy route ID	Enter the Policy route ID of the route in the Policy route table to move the selected route before or after.

Transparent mode static routing

FortiOS operating modes allow you to change the configuration of your FortiGate unit depending on the role it needs to fill in your network.

NAT/Route operating mode is the standard mode where all interfaces are accessed individually, and traffic can be routed between ports to travel from one network to another.

In transparent operating mode, all physical interfaces act like one interface. The FortiGate unit essentially becomes a bridge — traffic coming in over any interface is broadcast back out over all the interfaces on the FortiGate unit.

In transparent mode, there is no entry for routing at the main level of the menu on the web-based manager display as there is in NAT/Route mode. Routing is instead accessed through the network menu option.

To view the routing table in transparent mode, go to *System* > *Network* > *Routing Table*.

When viewing or creating a static route entry in transparent mode there are only three fields available.

Destination IP/Mask	The destination of the traffic being routed. The first entry is attempted first for a match, then the next, and so on until a match is found or the last entry is reached. If no match is found, the traffic will not be routed. Use 0.0.0.0 to match all traffic destinations. This is the default route.
Gateway	Specifies the next hop for the traffic. Generally the gateway is the address of a router on the edge of your network.
Priority	The priority is used if there is more than one match for a route. This allows multiple routes to be used, with one preferred. If the preferred route is unavailable the other routes can be used instead. Valid range of priority can be from 0 to 4 294 967 295. If more than one route matches and they have the same priority it becomes an ECMP situation and traffic is shared among those routes. See “Route priority” on page 280.

When configuring routing on a FortiGate unit in transparent mode, remember that all interfaces must be connected to the same subnet. That means all traffic will be coming from and leaving on the same subnet. This is important because it limits your static routing options to only the gateways attached to this subnet. For example, if you only have one router connecting your network to the Internet then all static routing on the FortiGate unit will use that gateway. For this reason static routing on FortiGate units in transparent mode may be a bit different, but it is not as complex as routing in NAT/Route mode.

Static routing example

This is an example of a typical small network configuration that uses only static routing.

This network is in a dentist office that includes a number of dentists, assistants, and office staff. The size of the office is not expected to grow significantly in the near future, and the network usage is very stable—there are no new applications being added to the network.

The users on the network are:

- admin staff - access to local patient records, and go online for billing purposes
- dentists - access and update local patient records, research online from desk
- assistants - access and update local patient records in exam rooms

The distinction here is mainly that only the admin staff and dentist's office proper need access to the internet—all the other traffic is local and doesn't need to need to leave the local network. Routing is only required for the outbound traffic, and the computers that have valid outbound traffic.

Only configuring routing on computers that need it will act as an additional layer of security by helping prevent malicious traffic from leaving the network.

This section includes the following topics:

Network layout and assumptions

The computers on the network are admin staff computers, dentist office computers, and dental exam room computers. While there are other devices on the local network such as printers, they do not need Internet access or any routing.

This networked office equipment includes 1 admin staff PC, 3 dentist PCs, and 5 exam room PCs. There are also a network printer, and a router on the network as well.

Assumptions about these computers, and network include:

- the FortiGate unit is a model with interfaces labeled port1 and port2
- the FortiGate unit has been installed and is configured in NAT/Route mode
- VDOMs are not enabled
- the computers on the network are running MS Windows software
- any hubs required in the network are not shown in the network diagram
- the network administrator has access to the ISP IP addresses, and is the super_admin administrator on the FortiGate unit

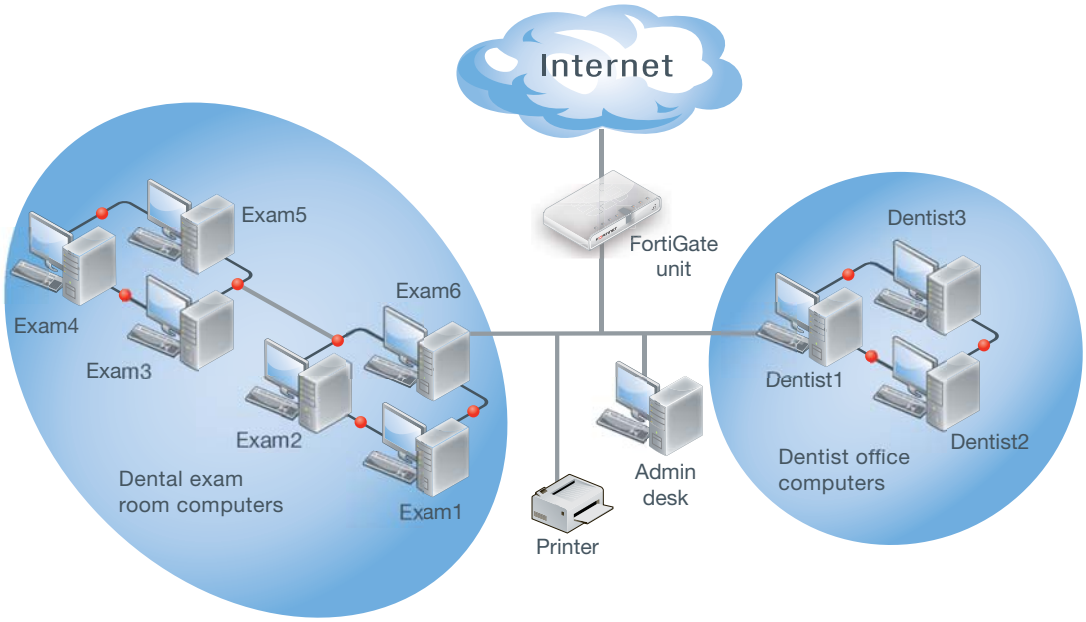

Table 6: Static routing example device names, IP addresses, and level of access

Device Name(s)	IP address	Need external access?
Router	192.168.10.1	YES
Admin	192.168.10.11	YES
Dentist1-3	192.168.10.21-23	YES
Exam1-5	192.168.10.31-35	NO
Printer	192.168.10.41	NO

General configuration steps

The steps to configuring routing on this network are:

1. Get your ISP information such as DNS, gateway, etc.
2. Configure FortiGate unit
3. Configure Admin PC and Dentist PCs
4. Testing network configuration

Get your ISP information such as DNS, gateway, etc.

Your local network connects to the Internet through your Internet Service Provider (ISP). They have IP addresses that you need to configure your network and routing.

The addresses needed for routing are your assigned IP address, DNS servers, and the gateway.

Configure FortiGate unit

The FortiGate unit will have two interfaces in use—one connected to the internal network and one connected to the external network. Port1 will be the internal interface, and port2 will be the external interface.

To configure the FortiGate unit:

1. Configure the internal interface (port1)
2. Configure the external interface (port2)
3. Configure networking information
4. Configure basic security policies
5. Configure static routing

Configure the internal interface (port1)

To configure the internal interface (port1) - web based manager

1. Go to *System* > *Network* > *port1* and select *Edit*.
2. Enter the following:

Addressing Mode	Manual
IP/Netmask	172.100.1.1/255.255.255.0
Administrative Access	HTTPS, PING, TELNET
Description	Internal network

To configure the internal interface (port1) - CLI

```
config system interface
  edit port1
    set IP 192.168.10.1 255.255.255.0
    set allowaccess https ping telnet
    set description "internal network"
  end
end
```

Configure the external interface (port2)

The external interface connects to your ISP's network. You need to know the IP addresses in their network that you should connect to. Use their addresses when you get them, however for this example we will assume the address your ISP gave you is 172.100.20.20 will connect to the gateway at 172.100.20.5 on their network, and their DNS servers are 172.11.22.33 and 172.11.22.34.

To configure the internal interface (port2) - web based manager

1. Go to *System* > *Network* > *port2* and select *Edit*.

2. Enter the following:

Addressing Mode	Manual
IP/Netmask	172.100.20.20/255.255.255.0
Administrative Access	HTTPS, PING, TELNET
Description	Internal network

To configure the internal interface (port2) - CLI

```
configure system interface
  edit port2
    set IP 172.100.20.20 255.255.255.0
    set allowaccess https ping telnet
    set description "internal network"
  end
end
```

Configure networking information

Networking information includes the gateway, and DNS servers. Your FortiGate unit requires a connection to the Internet for antivirus and other periodic updates.

To configure networking information - web-based manager

1. Go to *System* > *Network* > *Options*.
2. Enter the primary and secondary DNS addresses.
3. Select *Apply*.

To configure networking information - CLI

```
config system global
  set dns_1 172.11.22.33
  set dns_2 172.11.22.34
end
```

Configure basic security policies

For traffic to flow between the internal and external ports in both directions, two security policies are required as a minimum. More can be used to farther limit or direct traffic as needed, but will not be included here.

Before configuring the security policies, a firewall address group is configured for the PCs that are allowed Internet access. This prevents PC without Internet privileges from accessing the Internet.

The security policy assumptions are:

- Only the basic networking services have been listed as allowed for added security. Others can easily be added as the users require them.
- In this example to keep things simple, both incoming and outgoing security policies are the same. In a real network there are applications that are allowed out but not in, and vice versa.
- Endpoint control has been enabled to ensure that all computers on the local network are running FortiClient and those installs are up to date. This feature ensures added security on your local network without the need for the network administrator to continually bother users

to update their software. The FortiGate unit can store an up to date copy of the FortiClient software and offer a URL to it for users to install it if they need to.

To configure security policies - web-based manager

1. Go to *Firewall Objects* > *Address*.
2. Create a new Firewall Address entry for each of:

PC Name	IP Address	Interface
Admin	192.168.10.11	port1
Dentist1	192.168.10.21	port1
Dentist2	192.168.10.22	port1
Dentist3	192.168.10.23	port1

3. Go to *Firewall Objects* > *Address* > *Groups*.
4. Select *Create New*.
5. Name the group Internet_PCs.
6. Select Admin, Dentist1, Dentist2, and Dentist3 to be members of the group.
7. Select *OK*.
8. Go to *Policy* > *Policy* > *Policy*.
9. Select *Create New*.
10. Enter the following: DH - port2(external) -> port1(internal)

Source Interface/Zone	port2
Source Address	all
Destination Interface/Zone	port1
Destination Address	Internet_PCs
Schedule	always
Service	Multiple. Select *DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.*
Action	ACCEPT
Enable Endpoint Control Check	Enabled Enforce FortiClient AV Up-to-date
Log Allowed Traffic	Enabled

11. Select OK.
12. Select *Create New*.
13. Enter the following:

Source Interface/Zone	port1
Source Address	Internet_PCs
Destination Interface/Zone	port2
Destination Address	all
Schedule	always
Service	Multiple. Select *DHCP, DNS,FTP, HTTP, HTTPS, NTP, POP3, SMTP, SSH.*
Action	ACCEPT
Enable Endpoint Control Check	Enabled Enforce FortiClient AV Up-to-date
Log Allowed Traffic	Enabled

14. Select OK.

To configure security policies - CLI

```
config firewall address
  edit "Admin"
    set associated-interface "port1"
    set subnet 192.168.10.11 255.255.255.255
  next
  edit "Dentist1"
    set associated-interface "port1"
    set subnet 192.168.10.21 255.255.255.255
  next
  edit "Dentist2"
    set associated-interface "port1"
    set subnet 192.168.10.22 255.255.255.255
  next
  edit "Dentist3"
    set associated-interface "port1"
    set subnet 192.168.10.23 255.255.255.255
  end
config firewall addrgrp
  edit Internet_PCs
    set member Admin Dentist1 Dentist2 Dentist3
  end
config firewall policy
  edit 1
    set srcintf port1
    set dstintf port2
    set srcaddr Internet_PCs
```

```
    set dstaddr all
    set action accept
    set schedule always
    set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3"
        "SMTP" "SSH"
    set logtraffic enable
    set endpoint-check enable
    set label "Section2"
    set endpoint-restrict-check no-av db-outdated
  next
  edit 2
    set srcintf port2
    set dstintf port1
    set srcaddr all
    set dstaddr Internet_PCs
    set action accept
    set schedule always
    set service "DHCP" "DNS" "FTP" "HTTP" "HTTPS" "NTP" "POP3"
        "SMTP" "SSH"
    set logtraffic enable
    set endpoint-check enable
    set label "Section2"
    set endpoint-restrict-check no-av db-outdated
  end
end
```

Configure static routing

With the rest of the FortiGate unit configured, static routing is the last step before moving on to the rest of the local network. All traffic on the local network will be routed according to this static routing entry.

To configure Fortinet unit static routing - web-based manager

1. Go to *Routing* > *Static*.
2. Select *Edit* for the top route on the page.
3. Enter the following:

Destination IP/Mask	172.100.20.5
Device	port2
Gateway	172.100.20.5
Distance	10

4. Select *OK*.

To configure Fortinet unit static routing - CLI

```
configure routing static
  edit 1
    set gateway 172.100.20.5
    set distance 10
    set device port2
    set dst 0.0.0.0
  end
end
```

Configure Admin PC and Dentist PCs

With the router configured, next we need to configure the computers that need Internet access. These computers need routing to be configured on them. As the other computers do not require routing, they are not included here.

The procedure to configure these computers is the same. Repeat the following procedure for the corresponding PCs.

The Windows CLI procedure does not configure the DNS entries. It just adds the static routes.

To configure routing and DNS on Admin and Dentist PCs - Windows GUI

1. On PC, select *Start* > *Control Panel* > *Network Connections*.
2. Right click on the network connection to your local network that has a status of Connected, and select *Properties*.
3. Under the *General* tab, from the list select *TCP/IP*, and *Properties*.
4. Under *Gateway*, enter the FortiGate unit address (192.168.10.1).
5. Enter the primary and secondary DNS server addresses from your ISP (172.11.22.33 and 172.11.22.34).
6. Select *OK*.

To configure routing on Admin and Dentist PCs - Windows CLI

1. On PC, select *Start* > *Run*, enter "`cmd`", and select *OK*.
2. At the command prompt, type

   ```
   route ADD 0.0.0.0 MASK 0.0.0.0 172.100.20.5 METRIC 10
   route ADD 192.168.10.0 MASK 255.255.255.0 192.168.10.1 METRIC 5
   ```
3. Confirm these routes have been added. Type:

   ```
   route PRINT
   ```

   If you do not see the two routes you added, try adding them again paying attention to avoid spelling mistakes.
4. Test that you can communicate with other computers on the local network, and with the Internet. If there are no other computers on the local network, connect to the FortiGate unit.

Configure other PCs on the local network

The PCs on the local network without Internet access (the exam room PCs) can be configured now.

As this step does not require any routing, details have not been included.

Testing network configuration

There are three tests to run on the network to ensure proper connectivity.

- To test that PCs on the local network can communicate
- Test that Internet_PCs on the local network can access the Internet.
- Test that non-Internet_PCs can not access the Internet.

To test that PCs on the local network can communicate

1. Select any two PCs on the local network, such as Exam4 and Dentist3.
2. On the Exam4 PC, at the command prompt enter `ping 192.168.10.23.`

   The output from this command should appear similar to the following.

```
Pinging 192.168.10.23 with 32 bytes of data:

Reply from 192.168.10.23: bytes=32 time<1m TTL=255
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
Reply from 192.168.10.23: bytes=32 time<1m TTL=255
```

3. At the command prompt enter `exit` to close the window.
4. On the Dentist3 PC, at the command prompt enter `ping 192.168.10.34.`

   The output from this command should appear similar to the following.

```
Pinging 192.168.10.34 with 32 bytes of data:

Reply from 192.168.10.34: bytes=32 time<1m TTL=255
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
Reply from 192.168.10.34: bytes=32 time<1m TTL=255
```

5. At the command prompt enter `exit` to close the window.
6. Repeat these steps for all PCs on the local network.

   If the output does not appear similar to above, there is a problem with the network configuration between these two PCs.

To test that Internet_PCs can reach the Internet

The easiest way to access the internet is with an Internet browser. However, if that doesn't work its best to do a traceroute to see at what point the problem is. This can help determine if it is a networking problem such as cabling, or if its an access problem such as this PC not having Internet access.

1. Select any PC on the local network that is supposed to have Internet access, such as Admin.
2. On the Admin PC, open an Internet browser and attempt to access a website on the Internet such as http://www.fortinet.com.

   If this is successful, this PC has Internet access.

3. If step 2 was not successful, at the command prompt on the PC enter `traceroute 22.11.22.33`.

   The output from this command should appear similar to:

```
Pinging 22.11.22.33 with 32 bytes of data:

Reply from 22.11.22.33: bytes=32 time<1m TTL=255
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
Reply from 22.11.22.33: bytes=32 time<1m TTL=255
```

Advanced static example: ECMP failover and load balancing

Equal Cost Multi-Path (ECMP) load balancing and failover are methods that extend basic static routing. They allow you to use your network bandwidth more effectively and with less down time than if you used basic static routing alone.

The concepts in this section include:

- Equal-Cost Multi-Path (ECMP)
- Configuring interface status detection for gateway load balancing
- Configuring spillover or usage-based ECMP
- Configuring weighted static route load balancing

Equal-Cost Multi-Path (ECMP)

FortiOS uses equal-cost multi-path (ECMP) to distribute traffic to the same destination such as the Internet or another network. Using ECMP you can add multiple routes to the destination and give each of those routes the same distance and priority.

If multiple routes to the same destination have the same priority but different distances, the route with the lowest distance is used. If multiple routes to the same destination have the same distance but different priorities, the route with the lowest priority is used. Distance takes precedence over priority. If multiple routes to the same destination have different distances and different priorities, the route with the lowest distance is always used even if it has the highest priority.

If more than one ECMP route is available, you can configure how the FortiGate unit selects the route to be used for a communication session. If only one ECMP route is available (for example, because an interface cannot process traffic because interface status detection does not receive a reply from the configured server) then all traffic uses this route.

Previous versions of FortiOS provided source IP-based load balancing for ECMP routes, but now FortiOS includes three configuration options for ECMP route failover and load balancing:

Source based (also called source IP based)	The FortiGate unit load balances sessions among ECMP routes based on the source IP address of the sessions to be load balanced. This is the default load balancing method. No configuration changes are required to support source IP load balancing.

Weighted Load Balance (also called weight-based)	The FortiGate unit load balances sessions among ECMP routes based on weights added to ECMP routes. More traffic is directed to routes with higher weights. After selecting weight-based you must add weights to static routes.
Spillover (also called usage-based)	The FortiGate unit distributes sessions among ECMP routes based on how busy the FortiGate interfaces added to the routes are. After selecting spill-over you add route Spillover Thresholds to interfaces added to ECMP routes. The FortiGate unit sends all ECMP-routed sessions to the lowest numbered interface until the bandwidth being processed by this interface reaches its spillover threshold. The FortiGate unit then spills additional sessions over to the next lowest numbered interface. The Spillover Thresholds range is 0-2097000 KBps.

You can configure only one of these ECMP route failover and load balancing methods in a single VDOM. If your FortiGate unit is configured for multiple VDOM operation, each VDOM can have its own ECMP route failover and load balancing configuration.

To configure the ECMP load balancing method from the web-based manager

1. Go to *Router* > *Static* > *Settings*.
2. Set *ECMP Load Balance Method* to *Source IP based*, *Weighted Load Balance*, or *Spillover.*

To configure the ECMP load balancing method from the CLI

For example, to set the load balancing method to usage-based, enter the following:

```
config system settings
  set v4-ecmp-mode usage-based
end
```

ECMP routing of simultaneous sessions to the same destination IP address

When the FortiGate unit selects an ECMP route for a session, a route cache is created that matches the route with the destination IP address of the session. All new sessions to the same destination IP address use the same route until the route is flushed from the cache. Routes are flushed from the cache after a period of time when no new sessions to the destination IP address are received.

The route cache improves FortiGate unit routing performance by reducing how often the FortiGate unit looks up routes in the routing table.

If the FortiGate unit receives a large number of sessions with the same destination IP address, because all of these sessions will be processed by the same route, it may appear that sessions are not distributed according to the ECMP route failover and load balancing configuration.

Configuring interface status detection for gateway load balancing

Interface status detection is used for ECMP route failover and load balancing. Interface status detection consists of the unit confirming that packets sent from an interface result in a response from a server. You can use up to three different protocols to confirm that an interface can connect to the server. Usually the server is the next-hop router that leads to an external network or the Internet. Interface status detection sends a packet using the configured protocols. If a response is received from the server, the unit assumes the interface can connect to the network. If a response is not received, the unit assumes that the interface cannot connect to the network.

Since it is possible that a response may not be received, even if the server and the network are operating normally, the dead gateway detection configuration controls the time interval between testing the connection to the server and the number of times the test can fail before the unit assumes that the interface cannot connect to the server.

As long as the unit receives responses for at least one of the protocols that you select, the unit assumes the server is operating and can forward packets. Responding to more than one protocol does not enhance the status of the server or interface.

To configure gateway failover detection for an interface

1. Go to *Router* > *Static* > *Settings*.
2. Under *Dead Gateway Detection*, select *Create New*.
3. Enter the following information:

Interface		Select the interface to test.
Gateway IP		Enter the IP address of the gateway.
Ping Server		Enter the IP address of the server to test.
Detect Protocol		Select one of the following protocols.
	ICMP Ping	Use standard ICMP ping to confirm that the server is responding. Ping confirms that the server can respond to an ICMP ping request.
	TCP Echo	Use TCP echo to confirm that the server is responding. Select this option if the server is configured to provide TCP echo services. In some cases a server may be configured to reply to TCP echo requests but not to reply to ICMP pings. TCP echo uses TCP packets on port number 7 to send a text string to the server and expect an echo reply back from the server. The echo reply just echoes back the same text to confirm that the server can respond to TCP requests. FortiGate units do not recognize RST (reset) packets from TCP Echo servers as normal TCP echo replies. If the unit receives an RST response to a TCP echo request, the unit assumes the server is unreachable.
	UDP Echo	Use UDP echo to detect the server. Select this option if the server is configured to provide UDP echo services. In some cases a server may be configured to reply to UDP echo requests but not to reply ICMP pings. UDP echo uses UDP packets on port number 7 to send a text string to the server and expects an echo reply from the server. The echo reply just echoes back the same text to confirm that the server can respond to UDP requests.
Ping Interval		Enter the interval between pings, in seconds.
Failover Threshold		Enter the number of times the test can fail before the unit assumes that the interface cannot connect to the server.
HA Priority		Set the HA priority, if configuring an HA cluster.

4. Select *OK*.

To configure gateway failover detection for an interface - CLI

```
config router gwdetect
  edit port1
    set protocol ping
    set server 10.10.10.1
    set interval 5
    set failtime 5
  end
```

Configuring spillover or usage-based ECMP

Spill-over or usage-based ECMP routes new sessions to interfaces that have not reached a configured bandwidth limit (called the *Spillover Threshold* or a route-spillover threshold). To configure spill-over or usage-based ECMP routing, you enable spill-over ECMP, add ECMP routes, and add a *Spillover Threshold* to the interfaces used by the ECMP routes. Set the *Spillover Thresholds* to limit the amount of bandwidth processed by each interface. The range is 0 to 2 097 000 Kbps. The threshold counts only outgoing traffic.

With spill-over ECMP routing configured, the FortiGate unit routes new sessions to an interface used by an ECMP route until that interface reaches its *Spillover Threshold*. Then, when the threshold of that interface is reached, new sessions are routed to one of the other interfaces used by the ECMP routes.

To add Spillover Thresholds to interfaces - web-based manager

Use the following steps to enable usage based ECMP routing, add Spillover Thresholds to FortiGate interfaces port3 and port4, and then to configure EMCP routes with device set to port3 and port4.

1. Go to *Router* > *Static* > *Settings*.
2. Set *ECMP Load Balance Method* to *Spillover*.
3. Go to *Router* > *Static* > *Static Route*s.
4. Add ECMP routes for `port3` and `port4`.

Destination IP/Mask	192.168.20.0/24
Device	port3
Gateway	172.20.130.3
Advanced	
Distance	10

Destination IP/Mask	192.168.20.0/24
Device	port4
Gateway	172.20.140.4
Advanced	
Distance	10

5. Go to *System* > *Network* > *Settings*.
6. Edit `port3` and `port4` and add the following spillover-thresholds:

Interface	port3
Spillover Threshold	100

Interface	port4
Spillover Threshold	200

To add Spillover Thresholds to interfaces - CLI

```
config system settings
  set v4-ecmp-mode usage-based
end
config router static
  edit 1
    set device port3
    set dst 192.168.20.0 255.255.255.0
    set gateway 172.20.130.3
  next
  edit 2
    set device port4
    set dst 192.168.20.0 255.255.255.0
    set gateway 172.20.140.4
  end
config system interface
  edit port3
    set spillover-threshold 100
  next
  edit port4
    set spillover-threshold 200
  end
```

Detailed description of how spill-over ECMP selects routes

When you add ECMP routes they are added to the routing table in the order displayed by the routing monitor or by the `get router info routing-table static` command. This order is independent of the configured bandwidth limit.

The FortiGate unit selects an ECMP route for a new session by finding the first route in the routing table that sends the session out a FortiGate unit interface that is not processing more traffic that its configured route spill-over limit.

A new session to a destination IP address that already has an entry in the routing cache is routed using the route already added to the cache for that destination address. See “ECMP routing of simultaneous sessions to the same destination IP address” on page 298.

For example, consider a FortiGate unit with interfaces port3 and port4 both connected to the Internet through different ISPs. ECMP routing is set to usage-based and route spillover for to 100 Kbps for port3 and 200 Kbps for port4. Two ECMP default routes are added, one for port3 and one for port4.

If the route to port3 is higher in the routing table than the route to port4, the FortiGate unit sends all default route sessions out port3 until port3 is processing 100Kbps of data. When port3 reaches its configured bandwidth limit, the FortiGate unit sends all default route sessions out

port4. When the bandwidth usage of port3 falls below 100Kbps, the FortiGate again sends all default route sessions out port3.

New sessions with destination IP addresses that are already in the routing cache; however, use the cached routes. This means that even if port3 is exceeding its bandwidth limit, new sessions can continue to be sent out port3 if their destination addresses are already in the routing cache. As a result, new sessions are sent out port4 only if port3 exceeds its bandwidth limit and if the routing cache does not contain a route for the destination IP address of the new session.

Also, the switch over to port4 does not occur as soon as port3 exceeds its bandwidth limit. Bandwidth usage has to exceed the limit for a period of time before the switch over takes place. If port3 bandwidth usage drops below the bandwidth limit during this time period, sessions are not switched over to port4. This delay reduces route flapping.

FortiGate usage-based ECMP routing is not actually load balancing, since routes are not distributed evenly among FortiGate interfaces. Depending on traffic volumes, most traffic would usually be processed by the first interface with only spillover traffic being processed by other interfaces.

If you are configuring usage-based ECMP in most cases you should add spillover thresholds to all of the interfaces with ECMP routes. The default spillover threshold is 0 which means no bandwidth limiting. If any interface has a spillover threshold of 0, no sessions will be routed to interfaces lower in the list unless the interface goes down or is disconnected. An interface can go down if *Detect interface status for Gateway Load Balancing* does not receive a response from the configured server.

Determining if an interface has exceeded its Spillover Threshold

You can use the `diagnose netlink dstmac list` CLI command to determine if an interface is exceeding its Spillover Threshold. If the command displays *over_bps=1* the interface is exceeding its threshold. If *over_bps=0* the interface has not exceeded its threshold.

```
dev=Wifi mac=00:00:00:00:00:00 src-vis-os src-vis-host src-vis-user
rx_tcp_mss=0 tx_tcp_mss=0 overspill-threshold=0 bytes=0 over_bps=0
sampler_rate=0
```

Configuring weighted static route load balancing

Configure weighted load balancing to control how the FortiGate unit distributes sessions among ECMP routes by adding weights for each route. Add higher weights to routes that you want to load balance more sessions to.

With the ECMP load balancing method set to weighted, the FortiGate unit distributes sessions with different destination IPs by generating a random value to determine the route to select. The probability of selecting one route over another is based on the weight value of each route. Routes with higher weights are more likely to be selected.

Large numbers of sessions are evenly distributed among ECMP routes according to the route weight values. If all weights are the same, sessions are distributed evenly. The distribution of a small number of sessions; however, may not be even. For example, its possible that if there are two ECMP routes with the same weight; two sessions to different IP addresses could use the same route. On the other hand, 10,000 sessions with different destination IPs should be load balanced evenly between two routes with equal rates. The distribution could be 5000:5000 or 50001:4999. Also, 10 000 sessions with different destination IP addresses should be load balanced as 3333:6667 if the weights for the two routes are 100 and 200.

Weights only affect how routes are selected for sessions to new destination IP addresses. New sessions to IP addresses already in the routing cache are routed using the route for the session already in the cache. So in practice sessions will not always be distributed according to the routing weight distribution.

To add weights to static routes from the web-based manager

1. Go to *Router* > *Static* > *Settings*.
2. Set *ECMP Load Balance Method* to *Weighted Load Balance*.
3. Go to *Router* > *Static* > *Static Routes*.
4. If needed, add new static routes, for example:

Destination IP/Mask	192.168.20.0/24
Device	port1
Gateway	172.20.110.1
Distance	10

Destination IP/Mask	192.168.20.0/24
Device	port2
Gateway	172.20.120.2
Distance	10

5. Go to *Router* > *Static* > *Settings*.
6. Select a number next to an interface name, and choose *Edit* to change it.

For example, set the weight of port1 to 100 and the weight of port2 to 200.

Dynamic Routing Overview

This section provides an overview of dynamic routing, and how it compares to static routing. For details on various dynamic routing protocols, see the following chapters for detailed information.

The following topics are included in this section:

- What is dynamic routing?
- Comparison of dynamic routing protocols
- Choosing a routing protocol
- Dynamic routing terminology
- IPv6 in dynamic routing

What is dynamic routing?

Dynamic routing uses a dynamic routing protocol to automatically select the best route to put into the routing table. So instead of manually entering static routes in the routing table, dynamic routing automatically receives routing updates, and dynamically decides which routes are best to go into the routing table. Its this intelligent and hands-off approach that makes dynamic routing so useful.

Dynamic routing protocols vary in many ways and this is reflected in the various administrative distances assigned to routes learned from dynamic routing. These variations take into account differences in reliability, speed of convergence, and other similar factors. For more information on these administrative distances, see “Multipath routing and determining the best route” on page 279.

This section includes:

- Comparing static and dynamic routing
- Dynamic routing protocols
- Minimum configuration for dynamic routing

Comparing static and dynamic routing

A common term used to describe dynamic routing is convergence. Convergence is the ability to work around network problems and outages — for the routing to come together despite obstacles. For example, if the main router between two end points goes down, convergence is the ability to find a way around that failed router and reach the destination. Static routing has zero convergence beyond trying the next route in its limited local routing table — if a network administrator doesn’t fix a routing problem manually, it may never be fixed, resulting in a downed network. Dynamic routing solves this problem by involving routers along the route in the decision-making about the optimal route, and using the routing tables of these routers for potential routes around the outage. In general, dynamic routing has better scalability, robustness, and convergence. However, the cost of these added benefits include more

complexity and some overhead: the routing protocol uses some bandwidth for its own administration.

Table 7: Comparing static and dynamic routing

Feature	Static Routing	Dynamic Routing
Hardware support	Supported by all routing hardware	May require special, more expensive routers
Router Memory Required	Minimal	Can require considerable memory for larger tables
Complexity	Simple	Complex
Overhead	None	Varying amounts of bandwidth used for routing protocol updates
Scalability	Limited to small networks	Very scalable, better for larger networks
Robustness	None - if a route fails it has to be fixed manually	Robust - traffic routed around failures automatically
Convergence	None	Varies from good to excellent

Dynamic routing protocols

A dynamic routing protocol is an agreed-on method of routing that the sender, receiver, and all routers along the path (route) support. Typically the routing protocol involves a process running on all computers and routers along that route to enable each router to handle routes in the same way as the others. The routing protocol determines how the routing tables are populated along that route, how the data is formatted for transmission, and what information about a route is included with that route. For example RIP, and BGP use distance vector algorithms, where OSPF uses a shortest path first algorithm. Each routing protocol has different strengths and weaknesses — one protocol may have fast convergence, while another may be very reliable, and a third is very popular for certain businesses like Internet Service Providers (ISPs).

Dynamic routing protocols are different from each other in a number of ways, such as:

- Classful versus classless routing protocols
- Interior versus exterior routing protocols
- Distance vector versus link-state protocols

Classful versus classless routing protocols

Classful or classless routing refers to how the routing protocol handes the IP addresses. In classful addresses there is the specific address, and the host address of the server that address is connected to. Classless addresses use a combination of IP address and netmask.

Classless Inter-Domain Routing (CIDR) was introduced in 1993 (originally with RFC 1519 and most recently with RFC 4632) to keep routing tables from getting too large. With Classful routing, each IP address requires its own entry in the routing table. With Classless routing, a series of addresses can be combined into one entry potentially saving vast amounts of space in routing tables.

Current routing protocols that support classless routing out of necessity include RIPv2, BGP, IS-IS, and OSPF. Older protocols such as RIPv1 do not support CIDR addresses.

Interior versus exterior routing protocols

The names ***interior*** and ***exterior*** are very descriptive. Interior routing protocols are designed for use within a contained network of limited size, whereas exterior routing protocols are designed to link multiple networks together. They can be used in combination in order to simplify network administration. For example, a network can be built with only border routers of a network running the exterior routing protocol, while all the routers on the network run the interior protocol, which prevents them from connecting outside the network without passing through the border. Exterior routers in such a configuration must have both exterior and interior protocols, to communicate with the interior routers and outside the network.

Nearly all routing protocols are interior routing protocols. Only BGP is commonly used as an exterior routing protocol.

You may see interior gateway protocol (IGP) used to refer to interior routing protocols, and exterior gateway protocol (EGP) used to refer to interior routing protocols.

Distance vector versus link-state protocols

Every routing protocol determines the best route between two addresses using a different method. However, there are two main algorithms for determining the best route — Distance vector and Link-state.

Distance vector protocols

In distance vector protocols, routers are told about remote networks through neighboring routers. The distance part refers to the number of hops to the destination, and in more advanced routing protocols these hops can be weighted by factors such as available bandwidth and delay. The vector part determines which router is the next step along the path for this route. This information is passed along from neighboring routers with routing update packets that keep the routing tables up to date. Using this method, an outage along a route is reported back along to the start of that route, ideally before the outage is encountered.

On distance vector protocols, RFC 1058 which defines RIP v1 states the following:

> Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.

There are four main weaknesses inherent in the distance vector method. Firstly, the routing information is not discovered by the router itself, but is instead reported information that must be relied on to be accurate and up-to-date. The second weakness is that it can take a while for the information to make its way to all the routers who need the information — in other words it can have slow convergence. The third weakness is the amount of overhead involved in passing these updates all the time. The number of updates between routers in a larger network can significantly reduce the available bandwidth. The fourth weakness is that distance vector protocols can end up with routing-loops. Routing loops are when packets are routed for ever around a network, and often occur with slow convergence. The bandwidth required by these infinite loops will slow your network to a halt. There are methods of preventing these loops however, so this weakness is not as serious as it may first appear.

Link-state protocols

Link-state protocols are also known as shortest path first protocols. Where distance vector uses information passed along that may or may not be current and accurate, in link-state protocols each router passes along only information about networks and devices directly connected to it. This results in a more accurate picture of the network topology around your router, allowing it to make better routing decisions. This information is passed between routers using link-state advertisements (LSAs). To reduce the overhead, LSAs are only sent out when information

changes, compared to distance vector sending updates at regular intervals even if no information has changed. The more accurate network picture in link-state protocols greatly speed up convergence and avoid problems such as routing-loops.

Minimum configuration for dynamic routing

Dynamic routing protocols do not pay attention to routing updates from other sources, unless you specifically configure them to do so using CLI redistribute commands within each routing protocol.

The minimum configuration for any dynamic routing to function is to have dynamic routing configured on one interface on the FortiGate unit, and one other router configured as well. Some protocols require larger networks to function as designed.

Table 8: Minimum configuration based on dynamic protocol

	BGP	RIP	OSPF / IS-IS
Interface	yes	yes	yes
Network	yes	yes	yes
AS	local and neighbor	no	yes
Neighbors	at least one	at least one	at least one
Version	no	yes	no
Router ID	no	no	yes

Comparison of dynamic routing protocols

Each dynamic routing protocol was designed to meet a specific routing need. Each protocol does some things well, and other things not so well. For this reason, choosing the right dynamic routing protocol for your situation is not an easy task.

Features of dynamic routing protocols

Each protocol is better suited for some situations over others.

Choosing the best dynamic routing protocol depends on the size of your network, speed of convergence required, the level of network maintenance resources available, what protocols the networks you connect to are using, and so on. For more information on these dynamic routing protocols, see “Routing Information Protocol (RIP)” on page 319, “Border Gateway Protocol (BGP)” on page 358, “Open Shortest Path First (OSPF)” on page 396, and “Intermediate System to Intermediate System Protocol (IS-IS)” on page 438.

Table 9: Comparing RIP, BGP, and OSPF dynamic routing protocols

Protocol	RIP	BGP	OSPF / IS-IS
Routing algorithm	Distance Vector, basic	Distance Vector, advanced	Link-state
Common uses	Small non-complex networks	Network backbone, ties multinational offices together	Common in large, complex enterprise networks

Table 9: Comparing RIP, BGP, and OSPF dynamic routing protocols (Continued)

Protocol	RIP	BGP	OSPF / IS-IS
Strengths	Fast and simple to implement Near universal support Good when no redundant paths	Graceful restart BFD support Only needed on border routers Summarize routes	Fast convergence Robust Little management overhead No hop count limitation Scalable
Weakness	Frequent updates can flood network Slow convergence Maximum 15 hops may limit network configuration	Required full mesh in large networks can cause floods Route flap Load-balance multi-homed networks Not available on low-end routers	Complex No support for unequal cost multipath routing Route summary can require network changes
Authentication	Optional authentication using text string or MD5 password. (RIP v1 has no authentication)		
IPv6 Support	Only in RIPng	Only in BGP4+	Only in OSPF6 / Integrated IS-IS

Routing protocols

Routing Information Protocol (RIP) uses classful routing, as well as incorporating various methods to stop incorrect route information from propagating, such as the poisoned horizon method. However, on larger networks its frequent updates can flood the network and its slow convergence can be a problem.

Border Gateway Protocol (BGP) has been the core Internet backbone routing protocol since the mid 1990s, and is the most used interior gateway protocol (IGP). However, some configurations require full mesh connections which flood the network, and there can be route flap and load balancing issues for multihomed networks.

Open Shortest Path First (OSPF) is commonly used in large enterprise networks. It is the protocol of choice mainly due to its fast convergence. However, it can be complicated to setup properly.

Intermediate System to Intermediate System (IS-IS) Protocol allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) not intended to be used between Autonomous Systems (ASes). IS-IS is a link state protocol well-suited to smaller networks that is in widespread use and has near universal support on routing hardware.

Multicast addressing is used to broadcast from one source to many destinations efficiently. Protocol Independent Multicast (PIM) is the protocol commonly used in enterprises, multimedia content delivery, and stock exchanges.

Routing algorithm

Each protocol uses a slightly different algorithm for choosing the best route between two addresses on the network. The algorithm is the “intelligent” part of a dynamic protocol because the algorithm is responsible for deciding which route is best and should be added to the local routing table. RIP and BGP use distance vector algorithms, where OSPF and IS-IS use link-state or a shortest path first algorithm.

Vector algorithms are essentially based on the number of hops between the originator and the destination in a route, possibly weighting hops based on how reliable, fast, and error-free they are.

The link-state algorithm used by OSPF and IS-IS is called the Dijkstra algorithm. Link-state treats each interface as a link, and records information about the state of the interface. The Dijkstra algorithm creates trees to find the shortest paths to the routes it needs based on the total cost of the parts of the routes in the tree.

For more information on the routing algorithm used, see “Distance vector versus link-state protocols” on page 306.

Authentication

If an attacker gains access to your network, they can masquerade as a router on your network to either gain information about your network or disrupt network traffic. If you have a high quality firewall configured, it will help your network security and stop many of this type of threat. However, the main method for protecting your routing information is to use authentication in your routing protocol. Using authentication on your FortiGate unit and other routers prevents access by attackers — all routers must authenticate with passwords, such as MD5 hash passwords, to ensure they are legitimate routers.

When configuring authentication on your network, ensure you configure it the same on all devices on the network. Failure to do so will create errors and outages as those forgotten devices fail to connect to the rest of the network.

For example, to configure an MD5 key of `123` on an OSPF interface called `ospf_test`, enter the following CLI command:

```
config router ospf
  config ospf-interface
    edit ospf_test
      set authentication md5
      set md5-key 123
    end
  end
```

Convergence

Convergence is the ability of a networking protocol to re-route around network outages. Static routing cannot do this. Dynamic routing protocols can all converge, but take various amounts of time to do this. Slow convergence can cause problems such as network loops which degrade network performance.

You may also hear robustness and redundancy used to describe networking protocols. In many ways they are the same thing as convergence. Robustness is the ability to keep working even though there are problems, including configuration problems as well as network outages. Redundancy involves having duplicate parts that can continue to function in the event of some malfunction, error, or outage. It is relatively easy to configure dynamic routing protocols to have backup routers and configurations that will continue to function no matter the network problem short of a total network failure.

IPv6 Support

IPv4 addressing is in common use everywhere around the world. IPv6 has much larger addresses and it is used by many large companies and government departments. IPv6 is not as common as IPv4 yet, but more companies are adopting it.

If your network uses IPv6, your dynamic routing protocol must support it. None of the dynamic routing protocols originally supported IPv6, but they all have additions, expansions, or new versions that do support IPv6. For more information, see “RIP and IPv6” on page 320, “BGP and IPv6” on page 359, “OSPFv3 and IPv6” on page 397, or “Integrated IS-IS” on page 444.

When to adopt dynamic routing

Static routing is more than enough to meet your networking needs when you have a small network. However, as your network grows, the question you need to answer is at what point do you adopt dynamic routing in your networking plan and start using it in your network? The main factors in this decision are typically:

- Budget
- Current network size and topology
- Expected network growth
- Available resources for ongoing maintenance

Budget

When making any business decision, the budget must always be considered. Static routing does not involve special hardware, fancy software, or expensive training courses.

Dynamic routing can include all of these extra expenses. Any new hardware, such as routers and switches, will need to support your chosen routing protocols. Network management software and routing protocol drivers may be necessary as well to help configure and maintain your more complex network. If the network administrators are not well versed in dynamic routing, either a training course or some hands-on learning time must be budgeted so they can administer the new network with confidence. Together, these factors can impact your budget.

Additionally, people will always account for network starting costs in the budgets, but usually leave out the ongoing cost of network maintenance. Any budget must provide for the hours that will be spent on updating the network routing equipment, and fixing any problems. Without that money in the budget, you may end up back at static routing before you know it.

Current network size and topology

As stated earlier static routing works well on small networks. At those networks get larger, routing takes longer, routing tables get very large, and general performance isn’t what it could be.

Topology is a concern as well. If all your computers are in one building, its much easier to stay with static routing longer. However, connecting a number of locations will be easier with the move to dynamic routing.

If you have a network of 20 computers, you can still likely use static routing. If those computers are in two or three locations, static routing will still be a good choice for connecting them. Also, if you just connect to your ISP and don’t worry about any special routing to do that, you are likely safe with just static routing.

If you have a network of 100 computers in one location, you can use static routing but it will be getting slower, more complex, and there won’t be much room for expansion. If those 100 computers are spread across three or more locations, dynamic routing is the way to go.

If you have 1000 computers, you definitely need to use dynamic routing no matter how many locations you have.

Hopefully this section has given you an idea of what results you will likely experience from different sized networks using different routing protocols. Your choice of which dynamic routing protocol to use is partly determined by the network size, and topology.

Expected network growth

You may not be sure if your current network is ready for dynamic routing. However, if you are expecting rapid growth in the near future, it is a good idea to start planning for that growth now so you are ready for the coming expansion.

Static routing is very labor intensive. Each network device's routing table needs to be configured and maintained manually. If there is a large number of new computers being added to the network, they each need to have the static routing table configured and maintained. If devices are being moved around the network frequently, they must also be updated each time.

Instead, consider putting dynamic routing in place before those new computers are installed on the network. The installation issues can be worked out with a smaller and less complex network, and when those new computers or routers are added to the network there will be nowhere near the level of manual configuration required. Depending on the level of growth, this labor savings can be significant. For example, in an emergency you can drop a new router into a network or AS, wait for it to receive the routing updates from its neighbors, and then remove one of the neighbors. While the routes will not be the most effective possible, this method is much less work than static routing in the same situation, with less chance of mistakes.

Also, as your network grows and you add more routers, those new routers can help share the load in most dynamic routing configurations. For example if you have 4 OSPF routers and 20,000 external routes those few routers will be overwhelmed. But in a network with 15 OSPF routers they will better be able to handle that number of routes. Be aware though that adding more routers to your network will increase the amount of updates sent between the routers, which will use up a greater part of your bandwidth and use more bandwidth overall.

Available resources for ongoing maintenance

As touched on in the budget section, there must be resources dedicated to ongoing network maintenance, upgrades, and troubleshooting. These resources include administrator hours to configure and maintain the network, training for the administrator if needed, extra hardware and software as needed, and possible extra staff to help the administrator in emergencies. Without these resources, you will quickly find the network reverting to static routing out of necessity. This is because:

- Routing software updates will require time.
- Routing hardware updates will require time.
- Office reorganizations or significant personnel movement will require time from a networking point of view.
- Networking problems that occur, such as failed hardware, require time to locate and fix the problem.

If the resources to accomplish these tasks are not budgeted, they will either not happen or not happen at the required level to continue operation. This will result in both the network administration staff and the network users being very frustrated.

A lack of maintenance budget will also result in increasingly heavy reliance on static routing as the network administrators are forced to use quick fixes for problems that come up. This invariably involves going to static routing, and dropping the more complex and time-consuming dynamic routing.

Choosing a routing protocol

One of that hardest decisions in routing can be choosing which routing protocol to use on your network. It can be easy to decide when static routing will not meet your needs, but how can you tell which dynamic routing protocol is best for your network and situation?

Here is a brief look at the routing protocols including their strongest and weakest points. The steps to choosing your routing protocol are:

1. Answer questions about your network
2. Dynamic routing terminology
3. Evaluate your chosen protocol
4. Implement your dynamic routing protocol

Answer questions about your network

Before you can decide what is best for your situation, you need to examine what the details of your situation are such as what you have for budget, equipment, and users.

The following questions will help you form a clear idea of your routing needs:

How many computers or devices are on your network?

It matters if you only have a few computers, or if you have many and if they are all at one location or not as well. All routing protocols can be run on any sized network, however it can be inefficient to run some on very small networks. However, routers and network hardware that support dynamic routing can be more expensive than more generic routers for static routing.

What applications typically run over the network?

Finding out what application your users are running will help you determine their needs and the needs of the network regarding bandwidth, quality of service, and other such issues.

What level of service do the users expect from the network?

Different network users have different expectations of the network. Its not critical for someone surfing the Internet to have 100% uptime, but it is required for a stock exchange network or a hospital.

Is there network expansion in your near future?

You may have a small network now, but if it will be growing quickly, you should plan for the expected size so you don't have to chance technologies again down the road.

What routing protocols do your networks connect to?

This is most often how routing protocol decisions are made. You need to be able to communicate easily with your service provider and neighbors, so often people simply use what everyone else is using.

Is security a major concern?

Some routing protocols have levels of authentication and other security features built in. Others do not. If security is important to you, be aware of this.

What is your budget — both initial and maintenance?

More robust and feature laden routing protocols generally mean more resources are required to keep them working well. Also more secure configurations require still more resources. This includes both set up costs, as well as ongoing maintenance costs. Ignore these costs at the risk of having to drop the adoption of the new routing protocol mid-change.

Evaluate your chosen protocol

Once you have examined the features of the routing protocols listed above and chosen the one that best meets your needs, you can set up an evaluation or test install of that protocol.

The test install is generally set up in a sandbox configuration so it will not affect critical network traffic. The aim of the test install is to prove that it will work on a larger scale on your network. So be sure that the test install mirrors your larger network well enough for you to discover any problems. If its too simplistic, these problems may not appear.

If your chosen protocol does not meet your goals choose a different protocol and repeat the evaluation process until either a protocol meets your needs, or you change your criteria.

Implement your dynamic routing protocol

You have examined your needs, selected the best matching dynamic routing protocol, tested it, and now you are ready to implement it with confidence.

This guide will help you configure your FortiGate unit to support your chosen dynamic routing protocol. Refer to the various sections in this guide as needed during your implementation to help ensure a smooth transition. Examples for each protocol have been included to show proper configurations for different types of networks.

Dynamic routing terminology

Dynamic routing is a complex subject. There are many routers on different networks and all can be configured differently. It become even more complicated when you add to this each routing protocol having slightly different names for similar features, and many configurable features for each protocol.

To better understand dynamic routing, here are some explanations of common dynamic routing terms.

- Aggregated routes and addresses
- Autonomous system (AS)
- Area border router (ABR)
- Neighbor routers
- Route maps
- Access lists
- Bi-directional forwarding detection (BFD)

For more details on a term as it applies to a dynamic routing protocol, see one of “Border Gateway Protocol (BGP)” on page 358, “Routing Information Protocol (RIP)” on page 319, or “Open Shortest Path First (OSPF)” on page 396.

Aggregated routes and addresses

Just as an aggregate interface combines multiple interfaces into one virtual interface, an aggregate route combines multiple routes into one. This reduces the amount of space those routes require in the routing tables of the routers along that route. The trade-off is a small amount of processing to aggregate and de-aggregate the routes at either end.

The benefit of this method is that you can combine many addresses into one, potentially reducing the routing table size immensely. The weakness of this method is if there are holes in the address range you are aggregating you need to decide if its better to break it into multiple ranges, or accept the possibility of failed routes to the missing addresses.

For information on aggregated routes in BGP, see “ATOMIC_AGGREGATE” on page 367, and “Aggregate routes and addresses” on page 370.

To manually aggregate the range of IP addresses from 192.168.1.100 to 192.168.1.103

1. Convert the addresses to binary

   ```
   192.168.1.100 = 11000000 10101000 00000001 01100100
   192.168.1.101 = 11000000 10101000 00000001 01100101
   192.168.1.102 = 11000000 10101000 00000001 01100110
   192.168.1.103 = 11000000 10101000 00000001 01100111
   ```

2. Determine the maximum number of matching bits common to the addresses.

   There are 30-bits in common, with only the last 2-bits being different.

3 Record the common part of the address.

   ```
   11000000 10101000 00000001 0110010X = 192.168.1.100
   ```

4 For the netmask, assume all the bits in the netmask are 1 except those that are different which are 0.

   ```
   11111111 11111111 11111111 11111100 = 255.255.255.252
   ```

5 Combine the common address bits and the netmask.

   ```
   192.168.1.100/255.255.255.252
   ```

   Alternately the IP mask may be written as a single number:

   ```
   192.168.1.100/2
   ```

6 As required, set variables and attributes to declare the routes have been aggregated, and what router did the aggregating.

Autonomous system (AS)

An Autonomous System (AS) is one or more connected networks that use the same routing protocol, and appear to be a single unit to any externally connected networks. For example an ISP may have a number of customer networks connected to it, but to any networks connected externally to the ISP it appears as one system or AS. An AS may also be referred to as a routing domain.

It should be noted that while OSPF routing takes place within one AS, the only part of OSPF that deals with the AS is the AS border router (ASBR).

There are multiple types of AS defined by how they are connected to other ASes. A multihomed AS is connected to at least two other ASes and has the benefit of redundancy — if one of those ASes goes down, your AS can still reach the Internet through its other connection. A stub AS only has one connection, and can be useful in specific configurations where limited access is desirable.

Each AS has a number assigned to it, known as an ASN. In an internal network, you can assign any ASN you like (a private AS number), but for networks connected to the Internet (public AS) you need to have an officially registered ASN from Internet Assigned Numbers Authority (IANA). ASNs from 1 to 64,511 are designated for public use.

As of January 2010, AS numbers are 4 bytes long instead of the former 2 bytes. RFC 4893 introduced 32-bit ASNs, which FortiGate units support for BGP and OSPF

Do you need your own AS?

The main factors in deciding if you need your own AS or if you should be part of someone else's are:

- exchanging external routing information
- many prefixes should exist in one AS as long as they use the same routing policy
- when you use a different routing protocol than your border gateway peers (for example your ISP uses BGP, and you use OSPF)
- connected to multiple other AS (multi-homed)

You should not create an AS for each prefix on your network. Neither should you be forced into an AS just so someone else can make AS-based policy decisions on your traffic.

There can be only one AS for any prefix on the Internet. This is to prevent routing issues.

What AS number to use?

In addition to overseeing IP address allocation and Domain Name Systems (DNS), the Internet Assigned Numbers Authority (IANA) assigns public AS numbers. The public AS numbers are from 1 to 64,511. The ASNs 0, 54272–64511, and 65535 are reserved by the IANA. These ASNs should not be used.

ASNs are assigned in blocks by the Internet Assigned Numbers Authority (IANA) to Regional Internet Registries (RIRs) who then assign ASNs to companies within that RIRs geographic area. Usually these companies are ISPs, and to receive an ASN you must complete the application process of the local RIR and be approved before being assigned an ASN. The RIRs names and regions are:

AFRINIC	Serves the African continent
APNIC	Asia-Pacific including China, India, and Japan
ARIN	American registry including Canada and United States
LACNIC	Latin America, including Mexico, Caribbean, Central and South America
RIPE NCC	Europe, the Middle East, former USSR, and parts of Central Asia

AS numbers from 64512 to 65534 are reserved for private use. Private AS numbers can be used for any internal networks with no outside connections to the Internet such as test networks, classroom labs, or other internal-only networks that do not access the outside world. You can also configure border routers to filter out any private ASNs before routing traffic to the outside world. If you must use private ASNs with public networks, this is the only way to configure them. However, it is risky because many other private networks could be using the same ASNs and conflicts will happen. It would be very much like your local 192.168.0.0 network being made public — the resulting problems would be widespread.

In 1996, when RFC 1930 was written only 5,100 ASes had been allocated and a little under 600 ASes were actively routed in the global Internet. Since that time many more public ASNs have been assigned, leaving only a small number. For this reason 32-bit ASNs (four-octet ASNs) were defined to provide more public ASNs. RFC 4893 defines 32-bit ASNs, and FortiGate units support these larger ASNs.

Area border router (ABR)

Routers within an AS advertise updates internally and only to each other. However, routers on the edge of the AS must communicate both with routers inside their AS and with routers external to their AS, often running a different routing protocol. These routers are called Area Border Routers (ABRs) or edge routers. Often ABRs run multiple routing protocols to be able to

redistribute traffic between different ASes that are running different protocols, such as the edge between an ISP's IS-IS routing network and a large company's OSPF network.

OSPF defines ABRs differently from other routers. In OSPF, an ABR is an OSPF router that connects another AS to the backbone AS, and is a member of all the areas it connects to. An OSPF ABR maintains a LSA database for each area that it is connected to. The concept of the edge router is present, but its the edge of the backbone instead of the edge of the OSPF supported ASes.

Neighbor routers

Routing involves routers communicating with each other. To do this, routers need to know information about each other. These routers are called neighbor routers, and are configured in each routing protocol. Each neighbor has custom settings since some routers may have functionality others routers lack. Neighbour routers are sometimes called peers.

Generally neighbor routers must be configured, and discovered by the rest of the network before they can be integrated to the routing calculations. This is a combination of the network administrator configuring the new router with its neighbor router addresses, and the routing network discovering the new router, such as the hello packets in OSPF. That discovery initiates communication between the new router and the rest of the network.

Route maps

Route maps are a way for the FortiGate unit to evaluate optimum routes for forwarding packets or suppressing the routing of packets to particular destinations. Compared to access lists, route maps support enhanced packet-matching criteria. In addition, route maps can be configured to permit or deny the addition of routes to the FortiGate unit routing table and make changes to routing information dynamically as defined through route-map rules.

Route maps can be used for limiting both received route updates, and sent route updates. This can include the redistribution of routes learned from other types of routing. For example if you don't want to advertise local static routes to external networks, you could use a route map to accomplish this.

The FortiGate unit compares the rules in a route map to the attributes of a route. The rules are examined in ascending order until one or more of the rules in the route map are found to match one or more of the route attributes.

As an administrator, route maps allow you to group a set of addresses together and assign them a meaningful name. Then during your configuration, you can use these route-maps to speed up configuration. The meaningful names ensure fewer mistakes during configuration as well.

The default rule in the route map (which the FortiGate unit applies last) denies all routes. For a route map to take effect, it must be called by a FortiGate unit routing process.

The syntax for route maps are:

```
config router route-map
  edit <route_map_name>
    set comments
    config rule
      edit <route_map_rule_id>
        set action
        set match-*
        set set-*
        ...
      end
```

The `match-*` commands allow you to match various parts of a route. The `set-*` commands allow you to set routing information once a route is matched.

For an example of how route maps can be used to create receiving or sending “groups” in routing, see “Redistributing and blocking routes in BGP” on page 389.

Access lists

Use this command to add, edit, or delete access lists. Access lists are filters used by FortiGate unit routing processes. For an access list to take effect, it must be called by a FortiGate unit routing process (for example, a process that supports RIP or OSPF). Use `access-list6` for IPv6 routing.

Access lists can be used to filter which updates are passed between routers, or which routes are redistributed to different networks and routing protocols. You can create lists of rules that will match all routes for a specific router or group of routers.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

The syntax for access lists is:

```
config router access-list, access-list6
  edit <access_list_name>
    set comments
    config rule
    edit <access_list_id>
      set action
      set exact-match
      set prefix
      set prefix6
      set wildcard
```

For an example of how access lists can be used to create receiving or sending “groups” in routing, see “Redistributing and blocking routes in BGP” on page 389.

Bi-directional forwarding detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-protected router fail to arrive, then that router is declared down. BFD communicates this information to the routing protocol and the routing information is updated.

BFD neighbors establish if BFD is enabled in OSPF or BFP routers that establish as neighbors.

The CLI commands associated with BFD include:

```
config router bgp
  config neighbor
    set bfd

config router ospf
  set bfd
```

Per-VDOM configuration:

```
config system settings
  set bfd
  set bfd-desired-min-tx
  set bfd-required-min-rx
  set bfd-detect-mult
  set bfd-dont-enforce-src-port
```

Per-interface (override) configuration:

```
config system interface
  edit <interface_name>
    set bfd enable
    set bfd-desired-min-tx
    set bfd-detect-mult
    set bfd-required-min-rx
```

For more information about BFD in BGP, see “Bi-directional forwarding detection (BFD)” on page 374.

IPv6 in dynamic routing

Unless otherwise stated, routing protocols apply to IPv4 addressing. This is the standard address format used. However, IPv6 is becoming more popular and new versions of the dynamic routing protocols have been introduced.

Dynamic routing supports IPv6 on your FortiGate unit. The new versions of these protocols and the corresponding RFCs are:

- **RIP next generation (RIPng)** — RFC 2080 - Routing Information Protocol next generation (RIPng). See “RIP and IPv6” on page 320.
- **BGP4+** — RFC 2545, and RFC 2858 Multiprotocol Extensions for IPv6 Inter-Domain Routing, and Multiprotocol Extensions for BGP-4 (MP-BGP) respectively. See “BGP and IPv6” on page 359.
- **OSPFv3** — RFC 2740 Open Shortest Path First version 3 (OSPFv3) for IPv6 support. See “OSPFv3 and IPv6” on page 397.
- **Integrated IS-IS** — RFC 5308 for IPv6 support. See “Integrated IS-IS” on page 444.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in *System* > *Admin* > *Settings*. Alternatively, you can directly configure IPv6 for RIP, BGP, or OSPF protocols using CLI commands.

Routing Information Protocol (RIP)

This section describes the Routing Information Protocol (RIP).

The following topics are included in this section:

RIP background and concepts

This section contains:

Background

Routing Information Protocol (RIP) is a distance-vector routing protocol intended for small, relatively homogeneous networks. Its widespread use started when an early version of RIP was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by RIP, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

RIP benefits include being well suited to smaller networks, is in widespread use, near universal support on routing hardware, quick to configure, and works well if there are no redundant paths. However, RIP updates are sent out node-by-node so it can be slow to find a path around network outages. RIP also lacks good authentication, can not choose routes based on different quality of service methods, and can create network loops if you are not careful.

The FortiGate implementation of RIP supports RIP version 1 (see RFC 1058), RIP version 2 (see RFC 2453), and the IPv6 version RIPng (see RFC 2080).

RIP v1

In 1988 RIP version 1, defined in RFC 1058, was released. The RFC even states that RIP v1 is based on Linux routed due to it being a “defacto standard”.

It uses classful addressing and uses broadcasting to send out updates to router neighbors. There is no subnet information included in the routing updates in classful routing, and it does not support CIDR addressing — subnets must all be the same size. Also, route summarization is not possible.

RIP v1 has no router authentication method, so it is vulnerable to attacks through packet sniffing, and spoofing.

RIP v2

In 1993, RIP version 2 was developed to deal with the limitations of RIP v1. It was not standardized until 1998. This new version supports classless routing, and subnets of various sizes.

Router authentication was added in RIP v2 — it supports MD5. MD5 hashes are an older encryption method, but this is much improved over no security at all.

In RIP v2 the hop count limit remained at 15 to be backwards compatible with RIP v1.

RIP v2 uses multicasting to send the entire routing table to router neighbors, thereby reducing the traffic for devices that are not participating in RIP routing.

Routing tags were added as well, which allow internal routes or redistributed routes to be identified as such.

RIPng

RIPng, defined in RFC 2080, is an extension of RIP2 designed to support IPv6. However, RIPng varies from RIPv2 in that it is not fully backwards compatible with RIPv1.

- RIPng does not support RIPv1 update authentication, it relies on IPsec
- RIPng does not allow attaching tags to routes as in RIPv2
- RIPng requires specific encoding of the next hop for a set of route entries, unlike RIPv2 that encodes the next-hop into each route entry.

Parts and terminology of RIP

Before you can understand how RIP functions, you need to understand some of the main concepts and parts of RIP.

This section includes:

RIP and IPv6

RIP Next Generation (RIPng) is a new version of RIP was released that includes support for IPv6.

The FortiGate unit command `config router ripng` is almost the same as `config router rip`, except that IPv6 addresses are used. Also if you are going to use prefix or access lists with RIPng, you must use the `config router access-list6` or `config prefix-list6` versions of those commands.

If you want to troubleshoot RIPng, it is the same as with RIP but specify the different protocol, and use IPv6 addresses. This applies to commands such as `get router info6` when you want to see the routing table, or other related information.

If you want to route IPv4 traffic over an IPv6 network, you can use the command `config system ip6-tunnel` to configure the FortiGate unit to do this. The IPv6 interface is configured under `config system interface`. All subnets between the source and destination addresses must support IPv6. This command is not supported in Transparent mode.

For example, you want to set up a tunnel on the port1 interface starting at 2002:C0A8:3201:: on your local network and tunnel it to address 2002:A0A:A01:: where it will need access to an IPv4 network again. Use the following command:

```
config system ipv6-tunnel
  edit test_tunnel
    set destination 2002:A0A:A01::
    set interface port1
    set source 2002:C0A8:3201::
  end
end
```

The CLI commands associated with RIPng include:

```
config router ripng
config router access-list6
config router prefix-list6
config system ipv6-tunnel
get router info6 *
```

Default information originate option

This is the second advanced option for RIP in the web-based manager, right after metric. Enabling default-information-originate will generate and advertise a default route into the FortiGate unit's RIP-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. RIP does not create the default route unless you use the always option.

Select *Disable* if you experience any issues or if you wish to advertise your own static routes into RIP updates.

You can enable or disable default-information-originate in *Router* > *Dynamic* > *RIP*, under *Advanced Options*, or use the CLI.

The CLI commands associated with default information originate include:

```
config router rip
  set default-information-originate
end
```

Garbage, timeout, and update timers

RIP uses various timers to regulate its performance including a garbage timer, timeout timer, and update timer. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations — if you change these settings, ensure that the new settings are compatible with local routers and access servers.

The Timeout period should be at least three times longer than the Update period. If the Update timer is smaller than Timeout or Garbage timers, you will experience an error.

You can set the three RIP timers in *Router* > *Dynamic* > *RIP*, under *Advanced Options*, or use the CLI.

The CLI commands associated with garbage, timeout, and update timers include:

```
config router rip
  set garbage-timer
  set timeout-timer
  set update-timer
end
```

Garbage timer

The garbage timer is the amount of time (in seconds) that the FortiGate unit will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This will result in a smaller routing table which is useful if you have a very large network, or if your network changes frequently.

Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, otherwise you will experience an error.

If you are experiencing significant RIP traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience time outs that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the FortiGate unit will keep a reachable route in the routing table while no updates for that route are received. If the FortiGate unit receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the depute period, otherwise you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods — it may be considerable time before the time the FortiGate unit is done waiting for all the timers to expire on unresponsive routes.

Authentication and key-chain

RIP version 2 uses authentication keys to ensure that the routing information exchanged between routers is reliable. RIP version 1 has no authentication. For authentication to work both the sending and receiving routers must be set to use authentication, and must be configured with the same keys.

The sending and receiving routers need to have their system dates and times synchronized to ensure both ends are using the same keys at the proper times. However, you can overlap the key lifetimes to ensure that a key is always available even if there is some difference in the system times.

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. The FortiGate unit migrates from one key to the next according to the scheduled send and receive lifetimes.

Key-chain is a CLI router command. You use this command to manage RIP version 2 authentication keys. You can add, edit or delete keys identified by the specified key number.

This example shows how to configure a key-chain with two keys that are valid sequentially in time. This example creates a key-chain called “rip_key” that has a password of “fortinet”. The accepted and send lifetimes are both set to the same values — a start time of 9:00am February 23, 2010 and an end time of 9:00am March 17, 2010. A second key is configured with a password of “my_fortigate” that is valid from March 17, 2010 9:01am to April 1 2010 9:00am. This “rip_key” keychain is then used on the port1 interface in RIP.

```
config router key-chain
  edit "rip_key"
    config key
    edit 1
      set accept-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
      set key-string "fortinet"
      set send-lifetime 09:00:00 23 02 2010 09:00:00 17 03 2010
    next
    edit 2
      set accept-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
      set key-string "my_fortigate"
      set send-lifetime 09:01:00 17 03 2010 09:00:00 1 04 2010
    next
    end
  end
config router rip
  config interface
    edit port1
      set auth-keychain “rip_key”
    end
  end
```

The CLI commands associated with authentication keys include:

```
  config router key-chain

  config router rip
    config interface
      edit <interface>
        set auth-keychain
        set auth-mode
        set auth-string
      end
    end
```

Access Lists

Access lists are filters used by FortiGate unit RIP and OSPF routing. An access list provides a list of IP addresses and the action to take for them — essentially an access list makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example if you wanted all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also its easier to troubleshoot since if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the RIPng or OSPF+ IPv6 protocols you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of `10.10.10.10` and `11.11.11.11`, enter the command:

```
config router access-list
  edit test_list
    config rule
      edit 1
        set prefix 10.10.10.10 255.255.255.255
        set action allow
        set exact-match enable
      next
      edit 2
        set prefix 11.11.11.11 255.255.255.255
        set action allow
        set exact-match enable
      end
    end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the command access-list6 as follows:

```
config router access-list6
  edit test_list_ip6
    config rule
      edit 1
        set prefix6 2002:A0A:A0A:0:0:0:0:0:/48
        set action deny
      next
      edit 2
        set prefix6 2002:B0B:B0B:0:0:0:0:0/48
        set action deny
      end
    end
```

To use an access_list, you must call it from a routing protocol such as RIP. The following example uses the access_list from the earlier example called test_list to match routes coming in

on the port1 interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially increase . Enter the following command:

```
config router rip
  config offset-list
    edit 5
      set access-list test_list
      set direction in
      set interface port1
      set offset 3
      set status enable
    end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route, 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose

How RIP works

As one of the original modern dynamic routing protocols, RIP is straightforward. Its routing algorithm is not complex, there are some options to allow fine tuning, and it's relatively simple to configure RIP on FortiGate units.

From RFC 1058:

> Distance vector algorithms are based on the exchange of only a small amount of information. Each entity (gateway or host) that participates in the routing protocol is assumed to keep information about all of the destinations within the system. Generally, information about all entities connected to one network is summarized by a single entry, which describes the route to all destinations on that network.

This section includes:

- RIP versus static routing
- RIP metric — hop count
- The Bellman–Ford routing algorithm
- Passive versus active RIP interfaces
- RIP packet structure

RIP versus static routing

RIP was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, RIP is a big step forward from simple static routing.

While RIP may be slow in response to network outages, static routing has zero response. The same is true for convergence — static routing has zero convergence. Both RIP and static routing have the limited hop count, so its not a strength or a weakness. Count to infinity can be a problem, but typically can be fixed as it happens or is the result of a network outage that would cause even worse problems on static routing network.

This compares to static routing where each time a packet needs to be routed, the FortiGate unit can only send it to the next hop towards the destination. That next hop then forwards it, and so on until it arrives at its destination. RIP keeps more routing information on each router so your FortiGate unit can send the packet farther towards its destination before it has to be routed again towards its destination. RIP reduces the amount of table lookups and therefore fewer network resources than static routing. Also since RIP is updated on neighboring routes it is aware of new routes or dead routes that static routing would not be aware of.

Overall, RIP is a large step forward when compared to static routing.

RIP metric — hop count

RIP uses hop count as the metric for choosing the best route. A hop count of 1 represents a network that is connected directly to the FortiGate unit, while a hop count of 16 represents a network that cannot be reached. Each network that a packet travels through to reach its destination usually counts as one hop. When the FortiGate unit compares two routes to the same destination, it adds the route having the lowest hop count to the routing table. As you can see in "RIP packet structure" on page 329, the hop count is part of a RIP v2 packet.

Similarly, when RIP is enabled on an interface, the FortiGate unit sends RIP responses to neighboring routers on a regular basis. The updates provide information about the routes in the FortiGate unit's routing table, subject to the rules that you specify for advertising those routes. You can specify how often the FortiGate unit sends updates, the period of time a route can be kept in the routing table without being updated, and for routes that are not updated regularly you can specify the period of time that the unit advertises a route as unreachable before it is removed from the routing table.

If hops are weighted higher than one, it becomes very easy to reach the upper limit. This higher weighting will effectively limit the size of your network depending on the numbers used. Merely changing from the default of 1.0 to 1.5 will lower the effective hop count from 15 to 10. This is acceptable for smaller networks, but can be a problem as your network expands over time.

In RIP, you can use the offset command to artificially increase the hop count of a route. Doing this will make this route less preferred, and in turn it will get less traffic. Offsetting routes is useful when you have network connections of different bandwidths, different levels of reliability, or different costs. In each of these situations you still want the redundancy of multiple route access, but you don't want the bulk of your traffic using these less preferred routes. For an example of RIP offset, see "Access Lists" on page 323.

The Bellman–Ford routing algorithm

The routing algorithm used by RIP was first used in 1967 as the initial routing algorithm of the ARPANET. The Bellman–Ford algorithm is distributed because it involves a number of nodes (routers) within an Autonomous system, and consists of the following steps:

1. Each node calculates the distances between itself and all other nodes within the AS and stores this information as a table.
2. Each node sends its table to all neighboring nodes.
3. When a node receives distance tables from its neighbors, it calculates the shortest routes to all other nodes and updates its own table to reflect any changes.

To examine how this algorithm functions let's look at a network with 4 routers — routers 1 through 4. The distance from router1 to router2 is 2 hops, 1 to 3 is 3 hops, and 2 to 3 is 4 hops. Router4 is only connected to routers 2 and 3, each distance being 2 hops.

1. Router1 finds all the distance to the other three routers — router 2 is 2, router 3 is 3. Router1 doesn't have a route to router 4.
2. Routers 2 through 4 do the same calculations from their point of views.
3. Once router 1 gets an update from router 2 or 3, it will get their route to router 4. At that point it now has a route to router 4 and installs that in its local table.
4. If router1 gets an update from router3 first, it has a hop count of 5 to reach router4. But when router2 sends its update, router1 will go with router2's shorter 4 hops to reach router4. Future updates don't change this unless they are shorter than 4 hops, or the routing table route goes down.

Figure 100:RIP algorithm example in 4 steps

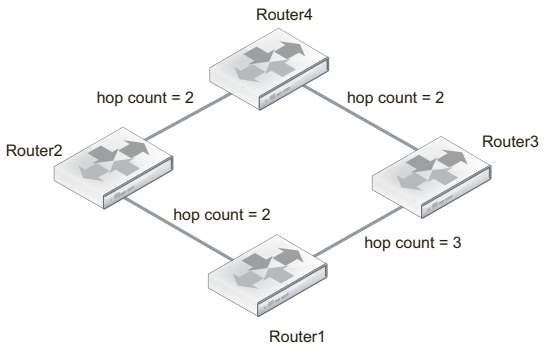
Step 1

Router1 finds the distance to other routers in the network.

It currently has no route to Router4.

Router1 routing table:

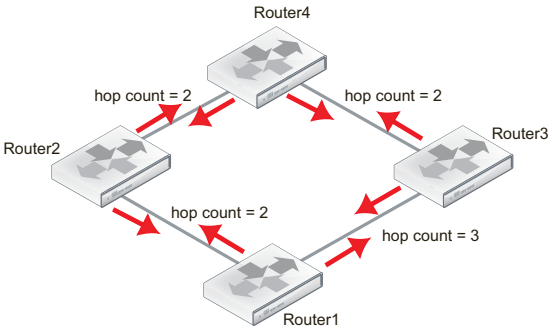
- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.



Step 2

All routers do the same as Router1, and send out updates containing their routing table.

Note that Router1 and Router4 do not update each other, but rely on Router2 and Router3 to pass along accurate updates.

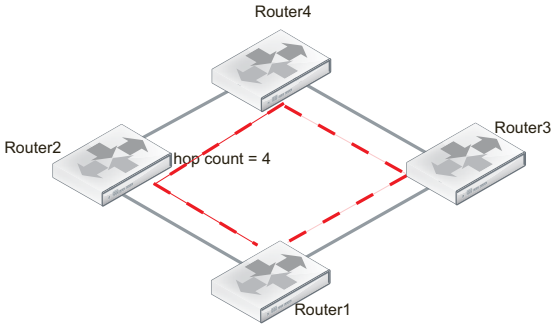


Step 3

Each router looks at the updates it has received, and adds any new or shorter routes to its table.

Router1 updated table:

- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.
- Distance to Router4 = 4 or 5 hops.

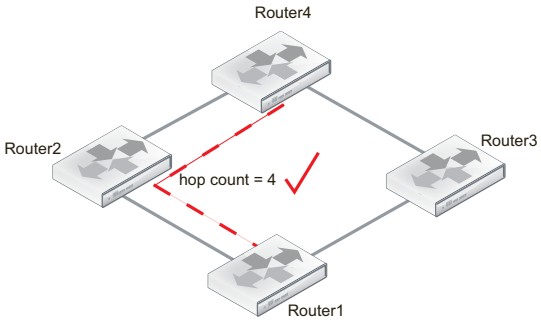


Step 4

Router1 installs the shortest route to Router4, and the other routes to it are removed from the routing table.

Router1 complete table:

- Distance to Router2 = 2 hops.
- Distance to Router3 = 3 hops.
- Distance to Router4 = 4 hops.



The good part about the Bellman-Ford algorithm in RIP is that the router only uses the information it needs from the update. If there are no newer, better routes than the ones the router already has in its routing table, there is no need to change its routing table. And no change means no additional update, so less traffic. But even when there is update traffic, the RIP packets are very small so it takes many updates to affect overall network bandwidth. For more information about RIP packets, see “RIP packet structure” on page 329.

The main disadvantage of the Bellman–Ford algorithm in RIP is that it doesn't take weightings into consideration. While it is possible to assign different weights to routes in RIP, doing so severely limits the effective network size by reducing the hop count limit. Also other dynamic routing protocols can take route qualities, such as reliability or delay, into consideration to provide not only the physically shortest but also the fastest or more reliable routes as you choose.

Another disadvantage of the Bellman-Ford algorithm is due to the slow updates passed from one RIP router to the next. This results in a slow response to changes in the network topology, which in turn results in more attempts to use routes that are down, which wastes time and network resources.

Passive versus active RIP interfaces

Normally the FortiGate unit's routing table is kept up to date by periodically asking the neighbors for routes, and sending your routing updates out. This has the downside of generating a lot of extra traffic for large networks. The solution to this problem is passive interfaces.

An standard interface that supports RIP is active by default — it both sends and receives updates by actively communicating with its neighbors. A passive RIP interface does not send out updates — it just listens to the updates of other routers. This is useful in reducing network traffic, and if there are redundant routers in the network that would be sending out essentially the same updates all the time.

The following example shows how to create a passive RIP v2 interface on port1, using MD5 authentication and a key-chain called `passiveRIPv2` that has already been configured. Note that in the CLI, you enable passive by disabling `send-version2-broadcast`.

To create a passive RIP interface - web-based manager

1. Go to *Router* > *Dynamic* > *RIP*.
2. Under *Interfaces*, select *Create*.
3. Select port1 as the *Interface*.
4. Select 2 as both the *Send Version* and *Receive Version*.
5. Select MD5 for *Authentication*.
6. Select the `passiveRIPv2` *Key-chain*.
7. Select *Passive Interface*.
8. Select *OK* to accept this configuration, and return to the main RIP display page.

To create a passive RIP v2 interface on port1 using MD5 authentication- CLI

```
config router rip
  config interface
    edit port1
      set send-version2-broadcast disable
      set auth-keychain "passiveRIPv2"
      set auth-mode md5
      set receive-version 2
      set send-version 2
    end
  end
```

RIP packet structure

It is hard to fully understand a routing protocol without knowing what information is carried in its packets. Knowing what information is exchanged between routers and how will help you better understand the RIP protocol, and better configure your network for it.

This section provides information on the contents of RIP 1 and RIP 2 packets.

RIP version 1

RIP version 1, or RIP IP packets are 24 bytes in length, with some empty areas left for future expansion.

Table 10: RIP IP packets

1-byte command	1-byte version	2-byte zero field	2-byte AFI	2-byte zero field
4-byte IP address	4-byte zero field	4-byte zero field	4-byte metric	

A RIP 1 packet contains the following fields:

Command — Indicates whether the packet is a request or a response. The request asks that a router send all or part of its routing table. The response can be an unsolicited regular routing update or a reply to a request. Responses contain routing table entries. Multiple RIP packets are used to convey information from large routing tables.

Version — Specifies the RIP version used. This field can signal different potentially incompatible versions.

Zero field — This field defaults to zero, and is not used by RFC 1058 RIP.

Address-family identifier (AFI) — Specifies the address family used. RIP is designed to carry routing information for several different protocols. Each entry has an address-family identifier to indicate the type of address being specified. The AFI for IP is 2.

IP Address — Specifies the IP address for the entry.

Metric — This is the number of hops or routers traversed along the route on its trip to the destination. The metric is between 1 and 15 for that number of hops. If the route is unreachable the metric is 16.

RIP version 2

RIP version 2 has more features than RIP 1, which is reflected in its packets which carry more information. All but one of the empty zero fields in RIP 1 packets are used in RIP 2.

Table 11: RIP 2 packets

1-byte command	1-byte version	2-byte unused	2-byte AFI	2-byte route tag	4-byte IP address	4-byte subnet	4-byte next hop	4-byte metric

A RIP 2 packet contains fields described above in RIP 1, as well as the following:

Unused — Has a value set to zero, and is intended for future use

Route tag — Provides a method for distinguishing between internal routes learned by RIP and external routes learned from other protocols.

Subnet mask — Contains the subnet mask for the entry. If this field is zero, no subnet mask has been specified for the entry.

Next hop — Indicates the IP address of the next hop to which packets for the entry should be forwarded.

Troubleshooting RIP

This section is about troubleshooting RIP. For general troubleshooting information, see the Troubleshooting chapter.

This section includes:

Routing Loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems getting information to its destination and also prevents it from returning to the source to report the inaccessible destination.

A routing loop happens when a normally functioning network has an outage, and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on those routers affected. The worst part is this situation will continue until the network administrator changes the router settings, or the downed routers come back online.

Routing loops' effect on the network

In addition to this "traffic jam" of routed packets, every time the routing table for a router changes that router sends an update out to all of the RIP routers connected to it. In a network loop, its possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How can you spot a routing loop

Any time network traffic slows down, you will be asking yourself if it is a network loop or not. Often slowdowns are normal, they are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

If you aren't running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it. Ping, traceroute, and other basic troubleshooting tools are largely the same between static and dynamic, and are covered in "Troubleshooting static routing" on page 281.

Check your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to *Log & Report*. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Use SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause, and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops

1. Go to *System* > *Config* > *SNMP*.
2. Enable *SMTP Agent* and select *Apply*.

   Optionally enter the *Description*, *Location*, and *Contact* information for this device for easier location of the problem report.
3. Under *SNMP v1/v2* or *SNMP v3* as appropriate, select *Create New*.

   SNMP v3

User Name	Enter the SNMP user ID.
Security Level	Select authentication or privacy as desired. Select the authentication or privacy algorithms to use and enter the required passwords.
Notification Host	Enter the IP addresses of up to 16 hosts to notify.
Enable Query	Select. The *Port* should be 161. Ensure that your security policies allow ports 161 and 162 (SNMP queries and traps) to pass.

   SNMP v1/v2

Hosts	Enter the IP addresses of up to 8 hosts to notify. You can also specify the network *Interface*, or leave it as *ANY*.

Queries	Enable *v1* and/or *v2* as needed. The *Port* should be 161. Ensure that your security policies allow port 161 to pass.
Traps	Enable v1 and/or v2 as needed. The Port should be 162. Ensure that your security policies allow port 162 to pass.

4. Select the events for which you want notification. For routing loops this should include *CPU usage is high*, *Memory is low*, and possibly *Log disk space is low* . If there are problems the log will be filling up quickly, and the FortiGate unit's resources will be overused.
5. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Use dead gateway detection and e-mail alerts

Another tool available to you on FortiGate units is the dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

To detect possible routing loops with dead gateway detection and e-mail alerts

1. To configure dead gateway detection, go to *Router* > *Static* > *Settings* and select *Create New*.
2. Enter the *Ping Server* IP address and select the *Interface* that connects to it.
3. Set the *Ping Interval* (how often to send a ping), and *Failover Threshold* (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.

To configure notification of failed gateways

1. Go to *Log & Report* > *Log Config* > *Alert E-mail*.
2. Enter your email details.
3. Select the *Configuration changes* event.
4. Select *Apply*.

You might also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email about the outage.

Look at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. This is same idea as police pulling over a car and asking the driver where they have been, and what the conditions were like.

The method used in the troubleshooting sections "Debugging IPv6 on RIPng" on page 334 and on debugging the packet flow apply here as well. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable.

Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you have mapped the problem on your network, and determined it is in fact a routing loop there are a number of steps to take in correcting it.

1. Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Holddowns and Triggers for updates

One of the potential problems with RIP is the frequent routing table updates that are sent every time there is a change to the routing table. If your network has many RIP routers, these updates can start to slow down your network. Also if you have a particular route that has bad hardware, it might be going up and down frequently, which will generate an overload of routing table updates.

One of the most common solutions to this problem is to use holddown timers and triggers for updates. These slow down the updates that are sent out, and help prevent a potential flood.

Holddown Timers

The holddown timer activates when a route is marked down. Until the timer expires, the router does not accept any new information about that route. This is very useful if you have a flapping route because it will prevent your router from sending out updates and being part of the problem in flooding the network. The potential down side is if the route comes back up while the timer has not expired, that route will be unavailable for that period of time. This is only a problem if this is a major route used by the majority of your traffic. Otherwise, this is a minor problem as traffic can be re-routed around the outage.

Triggers

Triggered RIP is an alternate update structure that is based around limiting updates to only specific circumstances. The most basic difference is that the routing table will only be updated when a specific request is sent to update, as opposed to every time the routing table changes. Updates are also triggered when a unit is ‘powered on’, which can include addition of new interfaces or devices to the routing structure, or devices returning to being available after being unreachable.

Split horizon and Poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let’s call them A, B, and C. A is only linked to B, C is only linked to B, and B is linked to both A and C. To get to C, A must go through B. If the link to C goes down, it is possible that B will try to use A’s route to get to C. This route is A-B-C, so it will loop endlessly between A and B.

This situation is called a split horizon because from B’s point of view the horizon stretches out in each direction, but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse “poisons” routes away from the destination that use the current router in their

route to the destination. This “poisoned” route is marked as unreachable for routers that cannot use it. In RIP this means that route is marked with a distance of 16.

Debugging IPv6 on RIPng

The debug commands are very useful to see what is happening on the network at the packet level. There are a few changes to debugging the packet flow when debugging IPv6.

The following CLI commands specify both IPv6 and RIP, so only RIPng packets will be reported. The output from these commands will show you the RIPng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

The addresses are in IPv6 format.

```
diagnose debug enable
diagnose ipv6 router rip level info
diagnose ipv6 router rip all enable
```

These three commands will:

- turn on debugging in general
- set the debug level to information, a verbose reporting level
- turn on all rip router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

For more information, see “Testing the IPv6 RIPng information” on page 357

Simple RIP example

This is an example of a typical medium sized network configuration using RIP routing.

Your company has 3 small local networks, one for each department. These networks are connected by RIP, and then connected to the Internet. Each subnet has more than one route, for redundancy. There are two central routers that are both connected to the internet, and to the other networks. If one of those routers goes down, the whole network can continue to function normally.

The ISP is running RIP, so no importing or exporting routes is required on the side of the network. However, since the internal networks have static networking running those will need to be redistributed through the RIP network.

To keep the example simple, there will be no authentication of router traffic.

With RIP properly configured, if the device fails or temporarily goes offline, the routes will change and traffic will continue to flow. RIP is good for a smaller network due to its lack of complex configurations.

This section includes the following topics:

Network layout and assumptions

Basic network layout

Your company has 3 departments each with their own network — Sales, R&D, and Accounting. Each network has routers that are not running RIP as well as FortiGate units running RIP.

The R&D network has two RIP routers, and each is connected to both other departments as well as being connected to the Internet through the ISP router. The links to the Internet are indicated in black.

The three internal networks do not run RIP. They use static routing because they are small networks. This means the FortiGate units have to redistribute any static routes they learn so that the internal networks can communicate with each other.

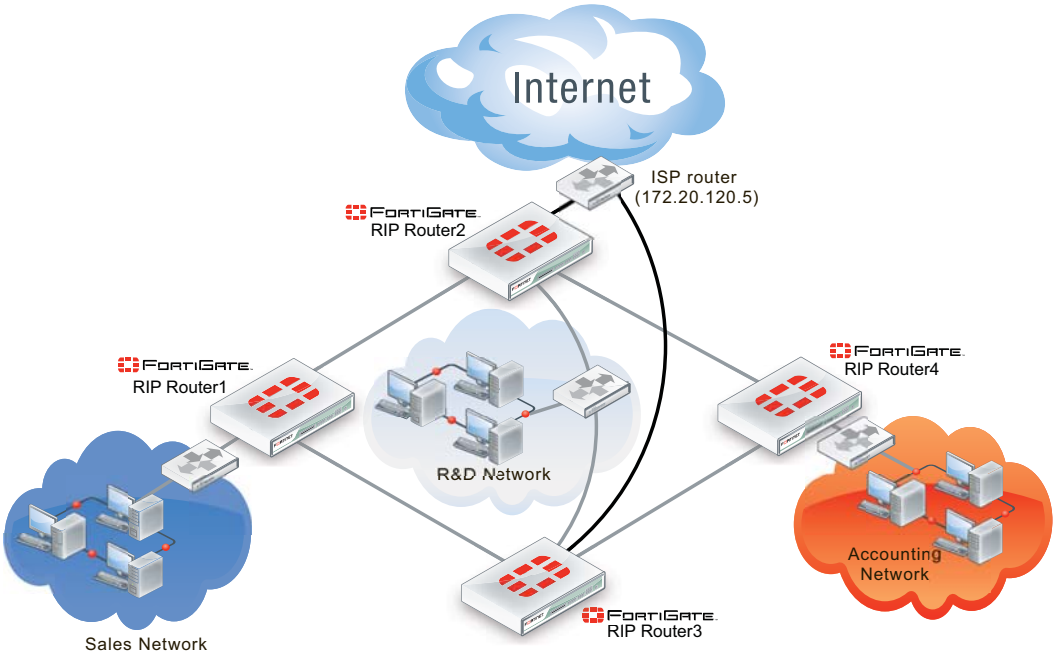
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows. Note that the Interfaces that connect Router2 and Router3 also connect to the R&D network.

Table 12: Rip example network topology

Network	Router	Interface & Alias	IP address
Sales	Router1	port1 (internal)	10.11.101.101
		port2 (router2)	10.11.201.101
		port3 (router3)	10.11.202.101
R&D	Router2	port1 (internal)	10.12.101.102
		port2 (router1)	10.11.201.102
		port3 (router4)	10.14.201.102
		port4 (ISP)	172.20.120.102
	Router3	port1 (internal)	10.12.101.103
		port2 (router1)	10.11.201.103
		port3 (router4)	10.14.202.103
		port4 (ISP)	172.20.120.103
Accounting	Router4	port1 (internal)	10.14.101.104
		port2 (router2)	10.14.201.104
		port3 (router3)	10.14.202.104

Figure 101: Network topology for the simple RIP example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 5.0 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 through port4 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- Only FortiGate units are running RIP on the internal networks.
- Router2 and Router3 are connected through the internal network for R&D.
- Router2 and Router3 each have their own connection to the Internet, indicated in black in Figure 101.

General configuration steps

This example is very straight forward. The only steps involved are:

- Configuring the FortiGate units system information
- Configuring FortiGate unit RIP router information
- Configuring other networking devices
- Testing network configuration

Configuring the FortiGate units system information

Each FortiGate unit needs their hostname, and interfaces configured.

For IP numbering, Router2 and Router3 use the other routers numbering where needed.

Router2 and Router3 have dead gateway detection enabled on the ISP interfaces using Ping. Remember to contact the ISP and confirm their server has ping enabled.

Configure the hostname, interfaces, and default route

To configure Router1 system information - web-based manager

1. Go to *System* > *Dashboard* > *Status* > *System Information*.
2. Next to *Host Name* select *Change*, and enter “Router1”.
3. Go to *Router* > *Static* > *Static Routes*.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)
Gateway	172.20.120.5/255.255.255.0
Distance	40

5. Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6. Go to *System* > *Network* > *Interfaces*.
7. Edit port1 (internal) interface.
8. Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.101.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal sales network
Administrative Status	Up

9. Edit port2 (router2) interface.
10. Set the following information, and select *OK*.

Alias	router2
IP/Netmask	10.11.201.101/255.255.255.0
Administrative Access	HTTPS SSH PING

Description	Link to R&D network & internet through Router2
Administrative Status	Up

11. Edit port3 (router3) interface.

12. Set the following information, and select *OK*.

Alias	router3
IP/Netmask	10.11.202.101/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and internet through Router3
Administrative Status	Up

To configure Router1 system information - CLI

```
config system global
  set hostname Router1
end
```

```
config router static
  edit 1
    set device "port2"
    set distance 45
    set gateway 10.11.201.102
  next
  edit 2
    set device “port3”
    set distance 45
    set gateway 10.11.202.103
  end
end

config system interface
  edit port1
    set alias internal
    set ip 10.11.101.101/255.255.255.0
    set allowaccess https ssh ping
    set description “Internal sales network”
  next
  edit port2
    set alias ISP
    set allowaccess https ssh ping
    set ip 10.11.201.101/255.255.255.0
    set description “Link to R&D network & internet through Router2”
  next
  edit port3
    set alias router3
    set ip 10.11.202.101/255.255.255.0
    set allowaccess https ssh ping
    set description “Link to R&D network & internet through Router2”
  end
end
```

To configure Router2 system information - web-based manager

1. Go to *System* > *Dashboard* > *Status* > *System Information*.
2. Next to *Host Name* select *Change*, and enter “Router2”.
3. Go to *Router* > *Static* > *Static Routes*.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5. Go to *System* > *Network* > *Interfaces*.
6. Edit port1 (internal) interface.
7. Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.12.101.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router3
Administrative Status	Up

8. Edit port2 (router1) interface.
9. Set the following information, and select *OK*.

Alias	router1
IP/Netmask	10.12.201.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and the Sales network
Administrative Status	Up

10. Edit port3 (router4) interface.
11. Set the following information, and select *OK*.

Alias	router4
IP/Netmask	10.12.301.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and the accounting network
Administrative Status	Up

12. Edit port4 (ISP) interface.
13. Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	172.20.120.102/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect Interface Status for Gateway Load Balancing	enable
Detect Server	172.20.120.5
Detect Protocol	Ping

Detect Interface Status for Gateway Load Balancing	enable
Description	Internet through ISP
Administrative Status	Up

To configure Router2 system information - CLI

```
config system global
  set hostname Router2
end
config router static
  edit 1
    set device "port4"
    set distance 5
    set gateway 172.20.130.5
  end
end
config system interface
  edit port1
    set alias internal
    set ip 10.11.101.102/255.255.255.0
    set allowaccess https ssh ping
    set description "Internal RnD network and Router3"
  next
  edit port2
    set alias router1
    set allowaccess https ssh ping
    set ip 10.11.201.102/255.255.255.0
    set description "Link to Router1"
  next
  edit port3
    set alias router3
    set ip 10.14.202.102/255.255.255.0
    set allowaccess https ssh ping
    set description "Link to Router4"
  next
  edit port4
    set alias ISP
    set ip 172.20.120.102/255.255.255.0
    set allowaccess https ssh ping
    set description "ISP and internet"
  end
end
```

To configure Router3 system information - web-based manager

1. Go to *System* > *Dashboard* > *Status* > *System Information*.
2. Next to *Host Name* select *Change*, and enter “Router3”.
3. Go to *Router* > *Static* > *Static Route*.

4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port4 (ISP)
Gateway	172.20.120.5/255.255.255.0
Distance	5

5. Go to *System* > *Network* > *Interfaces*.
6. Edit port1 (internal) interface.
7. Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.12.101.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	R&D internal network and Router2
Administrative Status	Up

8. Edit port2 (router1) interface.
9. Set the following information, and select *OK*.

Alias	router1
IP/Netmask	10.13.201.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router1 and Sales network
Administrative Status	Up

10. Edit port3 (router4) interface.
11. Set the following information, and select *OK*.

Alias	router4
IP/Netmask	10.13.301.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to Router4 and accounting network
Administrative Status	Up

12. Edit port4 (ISP) interface.

13. Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	172.20.120.103/255.255.255.0
Administrative Access	HTTPS SSH PING
Detect Interface Status for Gateway Load Balancing	enable
Detect Server	172.20.120.5
Detect Protocol	Ping
Description	Internet and ISP
Administrative Status	Up

To configure Router3 system information - CLI

```
config system global
  set hostname Router3
end

config router static
  edit 1
    set device "port4"
    set distance 5
    set gateway 172.20.130.5
  end
end

config system interface
  edit port1
    set alias internal
    set ip 10.12.101.103/255.255.255.0
    set allowaccess https ssh ping
    set description "Internal RnD network and Router2"
  next
  edit port2
    set alias ISP
    set allowaccess https ssh ping
    set ip 10.11.201.103/255.255.255.0
    set description "Link to Router1"
  next
  edit port3
    set alias router3
    set ip 10.14.202.103/255.255.255.0
    set allowaccess https ssh ping
    set description "Link to Router4"
  next
  edit port4
    set alias ISP
    set ip 172.20.120.103/255.255.255.0
    set allowaccess https ssh ping
    set description "ISP and internet"
  end
end
```

To configure Router4 system information - web-based manager

1. Go to *System* > *Dashboard* > *Status* > *System Information*.
2. Next to *Host Name* select *Change*, and enter "Router4".
3. Go to *Router* > *Static* > *Static Route*s.
4. Edit the default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2 (router2)

Gateway	172.20.120.5/255.255.255.0
Distance	40

5. Enter a second default route and enter the following information:

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3 (router3)
Gateway	172.20.120.5/255.255.255.0
Distance	40

6. Go to *System* > *Network* > *Interfaces*.
7. Edit port 1 (internal) interface.
8. Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.14.101.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal accounting network
Administrative Status	Up

9. Edit port 2 (router2) interface.
10. Set the following information, and select *OK*.

Alias	router2
IP/Netmask	10.14.201.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network & internet through Router2
Administrative Status	Up

11. Edit port 3 (router3) interface.
12. Set the following information, and select *OK*.

Alias	router3
IP/Netmask	10.14.301.104/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Link to R&D network and internet through Router3
Administrative Status	Up

To configure Router4 system information - CLI

```
config system global
  set hostname Router4
end

config router static
  edit 1
    set device "port2"
    set distance 45
    set gateway 10.14.201.102
  next
  edit 2
    set device “port3”
    set distance 45
    set gateway 10.14.202.103
  end
end

config system interface
  edit port1
    set alias internal
    set ip 10.14.101.104/255.255.255.0
    set allowaccess https ssh ping
    set description “Internal sales network”
  next
  edit port2
    set alias router2
    set allowaccess https ssh ping
    set ip 10.14.201.104/255.255.255.0
    set description “Link to R&D network & internet through Router2”
  next
  edit port3
    set alias router3
    set ip 10.14.202.104/255.255.255.0
    set allowaccess https ssh ping
    set description “Link to R&D network & internet through Router2”
  end
end
```

Configuring FortiGate unit RIP router information

With the interfaces configured, RIP can now be configured on the FortiGate units.

For each FortiGate unit the following steps will be taken:

- configure RIP version used
- redistribute static networks
- add networks serviced by RIP
- add interfaces that support RIP on the FortiGate unit

Router1 and Router4 are configured the same. Router2 and Router3 are configured the same. These routers will be grouped accordingly for the following procedures — repeat the procedures once for each FortiGate unit.

Configure RIP settings on Router1 and Router4 - web-based manager

1. Go to *Router* > *Dynamic* > *RIP*.
2. Select 2 for *RIP Version*.
3. In *Advanced Options*, under *Redistribute* enable *Static*.
4. Leave the other Advanced Options at default values.
5. Enter the following networks, and select *Add* after each:
   - 10.11.0.0/255.255.0.0
   - 10.12.0.0/255.255.0.0
   - 10.14.0.0/255.255.0.0
   - 172.20.120.0/255.255.255.0
6. For interface, select *Create New* and set the following information.

Interface	port1 (internal)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

7. For interface, select *Create New* and set the following information.

Interface	port2 (router2)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

8. For interface, select *Create New* and set the following information.

Interface	port3 (router3)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

Configure RIP settings on Router1 and Router4 - CLI

```
config router rip
  set version 2
  config interface
    edit "port1"
      set receive-version 1 2
      set send-version 1 2
    next
    edit "port2"
      set receive-version 1 2
      set send-version 1 2
    next
    edit "port3"
      set receive-version 1 2
      set send-version 1 2
    end
  config network
    edit 1
      set prefix 10.11.0.0 255.255.0.0
    next
    edit 2
      set prefix 10.12.0.0 255.255.0.0
    next
    edit 3
      set prefix 10.14.0.0 255.255.0.0
    next
    edit 4
      set prefix 172.20.120.0 255.255.255.0
    end
  config redistribute "static"
    set status enable
  end
end
```

Configure RIP settings on Router2 and Router3- web-based manager

1. Go to *Router* > *Dynamic* > *RIP*.
2. Select 2 for *RIP Version*.
3. In *Advanced Options*, under *Redistribute* enable *Static*.
4. Leave the other Advanced Options at default values.
5. Enter the following networks, and select *Add* after each:
   - 10.11.0.0/255.255.0.0
   - 10.12.0.0/255.255.0.0
   - 10.14.0.0/255.255.0.0
   - 172.20.120.0/255.255.255.0

6. For interface, select *Create New* and set the following information.

Interface	port1 (internal)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

7. For interface, select *Create New* and set the following information.

Interface	port2 (router1)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

8. For interface, select *Create New* and set the following information.

Interface	port3 (router4)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

9. For interface, select *Create New* and set the following information.

Interface	port4 (ISP)
Send Version	Both
Receive Version	Both
Authentication	None
Passive Interface	disabled

Configure RIP settings on Router2 and Router3- web-based manager

```
config router rip
  set version 2
  config interface
    edit "port1"
      set receive-version 1 2
      set send-version 1 2
    next
    edit "port2"
      set receive-version 1 2
      set send-version 1 2
    next
    edit "port3"
      set receive-version 1 2
      set send-version 1 2
    end
    edit "port4"
      set receive-version 1 2
      set send-version 1 2
    end
  config network
    edit 1
      set prefix 10.11.0.0 255.255.0.0
    next
    edit 2
      set prefix 10.12.0.0 255.255.0.0
    next
    edit 3
      set prefix 10.14.0.0 255.255.0.0
    next
    edit 4
      set prefix 172.20.120.0 255.255.255.0
    end
  config redistribute "static"
    set status enable
  end
end
```

Configuring other networking devices

In this example there are two groups of other devices on the the network — internal devices, and the ISP.

The first is the internal network devices on the Sales, R&D, and Accounting networks. This includes simple static routers, computers, printers and other network devices. Once the FortiGate units are configured, the internal static routers need to be configured using the internal network IP addresses. Otherwise there should be no configuration required.

The second group of devices is the ISP. This consists of the RIP router the FortiGate routers 2 and 3 connect to. You need to contact your ISP and ensure they have your information for your

network such as the IP addresses of the connecting RIP routers, what version of RIP your network supports, and what authentication (if any) is used.

Testing network configuration

Once the network has been configured, you need to test that it works as expected.

The two series of tests you need to run are to test the internal networks can communicate with each other, and that the internal networks can reach the internet.

Use ping, traceroute, and other networking tools to run these tests.

If you encounter problems, for troubleshooting help consult "Troubleshooting RIP" on page 330.

RIPng — RIP and IPv6

RIP next generation, or RIPng, is the version of RIP that supports IPv6.

This is an example of a typical small network configuration using RIPng routing.

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

This section includes the following topics:

Network layout and assumptions

Basic network layout

Your internal R&D network is working on a project for a large international telecom company that uses IPv6. For this reason, you have to run IPv6 on your internal network and you have decided to use only IPv6 addresses.

Your network has two FortiGate units running the RIPng dynamic routing protocol. Both FortiGate units are connected to the ISP router and the internal network. This configuration provides some redundancy for the R&D internal network enabling it to reach the internet at all times.

All internal computers use RIP routing, so no static routing is required. And all internal computers use IPv6 addresses.

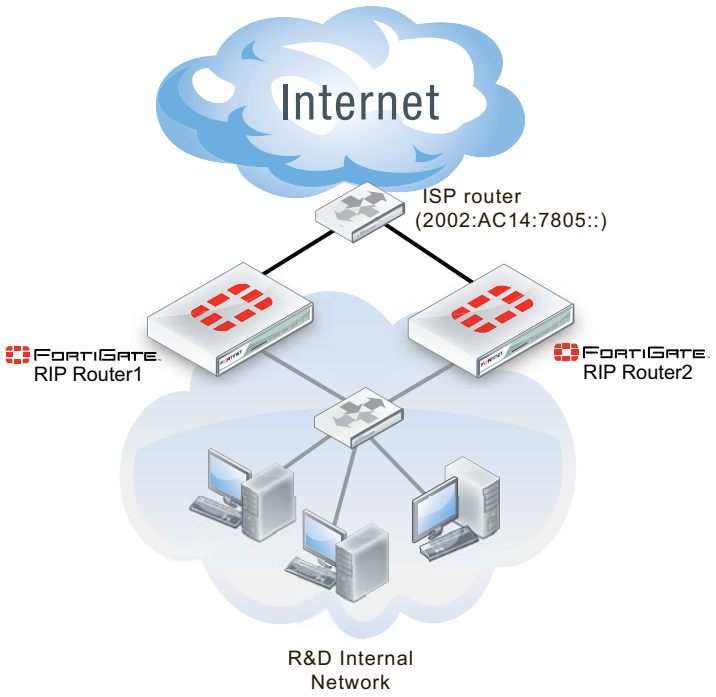
Where possible in this example, the default values will be used or the most general settings. This is intended to provide an easier configuration that will require less troubleshooting.

In this example the routers, networks, interfaces used, and IP addresses are as follows.

Table 13: Rip example network topology

Network	Router	Interface & Alias	IPv6 address
R&D	Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
		port2 (ISP)	2002:AC14:7865:0:0:0:0:0
	Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
		port2 (ISP)	2002:AC14:7866:0:0:0:0:0

Figure 102: Network topology for the IPV6 RIPng example



Assumptions

The following assumptions have been made concerning this example.

- All FortiGate units have 5.0 firmware, and are running factory default settings.
- All CLI and web-based manager navigation assumes the unit is running in NAT/Route operating mode, with VDOMs disabled.
- All FortiGate units have interfaces labelled port1 and port2 as required.
- All firewalls have been configured for each FortiGate unit to allow the required traffic to flow across interfaces.
- All network devices are support IPv6 and are running RIPng.

Configuring the FortiGate units system information

Each FortiGate unit needs IPv6 enabled, a new hostname, and interfaces configured.

To configure system information on Router1 - web-based manager

1. Go to *System* > *Dashboard* > *Status*.
2. For *Host name*, select *Change*.
3. Enter “Router1”.
4. Go to *System* > *Admin* > *Settings*.
5. In *Display Options on GUI*, enable *IPv6*, and select *Apply*.
6. Go to *System* > *Network* > *Interfaces*.
7. Edit port1 (internal) interface.
8. Set the following information, and select *OK*.

Alias	internal
IP/Netmask	2002:A0B:6565::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	2002:AC14:7865::/0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

To configure system information on Router1 - CLI

```
config system global
  set hostname Router1
  set gui-ipv6 enable
end
config system interface
  edit port1
    set alias internal
    set allowaccess https ping ssh
    set description "Internal RnD network"
    config ipv6
      set ip6-address 2002:a0b:6565::/0
    end
  next
  edit port2
    set alias ISP
    set allowaccess https ping ssh
    set description "ISP and internet"
    config ipv6
      set ip6-address 2002:AC14:7865::
    end
  end
```

To configure system information on Router2 - web-based manager

1. Go to *System* > *Dashboard* > *Status*.
2. For *Host name*, select *Change*.
3. Enter "Router2".
4. Go to *System* > *Admin* > *Settings*.
5. In *Display Options on GUI*, enable *IPv6*, and select *Apply*.
6. Go to *System* > *Network* > *Interfaces*.
7. Edit port1 (internal) interface.
8. Set the following information, and select *OK*.

Alias	internal
IP/Netmask	2002:A0B:6566::/0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

9. Edit port2 (ISP) interface.
10. Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	2002:AC14:7866::/0

Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

To configure system information on Router2 - CLI

```
config system global
   set hostname Router2
   set gui-ipv6 enable
end
config system interface
   edit port1
      set alias internal
      set allowaccess https ping ssh
      set description "Internal RnD network"
      config ipv6
         set ip6-address 2002:a0b:6566::/0
      end
   next
   edit port2
      set alias ISP
      set allowaccess https ping ssh
      set description "ISP and internet"
      config ipv6
         set ip6-address 2002:AC14:7866::
      end
   end
```

Configuring RIPng on FortiGate units

Now that the interfaces are configured, you can configure RIPng on the FortiGate units.

There are only two networks and two interfaces to include — the internal network, and the ISP network. There is no redistribution, and no authentication. In RIPng there is no specific command to include a subnet in the RIP broadcasts. There is also no information required for the interfaces beyond including their name.

As this is a CLI only configuration, configure the ISP router and the other FortiGate unit as neighbors. This was not part of the previous example as this feature is not offered in the web-based manager. Declaring neighbors in the configuration like this will reduce the discovery traffic when the routers start up.

Since RIPng is not supported in the web-based manager, this section will only be entered in the CLI.

To configure RIPng on Router1 - CLI

```
config router ripng
  config interface
    edit port1
    next
    edit port2
    end
  config neighbor
    edit 1
      set interface port1
      set ipv6 2002:a0b:6566::/0
    next
    edit 2
      set interface port2
      set ipv6 2002:AC14:7805::/0
    end
```

To configure RIPng on Router2 - CLI

```
config router ripng
  config interface
    edit port1
    next
    edit port2
    end
  config neighbor
    edit 1
      set interface port1
      set ipv6 2002:a0b:6565::/0
    next
    edit 2
      set interface port2
      set ipv6 2002:AC14:7805::/0
    end
```

Configuring other network devices

The other devices on the internal network all support IPv6, and are running RIPng where applicable. They only need to know the internal interface network addresses of the FortiGate units.

The ISP routers need to know the FortiGate unit information such as IPv6 addresses.

Testing the configuration

In addition to normal testing of your network configuration, you must also test the IPv6 part of this example.

For troubleshooting problems with your network, see the Troubleshooting chapter.

For troubleshooting problems with RIP, see“Troubleshooting RIP” on page 330.

Testing the IPv6 RIPng information

There are some commands to use when checking that your RIPng information is correct on your network. These are useful to check on your RIPng FortiGate units on your network. Comparing the output between devices will help you understand your network better, and also track down any problems.

```
diagnose ipv6 address list
```

View the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate unit.

```
diagnose ipv6 route list
```

View ipv6 addresses that are installed in the routing table.

```
get router info6 routing-table
```

View the routing table. This information is almost the same as the previous command (diagnose ipv6 route list) however it is presented in an easier to read format.

```
get router info6 rip interface external
```

View brief output on the RIP information for the interface listed. The information includes if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon are enabled.

```
get router info6 neighbor-cache list
```

View the IPv6/MAC address mapping. This also displays the interface index and name associated with the address.

Border Gateway Protocol (BGP)

This section describes Border Gateway Protocol (BGP).

The following topics are included in this section:

BGP background and concepts

The border gateway protocol contains two distinct subsets — internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect many different networks together, and is the main routing protocol for the Internet backbone. FortiGate units support iBGP, and eBGP only for communities.

The following topics are included in this section:

Background

BGP was first used in 1989. The current version, BGP-4, was released in 1995 and is defined in RFC 1771. That RFC has since been replaced by the more recent RFC 4271. The main benefits of BGP-4 are classless inter-domain routing, and aggregate routes. BGP is the only routing protocol to use TCP for a transport protocol. Other routing protocols use UDP.

BGP makes routing decisions based on path, network policies and rulesets instead of the hop-count metric as RIP does, or cost-factor metrics as OSPF does.

BGP-4+ supports IPv6. It was introduced in RFC 2858 and RFC 2545.

BGP is the routing protocol used on the Internet. It was designed to replace the old Exterior Gateway Protocol (EGP) which had been around since 1982, and was very limited. In doing so, BGP enabled more networks to take part in the Internet backbone to effectively decentralize it and make the Internet more robust, and less dependent on a single ISP or backbone network.

Parts and terminology of BGP

In a BGP network, there are some terms that need to be explained before going ahead. Some parts of BGP are not explained here as they are common to other dynamic routing protocols as well. When determining your network topology, note that the number of available or supported routes is not set by the configuration but depends on your FortiGate's available memory. For more information on parts of BGP that are not listed here, see "Dynamic routing terminology" on page 313.

BGP and IPv6

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config network6` or `set allowas-in6`. For more information about IPv6 BGP keywords, see the FortiGate CLI Reference.

IPv6 BGP commands include:

```
config router bgp
  set activate6 {enable | disable}
  set allowas-in6 <max_num_AS_integer>
  set allowas-in-enable6 {enable | disable}
  set as-override6 {enable | disable}
  set attribute-unchanged6 [as-path] [med] [next-hop]
  set capability-default-originate6 {enable | disable}
  set capability-graceful-restart6 {enable | disable}
  set capability-orf6 {both | none | receive | send}
  set default-originate-route-map6 <routemap_str>
  set distribute-list-in6 <access-list-name_str>
  set distribute-list-out6 <access-list-name_str>
  set filter-list-in6 <aspath-list-name_str>
  set filter-list-out6 <aspath-list-name_str>
  set maximum-prefix6 <prefix_integer>
  set maximum-prefix-threshold6 <percentage_integer>
  set maximum-prefix-warning-only6 {enable | disable}
  set next-hop-self6 {enable | disable}
  set prefix-list-in6 <prefix-list-name_str>
  set prefix-list-out6 <prefix-list-name_str>
  set remove-private-as6 {enable | disable}
  set route-map-in6 <routemap-name_str>
  set route-map-out6 <routemap-name_str>
  set route-reflector-client6 {enable | disable}
  set route-server-client6 {enable | disable}
  set send-community6 {both | disable | extended | standard}
  set soft-reconfiguration6 {enable | disable}
  set unsuppress-map6 <route-map-name_str>
  config network6
  config redistribute6
end
```

Roles of routers in BGP networks

Dynamic routing has a number of different roles routers can fill such as those covered in “Dynamic routing terminology” on page 313. BGP has a number of custom roles that routers can fill. These include:

- Speaker routers
- Peer routers or neighbors
- Route reflectors (RR)

Speaker routers

Any router configured for BGP is considered a BGP speaker. This means that a speaker router advertises BGP routes to its peers.

Any routers on the network that are not speaker routers, are not treated as BGP routers.

Peer routers or neighbors

In a BGP network, all neighboring BGP routers or peer routers are routers that are connected to your FortiGate unit. Your FortiGate unit learns about all other routers through these peers.

You need to manually configure BGP peers on your FortiGate unit as neighbors. Otherwise these routers will not be seen as peers, but instead as simply other routers on the network that don't support BGP. You can optionally use MD5 authentication to password protect BGP sessions with those neighbors. (see RFC 2385).

You can configure up to 1000 BGP neighbors on your FortiGate unit. You can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

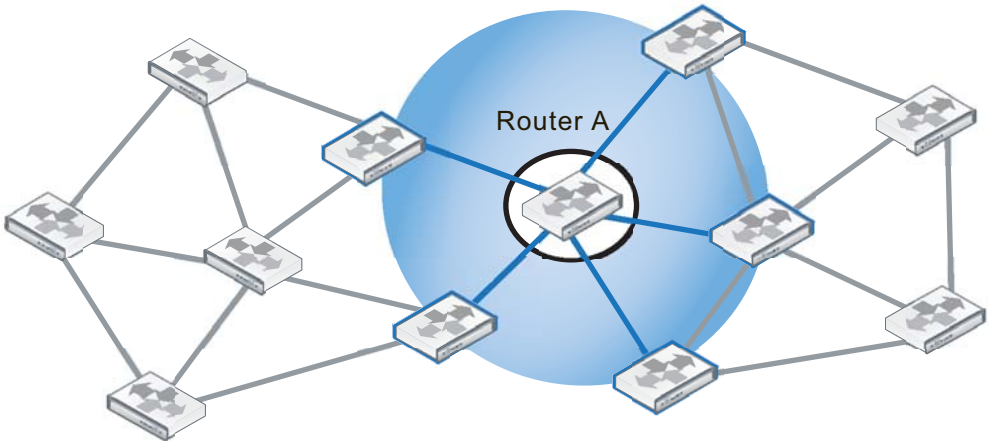
```
execute router clear bgp as 650001
```

To remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
execute router clear bgp dampening 10.10.0.0/16
```

In Figure 1, Router A is directly connected to five other routers in a network that contains 12 routers overall. These routers, the ones in the blue circle, are Router A's peers or neighbors.

Figure 103: Router A and its 5 peer routers



Router A's peer routers

As a minimum, when configuring BGP neighbors you must enter their IP address, and the AS number (remote-as). This is all the information the web-based manager interface allows you to enter for a neighbor.

The BGP commands related to neighbors are quite extensive and include:

```
config router bgp
  config neighbor
    edit <neighbor_address_ipv4>
      set activate {enable | disable}
      set advertisement-interval <seconds_integer>
      set allowas-in <max_num_AS_integer>
      set allowas-in-enable {enable | disable}
      set as-override {enable | disable}
      set attribute-unchanged [as-path] [med] [next-hop]
      set bfd {enable | disable}
      set capability-default-originate {enable | disable}
      set capability-dynamic {enable | disable}
      set capability-graceful-restart {enable | disable}

    end
end
```

Route reflectors (RR)

Route reflectors in BGP concentrate route updates so other routers need only talk to the route reflectors to get all the updates. This results in smaller routing tables, fewer connections between routers, faster responses to network topology changes, and less administration bandwidth. BGP route reflectors are defined in RFC 1966.

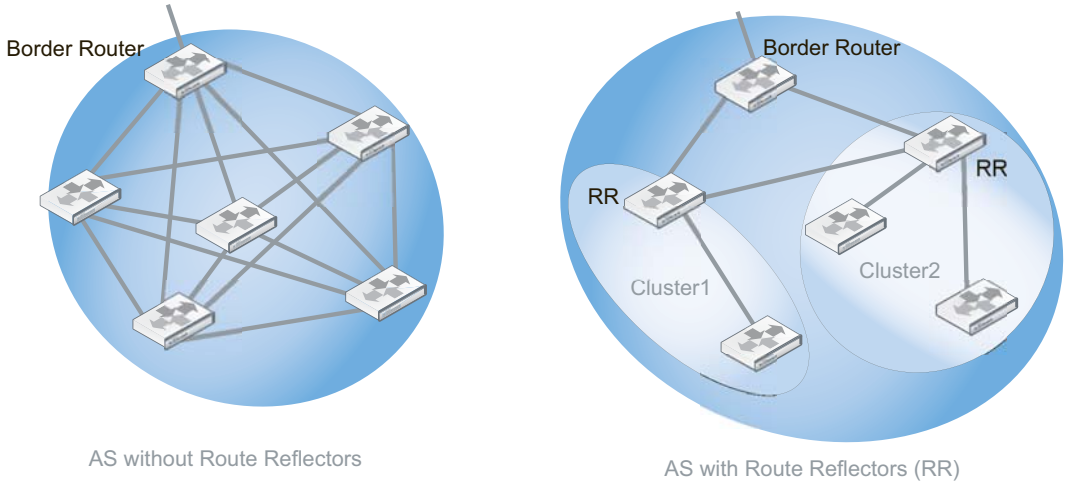
In a BGP route reflector configuration, the AS is divided into different clusters that each include client and reflector routers. The client routers supply the reflector routers with the client's route updates. The reflectors pass this information along to other route reflectors and border routers. Only the reflectors need to be configured, not the clients — the clients will find the closest reflector and communicate with it automatically. The reflectors communicate with each other as peers. FortiGate units can be configured as either reflectors or clients.

Since route reflectors are processing more than the client routers, the reflectors should have more resources to handle the extra workload.

Smaller networks running BGP typically don't require route reflectors (RR). However, RR is a useful feature for large companies, where their AS may include 100 routers or more. For example, for a full mesh 20 router configuration within an AS, there would have to be 190 unique BGP sessions — just for routing updates within the AS. The number of sessions jumps to 435 sessions for just 30 routers, or 4950 sessions for 100 routers. From these numbers, its plain that updating this many sessions will quickly consume the limited bandwidth and processing resources of the routers involved.

The following diagram illustrates how route reflectors can improve the situation when only six routers are involved. The AS without route reflectors requires 15 sessions between the routers. In the AS with route reflectors, the two route reflectors receive route updates from the reflector clients (unlabeled routers in the diagram) in their cluster as well as other route reflectors and pass them on to the border router. The RR configuration only require six sessions. This example shows a reduction of 60% in the number of required sessions.

Figure 104: Required sessions within an AS with and without route reflectors



The BGP commands related to route reflectors includes:

```
config router bgp
  config neighbor
    set route-reflector-client {enable | disable}
    set route-server-client {enable | disable}
  end
end
```

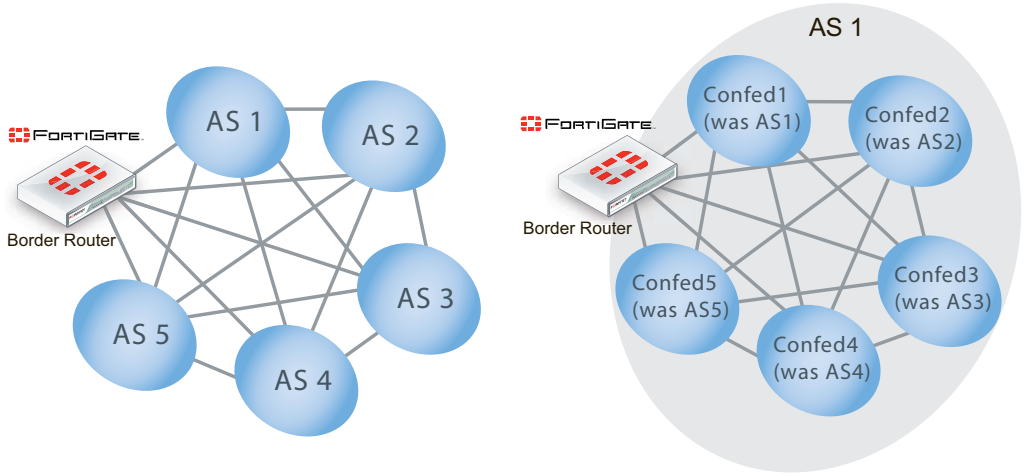
Confederations

Confederations were introduced to reduce the number of BGP advertisements on a segment of the network, and reduce the size of the routing tables. Confederations essentially break up an AS into smaller units. Confederations are defined in RFC 3065 and RFC 1965.

Within a confederation, all routers communicate with each other in a full mesh arrangement. Communications between confederations is more like inter-AS communications in that many of the attributes are changed as they would be for BGP communications leaving the AS, or eBGP.

Confederations are useful when merging ASs. Each AS being merged can easily become a confederation, requiring few changes. Any additional permanent changes can then be implemented over time as required. The figure below shows the group of ASs before merging, and the corresponding confederations afterward as part of the single AS with the addition of a new border router. It should be noted that after merging if the border router becomes a route reflector, then each confederation only needs to communicate with one other router, instead of five others.

Figure 105:AS merging using confederations



Multiple ASes before merging

Combined AS with confederations and new FortiGate unit border router

Confederations and route reflectors perform similar functions — they both sub-divide large ASes for more efficient operation. They differ in that route reflector clusters can include routers that are not members of a cluster, where routers in a confederation must belong to that confederation. Also, confederations place their confederation numbers in the AS_PATH attribute making it easier to trace.

It is important to note that while confederations essentially create sub-ASs, all the confederations within an AS appear as a single AS to external ASs.

Confederation related BGP commands include:

```
config router bgp
  set confederation-identifier <peerid_integer>
end
```

Network Layer Reachability Information (NLRI)

Network Layer Reachability Information (NLRI) is unique to BGP-4. It is sent as part of the update messages sent between BGP routers, and contains information necessary to supernet, or aggregate route, information. The NLRI includes the length and prefix that when combined are the address of the aggregated routes referred to.

There is only one NLRI entry per BGP update message.

BGP attributes

Each route in a BGP network has a set of attributes associated with it. These attributes define the route, and are modified as required along the route.

BGP can work well with mostly default settings, but if you are going to change settings you need to understand the roles of each attribute and how they affect those settings.

The BGP attributes include:

AS_PATH	A list of ASes a route has passed through. See “AS_PATH” on page 365.
MULTI_EXIT_DESC (MED)	Which router to use to exit an AS with more than one external connection. See “MULTI_EXIT_DESC (MED)” on page 366.

COMMUNITY	Used to apply attributes to a group of routes. See “COMMUNITY” on page 366.
NEXT_HOP	Where the IP packets should be forwarded to, like a gateway in static routing. See “NEXT_HOP” on page 366.
ATOMIC_AGGREGATE	Used when routes have been summarized to tell downstream routers not to de-aggregate the route. See “ATOMIC_AGGREGATE” on page 367.
ORIGIN	Used to determine if the route is from the local AS or not. See“ORIGIN” on page 367.
LOCAL_PREF	Used only within an AS to select the best route to a location (like MED)

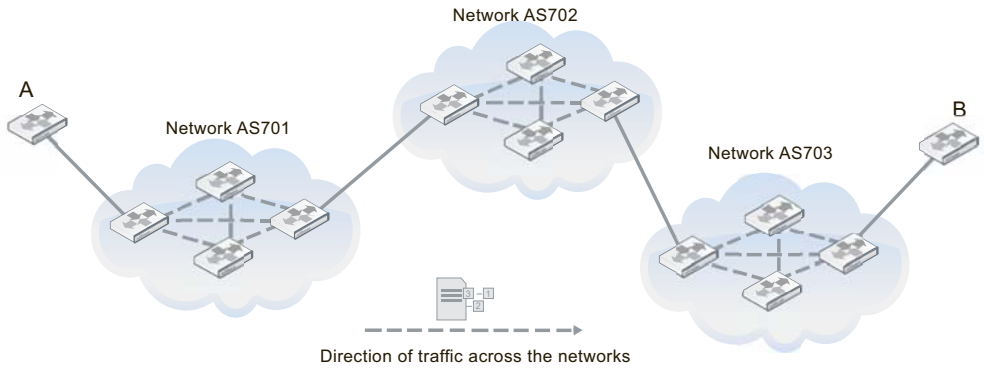
Inbound policies on FortiGate units can change the NEXT-HOP,LOCAL-PREF, MED and AS-PATH attributes of an internal BGP (iBGP) route for its local route selection purposes. However, outbound policies on the unit cannot affect these attributes.

AS_PATH

AS_PATH is the BGP attribute that keeps track of each AS a route advertisement has passed through. AS_PATH is used by confederations and by exterior BGP (EBGP) to help prevent routing loops. A router knows there is a loop if it receives an AS_PATH with that routers AS in it. The figure below shows the route between router A and router B. The AS_PATH from A to B would read 701,702,703 for each AS the route passes through.

As of the start of 2010, the industry upgraded from 2-byte to 4-byte AS_PATHs. This upgrade was due to the imminent exhaustion of 2-byte AS_PATH numbers. FortiOS supports 4-byte AS_PATHs in its BGP implementation.

Figure 106:AS_PATH of 701,702, 703 between routers A and B



The BGP commands related to AS_PATH include:

```
config router bgp
  set bestpath-as-path-ignore {enable | disable}
end
```

MULTI_EXIT_DESC (MED)

BGP AS systems can have one or more routers that connect them to other ASes. For ASes with more than one connecting router, the Multi-Exit Discriminator (MED) lists which router is best to use when leaving the AS. The MED is based on attributes such as delay. It is a recommendation only, as some networks may have different priorities.

BGP updates advertise the best path to a destination network. When the FortiGate unit receives a BGP update, the FortiGate unit examines the Multi-Exit Discriminator (MED) attribute of potential routes to determine the best path to a destination network before recording the path in the local FortiGate unit routing table.

FortiGate units have the option to treat any routes without an MED attribute as the worst possible routing choice. This can be useful because a lack of MED information is a lack of routing information which can be suspicious — possibly a hacking attempt or an attack on the network. At best it signifies an unreliable route to select.

The BGP commands related to MED include:

```
config router bgp
  set always-compare-med {enable | disable}
  set bestpath-med-confed {enable | disable}
  set bestpath-med-missing-as-worst {enable | disable}
  set deterministic-med {enable | disable}
  config neighbor
    set attribute-unchanged [as-path] [med] [next-hop]
  end
end
```

COMMUNITY

A community is a group of routes that have the same routing policies applied to them. This saves time and resources. A community is defined by the COMMUNITY attribute of a BGP route.

The FortiGate unit can set the COMMUNITY attribute of a route to assign the route to predefined paths (see RFC 1997). The FortiGate unit can examine the COMMUNITY attribute of learned routes to perform local filtering and/or redistribution.

The BGP commands related to COMMUNITY include:

```
config router bgp
  set send-community {both | disable | extended | standard}
end
```

NEXT_HOP

The NEXT_HOP attribute says what IP address the packets should be forwarded to next. Each time the route is advertised, this value is updated. The NEXT_HOP attribute is much like a gateway in static routing.

FortiGate units allow you to to change the advertising of the FortiGate unit's IP address (instead of the neighbor's IP address) in the NEXT_HOP information that is sent to IBGP peers. This is changed with the config neighbor, set next-hop-self command.

The BGP commands related to NEXT_HOP include:

```
config router bgp
  config neighbor
    set attribute-unchanged [as-path] [med] [next-hop]
    set next-hop-self {enable | disable}
  end
end
```

ATOMIC_AGGREGATE

The ATOMIC_AGGREGATE attribute is used when routes have been summarized. It indicates which AS and which router summarize the routes. It also tells downstream routers not to de-aggregate the route. Summarized routes are routes with similar information that have been combined, or aggregated, into one route that is easier to send in updates. When it reaches its destination, the summarized routes are split back up into the individual routes.

Your FortiGate unit doesn't specifically set this attribute in the BGP router command, but it is used in the route map command.

The commands related to ATOMIC_AGGREGATE include:

```
config router route-map
  edit <route_map_name>
    config rule
    edit <route_map_rule_id>
      set set-aggregator-as <id_integer>
      set set-aggregator-ip <address_ipv4>
      set set-atomic-aggregate {enable | disable}
    end
  end
end
```

ORIGIN

The ORIGIN attribute records where the route came from. The options can be IBGP, EBGP, or incomplete. This information is important because internal routes (IBGP) are by default higher priority than external routes (EBGP). However incomplete ORIGINs are the lowest priority of the three.

The commands related to ORIGIN include:

```
config router route-map
  edit <route_map_name>
    set comments <string>
    config rule
    edit <route_map_rule_id>
      set match-origin {egp | igp |  incomplete | none}
    end
  end
end
```

How BGP works

BGP is a link-state routing protocol and keeps link-state information about the status of each network link it has connected. A BGP router receives information from its peer routers that have

been defined as neighbors. BGP routers listen for updates from these configured neighboring routers on TCP port 179.

A BGP router is a finite state machine with six various states for each connection. As two BGP routers discover each other, and establish a connection they go from the idle state, through the various states until they reach the established state. An error can cause the connection to be dropped and the state of the router to be reset to either active or idle. These errors can be caused by: TCP port 179 not being open, a random TCP port above port 1023 not being open, the peer address being incorrect, or the AS number being incorrect.

When BGP routers start a connection, they negotiate which (if any) optional features will be used such as multiprotocol extensions that can include IPv6 and VPNs.

IBGP versus EBGP

When you read about BGP, often you see EBGP or IBGP mentioned. These are both BGP routing, but BGP used in different roles. Exterior BGP (EBGP) involves packets crossing multiple autonomous systems (ASes) where interior BGP (IBGP) involves packets that stay within a single AS. For example the AS_PATH attribute is only useful for EBGP where routes pass through multiple ASes.

These two modes are important because some features of BGP are only used for one of EBGP or IBGP. For example confederations are used in EBGP, and route reflectors are only used in IBGP. Also routes learned from IBGP have priority over EBGP learned routes.

FortiGate units have some commands specific to EBGP. These include:

- automatically resetting the session information to external peers if the connection goes down — `set fast-external-failover {enable | disable}`
- setting an administrative distance for all routes learned from external peers (must also configure local and internal distances if this is set) — `set distance-external <distance_integer>`
- enforcing EBGP multihops and their TTL (number of hops) — `set ebgp-enforce-multihop {enable | disable}` and `set ebgp-multihop-ttl <seconds_integer>`

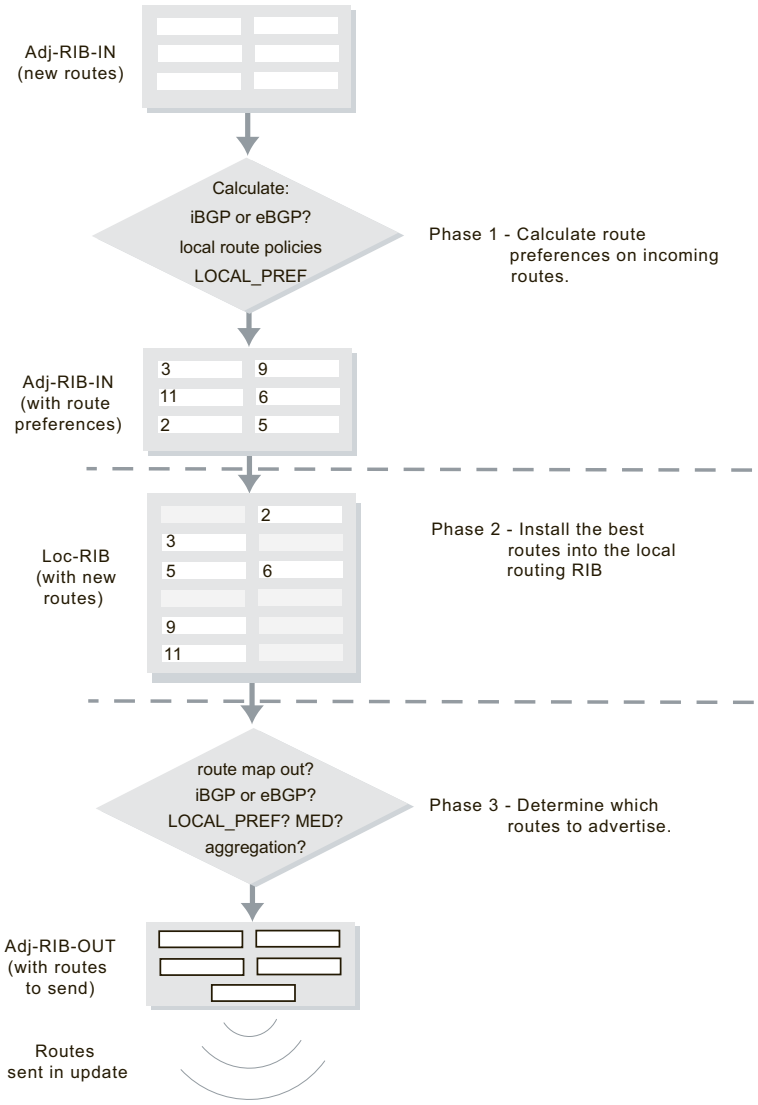
BGP path determination — which route to use

Firstly, recall that the number of available or supported routes is not set by the configuration but depends on your FortiGate's available memory. All learned routes and their attributes come into the BGP router in raw form. Before routes are installed in the routing table or are advertised to other routers, three levels of decisions must be made.

The three phases of BGP best path determination do not change. However, some manufacturers have added more information to the process, such as Cisco's WEIGHT attribute to enable an administrator to force one route's selection over another.

There is one Adj-RIB-IN and Adj-RIB-OUT for each configured neighbor. They are updated when the FortiGate unit receives BGP updates, or when the FortiGate unit sends out BGP updates.

Figure 107: Three phases of BGP routing decision



Decision phase 1

At this phase, the decision is to calculate how preferred each route and its NRLI are the Adjacent Routing Information Base Incoming (Adj-RIBs-In) compared to the other routes. For internal routes (IBGP), policy information or LOCAL_PREF is used. For external peer learned routes, it is based strictly on policy. These rules set up a list of which routes are most preferred going into Phase 2.

Decision phase 2

Phase 2 involves installing the best route to each destination into the local Routing Information Base (Loc-RIB). Effectively, the Loc-RIB is the master routing table. Each route from Phase 1 has their NEXT_HOP checked to ensure the destination is reachable. If it is reachable, the

AS_PATH is checked for loops. After that, routes are installed based on the following decision process:

- If there is only one route to a location, it is installed.
- If multiple routes to the same location, use the most preferred route from Level 1.
- If there is a tie, break the tie based on the following in descending order of importance: shortest AS_PATH, smallest ORIGIN number, smallest MED, EBGP over IBGP, smallest metric or cost for reaching the NEXT_HOP, BGP identifier, and lowest IP address.

Note that the new routes that are installed into the Loc-RIB are in addition to any existing routes in the table. Once Phase 2 is completed the Loc-RIB will consist of the best of both the new and older routes.

Decision phase 3

Phase 3 is route distribution or dissemination. This is the process of deciding which routes the router will advertise. If there is any route aggregation or summarizing, it happens here. Also any route filtering from route maps happens here.

Once Phase 3 is complete, an update can be sent out to update the neighbor of new routes.

Aggregate routes and addresses

BGP4 allows classless routing, which uses netmasks as well as IP addresses. This classless routing enables the configuration of aggregate routes by stating the address bits the aggregated addresses have in common. For more information, see “Aggregated routes and addresses” on page 313.

The ATOMIC_AGGREGATE attribute informs routers that the route has been aggregated, and should not be de-aggregated. An associated AGGREGATOR attribute include the information about the router that did the aggregating including its AS.

The BGP commands associated with aggregate routes and addresses are:

```
config router bgp
  config aggregate-address
    edit <aggr_addr_id>
    set as-set {enable | disable}
    set prefix <address_ipv4mask>
    set summary-only {enable | disable}
  end
  config aggregate-address6
    edit <aggr_addr_id>
    set as-set {enable | disable}
    set prefix6 <address_ipv6mask>
    set summary-only {enable | disable}
  end
  end
```

Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically the problems with a BGP network that has been configured, involve routes going offline frequently. This is called route flap and causes problems for the routers using that route.

Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the command:

```
execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the command:

```
execute router clear bgp as 650001
```

Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables which creates a lot of administration traffic on the network. And the same traffic happens again when that router comes back online. If the problem is something like a faulty network cable that wobbles on and offline every 10 seconds, there could easily be overwhelming amounts of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate units in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline resulting in route flap. While this doesn't occur often, or more than once at a time, it can still result in an interruption in traffic which is unpleasant for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they do not expire during the failover process. Also configuring graceful restart on the HA cluster will help with a smooth failover.

The first method of dealing with route flap should be to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either avoid using that interface or swap in a functioning router. If the power source is bad on a router, either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- Holddown timer
- Dampening
- Graceful restart
- Bi-directional forwarding detection (BFD)

Holddown timer

The first line of defence to a flapping route is the hold down timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the holddown timer won't allow the FortiGate unit to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate unit — for the duration of the other outages there will be no changes because the Fortigate unit is essentially treating this router as down. After the timer expires, if the route is still flapping it will happen all over again.

Even if the route isn't flapping — if it goes down, comes up, and stays back up — the timer still counts down and the route is ignored for the duration of the timer. In this situation the route will be seen as down longer than it really is, but there will be only the one set of route updates. This is not a problem in normal operation because updates are not frequent.

Also the potential for a route to be treated as down when it is really up can be viewed as a robustness feature. Typically you do not want most of your traffic being routed over an unreliable route. So if there is route flap going on, it is best to avoid that route if you can. This is enforced by the holddown timer.

How to configure the holddown timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the holddown timer.

For example, your network has two routes that you want to set the holddown timer for. One is your main route (to 10.12.101.4) that all your Internet traffic goes through, and it can't be down for long if its down. The second is a low speed connection to a custom network that is used infrequently (to 10.13.101.4). The holddown timer for the main route should be fairly short, lets say 60 seconds instead of the default 180 seconds. The second route timer can be left at the default or even longer since it is rarely used. In your BGP configuration this looks like:

```
config router bgp
   config neighbor
   edit 10.12.101.4
      set holddown-timer 60
   next
   edit 10.13.101.4
      set holddown-timer 180
   next
   end
end
```

Dampening

Dampening is a method used to limit the amount of network problems due to flapping routes. With dampening the flapping still occurs, but the peer routers pay less and less attention to that route as it flaps more often. One flap doesn't start dampening, but the second starts a timer where the router will not use that route — it is considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There is a period of time called the reachability half-life after which a route flap will only be suppressed for half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate units cache by using one of the `execute router clear bgp` commands:

```
execute router clear bgp dampening {<ip_address> | <ip/netmask>}
```

or

```
execute router clear bgp flap-statistics {<ip> | <ip/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the command:

```
execute router clear bgp dampening 10.10.0.0/16
```

The BGP commands related to route dampening are:

```
config router bgp
  set dampening {enable | disable}
  set dampening-max-suppress-time <minutes_integer>
  set dampening-reachability-half-life <minutes_integer>
  set dampening-reuse <reuse_integer>
  set dampening-route-map <routemap-name_str>
  set dampening-suppress <limit_integer>
  set dampening-unreachability-half-life <minutes_integer>
end
```

Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded, but the hardware can still function normally.

Graceful restart is best used for these situations where routing will not be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart does not have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster will advertise it is going offline, and will not appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table — if there is a flap the HA cluster routing table will be out of date.

For example, your FortiGate unit is one of four BGP routers that send updates to each other. Any of those routers may support graceful starting—when a router plans to go offline, it will send out a message to its neighbors how long it expects to be before being back online. That way its neighbor routers don't remove it from their routing tables. However if that router isn't back online when expected, the routers will mark it offline. This prevents routing flap and its associated problems.

Scheduled time offline

Graceful restart is a means for a router to advertise it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their routing table until after a set time elapses. During that time if the router comes back online, everything continues to function as normal. If that router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that router will be offline for a long time.

FortiGate units support both graceful restart of their own BGP routing software, and also neighboring BGP routers.

For example, if a neighbor of your FortiGate unit, with an IP address of 172.20.120.120, supports graceful restart, enter the command:

```
config router bgp
  config neighbor
  edit 172.20.120.120
    set capability-graceful-restart enable
  end
end
```

If you want to configure graceful restart on your FortiGate unit where you expect the Fortigate unit to be offline for no more than 2 minutes, and after 3 minutes the BGP network should consider the FortiGate unit offline, enter the command:

```
config router bgp
  set graceful-restart enable
  set graceful-restart-time 120
  set graceful-stalepath-time 180
end
```

The BGP commands related to BGP graceful restart are:

```
config router bgp
  set graceful-restart { disable| enable}
  set graceful-restart-time <seconds_integer>
  set graceful-stalepath-time <seconds_integer>
  set graceful-update-delay <seconds_integer>
  config neighbor
    set capability-graceful-restart {enable | disable}
  end
end

execute router restart
```

Before the restart, the router sends its peers a message to say it is restarting. The peers mark all the restarting router's routes as stale, but they continue to use the routes. The peers assume the router will restart and check its routes and take care of them if needed after the restart is complete. The peers also know what services the restarting router can maintain during its restart. After the router completes the restart, the router sends its peers a message to say it is done restarting.

Bi-directional forwarding detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

While BGP can detect route failures, BFD can be configured to detect these failures more quickly allowing faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

Configurable granularity

BFD can run on the entire FortiGate unit, selected interfaces, or on BGP for all configured interfaces. The hierarchy allows each lower level to override the upper level's BFD setting. For example, if BFD was enabled for the FortiGate unit, it could be disabled only for a single

interface or for BGP. For information about FortiGate-wide BFD options, see config system settings in the *FortiGate CLI Reference*.

BFD can only be configured through the CLI.

The BGP commands related to BFD are:

```
config system {setting | interface}
  set bfd {enable | disable | global}
  set bfd-desired-mix-tx <milliseconds>
  set bfd-detect-mult <multiplier>
  set bfd-required-mix-rx <milliseconds>
  set bfd-dont-enforce-src-port {enable | disable}

config router bgp
  config neighbor
    edit <neighbor_address_ipv4>
    set bfd {enable | disable}
  end
end

get router info bfd neighbor
execute router clear bfd session <src_ipv4> <dst_ipv4> <interface>
```

The `config system` commands allow you to configure whether BFD is enabled in a particular unit/vdom or individual interface, and how often the interface requires sending and receiving of BFD information.

The `config router bgp` commands allow you to set the addresses of the neighbor units that are also running BFD. Both units must be configured with BFD in order to make use of it.

Dual-homed BGP example

This is an example of a small network that uses BGP routing connections to two ISPs. This is a common configuration for companies that need redundant connections to the Internet for their business.

This configuration is for a small company connected to two ISPs. The company has one main office, the Head Office, and uses static routing for internal routing on that network.

Both ISPs use BGP routing, and connect to the Internet directly. They want the company to connect to the ISP networks using BGP. They also use graceful restart to prevent unneeded updates, and use smaller timer values to detect network failures faster.

As can be expected, the company wants to keep their BGP configuration relatively simple and easy to manage. The current configuration has only 3 routers to worry about — the 2 ISP border routers, and the FortiGate unit. This means the FortiGate unit will only have two neighbour routers to configure.

This configuration has the added benefit of being easy to expand if the Company wants to add a remote office in the future.

To keep the configuration simple, the Company is allowing only HTTP, HTTPS, FTP, and DNS traffic out of the local network. This will allow employees access to the Internet and their web-mail.

This section includes the following topics:

Why dual home?

Dual homing means having two separate independent connections to the Internet. Servers in this configuration have also been called bastion hosts and can include DNS servers which require multiple connections.

Benefits of dual homing can include:

- redundant Internet connection that essentially never fails
- faster connections through one ISP or the other for some destinations, such as other clients of those ISPs
- load balancing traffic to your Company network
- easier to enable more traffic through two connections than upgrading one connection to bigger bandwidth
- easier to create protection policies for different traffic through a specific ISP

Some companies require reliable internet access at all times as part of their business. Consider a doctor operating remotely who has their Internet connection fail — the consequences could easily be life or death.

Dual homing is extra expense for the second ISP connection, and more work to configure and maintain the more complex network topology.

Potential dual homing issues

BGP comes with load balancing issues, and dual homing is the same category. BGP does not inherently deal well with load balancing, or getting default routes through BGP. Ideally one connect may be best for certain destinations, but it may not have that traffic routed to it making the load balancing less than perfect. This kind of fine tuning can be very time consuming, and usually results in a best effort situation.

When dual homing is not configured properly, your network may become a link between your ISPs and result in very high traffic between the ISPs that does not originate from your network. The problems with this situation are that your traffic may not have the bandwidth it needs, and you will be paying for a large volume of traffic that is not yours. This problem can be solved by not broadcasting or redistributing BGP routes between the ISPs.

If you learn your default routes from the ISPs in this example, you may run into an asymmetric routing problem where your traffic loops out one ISP and back to you through the other ISP. If you think this may be happening you can turn on asymmetric routing on the FortiGate unit (config system settings, set asymmetric enable) to verify that really is the problem. Turn this feature off once this is established since it disables many features on the FortiGate by disabling stateful inspection. Solutions for this problem can include using static routes for default routes instead of learning them through BGP, or configuring VDOMs on your FortiGate unit to provide a slightly different path back that is not a true loop.

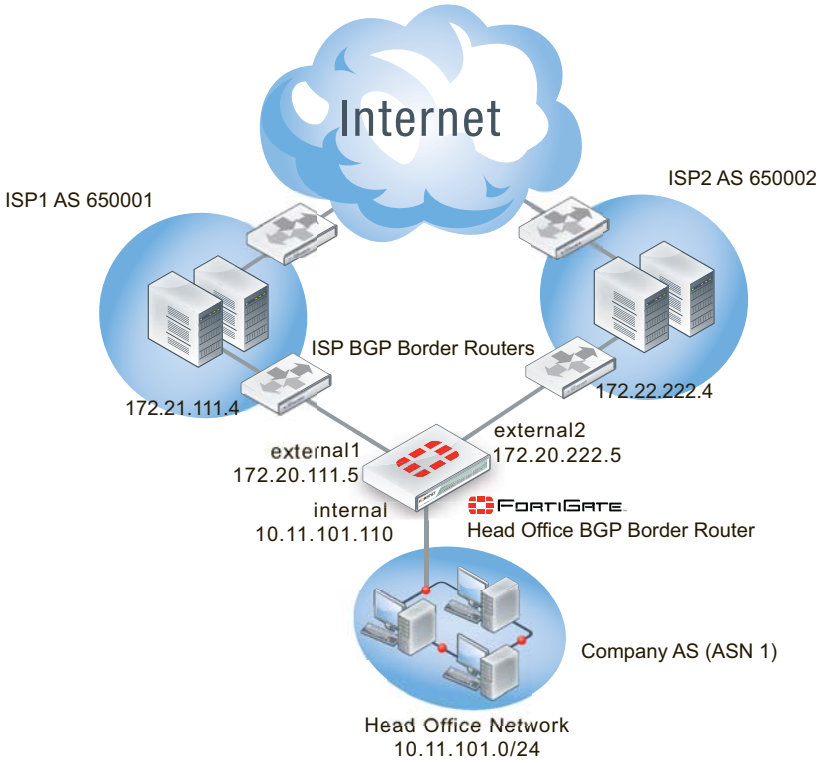
Network layout and assumptions

The network layout for the basic BGP example involves the company network being connected to both ISPs as shown below. In this configuration the FortiGate unit is the BGP border router between the Company AS, ISP1's AS, and ISP2's AS.

The components of the layout include:

- The Company AS (AS number 1) is connected to ISP1 and ISP2 through the FortiGate unit.
- The Company has one internal network — the Head Office network at 10.11.101.0/24.
- The FortiGate unit internal interface is on the the Company internal network with an IP address of 10.11.101.110.
- The FortiGate unit external1 interface is connected to ISP1's network with an IP address of 172.20.111.5, an address supplied by the ISP.
- The FortiGate unit external2 interface is connected to IPS2's network with an IP address of 172.20.222.5, an address supplied by the ISP.
- ISP1 AS has an AS number of 650001, and ISP2 has an AS number of 650002.
- Both ISPs are connected to the Internet.
- The ISP1 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.21.111.4.
- The ISP2 border router is a neighbor (peer) of the FortiGate unit. It has an address of 172.22.222.4.
- Apart from graceful restart, and shorter timers (holdtimer, and keepalive) default settings are to be used whenever possible.

Figure 108: Basic BGP network topology



Assumptions

The basic BGP configuration procedure follows these assumptions:

- ISP1 is the preferred route, and ISP2 is the secondary route
- all basic configuration can be completed in both GUI and CLI
- only one AS is used for the Company

For these reasons this example configuration does not include:

- Bi-directional forwarding detection (BFD)
- Route maps
- Access lists
- changing redistribution defaults — make link when example is set up
- IPv6

For more information on these features, see the corresponding section.

Configuring the FortiGate unit

In this topology, the FortiGate unit is the link between the Company Network and the ISP network. The FortiGate unit is the only BGP router on the Company Network, but there is at least one other BGP router on the ISP Network — there may be more but we don't have that information.

As mentioned in the general configuration steps, the ISP must be notified of the Company's BGP router configuration when complete as it will need to add the FortiGate BGP router as a neighbor router on its domain. This step is required for the FortiGate unit to receive BGP routing updates from the ISP network and outside networks.

If the ISP has any special BGP features enabled such as graceful restart, or route dampening that should be determined up front so those features can be enabled on the FortiGate unit.

To configure the FortiGate unit as a BGP router

1. Configure interfaces and default routes
2. Configure firewall services, addresses, and policies
3. Set the FortiGate BGP information
4. Add the internal network to the AS
5. Additional FortiGate BGP configuration

Configure interfaces and default routes

The FortiGate unit is connected to three networks — Company Network on the internal interface, ISP1 Network on external1interface, and ISP2 on external2 interface.

This example uses basic interface settings. Check with your ISP to determine if additional settings are required such as setting the maximum MTU size, or if gateway detection is supported.

High end FortiGate units do not have interfaces labeled Internal, or External. Instead, for clarity's sake, we are using the alias feature to name interfaces for these roles.

Default routes to both external interfaces are configured here as well. Both are needed in case one goes offline. ISP1 is the primary connection and has a smaller administrative distance so it will be preferred over ISP2. Both distances are set low so they will be preferred over any learned routes.

To configure the FortiGate interfaces - web-based manager

1. Go to *System* > *Network* > *Interface*.
2. Edit port 1 (internal) interface.

3. Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.101.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Company internal network
Administrative Status	Up

4. Edit port 2 (external1) interface.
5. Set the following information, and select *OK*.

Alias	external1
IP/Netmask	172.21.111.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP1 External BGP network
Administrative Status	Up

6. Edit port 3 (external2) interface.
7. Set the following information, and select *OK*.

Alias	external2
IP/Netmask	172.22.222.5/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP2 External BGP network
Administrative Status	Up

To configure the FortiGate interfaces - CLI

```
config system interface
  edit port1
    set alias internal
    set ip 10.11.101.110 255.255.255.0
    set allowaccess http https ssh
    set description "Company internal network"
    set status up
  next
  edit port2
    set alias external1
    set ip 172.21.111.5 255.255.255.0
    set allowaccess https ssh
    set description "ISP1 External BGP network"
    set status up
  next
  edit port3
    set alias external2
    set ip 172.22.222.5 255.255.255.0
    set allowaccess https ssh
    set description "ISP2 External BGP network"
    set status up
  next
end
```

To configure default routes for both ISPs - web-based manager

1. Go to *Router* > *Static* > *Static Route*s.
2. Delete any existing routes with a IP/Mask of address of 0.0.0.0/0.0.0.0
3. Select *Create New*, and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port2
Gateway	172.21.111.5
Distance	10

4. Select OK.
5. Select *Create New*, and set the following information.

Destination IP/Mask	0.0.0.0/0.0.0.0
Device	port3
Gateway	172.22.222.5
Distance	15

6. Select OK.

To configure default routes for both ISPs - CLI

```
config router static
  edit 1
    set device "port2"
    set distance 10
    set gateway 172.21.111.5
  next
  edit 2
    set device "port3"
    set distance 15
    set gateway 172.22.222.5
  next
end
```

Configure firewall services, addresses, and policies

To create the security policies, first you must create the firewall services group that will include all the services that will be allowed, then you must define the addresses that will be used in the security policies, and lastly you configure the security policies themselves.

To keep the configuration simple, the Company is allowing only HTTP traffic out of the local network. This will allow employees access to the Internet and their web-mail. DNS services will also be allowed through the firewall.

The security policies will allow HTTP traffic (port 80 and port 8080), HTTPS traffic (port 443), FTP traffic (port 21), and DNS traffic (port 53 and port 953) in both directions. Also BGP (port 179) may need access through the firewall.

For added security, you may want to define a smaller range of addresses for the internal network. For example if only 20 addresses are used, only allow those addresses in the range.

In the interest of keeping things simple, a zone will be used to group the two ISP interfaces together. This will allow using one security policy to apply to both ISPs at the same time. Remember to block intra-zone traffic as this will help prevent one ISP sending traffic to the other ISP through your FortiGate unit using your bandwidth. The zone keeps configuration simple, and in the future if there is a need for separate policies for each ISP, they can be created and the zone can be deleted.

The addresses that will be used are the addresses of the FortiGate unit internal and external ports, and the internal network.

More policies or services can be added in the future as applications are added to the network. For more information on security policies, see the firewall chapter of the FortiGate Administration Guide.

When configuring security policies always enable logging to help you track and debug your traffic flow.

To create a firewall services group - web-based manager

1. Go to *Firewall Objects* > *Service* > *Group*s, and select *Create New*.

2. For *Group Name*, enter “Basic_Services”.
3. From *Available Services*, move the following six services over to the *Member* list — BGP, FTP, FTP_GET, FTP_PUT, DNS, HTTP, and HTTPS.
4. Select *OK*.

To create a firewall services group - CLI

```
config firewall service group
  edit "Basic_Services"
    set member "BGP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS"
  next
end
```

To create a zone for the ISP interfaces - web-based manager

1. Go to *System* > *Network* > *Interfaces.*
2. Select the caret to the right of *Create New* and then select *Zone*.
3. Enter the following information.

Zone Name	ISPs
Block Intra-zone traffic	enable
interface members	port2 port3

4. Select *OK*.

To create a zone for the ISP interfaces - CLI

```
config system zone
  edit "ISPs"
    set interface "port2" "port3"
    set intrazone block
  next
end
```

To add the firewall addresses - web-based manager

1. Go to *Firewall Objects* > *Address* > *Addresses*.
2. Select *Create New*, and set the following information.

Address Name	Internal_network
Type	Subnet / IP Range
Subnet / IP Range	10.11.101.0 255.255.255.0
Interface	port1

3. Select OK.

To add the firewall addresses - CLI

```
config firewall address
  edit "Internal_network"
    set associated-interface "port1"
    set subnet 10.11.101.0 255.255.255.0
  next
end
```

To add the HTTP and DNS security policies - web-based manager

1. Go to *Policy* > *Policy* > *Policy*, and select *Create New*.
2. Set the following information.

Source Interface/Zone	port1(internal)
Source Address	Internal_network
Destination Interface/Zone	ISPs
Destination Address	All
Schedule	always
Service	Basic_services
Action	ACCEPT
Log Allowed Traffic	enable
Enable NAT	Enable
Comments	ISPs basic services out policy

3. Select *OK*.
4. Select *Create New*, and set the following information.

Source Interface/Zone	ISPs
Source Address	all
Destination Interface/Zone	port1(internal)
Destination Address	Internal_network
Schedule	always
Service	Basic_services
Action	ACCEPT
Log Allowed Traffic	enable
NAT	Enable
Comments	ISPs basic services in policy

To add the security policies - CLI

```
config firewall policy
  edit 1
    set srcintf "port1"
    set srcaddr "Internal_network"
    set dstintf "ISPs"
    set dstaddr "all"
    set schedule "always"
    set service "Basic_services"
    set action accept
    set nat enable
    set profile-status enable
    set logtraffic enable
    set comments "ISPs basic services out policy"
  next
  edit 2
    set srcintf "ISPs"
    set srcaddr "all"
    set dstintf "port1"
    set dstaddr "Internal_network"
    set schedule "always"
    set service "Basic_services"
    set action accept
    set nat enable
    set profile-status enable
    set logtraffic enable
    set comments "ISPs basic services in policy"
  next
end
```

Set the FortiGate BGP information

When using the default information, there are only two fields to set to configure the FortiGate unit as a BGP router.

For this configuration the FortiGate unit will be in a stub area with one route out — the ISP BGP router. Until you configure the ISP router as a neighbour, even that route out is not available. So while after this part of the configuration is complete your FortiGate unit will be running BGP, it won't know about any other routers running BGP until the next part of the configuration is complete.

To set the BGP router information - web-based mananger

1. Go to *Router* > *Dynamic* > *BGP*.
2. Set the following information, and select OK.

Local AS	1
Router ID	10.11.101.110

To set the BGP router information - CLI

```
config router BGP
  set as 1
  set router-id 10.11.101.110
end
```

Add the internal network to the AS

The Company is one AS with the FortiGate unit configured as the BGP border router connecting that AS to the two ISPs ASes. The internal network in the Company's AS must be defined. If there were other networks in the company such as regional offices, they would be added here as well.

To set the networks in the AS - web-based manager

1. Go to *Router* > *Dynamic* > *BGP*.
2. In *Networks*, set the following information and select *OK*.

IP/Netmask	10.11.101.0/255.255.255.0

To set the networks in the AS - CLI

```
config router bgp
  config network
  edit 1
    set prefix 10.11.101.0 255.255.255.0
  next
  end
end
```

Add BGP neighbor information

The configuration will not work unless you set *Remote AS* neighbors. This can be done in either the web-based manager or the CLI.

To configure the BGP neighbors - web-based manager

1. Go to *Router* > *Dynamic* > *BGP*.
2. Add a *Neighbors IP* of 172.21.111.4 with the *Remote AS* set to 650001, then click *Add*/*Edit*.
3. Add another *Neighbors IP* of 172.22.222.4 with the Remote AS set to 650002, then click *Add*/*Edit*.

To configure the BGP neighbors - CLI

```
config router BGP
  set as 1
    config neighbor
      edit "172.21.111.4"
        set remote-as 650001
      next
      edit "172.22.222.4"
        set remote-as 650002
      next
    end
  end
```

Additional FortiGate BGP configuration

At this point that is all the settings that can be done in both the web-based manger and the CLI. The remaining configuration must be completed in the CLI.

These additional settings are mainly determined by your ISP requirements. They will determine your timers such as keep alive timers, if extended features like BFD and graceful restart are being used, and so on. For this example, some common simply features are being used to promote faster detections of network failures which will result in better service for the Company's internal network users.

The ISPs do not require authentication between peer routers.

These commands will enable or modify the following features on the FortiGate unit, and where possible on neighboring routers as well:

- `bestpath-med-missing-as-worst` — treats a route without an MED as the worst possible available route due to expected unreliability
- `fast-external-failover` — immediately reset the session information associated with BGP external peers if the link used to reach them goes down
- `graceful-restart*` — advertise reboots to neighbors so they do not see the router as offline, wait before declaring them offline, and how long to wait when they reboot before advertising updates. These commands applies to neighbors and are part of the BGP capabilities. This prevents unneeded routing updates.
- `holdtime-timer` — how long the router will wait for a keepalive message before declaring a router offline. A shorter time will find an offline router faster.
- `keepalive-timer` — how often the router sends out keepalive messages to neighbor routers to maintain those sessions.
- `log-neighbor-changes` — log changes to neighbor routers' status. This can be useful for troubleshooting from both internal and external networks.
- `connect-timer` — how long in seconds the FortiGate unit will try to reach this neighbor before declaring it offline.
- `weight` — used to prefer routes from one neighbor over the other. In this example ISP1 is the primary connection so it is weighted higher than ISP2

To configure additional BGP options - CLI

```
config router bgp
  set bestpath-med-missing-as-worst enable
  set fast-external-failover enable
  set graceful-restart enable
  set graceful-restart-time 120
  set graceful-stalepath-time 180
  set graceful-update-delay 180
  set holdtime-timer 120
  set keepalive-timer 45
  set log-neighbor-changes enable
  config neighbor
    edit 172.21.111.4
      set connect-timer 60
      set description "ISP1"
      set holdtime-timer 120
      set keepalive-timer 45
      set weight 250
    next
    edit 172.22.222.4
      set connect-timer 60
      set description "ISP2"
      set holdtime-timer 120
      set keepalive-timer 45
      set weight 100
    next
  end
end
```

Configuring other networking devices

There are two other networking devices that need to be configured: both ISPs' BGP routers.

The ISPs' routers must add the FortiGate unit as a neighbor so route updates can be sent in both directions. Note that ISP1 is not directly connected to ISP2 that we are aware of.

Inform both of your ISPs of your FortiGate unit's BGP information. Once they have configured their router, you can test your BGP connection to the Internet.

They will require your FortiGate unit's:

- IP address of the connected interface
- Router ID
- your Company's AS number

Testing this configuration

With the dual-homed BGP configuration in place, you should be able to send and receive traffic, send and receive routes, and not have any routing loops. Testing the networks will confirm things are working as expected.

In general for routing you need to look at the routing table on different routers to see what routes are being installed. You also need to sniff packets to see how traffic is being routed in real time. These two sources of information will normally tell you what you need to know.

Testing of this example's network configuration should be completed in two parts:

- Testing network connectivity
- Verifying the FortiGate unit's routing tables
- Verifying traffic routing
- Verifying the dual-homed side of the configuration

Testing network connectivity

A common first step in testing a new network topology is to test if you can reach the internet and other locations as you expect you should. If not, you may be prevented be cabling issues, software or other issues.

The easiest way to test connections is to use ping, once you ensure that all the FortiGate unit's interfaces and ISP routers have ping support enabled. Also ensure that the security policies allow ping through the firewall.

Connections to test in this example are the internal network to ISP1's router or the internet, and the same for ISP2. If you can connect on the external side of the Fortinet unit, try to ping the internal network. Those three tests should prove your basic network connections are working.

Once you have completed testing the network connectivity, turn off ping support on the external interfaces for additional security.

Verifying the FortiGate unit's routing tables

The FortiGate routing table contains the routes stored for future use. If you are expecting certain routes to be there and they are not, that is a good indicator that your configuration is not what you expected.

The CLI command `get router info routing-table details` will provide you with every route's routing protocol, destination address, gateway address, interface, weighting, and if the address is directly connected or not.

If you want to limit the display to BGP routes only, use the CLI command `get router info routing-table bgp`. If there are no BGP routes in the routing table, nothing will be displayed. In the CLI command you can replace BGP with static, or other routing protocols to only display those routes.

If you want to see the contents of the routing information database (RIB), use the CLI command `get router info routing-table database`. This will display the incoming routes that may or may not make it into the routing table.

Verifying traffic routing

Traffic may be reaching the internal network, but it may be using a different route than you think to get there.

Use a browser to try and access the Internet.

If needed, allow traceroute and other diag ports to be opened until things are working properly. Then remove access for them again.

Look for slow hops on the traceroute, or pings to a location, as they may indicate network loops that need to be fixed.

Any locations that have an unresolved traceroute or ping must be examined and fixed.

Use network packet sniffing to ensure traffic is being routed as you expect.

Verifying the dual-homed side of the configuration

Since there are two connections to the internet in this example, theoretically you can pull the plug on one of the ISP connections, and all traffic will go through the other connection. Alternately, you may choose to remove a default route to one ISP, remove that ISP's neighbor settings, or change the weightings to prefer other other ISP. These alternate ways to test dual-homing do not change physical cabling, which may be preferred in some situations.

If this does not work as expected, things to check include:

- default static routes — if these are wrong or don't exist, the traffic can't get out.
- BGP neighbor information — If the ISP router information is incorrect, the FortiGate unit won't be able to talk to it.

Redistributing and blocking routes in BGP

During normal BGP operation, peer routers redistribute routes from each other. However, in some specific situations it may be best to not advertise routes from one peer, such as if the peer is redundant with another peer (they share the same routes exactly), if it might be unreliable in some way, or some other reason. The FortiGate can also take routes it learns from other protocols and advertise them in BGP, for example OSPF or RIP. If your Company hosts its own web or email servers, external locations will require routes to your networks to reach those services.

In this example the Company has an internal network in an OSPF area, and is connected to a BGP AS and two BGP peers. Company goes through these two peers to reach the Internet. However, Peer 1 routes will not be advertised to Peer 2. The Company internal user and server networks are running OSPF, and will redistribute those routes to BGP so external locations can reach the web and email servers.

This section includes the following topics:

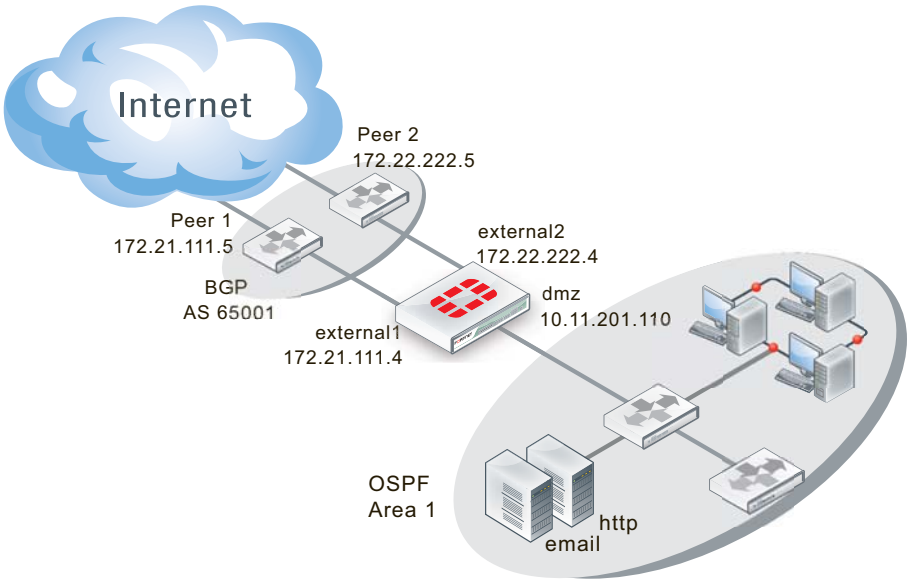
Network layout and assumptions

The network layout for the BGP redistributing routes example involves the company network being connected to two BGP peers as shown below. In this configuration the FortiGate unit is the BGP border router between the Company AS, and the peer routers.

The components of the layout include:

- There is only one BGP AS in this example — AS 65001, shared by the FortiGate unit and both peers.
- The Company's FortiGate unit connects to the Internet through two BGP peers.
- The Company internal networks on the dmz interface of the FortiGate unit with an IP of 10.11.201.0/24.
- The FortiGate units' interfaces are connected as follows:
  - port1 (dmz) has IP 10.11.201.110 and is the internal user and server network
  - port2 (external1) has IP 172.21.111.4 and is connected to Peer 1's network
  - port3 (external2) has IP 172.22.222.4 and is connected to Peer 2's network
- Peer 1 has IP 172.21.111.5, and Peer 2 has IP 172.22.222.5.
- OSPF Area 1 is configured on the dmz interface of the FortiGate unit, and is the routing protocol used by the internal users and servers.

Figure 109:BGP network topology



Assumptions

The the BGP redistributing routes configuration procedure follows these assumptions:

- the FortiGate unit has been configured following the Install Guide
- interfaces port1, port2, and port 3 exist on the FortiGate unit
- we don't know the router manufacturers of Peer 1 and Peer 2
- we don't know what other devices are on the BGP AS or OSPF Area
- all basic configuration can be completed in both GUI and CLI
- access lists and route maps will only be configured in CLI
- VDOMs are not enabled on the FortiGate unit

Configuring the FortiGate unit

1. Configuring the FortiGate unit — networks and firewalls
2. Configuring the FortiGate unit - BGP

3. Configuring the FortiGate unit - OSPF
4. Configuring other networking devices

Configuring the FortiGate unit — networks and firewalls

The FortiGate unit has three interfaces connected to networks — two external and one dmz.

Security policies must be in place to allow traffic to flow between these networks.

Firewall services will change depending on which routing protocol is being used on that network — either BGP or OSPF. Beyond that, all services that are allowed will be allowed in both directions due to the internal servers. The services allowed are web-server services (DNS, HTTP, HTTPS, SSH, NTP, FTP*, SYSLOG, and MYSQL), email services (POP3, IMAP, and SMTP), and general troubleshooting services (PING, TRACEROUTE). Those last two can be removed once the network is up and working properly to increase security. Other services can be added later as needed.

To configure the interfaces - GUI

1. Go to *System* > *Network* > *Interfaces*.
2. Edit port1 (dmz) interface.
3. Set the following information, and select *OK*.

Alias	dmz
IP/Netmask	10.11.201.110/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	OSPF internal networks
Administrative Status	Up

4. Edit port2 (external1) interface.
5. Set the following information, and select *OK*.

Alias	external1
IP/Netmask	172.21.111.4/255.255.255.0
Administrative Access	HTTPS SSH
Description	BGP external1 Peer 1
Administrative Status	Up

6. Edit port3 (external2) interface.
7. Set the following information, and select *OK*.

Alias	external2
IP/Netmask	172.22.222.4/255.255.255.0
Administrative Access	HTTPS SSH
Description	BGP external2 Peer2
Administrative Status	Up

To configure the FortiGate interfaces (CLI)

```
config system interface
  edit port1
    set alias dmz
    set ip 10.11.201.110 255.255.255.0
    set allowaccess https ssh ping
    set description "OSPF internal networks"
    set status up
  next
  edit port2
    set alias external1
    set ip 172.21.111.4 255.255.255.0
    set allowaccess https ssh
    set description "BGP external1 Peer 1"
    set status up
  next
  edit port3
    set alias external2
    set ip 172.22.222.4 255.255.255.0
    set allowaccess https ssh
    set description "BGP external2 Peer 2"
    set status up
  next
end
```

To configure the firewall addresses - GUI

1. Go to *Firewall Objects* > *Address* > *Addresses*.
2. Select *Create New*, and set the following information.

Address Name	BGP_services
Type	Subnet / IP Range
Subnet / IP Range	10.11.201.0 255.255.255.0
Interface	port1

3. Select *OK*.
4. Select *Create New*, and enter the following information:
5. Select *OK*.

To configure the firewall addresses - CLI

```
config firewall address
  edit "BGP_services"
    set associated-interface "port1"
    set subnet 10.11.201.0 255.255.255.0
  next
end
```

To configure firewall service groups - GUI

1. Go to *Firewall Objects* > *Service* > *Groups*.
2. Select *Create New*.
3. Name the group BGP_Services.
4. Move the following services to the right list: BGP, DHCP, DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
5. Select *OK*.
6. Select *Create New*.
7. Name the group OSPF_Services.
8. Move the following services to the right list: DNS, FTP, FTP_GET, FTP_PUT, HTTP, HTTPS, IMAP, MYSQL, NTP, OSPF, PING, POP3, SMTP, SSH, SYSLOG, and TRACEROUTE.
9. Select *OK*.

To configure firewall service groups - CLI

```
config firewall service group
  edit "BGP_services"
    set member “BGP”, "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP"
        "HTTPS" "IMAP" "MYSQL" "NTP" "PING" "POP3" "SMTP" "SSH"
        "TRACEROUTE" "SYSLOG"
  next
  edit "OSPF_services"
    set member "DHCP" "DNS" "FTP" "FTP_GET" "FTP_PUT" "HTTP" "HTTPS"
        "IMAP" "MYSQL" "NTP" "PING" "POP3" "SMTP" "SSH"
        "TRACEROUTE" "SYSLOG" "OSPF"
  next
end
```

Configuring the FortiGate unit - BGP

The only change from the standard BGP configuration for this example is configuring the blocking Peer 1’s routes from being advertised to Peer 2. From the network topology you can guess that both of these peers likely share many routes in common and it makes no sense to advertise unneeded routes.

Blocking Peer 1’s routes to Peer 2 is done with distribute-list-out keyword. They allow you to select which routes you will advertise to a neighbor using an access list. In this case we will block all incoming routes from Peer 1 when we send updates to Peer 2. Otherwise Peer 1 and Peer 2 are regular neighbors.

The FortiGate unit will redistribute routes learned from OSPF into BGP.

This is advanced configuration and the commands are only available in the CLI.

To create access list to block Peer 1 - CLI

```
config access-list
  edit "block_peer1"
    config rule
    edit 1
      set prefix 172.21.111.0 255.255.255.0
      set action deny
      set exact-match enable
    end
  end
end
```

To configure BGP on the FortiGate unit - CLI

```
config router bgp
  set as 65001
  set router-id 10.11.201.110
  config redistribute ospf
    set status enable
  end
  config neighbor
    edit 172.22.222.5
      set remote-as 65001
      set distribute-list-out "block_peer1"
    next
    edit 172.21.111.5
      set remote-as 65001
    end
end
```

Configuring the FortiGate unit - OSPF

This configuration involves only one OSPF Area, so all traffic will be intra-area. If there were two or more areas with traffic going between them it would be inter-area traffic. These two types are comparable to BGP's traffic within one AS (iBGP) or between multiple ASes (eBPG). Redistributing routes from OSPF to BGP is considered external because either the start or end point is a different routing protocol.

The OSPF configuration is basic apart from redistributing BGP routes learned.

To configure OSPF on the FortiGate unit - web-based manager

1. Go to *Router* > *Dynamic* > *OSPF*.
2. For Router ID enter `10.11.201.110` and then select *Apply*.
3. Under *Advanced Options* and *Redistribute*, select *BGP* and set BGP metric to 1.
4. For *Areas*, select *Create New,* enter the following information and then select *OK*.

Area (IP)	`0.0.0.0`
Type	Regular
Authentication	None

5. For *Networks*, select *Create New*.

6. Enter 10.11.201.0/255.255.255.0 for *IP/Netmask*, and select *OK*.
7. For *Interfaces*, select *Create New*.
8. Enter `OSPF_dmz_network` for *Name*.
9. Select `port1(dmz)` for *Interface*, and then select *OK*.

To configure OSPF on the FortiGate unit - CLI

```
config router ospf
  set router-id 10.11.201.110
  config area
    edit 0.0.0.0
      set type regular
      set authentication none
    end
  config network
    edit 1
      set area 0.0.0.0
      set prefix 10.11.201.0 255.255.255.0
    end
  config interface
    edit "OSPF_dmz_network"
      set interface port1(dmz)
      set status enable
    end
  config redistribute bgp
    set status enable
    set metric 1
  end
end
```

Configuring other networking devices

As with all BGP configurations, the peer routers will need to be updated with the FortiGate unit's BGP information including IP address, AS number, and what capabilities are being used such as IPv6, graceful restart, BFD, and so on.

Testing network configuration

Testing this configuration involves the standard connectivity checks, but also ensuring that routes are being passed between protocols as expected.

Check the routing table on the FortiGate unit to ensure that routes from both OSPF and BGP are present.

Check the routing table on devices on the OSPF network for routes redistributed from BGP. Also check those devices for connectivity to the Internet.

Check the routing table on Peer 2 to ensure no routes from Peer 1 are present, but routes from the internal OSPF network are present.

For help with troubleshooting, see "Troubleshooting BGP" on page 370.

Open Shortest Path First (OSPF)

This section describes OSPF routing.

The following topics are included in this section:

OSPF Background and concepts

OSPF (Open Shortest Path First) is a link-state interior routing protocol, that is widely used in large enterprise organizations. It only routes packets within a single autonomous system (AS). This is different from BGP as BGP can communicate between ASes.

This section includes:

Background

OSPF version 2 was defined in 1998 in RFC 2328. OSPF was designed to support classless IP addressing, and variable subnet masks. This was a shortcoming of the earlier RIP protocols.

Updates to OSPF version 2 are included in OSPF version 3 defined in 2008 in RFC 5340. OSPF3 includes support for IPv6 addressing where previously OSPF2 only supports IPv4 addressing.

The main benefit of OSPF is that it detects link failures in the network quickly and within seconds has converged network traffic successfully without any networking loops. Also OSPF has many features to control which routes are propagated and which are not, maintaining smaller routing tables. OSPF can also provide better load-balancing on external links than other interior routing protocols.

The parts and terminology of OSPF

Parts and terminology of OSPF includes:

OSPFv3 and IPv6

OSPFv3 (OSPF version 3) includes support for IPv6. Generally, all IP addresses are in IPv6 format instead of IPv4. However, OSPFv3 area numbers use the same 32-bit numbering system as OSPFv2, as described in RFC 2740. Likewise, the router ID and area ID are in the same format as OSPFv2.

As with most advanced routing features on your FortiGate unit, IPv6 settings for dynamic routing protocols must be enabled before they will be visible in the GUI. To enable IPv6 configuration in the GUI, enable it in *System* > *Admin* > *Settings*.

For IPv6, the main difference in OSPFv3 is that, rather than using a network statement to enable OSPFv3 on an interface, you define OSPF6 (OSPF for IPv6) interfaces, which are bound to interface and area. This configuration must be done in the CLI, as follows (with sample interfaces and addresses):

```
config router ospf6
  config area
    edit 0.0.0.0
  next
end
config ospf6-interface
  edit "tunnel"
  set interface "to_FGT300A-7"
next
  edit "internal_lan"
  set interface "port1"
next
  set router-id 10.174.0.113
end
```

Note that OSPFv3 neighbors use link-local IPv6 addresses, but with broadcast and point-to-point network types, neighbors are automatically discovered. You only have to manually configure neighbors when using non-broadcast network types.

Router ID

In OSPF, each router has a unique 32-bit number called its Router ID. Often this 32-bit number is written the same as a 32-bit IPv4 address would be written in dotted decimal notation. However some brands of routers, such as Cisco routers, support a router ID entered as an integer instead of an IP address.

It is a good idea to not use IP address in use on the router for the router ID number. The router ID does not have to be a particular IP address on the router. By choosing a different number, it will be harder to get confused which number you are looking at. A good idea can be to use the as much of the area's number as possible. For example if you have 15 routers in area 0.0.0.0 they could be numbered from 0.0.0.1 to 0.0.0.15. If you have an area 1.1.1.1, then routers in that area could start at 1.1.1.10 for example.

You can manually set the router ID on your FortiGate unit.

To manually set an OSPF router ID of 0.0.1.1 - web-based manager

1. Go to *Router* > *Dynamic* > *OSPF*.
2. For *Router ID*, enter `0.0.1.1`.
3. Select *Apply*.

To manually set an OSPF router ID of 0.0.1.1 - CLI

```
config router ospf
  set router-id 0.0.1.1
end
```

Adjacency

In an OSPF routing network, when an OSPF router boots up it sends out OSPF Hello packets to find any neighbors, routers that have access to the same network as the router booting up. Once neighbors are discovered and Hello packets are exchanged, updates are sent, and the Link State databases of both neighbors are synchronized. At this point these neighbors are said to be adjacent.

For two OSPF routers to become neighbors, the following conditions must be met.

- The subnet mask used on both routers must be the same subnet.
- The subnet number derived using the subnet mask and each router's interface IP address must match.
- The Hello interval & The Dead interval must match.
- The routers must have the same OSPF area ID. If they are in different areas, they are not neighbors.
- If authentication is used, they must pass authentication checks.

If any of these parameters are different between the two routers, the routers do not become OSPF neighbors and cannot be adjacent. If the routers become neighbors, they are adjacent.

Adjacency and neighbors

Neighbor routers can be in a Two-Way state, and not be adjacent. Adjacent routers normally have a neighbour state of FULL. Neighbors only exchange Hello packets, and do not exchange routing updates. Adjacent routers exchange LSAs (LSDB information) as well as Hello packets. A good example of an adjacent pair of routers is the DR and BDR.

You can check on the state of an OSPF neighbor using the CLI command `get router info ospf neighbor all`. See "Checking the state of OSPF neighbors" on page 409.

Why adjacency is important

It is important to have adjacent pairs of routers in the OSPF routing domain because routing protocol packets are only passed between adjacent routers. This means adjacency is required for two OSPF routers to exchange routes. If there is no adjacency between two routers, such as one on the 172.20.120.0 network and another on the 10.11.101.0 network, the routers do not exchange routes. This makes sense because if all OSPF routers on the OSPF domain exchanged updates it would flood the network. Also, it is better for updates to progress through adjacent routers to ensure there are no outages along the way. Otherwise, updates could skip over routers that are potentially offline, causing longer routing outages and delays while the OSPF domain learns of this outage later on.

If the OSPF network has multiple border routers and multiple connections to external networks, the designated router (DR) determines which router pairs become adjacent. The DR can accomplish this because it maintains the complete topology of the OSPF domain, including which router pairs are adjacent. The BDR also has this information in case the DR goes offline.

Designated router (DR) and backup router (BDR)

In OSPF a router can have a number of different roles to play.

A designated router (DR) is the designated broadcasting router interface for an AS. It looks after all the initial contact and other routing administration traffic. Having only one router do all this greatly reduces the network traffic and collisions.

If something happens and the designated router goes offline, the backup designated router (BDR) takes over. An OSPF FortiGate unit interface can become either a DR or BDR. Both the DR and the BDR cover the same area, and are elected at the same time. The election process doesn't have many rules, but the exceptions can become complex.

Benefits

The OSPF concept of the designated router is a big step above RIP. With all RIP routers doing their own updates all the time, RIP suffers from frequent and sometimes unnecessary updates that can slow down your network. With OSPF, not only do routing changes only happen when a link-state changes instead of any tiny change to the routing table, but the designated router reduces this overhead traffic even more.

However, smaller network topologies may only have a couple routers besides the designated router. This may seem excessive, but it maintains the proper OSPF form and it will still reduce the administration traffic but to a lesser extent than on a large network. Also, your network topology will be ready whenever you choose to expand your network.

DR and BDR election

An election chooses the DR and BDR from all the available routers. The election is primarily based on the priority setting of the routers—the highest priority becomes the DR, and the second highest becomes BDR. To resolve any ties, the router with the highest router ID wins. For example 192.168.0.1 would win over 10.1.1.2.

The router priority can vary from 0 to 255, but at 0 a router will never become a DR or BDR. If a router with a higher priority comes on line after the election, it must wait until after the DR and BDR go offline before it would become the DR.

If the original DR goes offline, but then is available when the BDR goes offline later on, the original DR will be promoted back to DR without an election leaving the new BDR as it is.

With your FortiGate unit, to configure the port1 interface to be a potential OSPF designated router or backup designed router called `ospf_DR` on the network, you need to raise the priority of the router to a very high number such as 250 out of 255. This will ensure the interface has a chance to be a DR, but will not guarantee that it will be one. Give the interface a low numbered IP address—such as 10.1.1.1 instead of 192.168.1.1—to help ensure it becomes a DR, but that is not part of this example. Enter the following command:

```
config router ospf
  config ospf-interface
  edit "ospf_DR"
    set priority 250
  end
end
```

Area

An OSPF area is a smaller part of the larger OSPF AS. Areas are used to limit the link-state updates that are sent out. The flooding used for these updates would overwhelm a large network, so it is divided into these smaller areas for manageability.

Within an area if there are two or more routers that are viable, there will always be a designated router (DR) and a backup DR (BDR). For more on these router roles, see "Designated router (DR) and backup router (BDR)" on page 398.

Defining a private OSPF area, involves:

- assigning a 32-bit number to the area that is unique on your network
- defining the characteristics of one or more OSPF areas
- creating associations between the OSPF areas that you defined and the local networks to include in the OSPF area
- if required, adjusting the settings of OSPF-enabled interfaces.

IPv6 OSPF area numbers use the same 32-bit number notation as IPv4 OSPF.

If you are using the web-based manager to perform these tasks, follow the procedures summarized below.

FortiGate units support the four main types of OSPF area:

- Backbone area
- NSSA
- Stub area
- Regular area

Backbone area

Every OSPF network has at least one AS, and every OSPF network has a backbone area. The backbone is the main area, or possibly the only area. All other OSPF areas are connected to a backbone area. This means if two areas want to pass routing information back and forth, that routing information will go through the backbone on its way between those areas. For this reason the backbone not only has to connect to all other areas in the network, but also be uninterrupted to be able to pass traffic to all points of the network.

The backbone area is referred to as area 0 because it has an IP address of 0.0.0.0.

Stub area

A stub area is an OSPF area that receives no outside routes advertised into it, and all routing in it is based on a default route. This essentially isolates it from outside areas.

Stub areas are useful for small networks that are part of a larger organization, especially if the networking equipment can't handle routing large amounts of traffic passing through, or there are other reasons to prevent outside traffic, such as security. For example most organizations don't want their accounting department to be the center of their network with everyone's traffic passing through there. It would increase the security risks, slow down their network, and it generally doesn't make sense.

A variation on the stub area is the totally stubby area. It is a stub area that does not allow summarized routes.

NSSA

A not-so-stubby-area (NSSA) is a stub area that allows for external routes to be injected into it. While it still does not allow routes from external areas, it is not limited to only using he default route for internal routing.

Regular area

A regular area is what all the other ASes are, all the non-backbone, non-stub, non-NSSA areas. A regular area generally has a connection to the backbone, does receive advertisements of outside routes, and does not have an area number of 0.0.0.0.

Authentication

In the OSPF packet header are two authentication related fields —AuType, and Authentication.

All OSPF packet traffic is authenticated. Multiple types of authentication are supported in OSPFv2. However in OSPFv3, there is no authentication built-in but it is assumed that IPsec will be used for authentication instead.

Packets that fail authentication are discarded.

Null authentication

Null authentication indicates there is no authentication being used. In this case the 16-byte Authentication field is not checked, and can be any value. However checksumming is still used to locate errors. On your FortiGate this is the `none` option for authentication.

Simple Password authentication

Simple password refers to a standard plain text string of characters. The same password is used for all transactions on a network. The main use of this type of authentication is to prevent routers from accidently joining the network. Simple password authentication is vulnerable to many forms of attack, and is not recommended as a secure form of authentication.

Cryptographic authentication

Cryptographic authentication involves the use of a shared secret key to authenticate all router traffic on a network. The key is never sent over the network in the clear—a packet is sent and a condensed and encrypted form of the packet is appended to the end of the packet. A non-repeating sequence number is included in the OSPF packet to protect against replay attacks that could try to use already sent packets to disrupt the network. When a packet is accepted as authentic the authentication sequence number is set to the packet sequence number. If a replay attack is attempted, the packet sent will be out of sequence and ignored.

Your FortiGate unit supports all three levels of authentication through the authentication keyword associated with creating an OSPF interface .

For example to create an OSPF interface called `Accounting` on the port1 interface that is a broadcast interface, has a hello interval of 10 seconds, has a dead interval of 40 seconds, uses text authentication (simple password) with a password of “ospf_test”, enter the command:

```
config router ospf
  config ospf-interface
  edit Accounting
    set interface port1
    set network-type broadcast
    set hello-interval 10
    set dead-interval 40
    set authentication text
    set authentication-key “ospf_test”
  end
end
```

Hello and dead intervals

The OSPF Hello protocol is used to discover and maintain communications with neighboring routers.

Hello packets are sent out at a regular interval for this purpose. The DR sends out the Hello packets. In a broadcast network, the multicast address of 224.0.0.5 is used to send out Hello packets. New routers on the network listen for and reply to these packets to join the OSPF area. If a new router never receives a Hello packet, other routers will not know it is there and will not communicate with it. However, once a new router is discovered the DR adds it to the list of routers in that area and it is integrated into the routing calculations.

Dead interval is the time other routers will wait before declaring a neighbor dead (offline). Setting a reasonable dead interval is very important. If this interval is too short, routers will be declared offline when they are just slow or momentarily inaccessible, and link-state updates will happen more than they need to, using more bandwidth. If the dead interval is too long, it will slow down network traffic overall if online routers attempt to contact offline ones instead of re-routing traffic. The CLI syntax for OSPF dead interval follows:

```
  config ospf-interface
    edit ospf1
      set interface port1
      set network-type broadcast
      set dead-interval 1
end
```

Access Lists

Access lists are filters used by FortiGate unit OSPF routing. An access list provides a list of IP addresses and the action to take for them — essentially an access list makes it easy to group addresses that will be treated the same into the same group, independent of their subnets or other matching qualities. You add a rule for each address or subnet that you want to include, specifying the action to take for it. For example if you wanted all traffic from one department to be routed a particular way, even in different buildings, you can add all the addresses to an access list and then handle that list all at once.

Each rule in an access list consists of a prefix (IP address and netmask), the action to take for this prefix (permit or deny), and whether to match the prefix exactly or to match the prefix and any more specific prefix.

The FortiGate unit attempts to match a packet against the rules in an access list starting at the top of the list. If it finds a match for the prefix, it takes the action specified for that prefix. If no match is found the default action is deny.

Access lists greatly speed up configuration and network management. When there is a problem, you can check each list instead of individual addresses. Also, it eases troubleshooting since if all addresses on one list have problems, it eliminates many possible causes right away.

If you are using the OSPF+ IPv6 protocols you will need to use access-list6, the IPv6 version of access list. The only difference is that access-list6 uses IPv6 addresses.

For example, if you want to create an access list called `test_list` that only allows an exact match of `10.10.10.10` and `11.11.11.11`, enter the command:

```
config router access-list
  edit test_list
  config rule
    edit 1
      set prefix 10.10.10.10 255.255.255.255
      set action allow
      set exact-match enable
    next
    edit 2
      set prefix 11.11.11.11 255.255.255.255
      set action allow
      set exact-match enable
    end
  end
```

Another example is if you want to deny ranges of addresses in IPv6 that start with the IPv6 equivalents of 10.10.10.10 and 11.11.11.11, enter the command access-list6 as follows:

```
config router access-list6
  edit test_list_ip6
    config rule
      edit 1
        set prefix6 2002:A0A:A0A:0:0:0:0:0:/48
        set action deny
      next
      edit 2
        set prefix6 2002:B0B:B0B:0:0:0:0:0/48
        set action deny
      end
```

To use an access_list, you must call it from a routing protocol such as RIP. The following example uses the access_list from the earlier example called test_list to match routes coming in on the port1 interface. When there is a match, it will add 3 to the hop count metric for those routes to artificially decrease their priority. Enter the following command:

```
config router ospf
  config distribute-list
    edit 5
      set access-list test_list
      set protocol connected
    end
```

If you are setting a prefix of 128.0.0.0, use the format 128.0.0.0/1. The default route 0.0.0.0/0 can not be exactly matched with an access-list. A prefix-list must be used for this purpose.

How OSPF works

An OSPF installation consists of one or more areas. An OSPF area is typically divided into logical areas linked by Area Border Routers. A group of contiguous networks form an area. An Area Border Router (ABR) links one or more areas to the OSPF network backbone (area ID 0). See “Area border router (ABR)” on page 315.

OSPF is an interior routing protocol. It includes a backbone AS, and possibly additional ASes. The DR and BDR are elected from potential routers with the highest priorities. The DR handles much of the administration to lower the network traffic required. New routers are discovered through hello packets sent from the DR using the multicast address of 224.0.0.5. If the DR goes offline at any time, the BDR has a complete table of routes that is uses when it takes over as the DR router.

OSPF does not use UDP or TCP, but is encapsulated directly in IP datagrams as protocol 89. This is in contrast to RIP, or BGP. OSPF handles its own error detection and correction functions.

The OSPF protocol, when running on IPv4, can operate securely between routers, optionally using a variety of authentication methods to allow only trusted routers to participate in routing. OSPFv3, running on IPv6, no longer supports protocol-internal authentication. Instead, it relies on IPv6 protocol security (IPsec).

Other important parts of how OSPF works includes:

- OSPF router discovery
- How OSPF works on FortiGate units
- External routes
- Link-state Database (LSDB) and route updates
- OSPF packets

OSPF router discovery

OSPF-enabled routers generate Link-State Advertisements (LSA) and send them to their neighbors whenever the status of a neighbor changes or a new neighbor comes online. As long as the OSPF network is stable, LSAs between OSPF neighbors do not occur. An LSA identifies the interfaces of all OSPF-enabled routers in an area, and provides information that enables OSPF-enabled routers to select the shortest path to a destination. All LSA exchanges between OSPF-enabled routers are authenticated.

When a network of OSPF routers comes online, the follow steps occur.

1. When OSPF routers come online, they send out Hello packets to find other OSPF routers on their network segment.
2. When they discover other routers on their network segment, generally they become adjacent. Adjacent routers can exchange routing updates. See “Adjacency” on page 398.
3. A DR and BDR are elected from the available routers using priority settings, and router ID. See “Designated router (DR) and backup router (BDR)” on page 398, and “DR and BDR election issues” on page 410.
4. Link state updates are sent between adjacent routers to map the topology of the OSPF area.
5. Once complete, the DR floods the network with the updates to ensure all OSPF routers in the area have the same OSPF route database. After the initial update, there are very few required updates if the network is stable.

How OSPF works on FortiGate units

When a FortiGate unit interface is connected to an OSPF area, that unit can participate in OSPF communications. FortiGate units use the OSPF Hello protocol to acquire neighbors in an area. A neighbor is any router that is directly connected to the same area as the FortiGate unit, and ideally is adjacent with a state of Full. After initial contact, the FortiGate unit exchanges Hello packets with its OSPF neighbors regularly to confirm that the neighbors can be reached.

The number of routes that a FortiGate unit can learn through OSPF depends on the network topology. A single unit can support tens of thousands of routes if the OSPF network is configured properly.

External routes

OSPF is an internal routing protocol. OSPF external routes are routes where the destination using a routing protocol other than OSPF. OSPF handles external routes by adjusting the cost of the route to include the cost of the other routing protocol. There are two methods of calculating this cost, used for OSPF E1 and OSPF E2.

OSPF external1 (E1)

In OSPF E1 the destination is outside of the OSPF domain. This requires a different metric to be used beyond the normal OSPF metrics. The new metric of a redistributed route is calculated by adding the external cost and the OSPF cost together.

OSPF external2 (E2)

OSPF E2 is the default external type when routes are redistributed outside of OSPF. With OSPF E2, the metric of the redistributed route is equivalent to the external cost only, expressed as an OSPF cost. Dropping the OSPF portion can be useful in a number of situations, on border routers that have no OSPF portion for example or where the OSPF routing cost is negligible compared to the external routing cost.

Comparing E1 and E2

The best way to understand OSPF E1 and E2 routes is to check routing tables on OSPF routers. If you look at the routes on an OSPF border router, the redistributed routes will have an associated cost that represents only the external route, as there is no OSPF cost to the route due to it already being on the edge of the OSPF domain. However, if you look at that same route on a different OSPF router inside the OSPF routing domain, it will have a higher associated cost - essentially the external cost plus the cost over the OSPF domain to that border router. The border router uses OSPF E2, where the internal OSPF router uses OSPF E1 for the same route.

Viewing external routes

When you are trying to determine the costs for routes in your network to predict how traffic will be routed, you need to see the external OSPF routes and their associated costs. On your FortiGate unit, you find this information through your CLI.

To view external routes - CLI

You can view the whole routing table using `get router info routing-table all` to see all the routes including the OSPF external routes, or for a shorter list you can use the command `get router info routing-table ospf`. The letter at the left will be either E1 or E2 for external OSPF routes. The output of will look similar to the following, depending on what routes are in your routing table.

```
FGT620B# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

O*E2   0.0.0.0/0 [110/10] via 10.1.1.3, tunnel_wan2, 00:02:11
O      10.0.0.1/32 [110/300] via 10.1.1.3, tunnel_wan2, 00:02:11
S      0.0.0.0/0 [10/0] via 192.168.183.254, port2
S      1.0.0.0/8 [10/0] via 192.168.183.254, port2
```

Link-state Database (LSDB) and route updates

OSPF is based on links. The links between adjacent neighbor routers allow updates to be passed along the network. Network links allow the DR to flood the area with Link-state database (LSDB) updates. External links allow the OSPF area to connect to destinations outside the OSPF autonomous system. Information about these links is passed throughout the OSPF network as link-state updates.

The LSDB contains the information that defines the complete OSPF area, but the LSDB is not the routing table. It contains the information from all the link-state updates passed along the network. When there are no more changes required, and the network is stable then the LSDB on each router in the network will be the same. The DR will flood the LSDB to the area to ensure each router has the same LSDB.

To calculate the best route (shortest path) to a destination, the FortiGate unit applies the Shortest Path First (SPF) algorithm, based on Dijkstra's algorithm, to the accumulated link-state information. OSPF uses relative path cost metric for choosing the best route. The path cost can be any metric, but is typically the bandwidth of the path, how fast traffic will get from one point to another.

The path cost, similar to "distance" for RIP, imposes a penalty on the outgoing direction of a FortiGate unit interface. The path cost of a route is calculated by adding together all of the costs associated with the outgoing interfaces along the path to the destination. The lowest overall path cost indicates the best route, and generally the fastest route. Some brands of OSPF routers, such as Cisco, implement cost as a direct result of bandwidth between the routers. Generally this is a good cost metric because larger bandwidth means more traffic can travel without slowing down. To achieve this type of cost metric on FortiGate units, you need to set the cost for each interface manually in the CLI.

The inter-area routes may not be calculated when a Cisco type ABR has no fully adjacent neighbor in the backbone area. In this situation, the router considers summary-LSAs from all Actively summary-LSAs from all Actively Attached areas (RFC 3509).

The FortiGate unit dynamically updates its routing table based on the results of the SPF calculation to ensure that an OSPF packet will be routed using the shortest path to its destination. Depending on the network topology, the entries in the FortiGate unit routing table may include:

- the addresses of networks in the local OSPF area (to which packets are sent directly)
- routes to OSPF area border routers (to which packets destined for another area are sent)
- if the network contains OSPF areas and non-OSPF domains, routes to area boundary routers, which reside on the OSPF network backbone and are configured to forward packets to destinations outside the OSPF AS.

OSPF Route updates

Once the OSPF domain is established, there should be few updates required on a stable network. When updates occur and a decision is required concerning a new route, this is the general procedure.

1. Our router gets a new route, and needs to decide if it should go in the routing table.
2. The router has an up to date LSDB of the entire area, containing information about each router, the next hop to it, and most importantly the cost to get there.
3. Our router, turns the LSDB into a shortest path first (SPF) tree using Dijkstra's algorithm. It doesn't matter if there is more than one path to a router on the network, the SPF tree only cares about the shortest path to that router.

4. Once the SPF tree has been created, and shows the shortest paths to all the OSPF routers on the network, the work is done. If the new route is the best route, it will be part of that tree. If it is not the shortest route, it will not be included in the LSDB.
5. If there has been a change from the initial LSDB to the new SPF tree, a link state update will be sent out to let the other routers know about the change so they can update their LSDBs as well. This is vital since all routers on the OSPF area must have the same LSDB.
6. If there was no change between the LSDB and the SPF tree, no action is taken.

OSPF packets

Every OSPF packet starts with a standard 24-byte header, and another 24 bytes of information or more. The header contains all the information necessary to determine whether the packet should be accepted for further processing.

Table 14: OSPF packet

1-byte Version field	1-byte Type field	2-byte Packet length	3-byte Router ID
4-byte Area ID	2-byte Checksum	2-byte Auth Type	8-byte Authentication
4-byte Network Mask	2-byte Hello interval	1-byte Options field	1-byte Router Priority
4-byte Dead Router interval	4-byte DR field	4-byte BDR field	4-byte Neighbor ID

The following descriptions summarize the OSPF packet header fields.

Version field— The OSPF version number. This specification documents version 2 of the protocol.

Type field—There are 5 OSPF packet types. From one to five, respectively, they are Hello, Database Description, Link State Request, Link State Update, and Link State Acknowledgment.

Packet length—The length of the OSPF protocol packet in bytes. This length includes the standard OSPF 24-byte header, so all OSPF packets are at 24-bytes long.

Router ID—The Router ID of the packet's source.

Area ID—A 32-bit number identifying the area that this packet belongs to. All OSPF packets are associated with a single area. Most travel a single hop only. Packets travelling over a virtual link are labelled with the backbone Area ID of 0.0.0.0.

Checksum—The standard IP checksum of the entire contents of the packet, starting with the OSPF packet header but excluding the 64-bit authentication field. This checksum is calculated as the 16-bit one's complement of the one's complement sum of all the 16-bit words in the packet, excepting the authentication field. If the packet's length is not an integral number of 16-bit words, the packet is padded with a byte of zero before checksumming. The checksum is considered to be part of the packet authentication procedure; for some authentication types the checksum calculation is omitted.

Auth Type—Identifies the authentication procedure to be used for the packet. Authentication types include Null authentication (0), Simple password (1), Cryptographic authentication (2), and all others are reserved for future use.

Authentication—A 64-bit field for use by the authentication scheme. When AuType indicates no authentication is being used, the Authentication fields is not checked and can be any value.

When AuType is set to 2 (Cryptographic authentication), the 64-bit authentication field is split into the following four fields: Zero field, Key ID field, Authentication data length field, and Cryptographic sequence field.

The Key ID field indicates the key and algorithm used to create the message digest appended to the packet. The authentication data length field indicates how many bytes long the message digest is, and the cryptographic sequence number is at non-decreasing number that is set when the packet is received and authenticated to prevent replay attacks.

Network Mask—The subnet where this packet is valid.

Hello interval—The period of time between sending out Hello packets. See "Hello and dead intervals" on page 402.

Options field— The OSPF protocol defines several optional capabilities. A router indicates the optional capabilities that it supports in its OSPF Hello packets, Database Description packets and in its LSAs. This enables routers supporting a mix of optional capabilities to coexist in a single Autonomous System.

Router priority—The priority between 0 and 255 that determines which routers become the DR and BDR. See "Designated router (DR) and backup router (BDR)" on page 398.

Dead router interval—The period of time when there is no response from a router before it is declared dead. See "Hello and dead intervals" on page 402.

DR and BDR fields—The DR and BDR fields each list the router that fills that role on this network, generally the routers with the highest priorities. See "Designated router (DR) and backup router (BDR)" on page 398.

Neighbor ID—The ID number of a neighboring router. This ID is used to discover new routers and respond to them.

Troubleshooting OSPF

As with other dynamic routing protocols, OSPF has some issues that may need troubleshooting from time to time. For basic troubleshooting, see the Troubleshooting chapter.

The more common issues include:

- Clearing OSPF routes from the routing table
- Checking the state of OSPF neighbors
- Passive interface problems
- Timer problems
- Authentication issues
- DR and BDR election issues

Clearing OSPF routes from the routing table

If you think the wrong route has been added to your routing table and you want to check it out, you first have to remove that route from your table before seeing if it is added back in or not. You can clear all or some OSPF neighbor connections (sessions) using the `execute router clear ospf` command. The exec router clear command is much more limiting for OSPF than it is for BGP. See "Clearing routing table entries" on page 371.

For example, if you have routes in the OSPF routing table and you want to clear the specific route to IP address 10.10.10.1, you will have to clear all the OSPF entries. Enter the command:

```
execute router clear ospf process
```

Checking the state of OSPF neighbors

In OSPF each router sends out link state advertisements to find other routers on its network segment, and to create adjacencies with some of those routers. This is important because routing updates are only passed between adjacent routers. If two routers you believe to be adjacent are not, that can be the source of routing failures.

To identify this problem, you need to check the state of the OSPF neighbors of your FortiGate unit. Use the CLI command `get router info ospf neighbor all` to see all the neighbors for your FortiGate unit. You will see output in the form of:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID  Pri  State     Dead Time   Address         Interface
10.0.0.2     1    Full/ -   00:00:39    10.1.1.2        tunnel_wan1
10.0.0.2     1    Full/ -   00:00:34    10.1.1.4        tunnel_wan2
```

The important information here is the `State` column. Any neighbors that are not adjacent to your FortiGate unit will be reported in this column as something other than `Full`. If the state is `Down`, that router is offline.

Passive interface problems

A passive OSPF interface doesn't send out any updates. This means it can't be a DR, BDR, or an area border router among other things. It will depend on other neighbor routers to update its link-state table.

Passive interfaces can cause problems when they aren't receiving the routing updates you expect from their neighbors. This will result in the passive OSPF FortiGate unit interface having an incomplete or out-of-date link-state database, and it will not be able to properly route its traffic. It is possible that the passive interface is causing a hole in the network where no routers are passing updates to each other, however this is a rare situation.

If a passive interface is causing problems, there are simple methods to determine it is the cause. The easiest method is to make it an active interface, and if the issues disappear, then that was the cause. Another method is to examine the OSPF routing table and related information to see if it is incomplete compared to other neighbor routers. If this is the case, you can clear the routing table, reset the device and allow it to repopulate the table.

If you cannot make the interface active for some reason, you will have to change your network to fix the "hole" by adding more routers, or changing the relationship between the passive router's neighbors to provide better coverage.

Timer problems

A timer mismatch is when two routers have different values set for the same timer. For example if one router declares a router dead after 45 seconds and another waits for 4 minutes that difference in time will result in those two routers being out of synch for that period of time—one will still see that offline router as being online.

The easiest method to check the timers is to check the configuration on each router. Another method is to sniff some packets, and read the timer values in the packets themselves from different routers. Each packet contains the hello interval, and dead interval periods, so you can compare them easily enough.

Bi-directional Forwarding Detection (BFD)

Bi-directional Forwarding Detection (BFD) is a protocol used to quickly locate hardware failures in the network. Routers running BFD communicate with each other, and if a timer runs out on a

connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

Authentication issues

OSPF has a number of authentication methods you can choose from. You may encounter problems with routers not authenticating as you expect. This will likely appear simply as one or more routers that have a blind spot in their routing - they won't acknowledge a router. This can be a problem if that router connects areas to the backbone as it will appear to be offline and unusable.

To confirm this is the issue, the easiest method is to turn off authentication on the neighboring routers. With no authentication between any routers, everything should flow normally.

Another method to confirm that authentication is the problem is to sniff packets, and look at their contents. The authentication type and password are right in the packets which makes it easy to confirm they are what you expect during real time. Its possible one or more routers is not configured as you expect and may be using the wrong authentication. This method is especially useful if there are a group of routers with these problems—it may only be one router causing the problem that is seen in multiple routers.

Once you have confirmed the problem is authentication related, you can decide how to handle it. You can turn off authentication and take your time to determine how to get your preferred authentication type back online. You can try another type of authentication, such as text instead of md5, which may have more success and still provide some level of protection. The important part is that once you confirm the problem, you can decide how to fix it properly.

DR and BDR election issues

You can force a particular router to become the DR and BDR by setting their priorities higher than any other OSPF routers in the area. This is a good idea when those routers have more resources to handle the traffic and extra work of the DR and BDR roles, since not all routers may be able to handle all that traffic.

However, if you set all the other routers to not have a chance at being elected, a priority of zero, you can run into problems if the DR and BDR go offline. The good part is that you will have some warning generally as the DR goes offline and the BDR is promoted to the DR position. But if the network segment with both the DR and BDR goes down, your network will have no way to send hello packets, send updates, or the other tasks the DR performs.

The solution to this is to always allow routers to have a chance at being promoted, even if you set their priority to one. In that case they would be the last choice, but if there are no other candidates you want that router to become the DR. Most networks would have already alerted you to the equipment problems, so this would be a temporary measure to keep the network traffic moving until you can find and fix the problem to get the real DR back online.

Basic OSPF example

This example sets up an OSPF network at a small office. There are 3 routers, all running OSPF v2. The border router connects to a BGP network.

All three routers in this example are FortiGate units. Router1 will be the designated router (DR) and router2 will be the backup DR (BDR) due to their priorities. Router3 will not be considered for either the DR or BDR elections. Instead, Router3 is the area border router (ASBR) routing all traffic to the ISP's BGP router on its way to the Internet.

Router2 has a modem connected that provides dialup access to the Internet as well, at a reduced bandwidth. This is a PPPoE connection to a DSL modem. This provides an alternate

route to the Internet if the other route goes down. The DSL connection is slow, and is charged by the amount of traffic. For these reasons OSPF will highly favor Router3's Internet access.

The DSL connection connects to an OSPF network with the ISP, so no redistribution of routes is required. The ISP network does have to be added to that router's configuration however.

This section includes the following topics:

Network layout and assumptions

There are three FortiGate units acting as OSPF v2 routers on the network—Router1, Router2, and Router3. Router1 will be the designated router (DR), and Router 2 the BDR. Router3 is the area border router (ASBR) that connects to the external ISP router running BGP. Router2 has a PPPoE DSL connection that can access the Internet.

The Head Office network is connected to Router1 and Router2 on the 10.11.101.0 subnet.

Router1 and Router3 are connected over the 10.11.103.0 subnet.

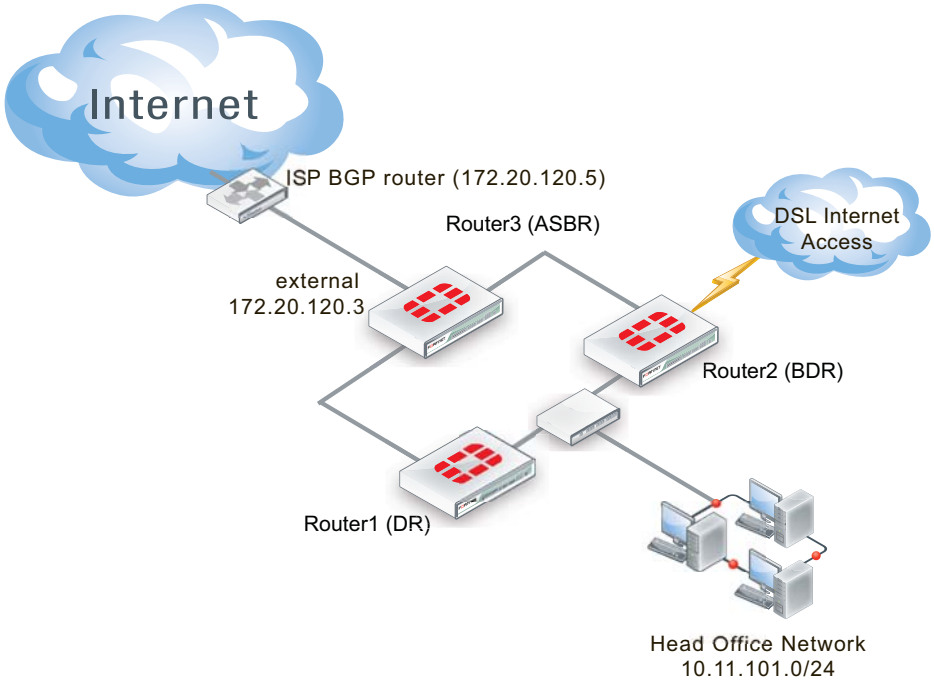
Router2 and Router3 are connected over the 10.11.102.0 subnet.

The following table lists the router, interface, address, and role it is assigned.

Table 15: Routers, interfaces, and IP addresses for basic OSPF example network

Router name	Interface	IP address	Interface is connected to:
Router1 (DR)	Internal (port1)	10.11.101.1	Head office network, and Router2
	External (port2)	10.11.102.1	Router3
Router2 (BDR)	Internal (port1)	10.11.101.2	Head office network, and Router1
	External (port2)	10.11.103.2	Router3
	DSL (port3)	10.12.101.2	PPPoE DSL access
Router3 (ASBR)	Internal1 (port1)	10.11.102.3	Router1
	Internal2 (port2)	10.11.103.3	Router2
	External (port3)	172.20.120.3	ISP's BGP network

Figure 110: Basic OSPF network topology



Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration, and are in NAT/Route mode.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF networks.
- Both Internet connections are always available.
- The modem connection is very slow and expensive.
- Other devices may be on the network, but do not affect this basic configuration.
- Router3 is responsible for redistributing all routes into and out of the OSPF AS.

Configuring the FortiGate units

Each FortiGate unit needs the interfaces, and basic system information such as hostname configured.

This section includes:

- Configuring Router1
- Configuring Router2
- Configuring Router3

Configuring Router1

Router1 has two interfaces connected to the network—internal (port1) and external (port2). Its host name must be changed to Router1.

To configure Router1 interfaces - web-based manager

1. Go to *System* > *Dashboard* > *Status*.
2. Beside the host name, select *Change*.
3. Enter a hostname of `Router1`, and select *OK*.
4. Go to *System* > *Network* > *Interfaces*, edit port1, set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Head office and Router2
Administrative Status	Up

5. Edit port2, set the following information, and select *OK*.

Alias	External
IP/Netmask	10.11.102.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

Configuring Router2

Router2 configuration is the same as Router1, except Router2 also has the DSL interface to configure.

The DSL interface is configured with a username of “user1” and a password of “ospf_example”. The default gateway will be retrieved from the ISP, and the defaults will be used for the rest of the PPPoE settings.

To configure Router2 interfaces - web-based manager

1. Go to *System* > *Dashboard* > *Status*.
2. Beside the host name, select *Change*.
3. Enter a hostname of `Router2`, and select *OK*.
4. Go to *System* > *Network* > *Interfaces*, edit port1, set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.101.2/255.255.255.0
Administrative Access	HTTPS SSH PING

Description	Head office and Router1
Administrative Status	Up

5. Edit port2, set the following information, and select *OK*.

Alias	External
IP/Netmask	10.11.103.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3
Administrative Status	Up

6. Edit DSL (port3), set the following information, and select *OK*.

Alias	DSL
Addressing Mode	PPPoE
Username	user1
Password	ospf_example
Unnumbered IP address	10.12.101.2/255.255.255.0
Retrieve default gateway from server	Enable
Administrative Access	HTTPS SSH PING
Description	DSL
Administrative Status	Up

Configuring Router3

Router3 is similar to Router1 and Router2 configurations. The main difference is the External (port3) interface connected to the ISP BGP network which has no administration access enabled for security reasons.

To configure Router3 interfaces - web-based manager

1. Go to *System* > *Status* > *Dashboard*.
2. Next to hostname, select *Change*.
3. Enter a hostname of `Router3`, and select *OK*.
4. Go to *System* > *Network* > *Interfaces, e*dit port1, set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.102.3/255.255.255.0
Administrative Access	HTTPS SSH PING

Description	Router1
Administrative Status	Up

5. Edit port2, set the following information, and select *OK*.

Alias	Internal2
IP/Netmask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2
Administrative Status	Up

6. Edit port3, set the following information, and select *OK*.

Alias	External
IP/Netmask	172.20.120.3/255.255.255.0
Administrative Access	
Description	ISP BGP
Administrative Status	Up

Configuring OSPF on the FortiGate units

With the interfaces configured, now the FortiGate units can be configured for OSPF on those interfaces. All routers are part of the backbone 0.0.0.0 area, so there is no inter-area communications needed.

For a simple configuration there will be no authentication, no graceful restart or other advanced features, and timers will be left at their defaults. Also the costs for all interfaces will be left at 10, except for the modem and ISP interfaces where cost will be used to load balance traffic. Nearly all advanced features of OSPF are only available from the CLI.

The network that is defined covers all the subnets used in this example - 10.11.101.0, 10.11.102.0, and 10.11.103.0. All routes for these subnets will be advertised. If there are other interfaces on the FortiGate units that you do not want included in the OSPF routes, ensure those interfaces use a different subnet outside of the 10.11.0.0 network. If you want all interfaces to be advertised you can use an OSPF network of 0.0.0.0 .

Each router will configure:

- router ID
- area
- network
- two or three interfaces depending on the router
- priority for DR (Router1) and BDR (Router2)
- redistribute for ASBR (Router3)

This section includes:

Configuring OSPF on Router1

Router1 has a very high priority to ensure it becomes the DR for this area. Also Router1 has the lowest IP address to help ensure it will win in case there is a tie at some point. Otherwise it is a standard OSPF configuration. Setting the priority can only be done in the CLI, and it is for a specific OSPF interface.

To configure OSPF on Router1 - web-based manager

1. Go to *Router* > *Dynamic* > *OSPF*.
2. Set *Router ID* to `10.11.101.1` and select *Apply*.
3. In *Areas*, select *Create New,* set the following information, and select *OK*.

Area	0.0.0.0
Type	Regular
Authentication	none

4. In *Networks*, select *Create New*, set the following information, and select *OK*.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5. In *Interfaces*, select *Create New*, set the following information, and select *OK*.

Name	Router1-Internal-DR
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

6. In *Interfaces*, select *Create New*, set the following information, and select *OK*.

Name	Router1-External
Interface	port2 (External)
IP	0.0.0.0
Authentication	none

Timers (seconds)	
Hello Interval	10
Dead Interval	40

7. Using the CLI, enter the following commands to set the priority for the Router1-Internal OSPF interface to maximum, ensuring this interface becomes the DR.

```
config router ospf
  config ospf-interface
    edit Router1-Internal-DR
      set priority 255
    end
```

To configure OSPF on Router1 - CLI

```
config router ospf
  set router-id 10.11.101.1
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0/255.255.255.0
    next
  end
  config ospf-interface
    edit "Router1-Internal"
      set interface "port1"
      set priority 255
    next
    edit "Router1-External"
      set interface "port2"
    next
  end
end
```

Configuring OSPF on Router2

Router2 has a high priority to ensure it becomes the BDR for this area, and configures the DSL interface slightly differently—assume this will be a slower connection resulting in the need for longer timers, and a higher cost for this route.

Otherwise it is a standard OSPF configuration.

To configure OSPF on Router2 - web-based manager

1. Go to *Router* > *Dynamic* > *OSPF*.
2. Set *Router ID* to `10.11.101.2` and select *Apply*.

3. In *Areas*, select *Create New*, set the following information, and select *OK*.

Area	0.0.0.0
Type	Regular
Authentication	none

4. In *Networks*, select *Create New*, set the following information, and select *OK*.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

5. In *Interfaces*, select *Create New,* set the following information, and select *OK*.

Name	Router2-Internal
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

6. In *Interfaces*, select *Create New*, set the following information, and select *OK*.

Name	Router2-External
Interface	port2 (External)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

7. In *Interfaces*, select *Create New,* set the following information, and select *OK*.

Name	Router2-DSL
Interface	port3 (DSL)
IP	0.0.0.0
Authentication	none
Cost	50

Timers (seconds)	
Hello Interval	20
Dead Interval	80

8. Using the CLI, enter the following commands to set the priority for the Router2-Internal OSPF interface to ensure this interface will become the BDR.

```
config router ospf
  config ospf-interface
    edit Router2-Internal
      set priority 250
    next
  end
```

To configure OSPF on Router2 - CLI

```
config router ospf
  set router-id 10.11.101.2
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0/255.255.0.0
    next
  end
  config ospf-interface
    edit "Router2-Internal"
      set interface "port1"
      set priority 255
    next
    edit "Router2-External"
      set interface "port2"
    next
   edit "Router2-DSL"
      set interface "port3"
     set cost 50
   next
  end
end
```

Configuring OSPF on Router3

Router3 is more complex than the other two routers. The interfaces are straightforward, but this router has to import and export routes between OSPF and BGP. That requirement makes Router3 a border router or ASBR. Also Router3 needs a lower cost on its route to encourage all traffic to the Internet to route through it.

In the advanced OSPF options, Redistribute is enabled for Router3. It allows different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics are assigned to these other types of routes to make them more or less preferred to regular OSPF routes.

To configure OSPF on Router3 - web-based manager

1. Go to *Router* > *Dynamic* > *OSPF*.
2. Set *Router ID* to `10.11.101.2` and select *Apply*.
3. Expand *Advanced Options*.
4. In *Redistribute*, set the following information, and select *OK*.

Route type	Redistribute	Metric
Connected	Enable	15
Static	Enable	15
RIP	Disable	n/a
BGP	Enable	5

5. In *Areas*, select *Create New*, set the following information, and select *OK*.

Area	0.0.0.0
Type	Regular
Authentication	none

6. In *Networks*, select *Create New,* set the following information, and select *OK*.

IP/Netmask	10.11.0.0/255.255.0.0
Area	0.0.0.0

7. In *Interfaces*, select *Create New, s*et the following information, and select *OK*.

Name	Router3-Internal
Interface	port1 (Internal)
IP	0.0.0.0
Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

8. In *Interfaces*, select *Create New, s*et the following information, and select *OK*.

Name	Router3-Internal2
Interface	port2 (Internal2)
IP	0.0.0.0

Authentication	none
Timers (seconds)	
Hello Interval	10
Dead Interval	40

9. In *Interfaces*, select *Create New, s*et the following information, and select *OK*.

Name	Router3-ISP-BGP
Interface	port3 (ISP-BGP)
IP	0.0.0.0
Authentication	none
Cost	2
Timers (seconds)	
Hello Interval	20
Dead Interval	80

10. Using the CLI, enter the following commands to set the priority for the Router3-Internal OSPF interface to ensure this interface will become the BDR.

```
config router ospf
   config ospf-interface
   edit Router3-Internal
      set priority 250
   next
end
```

To configure OSPF on Router3 - CLI

```
config router ospf
  set router-id 10.11.102.3
  config area
    edit 0.0.0.0
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0/255.255.255.0
    next
    edit 2
      set prefix 172.20.120.0/255.255.255.0
    next
  end
  config ospf-interface
    edit "Router3-Internal"
      set interface "port1"
      set priority 255
    next
    edit "Router3-External"
      set interface "port2"
    next
   edit “Router3-ISP-BGP”
      set interface “port3”
      set cost 2
   next
  end
end
```

Configuring other networking devices

The other networking devices required in this configuration are on the two ISP networks, the BGP network for the main Internet connection, and the DSL backup connection.

In both cases, the ISPs need to be notified of the OSPF network settings including router IP addresses, timer settings, and so on. The ISP will use this information to configure its routers that connect to this OSPF network.

Testing network configuration

Testing the network configuration involves two parts: testing the network connectivity, and testing the OSPF routing.

To test the network connectivity use ping, traceroute, and other network tools.

To test the OSPF routing in this example, refer to the troubleshooting outlined in “Troubleshooting OSPF” on page 408.

Advanced inter-area OSPF example

This example sets up an OSPF network at a large office. There are three areas, each with two routers. Typically OSPF areas would not be this small, and if they were the areas would be combined into one bigger area. However, the stub area services the accounting department which is very sensitive about their network and do not want any of their network information broadcast through the rest of the company. The backbone area contains the bulk of the company network devices. The regular area was established for various reasons such as hosting the company servers on a separate area with extra security.

One area is a small stub area that has no independent Internet connection, and only one connection to the backbone area. That connection between the stub area and the backbone area is only through a default route. No routes outside the stub area are advertised into that area. Another area is the backbone, which is connected to the other two areas. The third area has the Internet connection, and all traffic to and from the Internet must use that area's connection. If that traffic comes from the stub area, then that traffic is treating the backbone like a transit area that only uses it to get to another area.

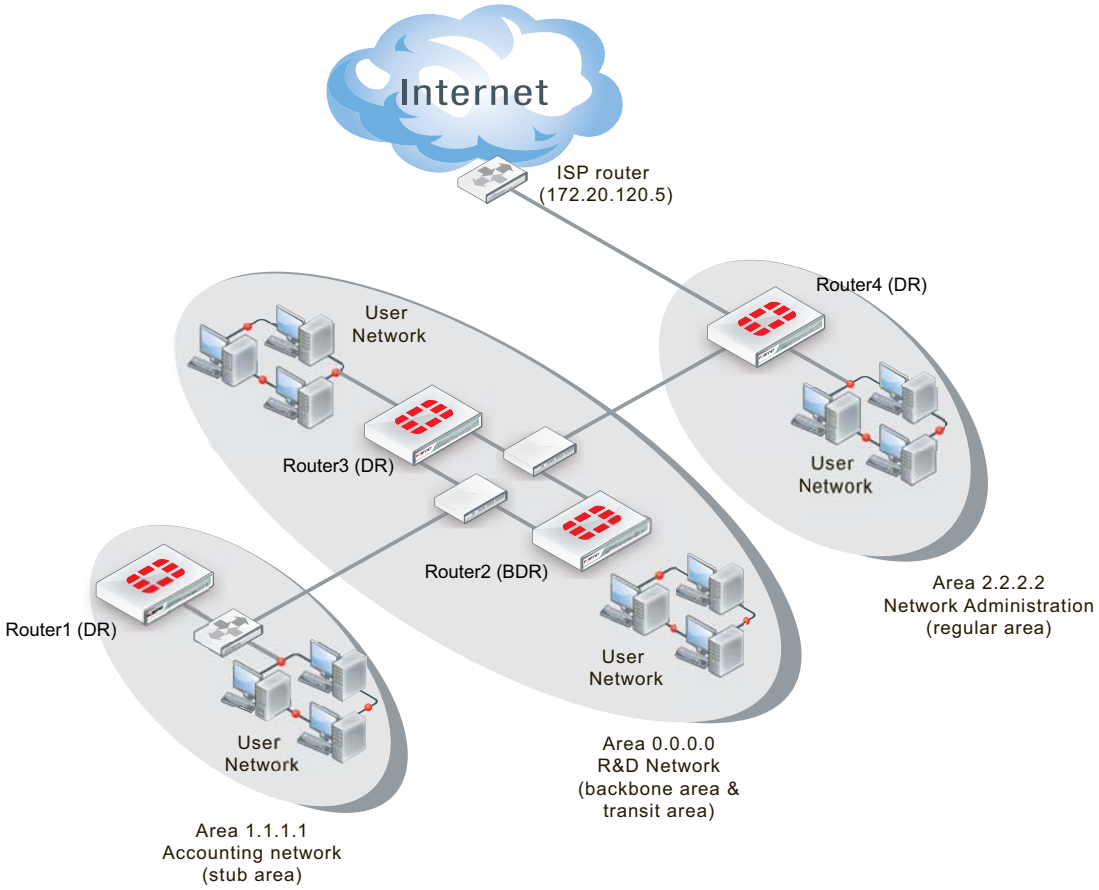
In the stub area, a subnet of computers is running the RIP routing protocol and those routes must be redistributed into the OSPF areas.

This section includes the following topics:

Network layout and assumptions

There are four FortiGate units in this network topology acting as OSPF routers.

Figure 111: Advanced inter-area OSPF network topology



Area 1.1.1.1 is a stub area with one FortiGate unit OSPF router called Router1 (DR). Its only access outside of that area is a default route to the backbone area, which is how it accesses the Internet. Traffic must go from the stub area, through the backbone, to the third area to reach the Internet. The backbone area in this configuration is called a transit area. Also in area 1.1.1.1 there is a RIP router that will be providing routes to the OSPF area through redistribution.

Area 0.0.0.0 is the backbone area, and has two FortiGate unit routers named Router2 (BDR) and Router3 (DR).

Area 2.2.2.2 is a regular area that has an Internet connection accessed by both the other two OSPF areas. There is only one FortiGate unit router in this area called Router4 (DR). This area is more secure and requires MD5 authentication by routers.

All areas have user networks connected, but they are not important for configuring the network layout for this example.

Internal interfaces are connected to internal user networks only. External1 interfaces are connected to the 10.11.110.0 network, joining Area 1.1.1.1 and Area 0.0.0.0.

External2 interfaces are connected to the 10.11.111.0 network, joining Area 0.0.0.0 and Area 2.2.2.2. The ISP interface is called ISP.

Table 16: Routers, areas, interfaces, IP addresses for advanced OSPF network

Router name	Area number and type	Interface	IP address
Router1 (DR)	1.1.1.1 - stub area (Accounting)	port1 (internal)	10.11.101.1
		port2 (external1)	10.11.110.1

Table 16: Routers, areas, interfaces, IP addresses for advanced OSPF network

Router2 (BDR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.102.2
		port2 (external1)	10.11.110.2
		port3 (external2)	10.11.111.2
Router3 (DR)	0.0.0.0 - backbone area (R&D Network)	port1 (internal)	10.11.103.3
		port2 (external1)	10.11.110.3
		port3 (external2)	10.11.111.3
Router4 (DR)	2.2.2.2 - regular area (Network Admin)	port1 (internal)	10.11.104.4
		port2 (external2)	10.11.111.4
		port3 (ISP)	172.20.120.4

Note that other subnets can be added to the internal interfaces without changing the configuration.

Assumptions

- The FortiGate units used in this example have interfaces named port1, port2, and port3.
- All FortiGate units in this example have factory default configuration, and are in NAT/Route mode.
- During configuration, if settings are not directly referred to they will be left at default settings.
- Basic firewalls are in place to allow unfiltered traffic between all connected interfaces in both directions.
- This OSPF network is not connected to any other OSPF areas outside of this example.
- The Internet connection is always available.
- Other devices may be on the network, but do not affect this configuration.

Configuring the FortiGate units

This section configures the basic settings on the FortiGate units to be OSPF routers. These configurations include multiple interface settings, and hostname.

There are four FortiGate units in this example. The two units in the backbone area can be configured exactly the same except for IP addresses, so only router3 (the DR) configuration will be given with notes indicating router2 (the BDR) IP addresses.

Configuring the FortiGate units includes:

Configuring Router1

Router1 is part of the Accounting network stub area (1.1.1.1).

To configure Router1 interfaces - web-based manager

1. Go to *System* > *Dashboard* > *Status*.
2. Next to hostname, select *Change*.
3. Enter a hostname of `Router1`, and select *OK*.
4. Go to *System* > *Network* > *Interfaces,* edit port1, set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.101.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

5. Edit port2, set the following information, and select *OK*.

Alias	External1
IP/Netmask	10.11.110.1/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Backbone network and internet
Administrative Status	Up

Configuring Router2

Router2 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

Router2 has three interfaces configured; one to the internal network, and two to Router3 for redundancy.

To configure Router2 interfaces - web-based manager

1. Go to *System* > *Dashboard* > *Status*.
2. Next to hostname, select *Change*.
3. Enter a hostname of `Router2`, and select *OK*.
4. Go to *System* > *Network* > *Interfaces*, edit port1 (internal), set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.102.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5. Edit port2 (external1), set the following information, and select *OK*.

Alias	external1
IP/Netmask	10.11.110.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3 first connection
Administrative Status	Up

6. Edit port3 (external2), set the following information, and select *OK*.

Alias	external2
IP/Netmask	10.11.111.2/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router3 second connection
Administrative Status	Up

Configuring Router3

Router3 is part of the R&D network backbone area (0.0.0.0). Router2 and Router3 are in this area. They provide a redundant connection between area 1.1.1.1 and area 2.2.2.2.

To configure Router3 interfaces - web-based manager

1. Go to *System* > *Dashboard* > *Status*.
2. Next to hostname, select *Change*.
3. Enter a hostname of `Router3`, and select *OK*.
4. Go to *System* > *Network* > *Interfaces*, edit port1 (internal), set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.103.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Internal RnD network
Administrative Status	Up

5. Edit port2 (external1), set the following information, and select *OK*.

Alias	external1
IP/Netmask	10.11.110.3/255.255.255.0
Administrative Access	HTTPS SSH PING

Description	Router2 first connection
Administrative Status	Up

6. Edit port3 (external2), set the following information, and select *OK*.

Alias	external2
IP/Netmask	10.11.111.3/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Router2 second connection
Administrative Status	Up

Configuring Router4

Router4 is part of the Network Administration regular area (2.2.2.2). This area provides internet access for both area 1.1.1.1 and the backbone area.

This section configures interfaces and hostname.

To configure Router4 interfaces - web-based manager

1. Go to *System* > *Dashboard* > *Status*.
2. Next to hostname, select *Change*.
3. Enter a hostname of `Router4`, and select *OK*.
1. Go to *System* > *Network* > *Interfaces*.
2. Edit port1 (internal).
3. Set the following information, and select *OK*.

Alias	internal
IP/Netmask	10.11.101.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Accounting network
Administrative Status	Up

4. Edit port2 (external2).
5. Set the following information, and select *OK*.

Alias	external2
IP/Netmask	10.11.110.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	Backbone and Accounting network
Administrative Status	Up

6. Edit port3 (ISP).

7. Set the following information, and select *OK*.

Alias	ISP
IP/Netmask	172.20.120.4/255.255.255.0
Administrative Access	HTTPS SSH PING
Description	ISP and internet
Administrative Status	Up

Configuring OSPF on the FortiGate units

Three of the routers are designated routers (DR) and one is a backup DR (BDR). This is achieved through the lowest router ID numbers, or OSPF priority settings.

Also each area needs to be configured as each respective type of area - stub, backbone, or regular. This affects how routes are advertised into the area.

To configure OSPF on Router1 - web-based manager

1. Go to *Router* > *Dynamic* > *OSPF*.
2. Enter `10.11.101.1` for the *Router ID* and select *Apply*.
3. In *Areas*, select *Create New,* set the following information, and select *OK*.

Area	1.1.1.1
Type	Stub
Authentication	None

4. In *Networks*, select *Create New,* set the following information, and select *OK*.

IP/Netmask	10.11.101.0/255.255.255.0
Area	1.1.1.1

5. In *Interfaces*, select *Create New,* set the following information, and select *OK*.

Name	Accounting
Interface	port1 (internal)
IP	10.11.101.1
Authentication	None

6. In *Interfaces*, select *Create New,* set the following information, and select *OK*.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.1
Authentication	None

To configure OSPF on Router2 - web-based manager

1. Go to *Router* > *Dynamic* > *OSPF*.
2. Enter `10.11.102.2` for the *Router ID* and select *Apply*.
3. In *Areas*, select *Create New,* set the following information, and select *OK*.

Area	0.0.0.0
Type	Regular
Authentication	None

4. In *Networks*, select *Create New,* set the following information, and select *OK*.

IP/Netmask	10.11.102.2/255.255.255.0
Area	0.0.0.0

5. In *Networks*, select *Create New,* set the following information, and select *OK*.

IP/Netmask	10.11.110.2/255.255.255.0
Area	0.0.0.0

6. In *Networks*, select *Create New,* set the following information, and select *OK*.

IP/Netmask	10.11.111.2/255.255.255.0
Area	0.0.0.0

7. In *Interfaces*, select *Create New,* set the following information, and select *OK*.

Name	RnD network
Interface	port1 (internal)
IP	10.11.102.2
Authentication	None

8. In *Interfaces*, select *Create New,* set the following information, and select *OK*.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.2
Authentication	None

9. In *Interfaces*, select *Create New,* set the following information, and select *OK*.

Name	Backbone2
Interface	port3 (external2)

IP	10.11.111.2
Authentication	None

To configure OSPF on Router3 - web-based manager

1. Go to *Router* > *Dynamic* > *OSPF*.
2. Enter `10.11.103.3` for the *Router ID* and then select *Apply*.
3. In *Areas*, select *Create New,* set the following information, and then select *OK*.

Area	0.0.0.0
Type	Regular
Authentication	None

4. In *Networks*, select *Create New,* set the following information, and select *OK*.

IP/Netmask	10.11.102.3/255.255.255.0
Area	0.0.0.0

5. In *Networks*, select *Create New,* set the following information, and select *OK*.

IP/Netmask	10.11.110.3/255.255.255.0
Area	0.0.0.0

6. In *Networks*, select *Create New,* set the following information, and select *OK*.

IP/Netmask	10.11.111.3/255.255.255.0
Area	0.0.0.0

7. In *Interfaces*, select *Create New,* set the following information, and select *OK*.

Name	RnD network
Interface	port1 (internal)
IP	10.11.103.3
Authentication	None

8. In *Interfaces*, select *Create New,* set the following information, and select *OK*.

Name	Backbone1
Interface	port2 (external1)
IP	10.11.110.3
Authentication	None

9. In *Interfaces*, select *Create New,* set the following information, and select *OK*.

Name	Backbone2
Interface	port3 (external2)
IP	10.11.111.3
Authentication	None

To configure OSPF on Router4 - web-based manager

1. Go to *Router* > *Dynamic* > *OSPF*.
2. Enter `10.11.104.4` for the *Router ID* and then select *Apply*.
3. In *Areas*, select *Create New*.
4. Set the following information, and select *OK*.

Area	2.2.2.2
Type	Regular
Authentication	None

5. In *Networks*, select *Create New,* set the following information, and select *OK*.

IP/Netmask	10.11.104.0/255.255.255.0
Area	0.0.0.0

6. In *Networks*, select *Create New*, set the following information, and select *OK*.

IP/Netmask	10.11.111.0/255.255.255.0
Area	0.0.0.0

7. In *Networks*, select *Create New*, set the following information, and select *OK*.

IP/Netmask	172.20.120.0/255.255.255.0
Area	0.0.0.0

8. In *Interfaces*, select *Create New*, set the following information, and select *OK*.

Name	Network Admin network
Interface	port1 (internal)
IP	10.11.104.4
Authentication	None

9. In *Interfaces*, select *Create New*, set the following information, and select *OK*.

Name	Backbone2
Interface	port2 (external2)
IP	10.11.111.4
Authentication	None

10. In *Interfaces*, select *Create New*, set the following information, and select *OK*.

Name	ISP
Interface	port3 (ISP)
IP	172.20.120.4
Authentication	None

Configuring other networking devices

All network devices on this network are running OSPF routing. The user networks (Accounting, R&D, and Network Administration) are part of one of the three areas.

The ISP needs to be notified of your network configuration for area 2.2.2.2. Your ISP will not advertise your areas externally as they are intended as internal areas. External areas have assigned unique numbers. The area numbers used in this example are similar to the 10.0.0.0 and 192.168.0.0 subnets used in internal networking.

Testing network configuration

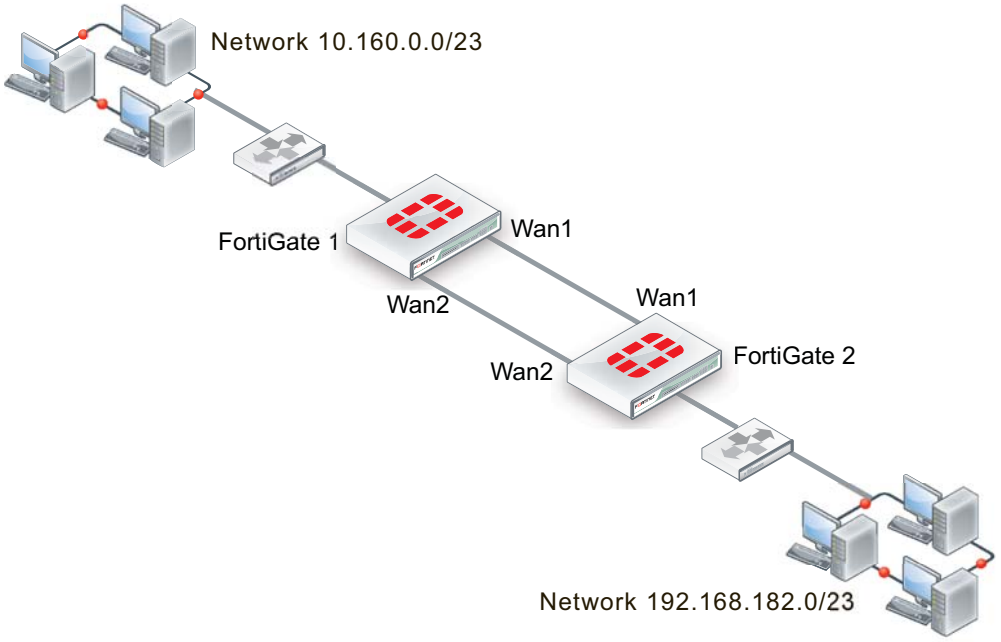
There are two main areas to test in this network configuration; network connectivity, and OSPF routing.

To test the network connectivity, see if computers on the Accounting or R&D networks can access the internet. If you need to troubleshoot network connectivity, see the Troubleshooting chapter.

To test the OSPF routing, check the routing tables on the FortiGate units to ensure the expected OSPF routes are present. If you need help troubleshooting OSPF routing, see “Troubleshooting OSPF” on page 408.

Controlling redundant links by cost

In this scenario, two FortiGate units have redundant links: one link between their WAN1 interfaces and another between their WAN2 interfaces.



FortiGate 1 should learn the route to network 192.168.182.0 and FortiGate 2 should learn the route to network 10.160.0.0. Under normal conditions, they should learn these routes through the WAN1 link. The WAN2 link should be used only as a backup.

With the default settings, each FortiGate unit learns these routes from both WAN1 and WAN2.

FortiGate 1:

```
FGT1 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.2.2.2 1 Full/Backup 00:00:33 10.182.0.187 wan1
10.2.2.2 1 Full/Backup 00:00:31 10.183.0.187 wan2

FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:01
[110/10] via 10.182.0.187, wan1, 00:00:01
O 192.168.182.0/23 [110/20] via 10.183.0.187, wan2, 00:02:04
[110/20] via 10.182.0.187, wan1, 00:02:04
```

FortiGate 2:

```
FGT2 # get router info ospf neighbor
OSPF process 0:
Neighbor ID Pri State Dead Time Address Interface
10.1.1.1 1 Full/DR 00:00:38 10.182.0.57 wan1
10.1.1.1 1 Full/DR 00:00:38 10.183.0.57 wan2

FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.183.0.57, wan2, 00:00:39
[110/20] via 10.182.0.57, wan1, 00:00:39
```

Adjusting the route costs

On both FortiGate units, the cost of the route through WAN2 is adjusted higher so that this route will only be used if the route through WAN1 is unavailable. The default cost is 10. The WAN2 route will be changed to a cost of 200.

On both FortiGate units:

```
config router ospf
  config ospf-interface
    edit "WAN2_higher_cost"
      set cost 200
      set interface "wan2"
    end
```

Now both FortiGate units use only the WAN1 route:

FortiGate 1:

```
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.182.0.187, wan1, 00:00:40
O 192.168.182.0/23 [110/20] via 10.182.0.187, wan1, 00:00:40
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/20] via 10.182.0.57, wan1, 00:09:37
```

LSDB check on FortiGate 1:

```
FGT1 # get router info ospf database router lsa
Router Link States (Area 0.0.0.0)

```

Verifying route redundancy

Bring down WAN1 and then check the routes on the two FortiGate units.

FortiGate 1:

```
FGT1 # get router info routing-table ospf
FGT1 # get router info routing-table ospf
O*E2 0.0.0.0/0 [110/10] via 10.183.0.187, wan2, 00:00:06
O 192.168.182.0/23 [110/210] via 10.183.0.187, wan2, 00:00:06
```

FortiGate 2:

```
FGT2 # get router info routing-table ospf
O 10.160.0.0/23 [110/210] via 10.183.0.57, wan2, 00:00:14
```

The WAN2 interface is now in use on both units.

Intermediate System to Intermediate System Protocol (IS-IS)

This section describes the Intermediate System to Intermediate System Protocol (IS-IS).

The following topics are included in this section:

- IS-IS background and concepts
- Troubleshooting IS-IS
- Simple IS-IS example

IS-IS background and concepts

Intermediate System to Intermediate System Protocol (IS-IS) allows routing of ISO's OSI protocol stack Connectionless Network Service (CLNS). IS-IS is an Interior Gateway Protocol (IGP) not intended to be used between Autonomous Systems (ASes).

This section contains:

- Background
- How IS-IS works
- Parts and terminology of IS-IS

Background

IS-IS was developed by Digital Equipment Corporation and later standardized by ISO in 1992 as ISO 19589 (see RFC 1142—note this RFC is different from the ISO version). At roughly the same time, the Internet Engineering Task Force developed OSPF (see "Open Shortest Path First (OSPF)" on page 396). After the initial version, IP support was added to IS-IS and this version was called Integrated IS-IS (see RFC 1195). Its widespread use started when an early version of IS-IS was included with BSD v4.3 Linux as the routed daemon. The routing algorithm used by IS-IS, the Bellman–Ford algorithm, first saw widespread use as the initial routing algorithm of the ARPANET.

IS-IS is a link state protocol well-suited to smaller networks that is in widespread use and has near universal support on routing hardware. It is quick to configure, and works well if there are no redundant paths. However, IS-IS updates are sent out node-by-node, so it can be slow to find a path around network outages. IS-IS also lacks good authentication, can not choose routes based on different quality of service methods, and can create network loops if you are not careful. IS-IS uses Djikstra's algorithm to find the best path, like OSPF.

While OSPF is more widely known, IS-IS is a viable alternative to OSPF in enterprise networks and ISP infrastructures, largely due to its native support for IPv6 and its non-disruptive methods for splitting, merging, migrating, and renumbering network areas.

The FortiGate implementation supports both IS-IS (see RFCs 1142 and 1162) and Integrated IS-IS (see RFCs 1195 and 5308).

How IS-IS works

As one of the original modern dynamic routing protocols, IS-IS is straightforward. Its routing algorithm is not complex, there are some options to allow fine tuning, and it is straightforward to configure IS-IS on FortiGate units.

From RFC 1142:

> *The routing algorithm used by the Decision Process is a shortest path first (SPF) algorithm. Instances of the algorithm are run independently and concurrently by all intermediate systems in a routing domain. IntraDomain routing of a PDU occurs on a hop-by-hop basis: that is, the algorithm determines only the next hop, not the complete path, that a data PDU will take to reach its destination.*

IS-IS versus static routing

IS-IS was one of the earliest dynamic routing protocols to work with IP addresses. As such, it is not as complex as more recent protocols. However, IS-IS is a big step forward from simple static routing.

While IS-IS may be slow in response to network outages, static routing has zero response. The same is true for convergence—static routing has zero convergence. Both IS-IS and static routing have the limited hop count, so it is neither a strength nor a weakness.

TLV

IS-IS uses *type-length-variable (TLV)* parameters to carry information in Link-State PDUs (LSPs). Each IS-IS LSP consists of a variable-length header to which TLVs are appended in order to extend IS-IS for IP routing. The TLV field consists of one octet of type (T), one octet of length (L), and "L" octets of Value (V). They are included in all of the IS-IS Packet types. For a complete breakdown of the LSP, refer to "LSP structure" on page 439.

In IS-IS, TLVs are used to determine route-leaking and authentication, and are also used for IPv4 and IPv6 awareness and reachability.

- To determine which TLVs are responsible for route-leaking, refer to "Default routing" on page 442.
- To determine which TLVs are responsible for authentication, refer to "Authentication" on page 443.
- To determine which TLVs are responsible for IPv4 and IPv6 awareness and reachability, refer to "Integrated IS-IS" on page 444.

For a complete list of reserved TLV codepoints, refer to RFC 3359.

LSP structure

It is difficult to fully understand a routing protocol without knowing what information is carried in its packets. Knowing how routers exchange each type of information will help you better understand the IS-IS protocol and will allow you to configure your network more appropriately.

This section provides information on the contents of the IS-IS LSP. LSPs describe the network topology and can include IP routes and checksums.

NSAP and NET

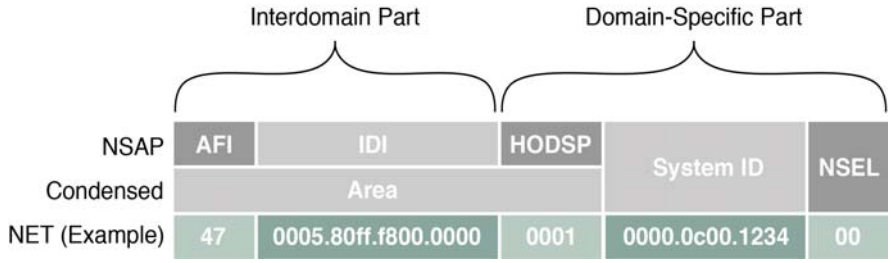
IS-IS routing protocol utilizes ISO network addressing to identify network interfaces. The addresses are known as Network Service Access Points (NSAPs). In general, IS-IS routers consist of only one NSAP, whereas IP addressing requires one IP address per interface.

In IS-IS, the NSAP address is translated into a Network Entity Title (NET), which is the same as the NSAP but can differentiate end systems by way of a byte called the *n-selector* (NSEL). In

order for adjacencies to form in IS-IS, the NSEL must necessarily be set to zero, to indicate “this system”. The total NET can be anywhere between 8 and 20 bytes long due to the support for variable length area addressing.

The following diagram identifies the individual parts of the NSAP, with explanations below.

Table 17: NSAP and NET example



AFI — The *Authority and Format Identifier (AFI)* specifies the format of the addressing family used. IS-IS is designed to carry routing information for several different protocols. Each entry has an address family identifier that identifies the globally unique Interdomain Part (IDP). For example, 49 is the AFI for private addresses, whereas 47 is the AFI for international organizations.

IDI — The *Initial Domain Identifier (IDI)* identifies the routing domain within an interconnected network. The length of the IDI is typically determined by the AFI. If you are using an AFI of 49, you do not need to specify an IDI, since the network is private.

HODSP — The *High Order Domain-Specific Part (HODSP)* identifies the unique address within a specific routing domain. Together, the AFI, IDI, and HODSP define the area address. All of the nodes within an area must have the same area address.

System ID — The *System ID* represents the 6-8 byte router identifier. The ID could be Media Access Control (MAC) format, as in the example above, or a static length IP address expressed in binary-coded decimal (BCD) format.

NSEL — The *n-selector (NSEL)*, as previously described, identifies the network layer transport service and must always be set to zero for IS-IS NETs.

Parts and terminology of IS-IS

Before you can understand how IS-IS functions, you need to understand some of the main concepts and parts of IS-IS.

This section includes:

- DIS election and pseudonode LSP
- Packet types
- Default routing
- Timer options
- Authentication
- Integrated IS-IS

DIS election and pseudonode LSP

In IS-IS routing protocol, a single router is chosen to be the designated intermediate system (DIS). The election of the DIS is determined automatically and dynamically on the LAN depending on highest interface priority and the subnetwork point of attachment (SNPA). The FortiGate is typically the DIS, and each router in its LAN is an intermediate system (IS).

Unlike OSPF, which elects a designated router (DR) and backup designated router (BDR), the DIS has no backup and determines the election of a new DIS whenever a router is added to the LAN or whenever the current DIS drops. A backup DIS is irrelevant since all of the routers on an IS-IS system are synchronized, and the short Hello interval used by the DIS quickly detects failures and the subsequent replacement of the DIS.

Synchronization of all the nodes in an IS-IS area could prove troublesome when updating the network infrastructure, and would demand ever-increasing resources each time a new router is added (at an exponential scale). For this purpose the DIS creates a pseudonode, which is essentially a virtual, logical node representing the LAN. The pseudonode requests adjacency status from all the routers in a multi-access network by sending IS-IS Hello (IIH) PDUs to Level 1 and Level 2 routers (where Level 1 routers share the same address as the DIS and Level 2 routers do not). Using a pseudonode to alter the representation of the LAN in the link-state database (LSD) greatly reduces the amount of adjacencies that area routers have to report. In essence, a pseudonode *collapses* a LAN topology, which allows a more linear scale to link-state advertising.

In order to maintain the database synchronization, the DIS periodically sends complete sequence number packets (CSNPs) to all participating routers.

Packet types

Four general packet types (PDUs) are communicated through IS-IS, appearing at both Level 1 and Level 2. They are described below.

Intermediate System-to-Intermediate System Hello (IIH) PDU — As mentioned previously, the IIH PDU, or Hello packet, detects neighboring routers and indicates to the pseudonode the area's adjacency mesh. The Hello packet, flooded to the multicast address, contains the system ID of the sending router, the holding time, the circuit type of the interface on which the PDU was sent, the PDU length, the DIS identifier, and the interface priority (used in DIS election). The Hello packet also informs its area routers that it is the DIS.

Hello packets are padded to the maximum IS-IS PDU size of 1492 bytes (the full MTU size) to assist in the detection of transmission errors with large frames or with MTU mismatches between adjacencies.

The DIS typically floods Hello packets to the entire LAN every three seconds.

Link-state PDU (LSP) — The LSP contains information about each router in an area and its connected interfaces. LSPs are refreshed periodically and acknowledged on the network by way of sequence number PDUs. If new LSP information is found, based on the most recent complete sequence number PDU (CSNP), then out-of-date entries in the link-state database (LSDB) are removed and the LSDB is updated.

For a more detailed breakdown of the LSP, see "LSP structure" on page 439.

Complete sequence number PDU (CSNP) — CSNPs contain a list of all LSPs in the current LSDB. The CSNP informs other area routers of missing or outdated links in the adjacency mesh. The receiving routers then use this information to update their own database to ensure that all area routers converge.

In contrast to Hello packets, CSNPs are sent every ten seconds and only between neighbor. In other words, they are never flooded.

Partial sequence number PDU (PSNP) — PSNPs are used to request and acknowledge LSP information from an adjacency. When a router compares a CSNP with its local database and determines a discrepancy, the router requests an updated LSP using a PSNP. Once received, the router stores the LSP in its local database and responds to the DIS with acknowledgement.

Default routing

The default route is used if either there are no other routes in the routing table or if none of the other routes apply to a destination. Including the gateway in the default route gives all traffic a next-hop address to use when leaving the local network. The gateway address is normally another router on the edge of the local network.

FortiGate units come with a default static route with an IPv4 address of 0.0.0.0, an administration distance of 10, and a gateway IPv4 address. Beginner administrators can use the default route settings until a more advanced configuration is warranted.

By default, all routes are displayed in the Routing Monitor list. To display the routes in the routing table, go to *Route* > *Monitor* > *Routing Monitor*.

Route leaking

Route leaking is the term used to describe the bi-directional flow of information between internal and external routing interfaces. By default, IS-IS leaks routing information from a Level 1 area into a Level 2 area. In order to leak Level 2 routing information into a Level 1 area, you must configure an export policy. Whether or not a route is leaked is determined by the ATT bit, using TLV 128 (for internal IP reachability) and TLV 130 (for external IP address information). For more information on TLVs, see "Troubleshooting IS-IS" on page 445.

To configure IS-IS route leaking, use the following CLI commands.

1. On a Level 1-2 router:
```
config router isis
  set redistribute-l2 enable
end
```
2. On a Level 1 router:
```
config router isis
  get router info routing-table isis
  get router info isis route
end
```

Default information originate option

Enabling default-information-originate generates and advertises a default route into the FortiGate unit's IS-IS-enabled networks. The generated route may be based on routes learned through a dynamic routing protocol, routes in the routing table, or both. IS-IS does not create the default route unless you use the `always` option.

Select *Disable* if you experience any issues or if you wish to advertise your own static routes into IS-IS updates.

The CLI commands associated with default information originate include:

```
config router isis
  set default-originate
end
```

Timer options

IS-IS uses various timers to regulate its performance including a garbage timer, update timer, and timeout timer. The FortiGate unit default timer settings (30, 180, and 120 seconds respectively) are effective in most configurations—if you change these settings, ensure that the new settings are compatible with local routers and access servers.

You can configure the three IS-IS timers in the CLI, using the following commands:

```
config router isis
  set garbage-timer
  set update-timer
  set timeout-timer
end
```

You will find more information on each timer below.

Garbage timer

The garbage timer is the amount of time (in seconds) that the DIS will advertise a route as being unreachable before deleting the route from the routing table. If this timer is shorter, it will keep more up-to-date routes in the routing table and remove old ones faster. This results in a smaller routing table which is useful if you have a very large network, or if your network changes frequently.

Update timer

The update timer determines the interval between routing updates. Generally, this value is set to 30 seconds. There is some randomness added to help prevent network traffic congestion, which could result from all routers simultaneously attempting to update their neighbors. The update timer should be at least three times smaller than the timeout timer, otherwise you will experience an error.

If you are experiencing significant traffic on your network, you can increase this interval to send fewer updates per minute. However, ensure you increase the interval for all the routers on your network or you will experience timeouts that will degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time (in seconds) that a route is considered reachable while no updates are received for the route. This is the maximum time the DIS will keep a reachable route in the routing table while no updates for that route are received. If the DIS receives an update for the route before the timeout period expires, the timer is restarted. The timeout period should be at least three times longer than the update period, otherwise you will experience an error.

If you are experiencing problems with routers not responding in time to updates, increase this timer. However, remember that longer timeout intervals result in longer overall update periods — it may be considerable time before the DIS is done waiting for all the timers to expire on unresponsive routes.

Authentication

In routing protocols, it is typically desirable to establish authentication rules that prevent malicious and otherwise unwanted information from being injected into the routing table. IS-IS routing protocol utilizes TLV 10 to establish authentication. For more information on TLVs, see “TLV” on page 439.

Initially, IS-IS used plain Clear Text to navigate the authentication rules, but this was found to be insecure since the Clear Text packets were unencrypted and could be exposed to packet sniffers. As per RFC 3567, HMAC-MD5 and Enhanced Clear Text authentication features were introduced to IS-IS, both of which encrypt authentication data, making them considerably more secure than using plain Clear Text authentication.

HMAC-MD5 authentication

Hashed Message Authentication Codes - Message Digest 5 (HMAC-MD5) is a mechanism for applying a cryptographic hash function to the message authentication process. It is applied at

both Level 1 and Level 2 routing. In IS-IS, an HMAC-MD5 can be applied to each type of LSP, on different interfaces, and with different passwords.

Authentication data is hashed using an AH (Authentication Header) key. From RFC 2085:

> *The "AH Key" is used as a shared secret between two communicating parties. The Key is not a "cryptographic key" as used in a traditional sense. Instead, the AH key (shared secret) is hashed with the transmitted data and thus, assures that an intervening party cannot duplicate the authentication data. [...] Implementation should, and as frequently as possible, change the AH key. Keys need to be chosen at random, or generated using a cryptographically strong pseudo-random generator seeded with a random seed."*

Clear Text authentication uses the configuration commands `area-password` and `domain-password` for authentication, but when migrating from Clear Text authentication to HMAC-MD5, these command settings are automatically overwritten.

By the year 2005, the MD5 hash function had been identified as vulnerable to collision search attacks and various weaknesses. While such vulnerabilities do not compromise the use of MD5 within HMAC, administrators need to be aware of potential developments in cryptanalysis and cryptographic hash functions in the likely event that the underlying hash function needs to be replaced.

Enhanced Clear Text authentication

Enhanced Clear Text authentication is an extension to Clear Text authentication that allows the encryption of passwords as they are displayed in the configuration. It includes a series of authentication mode commands and an authentication key chain, and allows for more simple password modification and password management. Enhanced Clear Text authentication also provides for smoother migration to and from changing authentication types. Intermediate systems continue to use the original authentication method until all the area routers are updated to use the new method.

Authentication key chain

A key chain is a list of one or more authentication keys including the send and receive lifetimes for each key. Keys are used for authenticating routing packets only during the specified lifetimes. A router migrates from one key to the next according to the scheduled send and receive lifetimes. If an active key is unavailable, then the PDU is automatically discarded.

From RFC 5310:

> *It should be noted that the cryptographic strength of the HMAC depends upon the cryptographic strength of the underlying hash function and on the size and quality of the key.*

Integrated IS-IS

Integrated IS-IS is an extended version of IS-IS that includes support for both IPv4 and IPv6. IPv4 and IPv6 interface addresses are determined by TLVs 132 and 232, respectively. The parameter responsible for IPv6 reachability is TLV 236. For more information on TLVs, see "Troubleshooting IS-IS" on page 445.

The FortiGate unit command `config router isis` is almost the same except that IPv6 addresses are used. Also, if you are going to use prefix or access lists with Integrated IS-IS, you must use the `config router access-list6` or `config prefix-list6` versions of those commands.

If you want to route IPv4 traffic over an IPv6 network, you can use the command `config system ipv6-tunnel` to configure the FortiGate unit to do this. The IPv6 interface is configured under `config system interface`. All subnets between the source and destination addresses must support IPv6. This command is not supported in Transparent mode.

For example, you want to set up a tunnel on the port1 interface starting at 2002:C0A8:3201:: on your local network and tunnel it to address 2002:A0A:A01:: where it will need access to an IPv4 network again. Use the following command:

```
config system ipv6-tunnel
  edit test_tunnel
    set destination 2002:A0A:A01::
    set interface port1
    set source 2002:C0A8:3201::
  end
end
```

The CLI commands associated with Integrated IS-IS include:

```
config router isis
config router access-list6
config router prefix-list6
config system ipv6-tunnel
get router info6 *
```

Troubleshooting IS-IS

If you want to troubleshoot Integrated IS-IS, it is the same as with IS-IS but you must specify the different protocol, and use IPv6 addresses. This applies to commands such as `get router info6` when you want to see the routing table, or other related information.

This section includes:

- Routing loops
- Split horizon and Poison reverse updates

Routing loops

Normally in routing, a path between two addresses is chosen and traffic is routed along that path from one address to the other. When there is a routing loop, that normal path doubles back on itself creating a loop. When there are loops, the network has problems.

A routing loop happens when a normally functioning network has an outage, and one or more routers are offline. When packets encounter this, an alternate route is attempted to maneuver around the outage. During this phase it is possible for a route to be attempted that involves going back a hop, and trying a different hop forward. If that hop forward is blocked by the outage as well, a hop back and possibly the original hop forward may be selected. You can see if this continues, how it can consume not only network bandwidth but also many resources on those routers affected. The worst part is this situation will continue until the network administrator changes the router settings, or the downed routers come back online.

Routing loop effect on the network

In addition to this “traffic jam” of routed packets, every time the routing table for a router changes that router sends an update out to all of the IS-IS routers connected to it. In a network loop, its possible for a router to change its routes very quickly as it tries and fails along these new routes. This can quickly result in a flood of updates being sent out, which can effectively grind the network to a halt until the problem is fixed.

How can you spot a routing loop

Any time network traffic slows down, you will be asking yourself if it is a network loop or not. Often slowdowns are normal, they are not a full stoppage, and normal traffic resumes in a short period of time.

If the slow down is a full halt of traffic or a major slowdown does not return to normal quickly, you need to do serious troubleshooting quickly.

Some methods to troubleshoot your outage include:

- Checking your logs
- Using SNMP network monitoring
- Using dead gateway detection and e-mail alerts
- Looking at the packet flow

If you aren't running SNMP, dead gateway detection, or you have non-Fortinet routers in your network, you can use networking tools such as ping and traceroute to define the outage on your network and begin to fix it.

Checking your logs

If your routers log events to a central location, it can be easy to check the logs for your network for any outages.

On your FortiGate unit, go to *Log & Report* > *Log & Archive Access*. You will want to look at both event logs and traffic logs. Events to look for will generally fall under CPU and memory usage, interfaces going offline (due to dead gateway detection), and other similar system events.

Once you have found and fixed your network problem, you can go back to the logs and create a report to better see how things developed during the problem. This type of forensics analysis can better help you prepare for next time.

Using SNMP network monitoring

If your network had no problems one minute and slows to a halt the next, chances are something changed to cause that problem. Most of the time an offline router is the cause, and once you find that router and bring it back online, things will return to normal.

If you can enable a hardware monitoring system such as SNMP or sFlow on your routers, you can be notified of the outage and where it is exactly as soon as it happens.

Ideally you can configure SNMP on all your FortiGate routers and be alerted to all outages as they occur.

To use SNMP to detect potential routing loops

1. Go to *System* > *Config* > *SNMP*.
2. Enable *SNMP Agent*.
3. Optionally enter the *Description*, *Location*, and *Contact* information for this device for easier location of the problem report.
4. In either *SNMP v1/v2c* section or *SNMP v3* section, as appropriate, select *Create New*.
5. Enter the *Community Name* that you want to use.
6. In *Hosts*, select Add to add an IP address where you will be monitoring the FortiGate unit. You can add up to 8 different addresses.
7. Ensure that ports 161 and 162 (SNMP queries and traps) are allowed through your security policies.
8. In *SNMP Event*, select the events you want to be notified of. For routing loops this should include *CPU Overusage*, *Memory Low*, and possibly *Log disk space low*. If there are

problems, the log will be filling up quickly, and the FortiGate unit's resources will be overused.

9. Select *OK*.
10. Configure SNMP host (manager) software on your administration computer. This will monitor the SNMP information sent out by the FortiGate unit. Typically you can configure this software to alert you to outages or CPU spikes that may indicate a routing loop.

Using dead gateway detection and e-mail alerts

Another tool available to you on FortiGate units is the dead gateway detection. This feature allows the FortiGate unit to ping a gateway at regular intervals to ensure it is online and working. When the gateway is not accessible, that interface is marked as down.

To detect possible routing loops with dead gateway detection and e-mail alerts

1. To configure dead gateway detection, go to *Router* > *Static* > *Settings* and select *Create New*.
2. Set the *Ping Interval* (how often to send a ping), and *Failover Threshold* (how many lost pings is considered a failure). A smaller interval and smaller number of lost pings will result in faster detection, but will create more traffic on your network.
3. To configure interface status change notification, go to *Log & Report* > *Log Config* > *Alert E-mail*.
4. After you enter your email details, select the events you want to be alerted about — in our case *Configuration changes*. You may also want to log CPU and Memory usage as a network outage will cause your CPU activity to spike.

If you have VDOMs configured, you will have to enter the basic SMTP server information in the Global section, and the rest of the configuration within the VDOM that includes this interface.

After this configuration, when this interface on the FortiGate unit cannot connect to the next router, the FortiGate unit will bring down the interface and alert you with an email to the outage.

Looking at the packet flow

If you want to see what is happening on your network, look at the packets travelling on the network. In this situation, you are looking for routes that have metrics higher than 15 as that indicates they are unreachable. Ideally if you debug the flow of the packets, and record the routes that are unreachable, you can create an accurate picture of the network outage.

Action to take on discovering a routing loop

Once you have mapped the problem on your network, and determined it is in fact a routing loop there are a number of steps to take in correcting it.

1. Get any offline routers back online. This may be a simple reboot, or you may have to replace hardware. Often this first step will restore your network to its normal operation, once the routing tables finish being updated.
2. Change your routing configuration on the edges of the outage. Even if step 1 brought your network back online, you should consider making changes to improve your network before the next outage occurs. These changes can include configuring features like holddowns and triggers for updates, split horizon, and poison reverse updates.

Split horizon and Poison reverse updates

Split horizon is best explained with an example. You have three routers linked serially, let's call them A, B, and C. A is only linked to B, C is only linked to B, and B is linked to both A and C. To get to C, A must go through B. If the link to C goes down, it is possible that B will try to use A's route to get to C. This route is A-B-C, so it will not work. However, if B tries to use it this begins an endless loop.

This situation is called a split horizon because from B's point of view the horizon stretches out in each direction, but in reality it only is on one side.

Poison reverse is the method used to prevent routes from running into split horizon problems. Poison reverse "poisons" routes away from the destination that use the current router in their route to the destination. This "poisoned" route is marked as unreachable for routers that cannot use it. In IS-IS this means that route is marked with a distance of 16.

Simple IS-IS example

This is an example of a typical medium-sized network configuration using IS-IS routing.

Imagine a company with four FortiGate devices connected to one another. A FortiGate at one end of the network connects to two routers, each with its own local subnet; one of these routers uses OSPF and the other uses RIP.

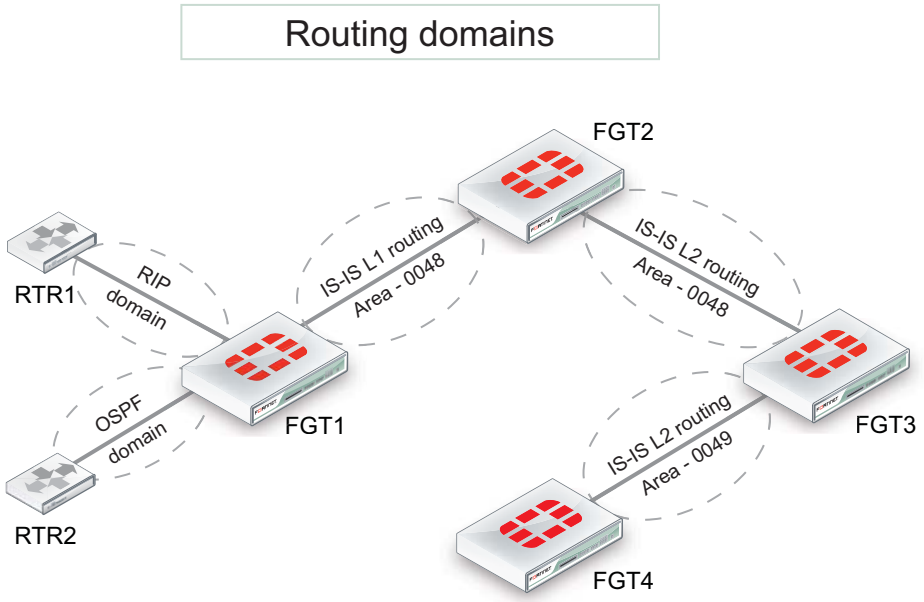
Your task is to configure the four FortiGates to route traffic and process network updates using IS-IS, such that the farthest FortiGate (see 'FGT4' in Network layout and assumptions) receives route updates for the two routers at the opposite end of the network. Furthermore, FGT4 has been given a loopback subnet that must be identified by the router running RIP.

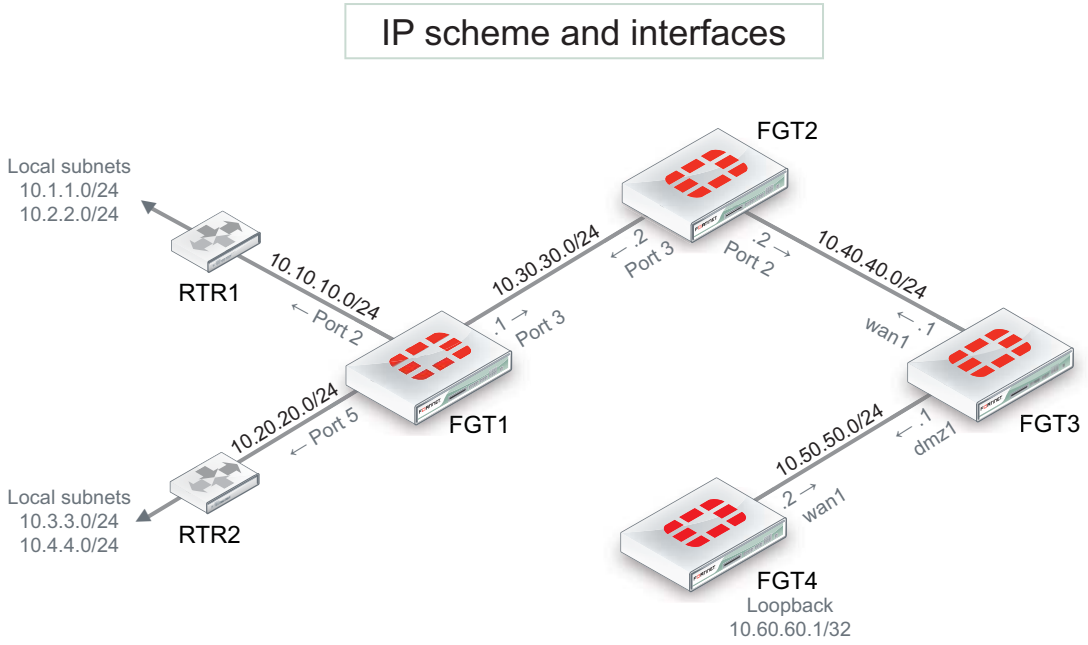
Since the internal networks use OSPF and RIP, those protocols will need to be redistributed through the IS-IS network. To keep the example simple, there will be no authentication of router traffic.

With IS-IS properly configured in this example, if a router fails or temporarily goes offline, the route change will propagate throughout the system.

This section includes the following topics:

Network layout and assumptions





- It is assumed that each FortiGate is operating in NAT mode.
- All interfaces have been previously assigned and no static routes are required.
- The AFI (Authority and Format Identifier) used is 49 : Locally administered (private).
- The Area identifiers are 0048 and 0049.

Expectations

- FGT4 must get the IS-IS route updates for RTR1 and RTR2 local subnets (10.1.1.0, 10.2.2.0, 10.3.3.0, 10.4.4.0).
- RTR1 must receive (via RIP2) the loopback subnet of FGT4 (10.60.60.1/32).

CLI configuration

The following CLI configuration occurs on each FortiGate (as identified), including only the relevant parts.

FGT1

```
config router isis
   config isis-interface
      edit "port3"
         set circuit-type level-1
         set network-type broadcast
         set status enable
      next
   end
   config isis-net
      edit 1
         set net 49.0048.1921.6818.2136.00
      next
   end
   config redistribute "connected"
   end
   config redistribute "rip"
      set status enable
      set level level-1
   end
   config redistribute "ospf"
      set status enable
      set level level-1
   end
end
config router rip
   config interface
      edit "port2"
         set receive-version 2
         set send-version 2
      next
   end
   config network
      edit 1
         set prefix 10.10.10.0 255.255.255.0
      next
   end
   config redistribute "isis"
      set status enable
   end
end
```

FGT2

```
config router isis
  config isis-interface
    edit "port3"
      set circuit-type level-1
      set network-type broadcast
      set status enable
    next
    edit "port2"
      set network-type broadcast
      set status enable
    next
  end
  config isis-net
    edit 1
      set net 49.0048.1221.6818.2110.00
    next
  end
  set redistribute-l1 enable
  set redistribute-l2 enable
end
```

FGT3

```
config router isis
  set is-type level-2-only
    config isis-interface
      edit "wan1"
        set network-type broadcast
        set status enable
      next
      edit "dmz1"
        set network-type broadcast
        set status enable
      next
    end
    config isis-net
      edit 1
        set net 49.0048.1921.6818.2108.00
      next
      edit 2
        set net 49.0049.1921.6818.2108.00
      next
    end
end
```

FGT4

```
config router isis
   set is-type level-2-only
      config isis-interface
         edit "wan1"
            set network-type broadcast
            set status enable
         next
      end
      config isis-net
         edit 1
            set net 49.0049.1721.0160.1004.00
         next
      end
      config redistribute "connected"
         set status enable
      end
end
```

Verification

Once the network has been configured, you need to test that it works as expected. Use the following CLI commands on the devices indicated.

Verifying if RTR1 receives loopback subnet of FGT4

```
(RTR1) # get router info routing-table all
```

Result:

```
C       10.1.1.0/24 is directly connected, vlan1
C       10.2.2.0/24 is directly connected, vlan2
C       10.10.10.0/24 is directly connected, dmz1
R       10.40.40.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
R       10.50.50.0/24 [120/2] via 10.10.10.1, dmz1, 00:04:07
R       10.60.60.1/32 [120/2] via 10.10.10.1, dmz1, 00:04:07
```

(*) If required, filtering out 10.50.50.0 and 10.40.40.0 from the routing table could be done with a route-map.

Verification on FGT2, which is the border between L1 and L2 routing levels; looking at IS-IS information

```
FGT2 # get router info isis interface
```

Result:

```
port2 is up, line protocol is up
   Routing Protocol: IS-IS ((null))

i L2   10.4.4.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2   10.10.10.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2   10.11.11.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2   10.20.20.0/24 [115/30] via 10.50.50.1, wan1, 00:12:46
i L2   10.30.30.0/24 [115/30] via 10.50.50.1, wan1, 00:13:55
i L2   10.40.40.0/24 [115/20] via 10.50.50.1, wan1, 00:15:30
C      10.50.50.0/24 is directly connected, wan1
C      10.60.60.1/32 is directly connected, loopback
```

Troubleshooting

The following diagnose commands are available for further IS-IS troubleshooting and will display all IS-IS activity (sent and received packets):

```
FGT # diagnose ip router isis level info
FGT # diagnose ip router isis all enable
FGT # diagnose debug enable
```

...to stop the debug type output :

```
FGT # diagnose ip router isis level none
```

Output and interpretation depends on the issue faced. You can provide this information to TAC if you open a support ticket.

Debugging IPv6 on IS-ISng

The debug command is very useful to see what is happening on the network at the packet level. The following CLI commands specify both IPv6 and IS-IS, so only IS-ISng packets will be reported. The output from these commands will show you the IS-ISng traffic on your FortiGate unit including RECV, SEND, and UPDATE actions.

```
FGT # diagnose ipv6 router isis level info
FGT # diagnose ipv6 router isis all enable
FGT # diagnose debug enable
```

These three commands will:

- turn on debugging in general
- set the debug level to information, a verbose reporting level
- turn on all IS-IS router settings

Part of the information displayed from the debugging is the metric (hop count). If the metric is 16, then that destination is unreachable since the maximum hop count is 15.

In general, you should see an update announcement, followed by the routing table being sent out, and a received reply in response.

Chapter 3 Authentication for FortiOS 5.0

This FortiOS Handbook chapter contains the following sections:

Introduction to authentication describes some basic elements and concepts of authentication.

Authentication servers describes external authentication servers, where a FortiGate unit fits into the topology, and how to configure a FortiGate unit to work with that type of authentication server.

Users and user groups describes the different types of user accounts and user groups. Authenticated access to resources is based on user identities and user group membership. Two-factor authentication methods, including FortiToken, provide additional security.

Managing Guest Access explains how to manage temporary accounts for visitors to your premises.

Configuring authenticated access provides detailed procedures for setting up authenticated access in security policies and authenticated access to VPNs.

Certificate-based authentication describes authentication by means of X.509 certificates.

SSO using a FortiAuthenticator unit describes how to use a FortiAuthenticator unit as an SSO agent that can integrate with external network authentication systems such as RADIUS and LDAP to gather user logon information and send it to the FortiGate unit. Users can also log on through a FortiAuthenticator-based web portal or the FortiClient SSO Mobility Agent.

Single Sign-On to Windows AD describes how to set up Single Sign-On in a Windows AD network by configuring the FortiGate unit to poll domain controllers for information user logons and user privileges.

Agent-based FSSO describes how to set up Single Sign-On in Windows AD, Citrix, or Novell networks by installing Fortinet Single Sign On (FSSO) agents on domain controllers. The FortiGate unit receives information about user logons and allows access to network resources based on user group memberships.

SSO using RADIUS accounting records describes how to set up Single Sign-On in a network that uses RADIUS authentication. In this configuration, the RADIUS server send RADIUS accounting records to the FortiGate unit when users log on or off the network. The record includes a user group name that can be used in FortiGate security policies to determine which resources each user can access.

Monitoring authenticated users describes FortiOS authenticated user monitor screens.

Examples and Troubleshooting provides configuration examples and troubleshooting suggestions.

Introduction to authentication

Identifying users and other computers—authentication—is a key part of network security. This section describes some basic elements and concepts of authentication.

The following topics are included in this section:

What is authentication?

Businesses need to authenticate people who have access to company resources. In the physical world this may be a swipe card to enter the building, or a code to enter a locked door. If a person has this swipe card or code, they have been authenticated as someone allowed in that building or room.

Authentication is the act of confirming the identity of a person or other entity. In the context of a private computer network, the identities of users or host computers must be established to ensure that only authorized parties can access the network. The FortiGate unit enables controlled network access and applies authentication to users of security policies and VPN clients.

Methods of authentication

FortiGate unit authentication is divided into three basic types: password authentication for people, certificate authentication for hosts or endpoints, and two-factor authentication for additional security beyond just passwords. An exception to this is that FortiGate units in an HA cluster and FortiManager units use password authentication.

Password authentication verifies individual user identities, but access to network resources is based on membership in user groups. For example, a security policy can be configured to permit access only to the members of one or more user groups. Any user who attempts to access the network through that policy is then authenticated through a request for their username and password.

Methods of authentication include:

Local password authentication

The simplest authentication is based on user accounts stored locally on the FortiGate unit. For each account, a username and password is stored. The account also has a disable option so that you can suspend the account without deleting it.

Local user accounts work well for a single-FortiGate installation. If your network has multiple FortiGate units that will use the same accounts, the use of an external authentication server can simplify account configuration and maintenance.

You create local user accounts in the web-based manager under *User & Device* > *User* > *User Definition*. This page is also used to create accounts where an external authentication server stores and verifies the password.

Server-based password authentication

Using external LDAP, RADIUS, or TACACS+ authentication servers is desirable when multiple FortiGate units need to authenticate the same users, or where the FortiGate unit is added to a network that already contains an authentication server.

When you use an external authentication server to authenticate users, the FortiGate unit sends the user's entered credentials to the external server. The password is encrypted. The server's response indicates whether the supplied credentials are valid or not.

You must configure the FortiGate unit to access the external authentication servers that you want to use. The configuration includes the parameters that authenticate the FortiGate unit to the authentication server.

You can use external authentication servers in two ways:

- Create user accounts on the FortiGate unit, but instead of storing each user's password, specify the server used to authenticate that user. As with accounts that store the password locally, you add these users to appropriate user groups.
- Add the authentication server to user groups. Any user who has an account on the server can be authenticated and have the access privileges of the FortiGate user group. Optionally, when an LDAP server is a FortiGate user group member, you can limit access to users who belong to specific groups defined on the LDAP server.

Certificate-based authentication

An RSA X.509 server certificate is a small file issued by a Certificate Authority (CA) that is installed on a computer or FortiGate unit to authenticate itself to other devices on the network. When one party on a network presents the certificate as authentication, the other party can validate that the certificate was issued by the CA. The identification is therefore as trustworthy as the Certificate Authority (CA) that issued the certificate.

To protect against compromised or misused certificates, CAs can revoke any certificate by adding it to a Certificate Revocation List (CRL). Certificate status can also be checked online using Online Certificate Status Protocol (OCSP).

RSA X.509 certificates are based on public-key cryptography, in which there are two keys: the private key and the public key. Data encrypted with the private key can be decrypted only with the public key and vice versa. As the names suggest, the private key is never revealed to anyone and the public key can be freely distributed. Encryption with the recipient's public key creates a message that only the intended recipient can read. Encryption with the sender's private key creates a message whose authenticity is proven because it can be decrypted only with the sender's public key.

Server certificates contain a signature string encrypted with the CA's private key. The CA's public key is contained in a CA root certificate. If the signature string can be decrypted with the CA's public key, the certificate is genuine.

Certificate authorities

A certificate authority can be:

- an organization, such as VeriSign Inc., that provides certificate services
- a software application, such as Microsoft Certificate Services or OpenSSH

For a company web portal or customer-facing SSL VPN, a third-party certificate service has some advantages. The CA certificates are already included in popular web browsers and customers trust the third-party. On the other hand, third-party services have a cost.

For administrators and for employee VPN users, the local CA based on a software application provides the required security at low cost. You can generate and distribute certificates as needed. If an employee leaves the organization, you can simply revoke their certificate.

Certificates for users

FortiGate unit administrators and SSL VPN users can install certificates in their web browsers to authenticate themselves. If the FortiGate unit uses a CA-issued certificate to authenticate itself to the clients, the browser will also need the appropriate CA certificate.

FortiGate IPsec VPN users can install server and CA certificates according to the instructions for their IPsec VPN client software. The FortiClient Endpoint Security application, for example, can import and store the certificates required by VPN connections.

FortiGate units are also compatible with some Public Key Infrastructure systems. For an example of this type of system, see "RSA ACE (SecurID) servers" on page 483.

Two-factor authentication

A user can be required to provide both something they know (their username and password combination) and something they have (certificate or a random token code). Certificates are installed on the user's computer.

Two-factor authentication is available for PKI users. For more information, see "Certificate" on page 495.

Another type of two-factor authentication is to use a randomly generated token (multi-digit number) along with the username and password combination. One method is a FortiToken — a one time passcode (OTP) generator that generates a unique code every 60 seconds. Others use email or SMS text messaging to deliver the random token code to the user or administrator.

When one of these methods is configured, the user enters this code at login after the username and password have been verified. The FortiGate unit verifies the token code after as well as the password and username. For more information, see "Two-factor authentication" on page 494

Types of authentication

FortiOS supports two different types of authentication based on your situation and needs.

Security policy authentication, or identity-based policies, is easily applied to all users logging on to a network, or network service. For example if a group of users on your network such as the accounting department who have access to sensitive data need to access the Internet, it is a good idea to make sure the user is a valid user and not someone trying to send company secrets to the Internet. Security policy authentication can be applied to as many or as few users

as needed, and it supports a number of authentication protocols to easily fit with your existing network.

VPN authentication can be for both the remote VPN device as well as the VPN users. VPNs are used to communicate with locations outside the company network as if they were part of the company network. This level of trust, once a VPN is established, is easily established with authentication to verify the remote user is in fact a valid user. In this situation without authentication, anyone malicious or otherwise could connect to the company network with potentially full access.

Firewall authentication (identity-based policies)

Security policies enable traffic to flow between networks. If you want to limit which users have access to particular resources, you create identity-based policies (IBP) that allow access only to members of specific user groups. Authentication, a request for username and password, is triggered when a user attempts to access a resource for which data must pass through an identity-based policy.

The user's authentication expires if the connection is idle for too long, 5 minutes by default but that can customized.

Identity-based policies are the mechanism for FSSO, NTLM, certificate based, and RADIUS SSO authentication.

FSSO

Fortinet Single Sign on (FSSO) provides seamless authentication support for Microsoft Windows Active Directory (AD) and Novell eDirectory users in a FortiGate environment.

On a Microsoft Windows or Novell network, users authenticate with the Active Directory or Novell eDirectory at logon. FSSO provides authentication information to the FortiGate unit so that users automatically get access to permitted resources. See "Introduction to FSSO agents" on page 564.

NTLM

The NT LAN Manager (NTLM) protocol is used when the MS Windows Active Directory (AD) domain controller can not be contacted. NTLM is a browser-based method of authentication.

The FSSO software is installed on each AD server and the FortiGate unit is configured to communicate with each FSSO client. When a user successfully logs into their Windows PC (and is authenticated by the AD Server), the FSSO client communicates the user's name, IP address, and group login information to the FortiGate unit. The FortiGate unit sets up a temporary access policy for the user, so when they attempt access through the firewall they do not need to re-authenticate. This model works well in environments where the FSSO client can be installed on all AD servers.

In system configurations where it is not possible to install FSSO clients on all AD servers, the FortiGate unit must be able to query the AD servers to find out if a user has been properly authenticated. This is achieved using the NTLM messaging features of Active Directory and Internet Explorer.

Even when NTLM authentication is used, the user is not asked again for their username and password. Internet Explorer stores the user's credentials and the FortiGate unit uses NTLM messaging to validate them in the Windows AD environment.

Note that if the authentication reaches the timeout period, the NTLM message exchange restarts. For more information on NTLM, see "NTLM authentication" on page 524 and "FSSO NTLM authentication support" on page 569.

Certificates

Certificates can be used as part of an identity-based policy. All users being authenticated against the policy are required to have the proper certificate. See “Certificate-based authentication” on page 458

RADIUS SSO

RADIUS Single Sign-On (RSSO) is a remote authentication method that does not require any local users to be configured, and relies on RADIUS Start records to provide the FortiGate unit with authentication information. That information identifies the user and user group, which is then matched using a security policy. See “SSO using RADIUS accounting records” on page 602.

FortiGuard Web Filter override authentication

Optionally, users can be allowed the privilege of overriding FortiGuard Web Filtering to view blocked web sites. Depending on the override settings, the override can apply to the user who requested it, the entire user group to which the user belongs, or all users who share the same web filter profile. As with other FortiGate features, access to FortiGuard overrides is controlled through user groups. Firewall and Directory Services user groups are eligible for the override privilege. For more information about web filtering and overrides, see the UTM chapter of this FortiOS Handbook.

VPN authentication

Authentication involves authenticating the user. In IPsec VPNs authenticating the user is optional, but authentication of the peer device is required.

This section includes:

- Authenticating IPsec VPN peers (devices)
- Authenticating IPsec VPN users
- Authenticating SSL VPN users
- Authenticating PPTP and L2TP VPN users

Authenticating IPsec VPN peers (devices)

A VPN tunnel has one end on a local trusted network, and the other end is at a remote location. The remote peer (device) must be authenticated to be able to trust the VPN tunnel. Without that authentication, it is possible for a malicious hacker to masquerade as a valid VPN tunnel device and gain access to the trusted local network.

The three ways to authenticate VPN peers are with a preshared key, RSA X.509 certificate, an a specific peer ID value.

The simplest way for IPsec VPN peers to authenticate each other is through the use of a preshared key, also called a shared secret. The preshared key is a text string used to encrypt the data exchanges that establish the VPN tunnel. The preshared key must be six or more characters. The VPN tunnel cannot be established if the two peers do not use the same key. The disadvantage of preshared key authentication is that it can be difficult to securely distribute and update the preshared keys. See “Authenticating the FortiGate unit with a pre-shared key” on page 1640.

RSA X.509 certificates are a better way for VPN peers to authenticate each other. Each peer offers a certificate signed by a Certificate Authority (CA) which the other peer can validate with the appropriate CA root certificate. For more information about certificates, see “Certificate-based authentication” on page 532.

You can supplement either preshared key or certificate authentication by requiring the other peer to provide a specific peer ID value. The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

Authenticating IPsec VPN users

An IPsec VPN can be configured to accept connections from multiple dynamically addressed peers. You would do this to enable employees to connect to the corporate network while traveling or from home. On a FortiGate unit, you create this configuration by setting the *Remote Gateway* to *Dialup User*.

It is possible to have an IPsec VPN in which remote peer devices authenticate using a common preshared key or a certificate, but there is no attempt to identify the user at the remote peer. To add user authentication, you can do one of the following:

- require a unique preshared key for each peer
- require a unique peer ID for each peer
- require a unique peer certificate for each peer
- require additional user authentication (XAuth)

The peer ID is a text string configured on the peer device. On a FortiGate peer or FortiClient Endpoint Security peer, the peer ID provided to the remote peer is called the Local ID.

Authenticating SSL VPN users

SSL VPN users can be

- user accounts with passwords stored on the FortiGate unit
- user accounts authenticated by an external RADIUS, LDAP or TACACS+ server
- PKI users authenticated by certificate

You need to create a user group for your SSL VPN. Simply create a firewall user group, enable SSL VPN access for the group, and select the web portal the users will access.

SSL VPN access requires an SSL VPN security policy that permits access to members of your user group.

Authenticating PPTP and L2TP VPN users

PPTP and L2TP are older VPN tunneling protocols that do not provide authentication themselves. FortiGate units restrict PPTP and L2TP access to users who belong to one specified user group. Users authenticate themselves to the FortiGate unit by username/password. You can configure PPTP and L2TP VPNs only in the CLI. Before you configure the VPN, create a firewall user group and add to it the users who are permitted to use the VPN. Users are authenticated when they attempt to connect to the VPN. For more information about configuring PPTP or L2TP VPNs, see the *FortiGate CLI Reference*.

Single Sign On authentication for users

“Single Sign-On” means that users logged on to a computer network are authenticated for access to network resources through the FortiGate unit without having to enter their username and password again. FortiGate units directly provide Single Sign On capability for:

- Microsoft Windows networks using either Active Directory or NTLM authentication
- Novell networks, using eDirectory

In combination with a FortiAuthenticator unit, the FortiGate unit can provide Single Sign-On capability that integrates multiple external network authentication systems such as Windows Active Directory, Novell e-Directory, RADIUS and LDAP. The FortiAuthenticator unit gathers user logon information from all of these sources and sends it to the FortiGate unit.

Through the SSO feature, the FortiGate unit knows the username, IP address, and external user groups to which the user belongs. When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

For detailed information about SSO, see

- "SSO using a FortiAuthenticator unit" on page 550
- "Agent-based FSSO" on page 563

User's view of authentication

From the user's point of view, they see a request for authentication when they try to access a protected resource, such as an FTP repository of intellectual property or simply access a website on the Internet. The way the request is presented to the user depends on the method of access to that resource.

VPN authentication usually controls remote access to a private network.

Web-based user authentication

Security policies usually control browsing access to an external network that provides connection to the Internet. In this case, the FortiGate unit requests authentication through the web browser.

The user types a username and password and then selects *Continue* or *Login*. If the credentials are incorrect, the authentication screen is redisplayed with blank fields so that the user can try again. When the user enters valid credentials, access is granted to the required resource. In some cases, if a user tries to authenticate several times without success, a message appears, such as: "Too many bad login attempts. Please try again in a few minutes." This indicates the user is locked out for a period of time. This prevents automated brute force password hacking attempts. The administrator can customize these settings if required.

After a defined period of user inactivity (the authentication timeout, defined by the FortiGate administrator), the user's access expires. The default is 5 minutes. To access the resource, the user will have to authenticate again.

VPN client-based authentication

A VPN provides remote clients with access to a private network for a variety of services that include web browsing, email, and file sharing. A client program such as FortiClient negotiates the connection to the VPN and manages the user authentication challenge from the FortiGate unit.

FortiClient can store the username and password for a VPN as part of the configuration for the VPN connection and pass them to the FortiGate unit as needed. Or, FortiClient can request the username and password from the user when the FortiGate unit requests them.

SSL VPN is a form of VPN that can be used with a standard Web browser. There are two modes of SSL VPN operation (supported in NAT/Route mode only):

- web-only mode, for remote clients equipped with a web-browser only
- tunnel mode, for remote computers that run a variety of client and server applications.

After a defined period of user inactivity on the VPN connection (the idle timeout, defined by the FortiGate administrator), the user's access expires. The default is 30 minutes. To access the resource, the user will have to authenticate again.

FortiGate administrator's view of authentication

Authentication is based on user groups. The FortiGate administrator configures authentication for security policies and VPN tunnels by specifying the user groups whose members can use the resource. Some planning is required to determine how many different user groups need to be created. Individual user accounts can belong to multiple groups, making allocation of user privileges very flexible.

A member of a user group can be:

- a user whose username and password are stored on the FortiGate unit
- a user whose name is stored on the FortiGate unit and whose password is stored on a remote or external authentication server
- a remote or external authentication server with a database that contains the username and password of each person who is permitted access

The general process of setting up authentication is as follows:

1. If remote or external authentication is needed, configure the required servers.
2. Configure local and peer (PKI) user identities. For each local user, you can choose whether the FortiGate unit or a remote authentication server verifies the password. Peer members can be included in user groups for use in security policies.
3. Create user groups.
4. Add local/peer user members to each user group as appropriate. You can also add an authentication server to a user group. In this case, all users in the server's database can authenticate. You can only configure peer user groups through the CLI.
5. Configure security policies and VPN tunnels that require authenticated access.

For authentication troubleshooting, see the specific chapter for the topic or for general issues see "Troubleshooting" on page 629.

General authentication settings

Go to *User & Device* > *Authentication* > *Settings* to configure authentication timeout, protocol support, and authentication certificates.

When user authentication is enabled within a security policy, the authentication challenge is normally issued for any of the four protocols (depending on the connection protocol):

- HTTP (can also be set to redirect to HTTPS)
- HTTPS
- FTP
- Telnet.

The selections made in the *Protocol Support* list of the Authentication Settings screen control which protocols support the authentication challenge. Users must connect with a supported protocol first so they can subsequently connect with other protocols. If HTTPS is selected as a method of protocol support, it allows the user to authenticate with a customized Local certificate.

When you enable user authentication within a security policy, the security policy user will be challenged to authenticate. For user ID and password authentication, users must provide their user names and passwords. For certificate authentication (HTTPS or HTTP redirected to HTTPS only), you can install customized certificates on the unit and the users can also have customized certificates installed on their browsers. Otherwise, users will see a warning message and have to accept a default Fortinet certificate.

Authentication Timeout	Enter a length of time in minutes, from 1 to 480. Authentication timeout controls how long an authenticated firewall connection can be idle before the user must authenticate again. The default value is 30
Protocol Support	Select the protocols to challenge during firewall user authentication.
Certificate	If using HTTPS protocol support, select the local certificate to use for authentication. Available only if HTTPS protocol support is selected.
Apply	Select to apply the selections for user authentication settings.

When you use certificate authentication, if you do not specify any certificate when you create the security policy, the global settings will be used. If you specify a certificate, the per-policy setting will overwrite the global setting.

Authentication servers

FortiGate units support the use of external authentication servers. An authentication server can provide password checking for selected FortiGate users or it can be added as a member of a FortiGate user group.

If you are going to use authentication servers, you must configure the servers before you configure FortiGate users or user groups that require them.

MAC OS and iOS devices, including iPhones and iPads, can perform user authentication with FortiOS units using RADIUS servers, but not with LDAP or TACACS+ servers.

This section includes the following topics:

FortiAuthenticator servers

FortiAuthenticator is an Authentication, Authorization, and Accounting (AAA) server, that includes a RADIUS server, an LDAP server, and can replace the FSSO Collector Agent on a Windows AD network. Multiple FortiGate units can use a single FortiAuthenticator for FSSO, remote authentication, and FortiToken management.

For more information, see the *FortiAuthenticator Administration Guide*.

RADIUS servers

Remote Authentication and Dial-in User Service (RADIUS) is a broadly supported client-server protocol that provides centralized authentication, authorization, and accounting functions. RADIUS clients are built into gateways that allow access to networks such as Virtual Private Network servers, Network Access Servers (NAS), as well as network switches and firewalls that use authentication. FortiGate units fall into the last category.

RADIUS servers use UDP packets to communicate with the RADIUS clients on the network to authenticate users before allowing them access to the network, to authorize access to resources by appropriate users, and to account or bill for those resources that are used. RADIUS servers are currently defined by RFC 2865 (RADIUS) and RFC 2866 (Accounting), and listen on either UDP ports 1812 (authentication) and 1813 (accounting) or ports 1645 (authentication) and 1646 (accounting) requests. RADIUS servers exist for all major operating systems.

You must configure the RADIUS server to accept the FortiGate unit as a client. FortiGate units use the authentication and accounting functions of the RADIUS server.

FortiOS does not accept all characters from auto generated keys from MS Windows 2008. These keys are very long and as a result RADIUS authentication will not work. Maximum key length for MS Windows 2008 is 128 bytes. In older versions of FSAE, it was 40 bytes.

Microsoft RADIUS servers

Microsoft Windows Server 2000, 2003, and 2008 have RADIUS support built-in. Microsoft specific RADIUS features are defined in RFC 2548. The Microsoft RADIUS implementation can use Active Directory for user credentials.

For details on Microsoft RADIUS server configurations, refer to Microsoft documentation.

RADIUS user database

The RADIUS user database is commonly an SQL or LDAP database, but can also be any combination of:

- usernames and passwords defined in a configuration file
- user account names and passwords configured on the computer where the RADIUS server is installed.

If users are members of multiple RADIUS groups, then the user group authentication timeout value does not apply. See “Membership in multiple groups” on page 506.

RADIUS authentication with a FortiGate unit

To use RADIUS authentication with a FortiGate unit

- configure one or more RADIUS servers on the FortiGate unit
- assign users to a RADIUS server

When a configured user attempts to access the network, the FortiGate unit will forward the authentication request to the RADIUS server which will match the username and password remotely. Once authenticated the RADIUS server passes the authorization granted message to the FortiGate unit which grants the user permission to access the network.

The RADIUS server uses a “shared secret” key along with MD5 hashing to encrypt information passed between RADIUS servers and clients, including the FortiGate unit. Typically only user credentials are encrypted. Additional security can be configured through IPsec tunnels.

RADIUS attribute value pairs

RADIUS packets include a set of attribute value pairs (AVP) to identify information about the user, their location and other information. The FortiGate unit sends the following RADIUS attributes.

Table 18: FortiOS supported RADIUS attributes

RADIUS Attribute	Name	Description	AVP type
1	Acct-Session-ID	Unique number assigned to each start and stop record to make it easy to match them, and to eliminate duplicate records.	44
2	username	Name of the user being authenticated	1
3	NAS-Identifier	Identifier or IP address of the Network Access Server (NAS) that is requesting authentication. In this case, the NAS is the FortiGate unit.	32
4	Framed-IP-Address	Address to be configured for the user.	8
5	Fortinet-VSA	See "Vendor-specific attributes" on page 469	26
6	Acct-Input-Octets	Number of octets received from the port over the course of this service being provided. Used to charge the user for the amount of traffic they used.	42
7	Acct-Output-Octets	Number of octets sent to the port while delivering this service. Used to charge the user for the amount of traffic they used.	43

Table 19 describes the supported authentication events and the RADIUS attributes that are sent in the RADIUS accounting message.

Table 19: RADIUS attributes sent in RADIUS accounting message

	RADIUS Attributes						
Authentication Method	**1**	**2**	**3**	**4**	**5**	**6**	**7**
Web	a	a	a		a		
XAuth of IPsec (without DHCP)	a	a	a		a		
XAuth of IPsec (with DHCP)	a	a	a	a	a		
PPTP/L2TP (in PPP)	a	a	a	a	a	a	a
SSL-VPN	a	a	a		a		

Vendor-specific attributes

Vendor specific attributes (VSA) are the method RADIUS servers and client companies use to extend the basic functionality of RADIUS. Some major vendors, such as Microsoft, have published their VSAs, however many do not.

In order to support vendor-specific attributes (VSA), the RADIUS server requires a dictionary to define which VSAs to support. This dictionary is typically supplied by the client or server vendor.

The Fortinet RADIUS vendor ID is 12356.

The FortiGate unit RADIUS VSA dictionary is supplied by Fortinet and is available through the Fortinet Knowledge Base (http://kb.forticare.com) or through Technical Support. Fortinet's dictionary for FortiOS 4.0 and up is configured this way:

```
##
Fortinet's VSA's
#
VENDOR fortinet 12356
BEGIN-VENDOR fortinet
ATTRIBUTE Fortinet-Group-Name   1   string
ATTRIBUTE Fortinet-Client-IP-Address   2   ipaddr
ATTRIBUTE Fortinet-Vdom-Name   3   string
ATTRIBUTE Fortinet-Client-IPv6-Address   4   octets
ATTRIBUTE Fortinet-Interface-Name   5   string
ATTRIBUTE Fortinet-Access-Profile   6   string
#
# Integer Translations
#
END-VENDOR Fortinet
```

Note that using the Fortinet-Vdom-Name, users can be tied to a specific VDOM on the FortiGate unit. See the documentation provided with your RADIUS server for configuration details.

Role Based Access Control

In Role Based Access Control (RBAC), network administrators and users have varying levels of access to network resources based on their role, and that role's requirement for access specific resources. For example, a junior accountant does not require access to the sales presentations, or network user account information.

There are three main parts to RBAC: role assignment, role authorization, and transaction authorization. Role assignment is accomplished when someone in an organization is assigned a specific role by a manager or HR. Role authorization is accomplished when a network administrator creates that user's RADIUS account and assigns them to the required groups for that role. Transaction authorization occurs when that user logs on and authenticates before performing a task.

RBAC is enforced when FortiOS network users are remotely authenticated via a RADIUS server. For users to authenticate, an identity-based security policy must be matched. That policy only matches a specific group of users. If VDOMs are enabled, the matched group will be limited to a specific VDOM. Using this method network administrators can separate users into groups that match resources, protocols, or VDOMs. It is even possible to limit users to specific FortiGate units if the RADIUS servers serve multiple FortiOS units.

For more information on identity-based policies, see "Authentication in security policies" on page 517.

Configuring the FortiGate unit to use a RADIUS server

The information you need to configure the FortiGate unit to use a RADIUS server includes

- the RADIUS server's domain name or IP address
- the RADIUS server's shared secret key.

You can optionally specify the NAS IP or Called Station ID. When configuring the FortiGate to use a RADIUS server, the FortiGate is a Network Access Server (NAS). If the FortiGate interface has multiple IP addresses, or you want the RADIUS requests to come from a different address you can specify it here. Called Station ID applies to carrier networks. However, if the NAS IP is not included in the RADIUS configuration, the IP of the FortiGate unit interface that communicates with the RADIUS server is used instead.

A maximum of 10 remote RADIUS servers can be configured on the FortiGate unit. One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see "Creating users" on page 491.

On the FortiGate unit, the default port for RADIUS traffic is 1812. Some RADIUS servers use port 1645. If this is the case with your server, you can either:

- Re-configure the RADIUS server to use port 1812. See your RADIUS server documentation for more information on this procedure.

or

- Change the FortiGate unit default RADIUS port to 1645 using the CLI:

```
config system global
  set radius-port 1645
end
```

One wildcard admin account can be added to the FortiGate unit when using RADIUS authentication. This uses the wildcard character to allow multiple admin accounts on RADIUS to use a single account on the FortiGate unit. See "Example — wildcard admin accounts - CLI" on page 476.

To configure the FortiGate unit for RADIUS authentication - web-based manager

1. Go to *User & Device* > *Authentication* > *RADIUS Servers* and select *Create New*.
2. Enter the following information and select OK.

Name	A name to identify the RADIUS server on the FortiGate unit.
Primary Server Name/IP	Enter the domain name (such as fgt.exmaple.com) or the IP address of the RADIUS server.
Primary Server Secret	Enter the server secret key, such as radiusSecret. This can be a maximum of 16 characters long. This must match the secret on the RADIUS primary server.
Secondary Server Name/IP	Optionally enter the domain name (such as fgt.exmaple.com) or the IP address of the secondary RADIUS server.
Secondary Server Secret	Optionally, enter the secondary server secret key, such as radiusSecret2. This can be a maximum of 16 characters long. This must match the secret on the RADIUS secondary server.
Authentication Scheme	If you know the RADIUS server uses a specific authentication protocol, select it from the list. Otherwise select *Use Default Authentication Scheme*. The Default option will usually work.

NAS IP/ Called Station ID	Enter the IP address to be used as an attribute in RADIUS access requests. **NAS-IP-Address** is RADIUS setting or IP address of FortiGate interface used to talk to RADIUS server, if not configured. **Called Station ID** is same value as NAS-IP Address but in text format.
Include in every User Group	When enabled this RADIUS server will automatically be included in all user groups. This is useful if all users will be authenticating with the remote RADIUS server.

For MAC OS and iOS devices to authenticate, you must use MS-CHAP-v2 authentication. In the CLI, the command is `set auth-type ms_chap_v2`.

3. Select *OK*.

To configure the FortiGate unit for RADIUS authentication - CLI example

```
config user radius
  edit ourRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret radiusSecret
  end
```

For more information about RADIUS server options, refer to the *FortiGate CLI Reference*.

Troubleshooting RADIUS

To test the connection to the RADIUS server use the following command:

```
diagnose test authserver radius-direct <server_name or IP> <port
    number> <secret>
```

For the port number, enter `-1` to use the default port. Otherwise enter the port number to check.

Additional RADIUS related troubleshooting is located at "Troubleshooting FSSO" on page 596

LDAP servers

Lightweight Directory Access Protocol (LDAP) is an Internet protocol used to maintain authentication data that may include departments, people, groups of people, passwords, email addresses, and printers. LDAP consists of a data-representation scheme, a set of defined operations, and a request/response network.

The scale of LDAP servers range from big public servers such as BigFoot and Infospace, to large organizational servers at universities and corporations, to small LDAP servers for workgroups that may be using OpenLDAP. This document focuses on the institutional and workgroup applications of LDAP.

This section includes:

Components and topology

LDAP organization starts with directories. A directory is a set of objects with similar attributes organized in a logical and hierarchical way. Generally, an LDAP directory tree reflects geographic and organizational boundaries, with the Domain name system (DNS) names to structure the top level of the hierarchy. The common name identifier for most LDAP servers is `cn`, however some servers use other common name identifiers such as `uid`.

When LDAP is configured and a user is required to authenticate the general steps are:

1. The FortiGate unit contacts the LDAP server for authentication.
2. To authenticate with the FortiGate unit, the user enters a username and password.
3. The FortiGate unit sends this username and password to the LDAP server.
4. If the LDAP server can authenticate the user, the user is successfully authenticated with the FortiGate unit.
5. If the LDAP server cannot authenticate the user, the connection is refused by the FortiGate unit.

Binding

Binding is the step where the LDAP server authenticates the user. If the user is successfully authenticated, binding allows the user access to the LDAP server based on that user's permissions.

The FortiGate unit can be configured to use one of three types of binding:

- anonymous - bind using anonymous user search
- regular - bind using username/password and then search
- simple - bind using a simple password authentication without a search

You can use simple authentication if the user records all fall under one domain name (`dn`). If the users are under more than one `dn`, use the anonymous or regular type, which can search the entire LDAP database for the required username.

If your LDAP server requires authentication to perform searches, use the regular type and provide values for username and password.

Supported versions

The FortiGate unit supports LDAP protocol functionality defined in RFC 2251: Lightweight Directory Access Protocol v3, for looking up and validating user names and passwords. FortiGate LDAP supports all LDAP servers compliant with LDAP v3, including FortiAuthenticator. In addition, FortiGate LDAP supports LDAP over SSL/TLS, which can be configured only in the CLI.

FortiGate LDAP does not support proprietary functionality, such as notification of password expiration, which is available from some LDAP servers. FortiGate LDAP does not supply information to the user about why authentication failed.

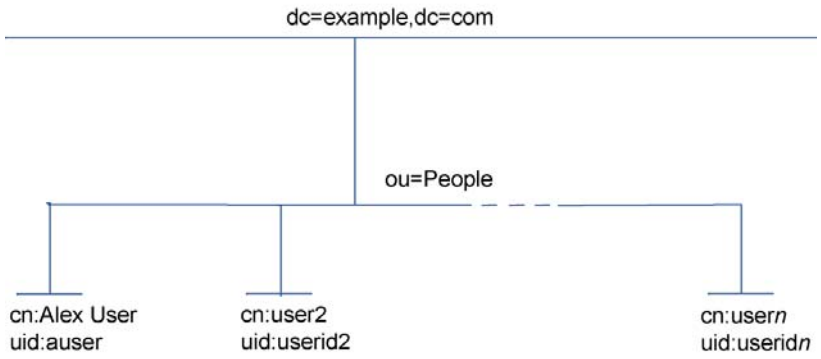
LDAP directory organization

To configure your FortiGate unit to work with an LDAP server, you need to understand the organization of the information on the server.

The top of the hierarchy is the organization itself. Usually this is defined as Domain Component (DC), a DNS domain. If the name contains a dot, such as `example.com`, it is written as two parts separated by a comma: `dc=example,dc=com`.

In this example, Common Name (CN) identifiers reside at the Organization Unit (OU) level, just below DC. The Distinguished Name (DN) is ou=People,dc=example,dc=com.

Figure 112:LDAP object hierarchy



In addition to the DN, the FortiGate unit needs an identifier for the individual person. Although the FortiGate unit GUI calls this the Common Name (CN), the identifier you use is not necessarily CN. On some servers, CN is the full name of a person. It might be more convenient to use the same identifier used on the local computer network. In this example, User ID (UID) is used.

Locating your identifier in the hierarchy

You need to determine the levels of the hierarchy from the top to the level that contain the identifier you want to use. This defines the DN that the FortiGate unit uses to search the LDAP database. Frequently used distinguished name elements include:

- uid (user identification)
- pw (password)
- cn (common name)
- ou (organizational unit)
- o (organization)
- c (country)

One way to test this is with a text-based LDAP client program. For example, OpenLDAP includes a client, `ldapsearch`, that you can use for this purpose.

Enter the following at the command line:

```
ldapsearch -x '(objectclass=*)'
```

The output is lengthy, but the information you need is in the first few lines:

```
version: 2
#
# filter: (objectclass=*)
# requesting: ALL

dn: dc=example,dc=com
dc: example
objectClass: top
objectClass: domain

dn: ou=People,dc=example,dc=com
ou: People
objectClass: top
objectClass: organizationalUnit
...
dn: uid=tbrown,ou=People,dc=example,dc=com
uid: tbrown
cn: Tom Brown
```

In the output above, you can see `tbrown` (uid) and `Tom Brown`(cn). Also note the dn is `ou=People, dc=example, dc=com`.

Configuring the FortiGate unit to use an LDAP server

After you determine the common name and distinguished name identifiers and the domain name or IP address of the LDAP server, you can configure the server on the FortiGate unit. The maximum number of remote LDAP servers that can be configured is 10.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see “Creating users” on page 491.

To configure the FortiGate unit for LDAP authentication - web-based manager

1. Go to *User & Device* > *Authentication* > *LDAP Servers* and select *Create New*.
2. Enter a *Name* for the LDAP server.
3. In *Server Name/IP* enter the server’s FQDN or IP address.
4. If necessary, change the *Server Port* number. The default is port 389.
5. Enter the *Common Name Identifier* (20 characters maximum).
6. `cn` is the default, and is used by most LDAP servers.
7. In the *Distinguished Name* field, enter the base distinguished name for the server using the correct X.500 or LDAP format.

   The FortiGate unit passes this distinguished name unchanged to the server. The maximum number of characters is 512.

   If you don’t know the distinguished name, leave the field blank and select the Query icon to the right of the field. See the “Using the Query icon” on page 475.
8. In *Bind Type*, select *Regular*.
9. In *User DN*, enter the LDAP administrator’s distinguished name.
10. In *Password*, enter the LDAP administrator’s password.

11. Select *OK*.

To verify your Distinguished Name field is correct, you can select the *Test* button. If your DN field entry is valid, you will see the part of the LDAP database it defines. If your DN field entry is not valid, it will display an error message and return no information.

For detailed information about configuration options for LDAP servers, see the Online Help on your FortiGate unit or the FortiGate CLI Reference.

To configure the FortiGate unit for LDAP authentication - CLI example

```
config user ldap
  edit ourLDAPsrv
    set server 10.11.101.160
    set cnid cn
    set dn cn=users,dc=office,dc=example,dc=com
    set type regular
    set username
        cn=administrator,cn=users,dc=office,dc=example,dc=com
    set password w5AiGVMLkgyPQ
    set password-expiry-warning enable
    set password-renewal enable
  end
```

password-expiry-warning and password-renewal

In SSLVPN, when an LDAP user is connecting to the LDAP server it is possible for them to receive any pending password expiry or renewal warnings. When the password renewal or expiry warning exists, SSLVPN users will see a prompt allowing them to change their password.

`password-expiry-warning` allows FortiOS to detect from the LDAP server when a password is expiring or has expired using server controls or error codes.

`password-renewal` allows FortiOS to perform the online LDAP password renewal operations the LDAP server expects.

On an OpenLDAP server, when a user attempts to logon with an expired password they are allowed to logon on but only to change their password.

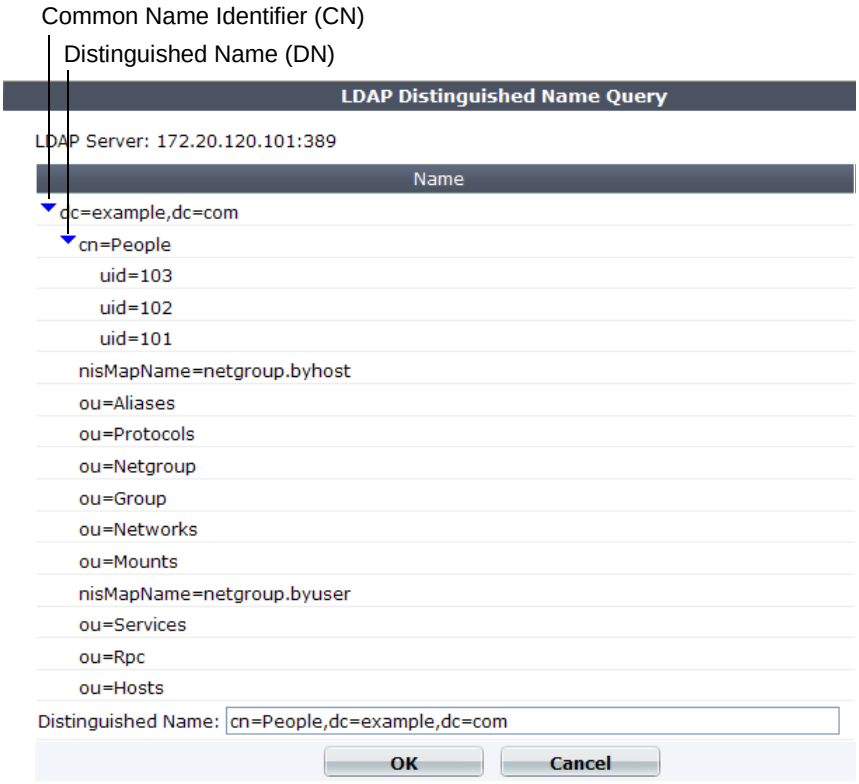
When changing passwords on a Windows AD system, the connection must be SSL-protected.

Using the Query icon

The LDAP Distinguished Name Query list displays the LDAP directory tree for the LDAP server connected to the FortiGate unit. This helps you to determine the appropriate entry for the DN field. To see the distinguished name associated with the Common Name identifier, select the Expand icon next to the CN identifier. Select the DN from the list. The DN you select is displayed in the Distinguished Name field. Select OK and the Distinguished Name you selected will be saved in the Distinguished Name field of the LDAP Server configuration.

To see the users within the LDAP Server user group for the selected Distinguished Name, expand the Distinguished Name in the LDAP Distinguished Name Query tree.

Figure 113:LDAP server Distinguished Name Query tree



Example — wildcard admin accounts - CLI

A wildcard admin account is an administrator account with the wildcard option enabled. This option allows multiple different remote administration accounts to match one local administration account, avoiding the need to set up individual admin accounts on the FortiGate unit. Instead multiple LDAP admin accounts will all be able to use one FortiGate admin account.

The initial benefit of wildcard admin accounts is fast configuration of the FortiGate unit's administration account to work with your LDAP network. The many to one ratio saves on effort, and potential errors.

The ongoing benefit is that as long as the users on the LDAP system belong to that group, and the test admin user settings don't change on the FortiGate unit, no other work is required. This point is important as it can help avoid system updates or changes that would otherwise require changes to the LDAP administrator account configuration. Even if a user is added to or removed from the LDAP group, no changes are required on the FortiGate unit.

Two potential issues with wildcard admin accounts are that multiple users may be logged on to the same account at the same time. This becomes an issue if they are changing the same information at the same time. The other potential issue is that security is reduced because multiple people have login access for the same account. If each user was assigned their own account, a hijacking of one account would not affect the other users.

Note that wildcard admin configuration also applies to RADIUS. When configuring for RADIUS, configure the RADIUS server, and RADIUS user group instead of LDAP. When using web-based management, wildcard admin is the only type of remote administrator account that does not require you to enter a password on account creation. That password is normally used when the remote authentication server is unavailable during authentication.

In this example, default values are used where possible. If a specific value is not mentioned, it is set to its default value.

Configuring the LDAP server

The important parts of this configuration are the username and group lines. The username is the domain administrator account. The group binding allows only the group with the name `GRP` to access.

The `dn` used here is as an example only. On your network use your own domain name.

To configure LDAP server - CLI

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
    set cnid "sAMAccountName"
    set dn "DC=example,DC=com,DC=au"
    set type regular
    set username "CN=Administrator,CN=Users,DC=example,DC=COM”
    set password *
    set group “CN=GRP,OU=training,DC=example,DC=COM”
    set filter ""
  next
end
```

To configure the user group and add the LDAP server - CLI

```
config user group
  edit "ldap_grp"
    set member "ldap"
    config match
    edit 1
      set server-name "ldap_server"
      set group-name "TRUE"
    next
    end
  next
end
```

Configuring the admin account

The wildcard part of this example is only available in the CLI for admin configuration. When enabled, this allows all LDAP group members to login to the FortiGate unit without the need to create a separate admin account for each user. In effect the members of that group will each be able to login as “test”.

To configure the admin account - CLI

```
config system admin
  edit "test"
    set remote-auth enable
    set accprofile "super_admin"
    set wildcard enable
    set remote-group "ldap_grp"
  next
end
```

For troubleshooting, test that the admin account is operational, and see "Troubleshooting LDAP" on page 479.

Example of LDAP to allow Dial-in through member-attribute - CLI

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to setup a VPN connection simply based on an attribute that is set to TRUE, instead of based on being part of a specific group.

In AD, the "Allow Dial-In" property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to "TRUE".

This same procedure can be used for other member attributes, as your system requires.

Configuring LDAP member-attribute settings

To accomplish this with a FortiGate unit, the member attribute must be set. Setting member attributes can only be accomplished through the CLI using the `member-attr` keyword - the option is not available through the web-based manager.

Before configuring the FortiGate unit, the AD server must be configured and have the `msNPAllowDialin` attribute set to "TRUE" for the users in question. If not, those users will not be able to properly authenticate.

The dn used here is as an example only. On your network use your own domain name.

To configure user LDAP member-attribute settings - CLI

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
    set cnid "sAMAccountName"
    set dn "DC=fortinet,DC=com,DC=au"
    set type regular
    set username "fortigate@example.com"
    set password ******
    set member-attr "msNPAllowDialin"
  next
end
```

Configuring LDAP group settings

A user group that will use LDAP must be configured. This example adds the member `ldap` to the group which is the LDAP server name that was configured earlier.

To configure LDAP group settings - CLI

```
config user group
  edit "ldap_grp"
    set member "ldap"
    config match
    edit 1
      set server-name "ldap"
      set group-name "TRUE"
    next
  end
end
```

Once these settings are in place, users can authenticate.

Troubleshooting LDAP

The examples in this section use the values from the previous example.

LDAP user test

A quick way to see if the LDAP configuration is correct is to run a diagnose CLI command with LDAP user information. The following command tests with a user called `netAdmin` and a password of `fortinet`. If the configuration is correct the test will be successful.

```
FGT# diag test authserver ldap ldap_server netAdmin fortinet
```

`'ldap_server' is not a valid ldap server name` — an LDAP server by that name has not been configured on the FortiGate unit, check your spelling.

`authenticate 'netAdmin' against 'ldap_server' failed!` — the user `netAdmin` does not exist on `ldap_server`, check your spelling of both the user and sever and ensure the user has been configured on the FortiGate unit.

LDAP authentication debugging

For a more in-depth test, you can use a `diag debug` command. The sample output from a shows more information about the authentication process that may prove useful if there are any problems.

Ensure the “Allow Dial-in” attribute is still set to “TRUE” and run the following CLI command. `fnbamd` is the Fortinet non-blocking authentication daemon.

```
FGT# diag debug enable
FGT# diag debug reset
FGT# diag debug application fnbamd -1
FGT# diag debug enable
```

The output will look similar to:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching
```

If the “Allow Dial-in” attribute is not set but it is expected, the last line of the above output will instead be:

```
fnbamd_auth_poll_ldap-Failed group matching
```

TACACS+ servers

When users connect to their corporate network remotely, they do so through a remote access server. As remote access technology has evolved, the need for security when accessing networks has become increasingly important. This need can be filled using a Terminal Access Controller Access-Control System (TACACS+) server.

TACACS+ is a remote authentication protocol that provides access control for routers, network access servers, and other networked computing devices via one or more centralized servers. TACACS+ allows a client to accept a username and password and send a query to a TACACS+ authentication server. The server host determines whether to accept or deny the request and sends a response back that allows or denies the user access to the network.

TACACS+ offers fully encrypted packet bodies, and supports both IP and AppleTalk protocols. TACACS+ uses TCP port 49, which is seen as more reliable than RADIUS’s UDP protocol.

There are several different authentication protocols that TACACS+ can use during the authentication process:

Table 20: Authentication protocols

Protocol	Definition
ASCII	Machine-independent technique that uses representations of English characters. Requires user to type a username and password that are sent in clear text (unencrypted) and matched with an entry in the user database stored in ASCII format.
PAP	Password Authentication Protocol (PAP) Used to authenticate PPP connections. Transmits passwords and other user information in clear text.
CHAP	Challenge-Handshake Authentication Protocol (CHAP) Provides the same functionality as PAP, but is more secure as it does not send the password and other user information over the network to the security server.
MS-CHAP	MicroSoft Challenge-Handshake Authentication Protocol v1 (MSCHAP) Microsoft-specific version of CHAP.
default	The default protocol configuration, Auto, uses PAP, MS-CHAP, and CHAP, in that order.

Configuring a TACACS+ server on the FortiGate unit

A maximum of 10 remote TACACS+ servers can be configured for authentication.

One or more servers must be configured on FortiGate before remote users can be configured. To configure remote users, see “Creating users” on page 491.

The TACACS+ page in the web-based manager is not available until a TACACS+ server has been configured in the CLI. For more information see the CLI Reference.

To configure the FortiGate unit for TACACS+ authentication - web-based manager

1. Go to *User & Device* > *Authentication* > *TACACS+ Servers* and select *Create New*.

2. Enter the following information, and select *OK*.

Name	Enter the name of the TACACS+ server.
Server Name/IP	Enter the server domain name or IP address of the TACACS+ server.
Server Key	Enter the key to access the TACACS+ server.
Authentication Type	Select the authentication type to use for the TACACS+ server. *Auto* tries PAP, MSCHAP, and CHAP (in that order).

To configure the FortiGate unit for TACACS+ authentication - CLI

```
config user tacacs+
  edit tacacs1
    set authen-type auto
    set key abcdef
    set port 49
    set server 192.168.0.101
  end
```

SSO servers

Novell and Microsoft Windows networks provide user authentication based on directory services: eDirectory for Novell, Active Directory for Windows. Users can log on at any computer in the domain and have access to resources as defined in their user account. The Fortinet Single Sign On (FSSO) agent enables FortiGate units to authenticate these network users for security policy or VPN access without asking them again for their username and password.

When a user logs in to the Windows or Novell domain, the FSSO agent sends the FortiGate unit the user's IP address and the names of the user groups to which the user belongs. The FortiGate unit uses this information to maintain a copy of the domain controller user group database. Because the domain controller authenticates users, the FortiGate unit does not perform authentication. It recognizes group members by their IP address.

In the FortiOS FSSO configuration, you specify the server where the FSSO Collector agent is installed. The Collector agent retrieves the names of the Novell or Active Directory user groups from the domain controllers on the domains, and then the FortiGate unit gets them from the Collector agent. You cannot use these groups directly. You must define FSSO type user groups on your FortiGate unit and then add the Novell or Active Directory user groups to them. The FSSO user groups that you created are used in security policies and VPN configurations to provide access to different services and resources.

FortiAuthenticator servers can replace the Collector agent when FSSO is using polling mode. The benefits of this is that FortiAuthenticator is a stand-alone server that has the necessary FSSO software pre-installed. For more information, see the *FortiAuthenticator Administration Guide*.

Single Sign-on Agent configuration settings

The following are SSO configuration settings in *User & Device* > *Authentication* > *Single Sign-On*.

SSO Server List	
Lists all the collector agents' lists that you have configured. On this page, you can create, edit or delete FSSO agents. **Note:** You can create a redundant configuration on your unit if you install a collector agent on two or more domain controllers. If the current (or first) collector agent fails, the Fortinet unit switches to the next one in its list of up to five collector agents.	
Create New	Creates a new agent. When you select *Create New*, you are automatically redirected to the New page.
Edit	Modifies the settings for the selected SSO server. To remove multiple entries from the list, for each servers you want removed, select the check box and then select *Delete*. To remove all agents from the list, on the FSSO Agent page, select the check box at the top of the check box column and then select *Delete*.
Delete	Removes an agent from the list on the page.
Settings when *Type* is *Poll Active Directory Server*	
Server	The IP address of the domain controller (DC).
User	The user ID used to access the domain controller.
Password	Enter the password for the account used to access the DC.
LDAP Server	Select the check box and select an LDAP server to access the Directory Service.
Enable Polling	Enable to allow the FortiGate unit to poll this DC.
Users/Groups	A list of user and user group names retrieved from the DC.
Settings when *Type* is *Fortinet Single Sign On Agent*	
Name	Enter a name for the SSO server.
Primary Agent IP/Name **Secondary Agent IP/Name**	Enter the IP address or name of the Directory Service server where this SSO agent is installed. The maximum number of characters is 63.
Password	Enter the password for the collector agent. This is required only if you configured your Fortinet Single Sign On Agent collector agent to require authenticated access.
More FSSO agents	Select to add up to three additional SSO agents.
Users/Groups	A list of user and user group names retrieved from the server.

RSA ACE (SecurID) servers

SecurID is a two-factor system that uses one-time password (OTP) authentication. It is produced by the company RSA. This system includes portable tokens carried by users, an RSA ACE/Server, and an Agent Host. In our configuration, the FortiGate unit is the Agent Host.

Components

When using SecurID, users carry a small device or "token" that generates and displays a random password. According to RSA, each SecurID authenticator token has a unique 64-bit symmetric key that is combined with a powerful algorithm to generate a new code every 60 seconds. The token is time-synchronized with the SecurID RSA ACE/Server.

The RSA ACE/Server is the management component of the SecurID system. It stores and validates the information about the SecurID tokens allowed on your network. Alternately the server could be an RSA SecurID 130 Appliance.

The Agent Host is the server on your network, in this case it is the FortiGate unit, that intercepts user logon attempts. The Agent Host gathers the user ID and password entered from their SecurID token, and sends that information to the RSA ACE/Server to be validated. If valid, a reply comes back indicating it is a valid logon and the FortiGate unit allows the user access to the network resources specified in the associated security policy.

Configuring the SecurID system

To use SecurID with a FortiGate unit, you need:

- to configure the RSA server and the RADIUS server to work with each other (see RSA server documentation)
- To configure the RSA SecurID 130 Appliance

  or
- To configure the FortiGate unit as an Agent Host on the RSA ACE/Server
- To configure the FortiGate unit to use the RADIUS server
- To create a SecurID user group and user
- To configure a security policy with SecurID authentication

The following instructions are based on RSA ACE/Server version 5.1, or RSA SecurID 130 Appliance, and assume that you have successfully completed all the external RSA and RADIUS server configuration steps listed above.

For this example, the RSA server is on the internal network, with an IP address of 192.128.100.100. The FortiGate unit internal interface address is 192.168.100.3, RADIUS shared secret is fortinet123, RADIUS server is at IP address 192.168.100.102.

To configure the RSA SecurID 130 Appliance

1. Go to the IMS Console for SecurID and logon.
2. Go to *RADIUS* > *RADIUS Clients*, and select *Add New.*
3. Enter the following information to configure your FortiGate as a SecurID Client, and select Save.

RADIUS Client Basics	
Client Name	FortiGate

Associated RSA Agent	FortiGate
RADIUS Client Settings	
IP Address	192.168.100.3 The IP address of the FortiGate unit internal interface.
Make / Model	Select Standard Radius
Shared Secret	fortinet123 The RADIUS shared secret.
Accounting	Leave unselected
Client Status	Leave unselected

To configure the FortiGate unit as an Agent Host on the RSA ACE/Server

1. On the RSA ACE/Server computer, go to *Start* > *Programs* > *RSA ACE/Server*, and then *Database Administration - Host Mode*.
2. On the *Agent Host* menu, select *Add Agent Host*.
3. Enter and save the following information.

Name	FortiGate
Network Address	192.168.100.3 The IP address of the FortiGate unit.
Secondary Nodes	Optionally enter other IP addresses that resolve to the FortiGate unit.

If needed, refer to the RSA ACE/Server documentation for more information.

To configure the FortiGate unit to use the RADIUS server

1. Go to *User & Device* > *Authentication* > *RADIUS Servers* and select *Create New*.
2. Enter the following information, and select OK.

Name	RSA
Type	Query
Primary Server Address	192.168.100.102 Optionally select Test to ensure the IP address is correct and the FortiGate can contact the RADIUS server.
Primary Server Secret	fortinet123
Authentication Scheme	Select *Use Default Authentication Scheme*.

To create a SecurID user group and user

1. Go to *User & Device* > *User* > *User Groups*, and select *Create New*.
2. Enter the following information, and select OK.

Name	RSA_group
Remote Authentication servers	Select the RSA server.

3. Go to *User & Device* > *User* > *User Definition*, and select *Create New*.
4. Enter the following information, and select OK.

User Name	wloman
Match User on RADIUS server	RSA
Add this user to groups	Select RSA_group

To test this configuration, on your FortiGate unit use the CLI command:

```
diag test auth rad RSA auto wloman 111111111
```

The series of 1s is the one time password that your RSA SecurID token generates and you enter.

Using the SecurID user group for authentication

You can use the SecurID user group in several FortiOS features that authenticate by user group including

- Security policy
- IPsec VPN XAuth
- PPTP VPN
- SSL VPN

The following sections assume the SecurID user group is called `securIDgrp` and has already been configured. Unless otherwise states, default values are used.

Security policy

To use SecurID in a security policy, you must include the SecurID user group in an identity-based security policy. This procedure will create a security policy that allows HTTP, FTP, and POP3 traffic from the `internal` interface to `wan1`. If these interfaces are not available on your FortiGate unit, substitute other similar interfaces.

To configure a security policy with SecurID authentication

1. Go to *Policy* > *Policy* > *Policy*.
2. Select *Create New*.
3. In *Policy Subtype*, select *User Identity*.

4. Enter

Incoming Interface	internal
Source Address	all
Outgoing Interface	wan1
Enable NAT	Selected.

5. In *Configure Authentication Rules*, select *Create New*.
6. Enter

Destination Address	all
Group(s)	securIDgrp
Schedule	always
Services	HTTP, FTP, POP3
Action	ACCEPT

7. To generate usage reports on traffic authenticated with this policy, enable *Log Allowed Traffic*.
8. To either limit traffic or guarantee minimum bandwidth for traffic that uses the SecurID security policy, enable *Traffic Shaping* and *Shared Traffic Shaper* and then select one of the default shapers from the list such as *guarantee-100kbps*.
9. Select OK.

   You are returned to the security policy creation page, with the information you just entered in the *Configure Authentication Rules* table.
10. Optionally, you can modify any challenge pages or logon pages users will see. Select *Customize Authentication Messages* and select the Edit icon that appears.
11. Select OK.

    The SecurID security policy is configured.

For more detail on configuring security policies, see the *FortiOS Handbook FortiGate Fundamentals chapter*.

IPsec VPN XAuth

Extended Authentication (XAuth) increases security by requiring additional user authentication information in a separate exchange at the end of the VPN Phase 1 negotiation. If the SecurID user group is used, this extended information will require users to enter their SecurID code. For more on XAuth, see "Configuring XAuth authentication" on page 529.

This Phase 1 configuration will be named `securIDxAuth` and it will connect with IP address `10.11.101.155` on the `wan1` interface.

To configure IPsec VPN XAuth with SecurID authentication - web-based manager

1. Go to *VPN* > *IPsec* > *Auto Key (IKE)*.

2. Select *Create Phase 1* and enter

Name	securIDxAuth
Remote Gateway	Dialup User
Local Interface	wan1
Mode	Main (ID protection)
Authentication Method	Preshared Key
Pre-shared Key	fortinet
Peer Options	Accept any peer ID.

3. Select *Advanced...* and enter

XAUTH	Enable as Server
Server Type	AUTO
User Group	`securIDgrp`

4. Select *OK*.

PPTP VPN

PPTP VPN is configured in the CLI. In the PPTP configuration (`config vpn pptp`), set `usrgrp` to the SecurID user group.

SSL VPN

In the SecurID user group, select the appropriate web portal for these users. In the security policy for the SSL VPN, include the SecurID user group in the list of selected user groups.

Users and user groups

FortiGate authentication controls system access by user group. By assigning individual users to the appropriate user groups you can control each user's access to network resources. The members of user groups are user accounts, of which there are several types. Local users and peer users are defined on the FortiGate unit. User accounts can also be defined on remote authentication servers.

This section describes how to configure local users and peer users and then how to configure user groups. For information about configuration of authentication servers see "Authentication servers" on page 466.

This section contains the following topics:

Users

A user is a user account consisting of username, password, and in some cases other information, configured on the FortiGate unit or on an external authentication server. Users can access resources that require authentication only if they are members of an allowed user group. There are several different types of user accounts with slightly different methods of authentication:

User type	Authentication
Local user, password stored on the FortiGate unit	The username and password must match a user account stored on the FortiGate unit. Authentication by FortiGate security policy.
Local user, password stored on a remote server	The username must match a user account stored on the FortiGate unit and the username and password must match a user account stored on the remote authentication server.
Authentication server user	A FortiGate user group can include user accounts or groups that exist on a remote authentication server.
FSSO user	With Fortinet Single Sign On (FSSO), users on a Microsoft Windows or Novell network can use their network authentication to access resources through the FortiGate unit. Access is controlled through FSSO user groups which contain Windows or Novell user groups as their members.
Peer user with certificate authentication	A peer user is a digital certificate holder that authenticates using a client certificate. No password is required, unless two-factor authentication is enabled.

User type	Authentication
IM Users	IM users are not authenticated. The FortiGate unit can allow or block each IM user name from accessing the IM protocols. A global policy for each IM protocol governs access to these protocols by unknown users.
Guest Users	Guest user accounts are temporary. The account expires after a selected period of time.

This section includes:

Local users

Local users are defined on the FortiGate unit in *User & Device* > *User* > *User Definition*.

User page

Lists each individual local user's list that you created. On this page, you can edit, delete or create a new local users list.

Note: If you want to have users always authenticate whenever their time expires, use the `hard-timeout` value in the `auth-type` command. This is available only in the CLI.

Create New	Creates a new local user account. When you select *Create New*, you are automatically redirected to New User page.
Edit	Modifies a user's account settings. When you select *Edit*, you are automatically redirected to the Edit User page.
Delete	Removes a user from the list. Removing the user name removes the authentication configured for the user. The *Delete* icon is not available if the user belongs to a user group. To remove multiple local user accounts from within the list, on the User page, in each of the rows of user accounts you want removed, select the check box and then select *Delete*. To remove all local user accounts from the list, on the User page, select the check box in the check box column and then select *Delete*.
User Name	The local user name. If the user is authenticated externally, the username on the FortiGate unit must be identical to the username on the authentication server.
Type	The authentication type to use for this user. The authentication types are Local (user and password stored on Fortinet unit), LDAP, RADIUS, and TACACS+ (user and password matches a user account stored on the authentication server).

Two-factor Authentication	Indicates whether two-factor authentication is configured for the user. Gray "X" — not enabled Green check mark — enabled
Ref.	Displays the number of times this object is referenced by other objects. Select the number to open the Object Usage window and view the list of referring objects. The list is grouped into expandable categories, such as Firewall Policy. Numbers of objects are shown in parentheses. To view more information about the referring object, use the icons: • **View the list page for these objects** – available for object categories. Goes to the page where the object is listed. For example, if the category is User Groups, opens User Groups list. • **Edit this object** – opens the object for editing. modifies • **View the details for this object** – displays current settings for the object.

New User or Edit User page

Provides settings for a new or existing local user.

User Name	A name that identifies the user.
Disable	Select to prevent this user from authenticating.
Password	Select to authenticate this user using a password stored on the FortiGate unit. Enter the password. Best practice is to create a password at least six characters long.
Match users on LDAP servers	Select to authenticate this user using a password stored on an LDAP server. Select the LDAP server from the list. You can select only an LDAP server that has been added to the Fortinet LDAP configuration. For more information, see "Configuring the FortiGate unit to use an LDAP server" on page 474.
Match users on RADIUS server	Select to authenticate this user using a password stored on a RADIUS server. Select the RADIUS server from the list. You can select only a RADIUS server that has been added to the Fortinet RADIUS configuration. For more information, see "Configuring the FortiGate unit to use a RADIUS server" on page 470.
Match users on TACACS+ server	Select to authenticate this user using a password stored on a TACACS server. Select the TACACS+ server from the list. You can select only a TACACS server that has been added to the Fortinet TACACS configuration. For more information, see "TACACS+ servers" on page 480.

Contact Info	Provide the email address or SMS cell number at which the user will receive token password codes. For custom SMS service, you must first enter the SMS service provider in *System* > *Config* > *Messaging Servers* before you can select it from the drop-down list. See "FortiToken" on page 497.
Enable Two-factor Authentication	Select to enable two-factor authentication. Then select the Token (FortiToken or FortiToken Mobile) for this user account. See "Associating FortiTokens with accounts" on page 500.

Creating users

Before configuring any authentication, except RADIUS SSO, you must first create local users. For more about RADIUS SSO, see "SSO using RADIUS accounting records" on page 602.

When creating a new user, there are only two differences between a local and a remote user:

- local users require a password to be configured
- remote users do not require a password, but do require a remote authentication server to be configured

To create a local user - web-based manager

1. Go to *User & Device* > *User* > *User Definition* and select *Create New*.
2. Enter the username in the *username* field.
   - Select *Password* and type a password. Best practices dictate that the password be at least six characters long.

To authenticate this user using an external authentication server, select the *Match user* option for the appropriate type of server and select the server name. Password is not required. You must configure the remote server access first. See "Authentication servers" on page 466.

3. Optionally select *Enable Two-factor Authentication* to use that option with this user.

   When enabled, additional options will be displayed. Select one of the following options and configure it as stated.
   - Select *FortiToken*, and choose the FortiToken serial number to associate with this user.
   - Select *Email to* and enter the user's email address to email them the token code.
   - Select *SMS* and enter the Mobile Provider from the list, and enter the user's mobile phone number that will receive the token code in a text message.
4. Select *OK*.

The Mobile Provider for SMS must be entered in the CLI using the `config system sms-server` command before it will be available to select in the web-based manager.

To create a local user - CLI examples

Locally authenticated user

```
config user local
  edit user1
    set type password
    set passwd ljt_pj2gpepfdw
  end
```

User authenticated on an LDAP server

```
config user local
  edit user2
    set type ldap
    set ldap_server ourLDAPsrv
  end
```

User authenticated on a RADIUS server

```
config user local
  edit user3
    set type radius
    set radius_server ourRADIUSsrv
  end
```

User authenticated on a TACACS+ server

```
config user local
  edit user4
    set type tacacs+
    set tacacs+_server ourTACACS+srv
  end
```

User authenticated with a FortiToken

```
config user local
  edit user5
    set type password
    set passwd ljt_pj2gpepfdw
    set two_factor fortitoken
    set fortitoken 182937197
  end
```

User authenticated using email

```
config user local
  edit user6
    set type password
    set passwd ljt_pj4h7epfdw
    set two_factor email
    set email-to user6@sample.com
  end
```

User authenticated using SMS text message

```
config system sms-server
  edit "Sample Mobile Inc"
    set mail-server mail.sample.com
  end

config user local
  edit user7
    set type password
    set passwd 3ww_pjt68dw
    set two_factor sms
    set sms-server custom
    set sms-custom-server "Sample Mobile Inc"
    set sms-phone 2025551234
  end
```

Removing users

Best practices dictate that when a user account is no longer in use, it be deleted. Removing local and remote users from FortiOS involve the same steps.

If the user account is references by any configuration objects those references must be removed before the user can be deleted. See "Removing references to users" on page 493.

To remove a user from the FortiOS configuration - web-based manager

1. Go to *User & Device* > *User* > *User Definition*.
2. Select the check box of the user that you want to remove.
3. Select *Delete*.
4. Select *OK*.

To remove a user from the FortiOS configuration - CLI example

```
config user local
  delete user4444
end
```

Removing references to users

You cannot remove a user that belongs to a user group. Remove the user from the user group first, and then delete the user.

To remove references to a user - web-based manager

1. Go to *User & Device* > *User* > *User Definition*.
2. If the number in the far right column for the selected user contains any number other than zero, select it.
3. A more detailed list of object references to this user is displayed. Use its information to find and remove these references to allow you to delete this user.

PKI or peer users

A PKI, or peer user, is a digital certificate holder. A PKI user account on the FortiGate unit contains the information required to determine which CA certificate to use to validate the user's

certificate. Peer users can be included in firewall user groups or peer certificate groups used in IPsec VPNs. For more on certificates, see “Certificates overview” on page 533.

To define a peer user you need:

- a peer username
- the text from the subject field of the user’s certificate, or the name of the CA certificate used to validate the user’s certificate

Creating a peer user

The configuration page for PKI users in the web-based manager. Follow the CLI-based instructions.

To create a peer user for PKI authentication - CLI example

```
config user peer
  edit peer1
    set subject peer1@mail.example.com
    set ca CA_Cert_1
  end
```

There are other configuration settings that can be added or modified for PKI authentication. For example, you can configure the use of an LDAP server to check access rights for client certificates. For information about the detailed PKI configuration settings, see the *FortiGate CLI Reference*.

Two-factor authentication

The standard logon requires a username and password. This is one factor authentication—your password is one piece of information you need to know to gain access to the system.

Two factor authentication adds the requirement for another piece of information for your logon. Generally the two factors are something you know (password) and something you have (certificate, token, etc.). This makes it harder for a hacker to steal your logon information. For example if you have a FortiToken device, the hacker would need to both use it and know your password to gain entry to your account.

Two-factor authentication is available on both user and admin accounts. But before you enable two-factor authentication on an administrator account, you need to ensure you have a second administrator account configured to guarantee administrator access to the FortiGate unit if you are unable to authenticate on the main admin account for some reason.

Two-factor authentication does not work with explicit proxies.

The methods of two-factor authentication include:

- Certificate
- Email
- SMS
- FortiToken

Certificate

You can increase security by requiring both certificate and password authentication for PKI users. Certificates are installed on the user's computer. Requiring a password also protects against unauthorized use of that computer.

Optionally peer users can enter the code from their FortiToken instead of the certificate.

To create a peer user with two-factor authentication - CLI example

```
config user peer
  edit peer1
    set subject E=peer1@mail.example.com
    set ca CA_Cert_1
    set two-factor enable
    set passwd fdktguefheygfe
  end
```

For more information on certificates, see "Certificates overview" on page 533.

Email

Two-factor email authentication sends a randomly generated six digit numeric code to the specified email address. Enter that code when prompted at logon. This token code is valid for 60 seconds. If you enter this code after that time, it will not be accepted.

A benefit is that you do not require mobile service to authenticate. However, a potential issue is if your email server does not deliver the email before the 60 second life of the token expires.

The code will be generated and emailed at the time of logon, so you must have email access at that time to be able to receive the code.

To configure an email provider - web-based manager

1. Go to *System* > *Config* > *Messaging Servers*.
2. Enter the *SMTP Server* and *Default Reply To* address.
3. If applicable, enable *Authentication* and enter the *SMTP User* and *Password* to use.
4. Select *Apply*.

To configure an email provider - CLI

```
config system email-server
  edit <provider_name>
    set server <server_domain-name>
  next
end
```

To enable email two-factor authentication - web-based manager

1. To modify an administrator account, go to *System* > *Admin* > *Administrators*. To modify a user account go to *User & Device* > *User* > *User Definition*.
2. Edit the user account.
3. Enable and enter the user's *Email Address*.
4. Select *Enable Two-factor Authentication*.
5. Select the *Token* that the user has.
6. Select *OK*.

To enable email two-factor authentication - CLI

```
config user local
  edit <user_name>
    set email-to <user_email>
    set two-factor email
  end
```

SMS

SMS two-factor authentication sends the token code in an SMS text message to the mobile device indicated when this user attempts to logon. This token code is valid for 60 seconds. If you enter this code after that time, it will not be accepted. Enter this code when prompted at logon to be authenticated.

SMS two-factor authentication has the benefit that you do not require email service before logging on. A potential issue is if the mobile service provider does not send the SMS text message before the 60 second life of the token expires.

If you do not use the FortiGuard Messaging Service, you need to configure an SMS service.

To configure an SMS service for your FortiGate unit - web-based manager

1. Go to *System* > *Config* > *Messaging Servers*.
2. In *SMS Service*, select *Create New*.
3. Enter a *Name* for the SMS service and the service *Address* (domain name), then select *OK*.
4. Select *Apply*.

To configure an SMS service - CLI

```
config system sms-server
  edit <provider_name>
    set mail-server <server_domain-name>
  next
end
```

To configure SMS two-factor authentication - web-based manager

1. To modify an:
   - administrator account, go to *System* > *Admin* > *Administrators, or*
   - user account go to *User & Device* > *User* > *User Definition*.
2. Edit the user account.
3. Select SMS and either:
   - Select *FortiGuard Messaging Service*

   or
   - Select *Custom* and then choose the *SMS Provider* to use.
4. Enter the phone number of the mobile device that will receive the SMS text messages.
5. Select *Enable Two-factor Authentication*.
6. Select the *Token* that the user has.
7. Select *OK*.

To enable SMS two-factor authentication - CLI

```
config user local
  edit <user_name>
    set sms-phone <user_phone>
    set sms-server fortiguard
    set two-factor sms
  end
```

If you have problems receiving the token codes via SMS messaging, contact your mobile provider to ensure you are using the correct phone number format to receive text messages and that your current mobile plan allows text messages.

FortiToken

FortiToken is a disconnected one-time password (OTP) generator. It is a small physical device with a button that when pressed displays a six digit authentication code. This code is entered with a user's username and password as two-factor authentication. The code displayed changes every 60 seconds, and when not in use the LCD screen is blanked to extend the battery life.

There is also a mobile phone application, FortiToken Mobile, that performs much the same function.

FortiTokens have a small hole in one end. This is intended for a lanyard to be inserted so the device can be worn around the neck, or easily stored with other electronic devices. Do not put the FortiToken on a key ring as the metal ring and other metal objects can damage it. The FortiToken is an electronic device like a cell phone and must be treated with similar care.

Any time information about the FortiToken is transmitted, it is encrypted. When the FortiGate unit receives the code that matches the serial number for a particular FortiToken, it is delivered and stored encrypted. This is in keeping with the Fortinet's commitment to keeping your network highly secured.

FortiTokens can be added to user accounts that are local, IPsec VPN, SSL VPN, and even Administrators. See "Associating FortiTokens with accounts" on page 500.

A FortiToken can be associated with only one account on one FortiGate unit.

If a user loses their FortiToken, it can be locked out using the FortiGate so it will not be used to falsely access the network. Later if found, that FortiToken can be unlocked on the FortiGate to allow access once again. See "FortiToken maintenance" on page 501.

There are three tasks to complete before FortiTokens can be used to authenticate accounts:

1. Adding FortiTokens to the FortiGate
2. Activating a FortiToken on the FortiGate
3. Associating FortiTokens with accounts

The FortiToken authentication process

The steps during FortiToken two-factor authentication are as follows.

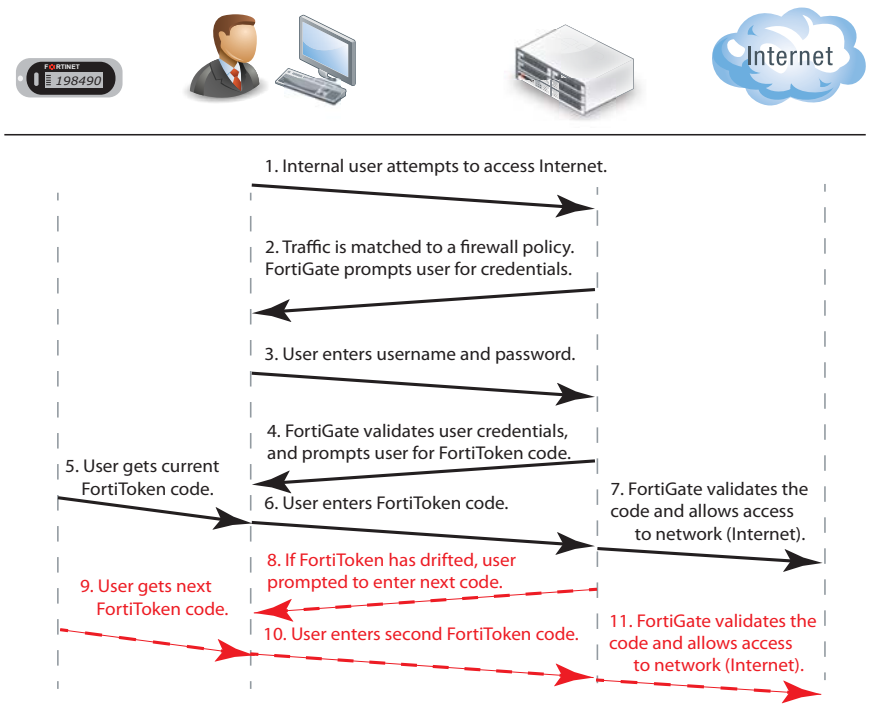
1. User attempts to access a network resource.
2. FortiGate unit matches the traffic to an authentication security policy, and FortiGate unit prompts the user for username and password.
3. User enters their username and password.
4. FortiGate unit verifies their information, and if valid prompts the user for the FortiToken code.
5. User gets the current code from their FortiToken device.

6. User enters current code at the prompt.
7. FortiGate unit verifies the FortiToken code, and if valid allows access to the network resources such as the Internet.

The following steps are only if the time on the FortiToken has drifted from the time on the FortiGate unit and needs to be synchronized.

8. If time on FortiToken has drifted, FortiGate unit will prompt user to enter a second code to confirm.
9. User gets the next code from their FortiToken device
10. User enters the second code at the prompt.
11. FortiGate unit uses both codes to update its clock to match the FortiToken and then proceeds as in step 7.

Figure 114: FortiToken authentication process



When configured the FortiGate unit accepts the username and password, authenticates them either locally or remotely, and prompts the user for the FortiToken code. The FortiGate then authenticates the FortiToken code. When FortiToken authentication is enabled, the prompt field for entering the FortiToken code is automatically added to the authentication screens.

Even when an Administrator is logging in through a serial or Telnet connection and their account is linked to a FortiToken, that Administrator will be prompted for the token's code at each login.

If you have attempted to add invalid FortiToken serial numbers, there will be no error message. The serial numbers will simply not be added to the list.

Adding FortiTokens to the FortiGate

Before one or more FortiTokens can be used to authenticate logons, they must be added to the FortiGate. The import feature is used to enter many FortiToken serial numbers at one time. The serial number file must be a text file with one FortiToken serial number per line.

One FortiToken can be added to multiple FortiGate units. This is useful for maintaining two-factor authentication for employees over multiple office locations, such as for employees who travel frequently between offices.

To manually add a FortiToken to the FortiGate - web-based manager

1. Go to *User & Device* > *Two-factor Authentication* > *FortiTokens*.
2. Select *Create New*.
3. In *Type*, select *Hard Token* or *Mobile Token*.
4. Enter one or more FortiToken serial numbers (hard token) or activation codes (mobile token).
5. Select *OK*.

To import multiple FortiTokens to the FortiGate - web-based manager

1. Go to *User & Device* > *Two-factor Authentication* > *FortiTokens*.
2. Select *Create New*.
3. In *Type*, select *Hard Token*.
4. Select *Import*.
5. Select *Serial Number File* or *Seed File*, depending on which file you have.
6. Browse to the local file location on your local computer.
7. Select OK.

   The file is imported.
8. Select OK.

To add two FortiTokens to the FortiGate - CLI

```
config user fortitoken
  edit <serial_number>
  next
  edit <serial_number2>
  next
end
```

Activating a FortiToken on the FortiGate

Once one or more FortiTokens have been added to the FortiGate unit, they must be activated before being available to be associated with accounts.The process of activation involves the FortiGate querying FortiGuard servers about the validity of each FortiToken. The serial number and information is encrypted before it is sent for added security.

A FortiGate unit requires a connection to FortiGuard servers to activate a FortiToken.

To activate a FortiToken on the FortiGate unit - web-based manager

1. Go to *User & Device* > *Two-factor Authentication* > *FortiTokens*.

2. Select one or more FortiTokens with a status of New.
3. Select *Activate*.
4. Refresh web browser. The status of selected FortiTokens will change to Activated.

The selected FortiTokens are now available for use with user and admin accounts.

To activate a FortiToken on the FortiGate unit - CLI

```
config user fortitoken
  edit <token_serial_num>
    set status activate
  next
end
```

Associating FortiTokens with accounts

The final step before using the FortiTokens to authenticate logons is associating a FortiToken with an account. The accounts can be local user or administrator accounts.

To add a FortiToken to a local user account - web-based manager

1. Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Activated.
2. Go to *User & Device* > *User* > *User Definition*, and select *Create New*.
3. Enter the username and password for this user account.
4. Select *Enable Two-factor Authentication*.
5. Select FortiToken, and select the serial number from the list that matches that user's FortiToken.
6. Select OK.

To add a FortiToken to a local user account - CLI

```
config user local
  edit <username>
    set type password
    set passwd "myPassword"
    set two-factor fortitoken
    set fortitoken <serial_number>
    set status enable
  next
  end
```

To add a FortiToken to an administrator account - web-based manager

1. Ensure that your FortiToken serial number has been added to the FortiGate successfully, and its status is Activated.
2. Go to *System* > *Admin* > *Administrators*, and select an admin account.

   This account is assumed to be configured except for two-factor authentication.
3. Select *Enable Two-factor Authentication*.
4. Select FortiToken, and select the serial number from the list that matches that user's FortiToken.
5. Select OK.

To add a FortiToken to a local user account - CLI

```
config user local
  edit <username>
    set type password
    set passwd "myPassword"
    set two-factor fortitoken
    set fortitoken <serial_number>
    set status enable
  next
  end
```

The `fortitoken` keyword will not be visible until `fortitoken` is selected for the `two-factor` keyword.

Before a new FortiToken can be used, it may need to be synchronized due to clock drift.

FortiToken maintenance

Once FortiTokens are entered into the FortiGate unit, there are only two tasks to maintain them — changing the status,

To change the status of a FortiToken between Activated and Locked - CLI

```
config user fortitoken
  edit <token_serial_num>
    set status lock
  next
end
```

Any user attempting to login using this FortiToken will not be able to authenticate.

To list the drift on all FortiTokens configured on this FortiGate unit - CLI

```
# diag fortitoken drift
FORTITOKEN       DRIFT
```

This command lists the serial number and drift for each FortiToken configured on this FortiGate unit. This command is useful to check if it is necessary to synchronize the FortiGate and any particular FortiTokens.

IM users

Instant Messenger (IM) protocols are gaining in popularity as an essential way to communicate between two or more individuals in real time. Some companies even rely on IM protocols for critical business applications such as Customer/Technical Support.

The most common IM protocols in use today include AOL Instant Messenger (AIM), Yahoo Instant Messenger, MSN messenger, and ICQ. You configure each IM user as either allowed or denied use of IM applications. For each protocol, a global allow or deny policy configured in `config imp2p policy` governs unknown IM users. IM User settings are not available in the web-based manager.

Monitoring users

To monitor user activity in the web-based manager, go to *User & Device* > *Monitor* > *Firewall*. The list of users who are logged on is displayed with some information about them such as their user group, security policy ID, how long they have been logged on, their IP address, traffic volume, and their authentication method as one of FSSO, NTLM, or firewall (FW-auth).

From this screen you can de-authenticate all users who are logged on. The de-authenticate button is at the top left of this screen.

To see information about banned users go to *User & Device* > *Monitor* > *Banned User*. Displayed information about users who have been banned includes what application the triggered the ban (Application Protocol), the reason for the ban (Cause or rule), Created, and when the ban expires.

Filtering the list of users

When there are many users logged on, it can be difficult to locate a specific user or multiple users to analyze. Applying filters to the list allows you to organize the user list to meet your needs, or only display some the users that meet your current requirements.

Select *Column Settings* at the bottom of the screen to adjust columns that are displayed for users, including what order they are displayed in. This can be very helpful in locating information you are looking for.

The *username* column includes a green arrow to the right of the title. Select this arrow to sort the list of users by ordering them in ascending (down arrow) or descending order. This is the only column that allows this.

Each column heading has a grey filter icon. Click on the filter icon to configure a filter for the data displayed in that column. Each column has similar options including a field to enter the filtering information, a check box to select the negative of the text in the field, and the options to add more fields, apply the filter, clear all filters, or cancel without saving. To enter multiple terms in the field, separate each of them with a comma. To filter entries that contain a specific prefix, use an * (asterisk).

For example, to create a filter to display only users with an IP address of `10.11.101.x` who authenticated using one of security policies five through eight, and who belong to the user group `Accounting`.

1. Go to *User & Device* > *Monitor* > *Firewall*.
2. Select the filter icon beside *IP address*.
3. Enter `10.11.101.0`. and select *Apply*.
4. Select the filter icon beside *Policy ID.*
5. Enter `5-8` and select *Apply*.
6. Select *Add new filter*.
7. Select the filter icon beside *User Group.*
8. Enter `Accounting` and select *Apply*.

User groups

A user group is a list of user identities. An identity can be:

- a local user account (username/password) stored on the FortiGate unit
- a local user account with the password stored on a RADIUS, LDAP, or TACACS+ server
- a PKI user account with digital client authentication certificate stored on the FortiGate unit
- a RADIUS, LDAP, or TACACS+ server, optionally specifying particular user groups on that server
- a user group defined on an FSSO server.

Identity-based policies and some types of VPN configurations allow access to specified user groups only. This restricted access enforces Role Based Access Control (RBAC) to your organization's network and its resources.Users must be in a group and that group must be part of the security policy.

You cannot change the type of a group unless the group is empty.

In most cases, the FortiGate unit authenticates users by requesting their username and password. The FortiGate unit checks local user accounts first. If a match is not found, the FortiGate unit checks the RADIUS, LDAP, or TACACS+ servers that belong to the user group. Authentication succeeds when a matching username and password are found. If the user belongs to multiple groups on a server, those groups will be matched as well.

FortiOS does not allow username overlaps between RADIUS, LDAP, or TACACS+ servers.

There are two types of FortiGate user groups: Firewall user groups, and FSSO user groups.

Firewall user groups

Firewall user groups are used locally as part of authentication and can contain any type of user identity except an FSSO group. When a user attempts to access resources controlled by an Identity-Based Policy (IBP), the FortiGate unit requires authentication from that user. If the user authenticates successfully and is a member of one of the permitted groups, the session is allowed to proceed.

This section includes:

SSL VPN access

In any firewall user group, you can enable SSL VPN access and select the web-portal that the users can access. When the user connects to the FortiGate unit via HTTPS on the SSL VPN port (default 10443), the FortiGate unit requests a username and password.

SSL VPN access also requires an SSL VPN security policy (*Action* is *SSL VPN*) with an identity-based rule enabling access for the user group. For more information, see the *FortiOS Handbook SSL VPN chapter*.

IPsec VPN access

A firewall user group can provide access for dialup users of an IPsec VPN. In this case, the IPsec VPN phase 1 configuration uses the *Accept peer ID in dialup group* peer option. The user's VPN client is configured with the username as peer ID and the password as pre-shared key. The user can connect successfully to the IPsec VPN only if the username is a member of the allowed user group and the password matches the one stored on the FortiGate unit.

A user group cannot be used as a dialup group if any member of the group is authenticated using an external authentication server.

For more information, see the *FortiOS Handbook IPsec VPN chapter*.

Configuring a firewall user group

A user group can contain:

- local users, whether authenticated by the FortiGate unit or an authentication server
- PKI users
- authentication servers, optionally specifying particular user groups on the server

To create a Firewall user group - web-based manager

1. Go to *User & Device* > *User* > *User Groups* and select *Create New*.
2. Enter a name for the user group.
3. In *Type*, select *Firewall*.
4. From the *Available Users* list, select users and then select the right arrow button to move the names to the *Members* list.

   If you select an authentication server as a group member, by default all user accounts on the authentication server are members of this FortiGate user group. Follow steps 5 through 8 if you want to include only specific user groups from the authentication server. Otherwise, select *OK*.
5. Select *Add*.
6. To add a remote authentication server, select *Add* and select the authentication server from the drop down *Remote Server* list.

   The option to add remote servers is available only if at least one remote server has been configured.
7. In the *Group Name* field, either select *Any* to match all possible groups, or select *Specify* and enter the group name in the appropriate format for the type of server.

   For example, an LDAP server requires LDAP format, such as: cn=users,dn=office,dn=example,dn=com
8. Repeat steps 5 through 7 to add all the authentication server user groups that are required.

9. Select *OK*.

To create a firewall user group - CLI example

In this example, the members of `accounting_group` are `User1` and all of the members of `rad_accounting_group` on `myRADIUS` external RADIUS server.

```
config user group
  edit accounting_group
    set group-type firewall
    set member User1 myRADIUS
    config match
      edit 0
        set server-name myRADIUS
        set group-name rad_accounting_group
      end
  end
```

Matching user group names from an external authentication server might not work if the list of group memberships for the user is longer than 8000 bytes. Group names beyond this limit are ignored.

`server_name` is the name of the RADIUS, LDAP, or TACACS+ server, but it must be a member of this group first and must also be a configured remote server on the FortiGate unit.

`group_name` is the name of the group on the RADIUS, LDAP, or TACACS+ server such as “engineering” or “cn=users,dc=test,dc=com”.

Before using group matching with TACACS+, you must first enable authentication. For example if you have a configured TACACS+ server called myTACS, use the following CLI commands.

```
config user tacacs+
  edit myTACS
  set authorization enable
  next
end
```

For more information about user group CLI commands, see the *Fortinet CLI Guide*.

Multiple group enforcement support

Previously, when a user belonged to multiple user groups, this user could only access the group services that were within one group. With multiple group enforcement, a user can access the services within the groups that the user is part of.

For example, `userA` belongs to `user_group1`, `user_group2`, `user_group3`, and `user_group4`; previously `userA` could only access services within one of those four groups, typically the group that matches the first security policy. This can be annoying if HTTP access is in `user_group1`, FTP access is in `user_group2`, and email access is in `user_group3`. Now `userA` can access services within `user_group1`, `user_group2`, `user_group3`, and `user_group4`.

This feature is available only in the CLI and is enabled by default. It applies to RADIUS, LDAP, and TACACS+ servers. The new command for this feature is `auth-multi-group` found in `config user settings` and checks all groups a user belongs to for authentication.

User group timeouts

User groups can have timeout values per group in addition to FortiGate-wide timeouts. There are essentially three different types of timeouts that are configurable for user authentication on the FortiGate unit — idle timeout, hard timeout, and session timeout. These are in addition to any external timeouts such as those associated with RADIUS servers.

If VDOMs are enabled, the global level user setting `authtimeout` is the default all VDOMs inherit. If VDOMs are not enabled, user settings authtimeout is the default. The default timeout value is used when the `authtimeout` keyword for a user group is set to zero.

Each type of timeout will be demonstrated using the existing user group `example_group`. Timeout units are minutes. A value of zero indicates the global timeout is used.

Membership in multiple groups

When a user belongs to multiple groups in RADIUS groups, the group auth-timeout values are ignored. Instead the global timeout value is used. The default value is 5 minutes, but it can be set from 1 to 480 minutes.

```
config user setting
   set auth-timeout-type idle-timeout
   set auth-timeout 300
end
```

Idle timeout

The default type of timeout is idle timeout. When a user initiates a session, it starts a timer. As long as data is transferred in this session, the timer continually resets. If data flow stops, the timer is allowed to advance until it reaches its limit. At that time the user has been idle for too long, and the user is forced to re-authenticate before traffic is allowed to continue in that session.

To configure user group authentication idle timeout - CLI

```
config user settings
   set auth-timeout-type idle-timeout
end
config user group
   edit example_group
      set auth-timeout 480
   next
end
```

Hard timeout

Where the idle timeout is reset with traffic, the hard timeout is absolute. From the time the first session a user establishes starts, the hard timeout counter starts. When the timeout is reached, all the sessions for that user must be re-authenticated. This timeout is not affected by any event.

To configure user group authentication hard timeout - CLI

```
config user settings
  set auth-timeout-type hard-timeout
end
config user group
  edit example_group
    set auth-timeout 480
  next
end
```

Session timeout

The session timeout works much like the hard timeout in that its an absolute timer that can not be affected by events. However, when the timeout is reached existing sessions may continue but new sessions are not allowed until re-authentication takes place. The timeout can be set from 1 to 480 minutes. Setting the timeout value to zero removes the timeout value allowing the user to remain logged on without limit.

To configure a user group authentication new session hard timeout - CLI

```
config user setting
  set auth-timeout-type new-session
end

config user group
  edit example_group
    set authtimeout 30
  next
end
```

SSO user groups

SSO user groups are part of FSSO authentication and contain only Windows or Novell network users. No other user types are permitted as members. Information about the Windows or Novell user groups and the logon activities of their members is provided by the Fortinet Single Sign On (FSSO) which is installed on the network domain controllers.

You can specify FSSO user groups in identity-based security policies in the same way as you specify firewall user groups. FSSO user groups cannot have SSL VPN or dialup IPsec VPN access.

For information about configuring FSSO user groups, see “Creating Fortinet Single Sign-On (FSSO) user groups” on page 591. For complete information about installing and configuring FSSO, see “Agent-based FSSO” on page 563.

Configuring Peer user groups

Peer user groups can only be configured using the CLI. Peers are digital certificate holders defined using the `config user peer` command. The peer groups you define here are used in dialup IPsec VPN configurations that accept RSA certificate authentication from members of a peer certificate group. For more information, see “Authenticating IPsec VPN users with security certificates” on page 545.

To create a peer group - CLI example

```
config user peergrp
  edit vpn_peergrp1
    set member pki_user1 pki_user2 pki_user3
  end
```

Viewing, editing and deleting user groups

To view the list of FortiGate user groups, go to *User & Device* > *User* > *User Groups*.

Editing a user group

When editing a user group in the CLI you must set the type of group this will be — either a firewall group, or a Fortinet Single Sign-On Service group. Once the type of group is set, and members are added you cannot change the group type without removing the members.

In the web-based manager, if you change the type of the group any members will be removed automatically.

To edit a user group - web-based manager

1. Go to *User & Device* > *User* > *User Groups*.
2. Select the check box for the user group that you want to edit.
3. Select the *Edit* button.
4. Modify the user group as needed.
5. Select *OK*.

To edit a user group - CLI example

This example adds user3 to Group1. Note that you must re-specify the full list of users:

```
config user group
  edit Group1
  set group-type firewall
    set member user2 user4 user3
  end
```

Deleting a user group

Before you delete a user group, you must ensure there are no objects referring to, it such as security policies. If there are, you must remove those references before you are able to delete the user group.

To remove a user group - web-based manager

1. Go to *User & Device* > *User* > *User Groups*.
2. Select the check box for the user group that you want to remove.
3. Select the *Delete* button.
4. Select *OK*.

To remove a user group - CLI example

```
config user group
  delete Group2
end
```

Managing Guest Access

Introduction

Visitors to your premises might need user accounts on your network for the duration of their stay. If you are hosting a large event such as a conference, you might need to create many such temporary accounts. The FortiOS Guest Management feature is designed for this purpose.

A guest user account User ID can be the user's email address, a randomly generated string, or an ID that the administrator assigns. Similarly, the password can be administrator-assigned or randomly generated.

You can create many guest accounts at once using randomly-generated User IDs and passwords. This reduces administrator workload for large events.

User's view of guest access

1. The user receives an email, SMS message, or printout from a FortiOS administrator listing a User ID and password.
2. The user logs onto the network with the provided credentials.
3. After the expiry time, the credentials are no longer valid.

Administrator's view of guest access

1. Create one or more guest user groups.

   All members of the group have the same characteristics: type of User ID, type of password, information fields used, type and time of expiry.
2. Create guest accounts using Guest Management.
3. Use captive portal authentication and select the appropriate guest group.

Configuring guest user access

Creating guest management administrators

The guest management administrator can be a regular FortiGate administrator. Optionally, you can create administrator accounts that can perform only guest management. This type of administrator is also limited to specific guest user groups.

To create a guest management administrator

1. Go to *System* > *Admin* > *Administrators* and create a regular administrator account.

   For detailed information see the System Administration chapter.
2. Select *Restrict to Provision Guest Accounts*.
3. In *Guest Groups*, add the guest groups that this administrator manages.

Creating guest user groups

The guest group configuration determines the fields that are provided when you create a guest user account.

To create a guest user group

1. Go to *User & Device* > *User* > *User Groups* and select *Create New*.
2. Enter

Name	Enter a name for the group.
Type	Guest
Enable Batch Account Creation	Create multiple accounts automatically. When this is enabled: • *User ID* and *Password* are set to *Auto-Generate*. • The user accounts have only *User ID, Password*, and *Expiration* fields. Only the *Expiration* field is editable. If the expiry time is a duration, such as “8 hours”, this is the time after first login. • You can print the account information. Users do not receive email or SMS notification. See “To create multiple guest user accounts automatically” on page 511.
User ID	Select one of: • Email — User’s email address • Specify — Administrator assigns user ID • Auto-Generate — FortiGate unit creates a random user ID
Password	Select one of: • Specify — Administrator assigns user ID • Auto-Generate — FortiGate unit creates a random password • Disable — no password
Expire Type	Choose one of: Immediately —expiry time is counted from creation of account After first login — expiry time is counted from user’s first login
Default Expire Time	Set the expire time. The administrator can change this for individual users.
Enable Name	If enabled, user must provide a name.
Enable Sponsor	If enabled, user form has Sponsor field. Select *Required* or *Optional*.
Enable Company	If enabled, user form has Company field. Select *Required* or *Optional*.
Enable Email	If enabled, user is notified by email.
Enable SMS	If enabled, user is notified by SMS. Select whether FortiGuard Messaging Service or a another SMS provider is used. You can add SMS providers in *System* > *Config* > *Messaging Servers*.

Creating guest user accounts

Guest user accounts are not the same as local user accounts created in *User & Device* > *User* > *User Definition*. Guest accounts are not permanent; they expire after a defined time period. You create guest accounts in *User & Device* > *User* > *Guest Management*.

To create a guest user account

1. Go to *User & Device* > *User* > *Guest Management.*
2. In *Guest Groups*, select the guest group to manage.
3. Select *Create New* and fill in the fields in the *New User* form.

   Fields marked Optional can be left blank. The guest group configuration determines the fields that are available.
4. Select *OK*.

To create multiple guest user accounts automatically

1. Go to *User & Device* > *User* > *Guest Management.*
2. In *Guest Groups*, select the guest group to manage.

   The guest group must have the *Enable Batch Guest Account Creation* option enabled.
3. Select *Create New* > *Multiple Users*.

   Use the down-pointing caret to the right of *Create New*.
4. Enter *Number of Accounts*.
5. Optionally, change the *Expiration*.
6. Select *OK*.

Guest Management Account List

Go to *User & Device* > *User* > *Guest Management* to create, view, edit or delete guest user accounts.

Create New	Creates a new guest user account.
Edit	Edit the selected guest user account.
Delete	Delete the selected guest user account.
Purge	Remove all accounts from the list.
Send	Send the user account information to a printer or to the guest. Depending on the group settings and user information, the information can be sent to the user by email or SMS.
Refresh	Update the list.
Guest Groups	Select the guest group to list. New accounts are added to this group.
User ID	The user ID. Depending on the guest group settings, this can be the user's email address, an ID that the administrator specified, or a randomly-generated ID.
Expires	Indicates a duration such as "3 hours". A duration on its own is relative to the present time. Or, the duration is listed as "after first login."

Guest access in a retail environment

Some retail businesses such as coffee shops provide free WiFi Internet access for their customers. For this type of application, the FortiOS guest management feature is not required; the WiFi access point is open and customers do not need logon credentials. However, the business might want to contact its customers later with promotional offers to encourage further patronage. Using FortiOS device-based security policies, it is possible to collect customer email addresses for this purpose.

The first time a customer's device attempts to use the WiFi connection, FortiOS requests an email address, which it validates. The customer's subsequent connections go directly to the Internet without interruption.

Implementing email harvesting

The customer's first contact with your network will be with a captive portal which presents a web page requesting an email address. When FortiOS has validated the email address, the customer's device MAC address is added to the Collected Emails device group.

You need configure a device policy that allows traffic to flow from the WiFi SSID to the Internet interface. Within that policy, you need an authentication rule to allow members of the Collected Emails device group to access the Internet. This rule must be listed first. Unknown devices are not members of the Collected Emails device group, so they don't match the rule.

You also need to select *Prompt E-mail collection Portal for all devices*.

To create the device policy

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Enter the following information:

Policy Type	Firewall
Policy Subtype	Device Identity
Incoming Interface	wifi
Source Address	all
Outgoing Interface	wan1
Enable NAT	Enable.

You are now ready to create the authentication rule.

To create the authentication rule - web-based manager

1. In *Configure Authentication Rules*, select *Create New* and enter:

Destination Address	all
Device	Collected Emails
Compliant with Endpoint Profile	not selected
Schedule	always
Service	ALL

Action	ACCEPT

2. Select *OK*.
3. If asked, confirm that you accept FortiOS will enable device identification on the source interface.
4. In *Device Policy Options*, select *Prompt E-mail Collection Portal for all devices*.
5. Optionally, customize authentication messages.
6. Select *OK* to complete configuration of the security policy.

To create the authentication rule - CLI

```
config firewall policy
  edit 3
    set srcintf "wifi"
    set dstintf "wan1"
    set srcaddr "all"
    set action accept
    set email-collection-portal enable
    set identity-based enable
    set identity-from device
    set nat enable
    config identity-based-policy
      edit 1
        set schedule "always"
        set dstaddr "abc"
        set service "ALL"
        set devices "collected-emails"
      end
  end
```

Checking for harvested emails

In the web-based manager, go to *User & device* > *Device* > *Device Definitions*. In the CLI you can use the `diagnose user device list` command. For example,

```
FGT-100D # diagnose user device list
hosts
  vd 0  d8:d1:cb:ab:61:0f  gen 35  req 30  redir 1  last 43634s
    7-11_2-int
    ip 10.0.2.101  ip6 fe80::dad1:cbff:feab:610f
    type 2 'iPhone'  src http  c 1  gen 29
    os 'iPhone'  version 'iOS 6.0.1'  src http  id  358  c 1
    email 'yo@yourdomain.com'
  vd 0  74:e1:b6:dd:69:f9  gen 36  req 20  redir 0  last 39369s
    7-11_2-int
    ip 10.0.2.100  ip6 fe80::76e1:b6ff:fedd:69f9
    type 1 'iPad'  src http  c 1  gen 5
    os 'iPad'  version 'iOS 6.0'  src http  id  293  c 1
    host 'Joes's-iPad'  src dhcp
    email 'you@fortinet.com'
```

Configuring authenticated access

When you have configured authentication servers, users, and user groups, you are ready to configure security policies and certain types of VPNs to require user authentication.

This section describes:

Authentication timeout

An important feature of the security provided by authentication is that it is temporary—a user must re-authenticate after logging out. Also if a user is logged on and authenticated for an extended period of time, it is a good policy to have them re-authenticate at set periods. This ensures a user's session is cannot be spoofed and used maliciously for extended periods of time — re-authentication will cut any spoof attempts short. Shorter timeout values are more secure.

Security authentication timeout

You set the security user authentication timeout to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 480 minutes (8 hours).

To set the security authentication timeout - web-based manager

1. Go to *User & Device* > *Authentication* > *Settings*.
2. Enter the *Authentication Timeout* value in minutes.

   The default authentication timeout is 5 minutes.
3. Select *Apply*.

SSL VPN authentication timeout

You set the SSL VPN user authentication timeout (*Idle Timeout*) to control how long an authenticated connection can be idle before the user must authenticate again. The maximum timeout is 28 800 seconds. The default timeout is 300 seconds.

To set the SSL VPN authentication timeout - web-based manager

1. Go to *VPN* > *SSL* > *Config*.
2. Enter the *Idle Timeout* value (seconds).
3. Select *Apply*.

Password policy

Password authentication is effective only if the password is sufficiently strong and is changed periodically. By default, the FortiGate unit requires only that passwords be at least eight characters in length. You can set a password policy to enforce higher standards for both length and complexity of passwords. Password policies can apply to administrator passwords or IPsec VPN preshared keys.

To set a password policy in the web-based manager, go to *System* > *Admin* > *Settings*. In the CLI, use the `config system password-policy` command.

The default minimum password length on the FortiGate unit is eight characters, but up to 32 characters is permitted. Fortinet suggests a minimum length of 14 characters.

Users usually create passwords composed of alphabetic characters and perhaps some numbers. Password policy can require the inclusion of uppercase letters, lowercase letters, numerals or punctuation characters.

Configuring password minimum requirement policy

Best practices dictate that passwords include:

- one or more uppercase characters
- one or more lower care characters
- one or more of the numerals
- one or more non alphanumeric characters, such as punctuation marks.

The minimum number of each of these types of characters can be set in both the web-based manager and the CLI.

The following procedures show how to force administrator passwords to contain at least two uppercase, four lower care, two digits, and one non-alphanumeric characters. Leave the minimum length at the default of eight characters.

To change administrator password minimum requirements - web-based manager

1. Go to *System* > *Admin* > *Settings*.
2. Select *Enable Password Policy*.
3. Select *Must Contain*.
4. Enter the following information:

uppercase Letters	2
lower case Letters	4
Numerical Digits	2
Non-alphanumeric Letters	1

5. Under *Apply Password Policy to*, select *Admin Password*.
6. Select *Apply*.

To change administrator password minimum requirements - CLI

```
config system password-policy
  set status enable
  set apply-to admin-password
  set min-upper-case-letter 2
  set min-lower-case-letter 4
  set min-number 2
  set min-non-alphanumeric 1
  set change-4-characters enable
end
```

The `change-4-characters` option forces new passwords to change a minimum of four characters in the old password. Changing fewer characters results in the new password being rejected. This option is only available in the CLI.

Password best practices

In addition to length and complexity, there are security factors that cannot be enforced in a policy. Guidelines issued to users will encourage proper password habits.

Best practices dictate that password expiration also be enabled. This forces passwords to be changed on a regular basis. You can set the interval in days. The more sensitive the information this account has access to, the shorter the password expiration interval should be. For example 180 days for guest accounts, 90 days for users, and 60 days for administrators.

Avoid:

- real words found in any language dictionary
- numeric sequences, such as “12345”
- sequences of adjacent keyboard characters, such as “qwerty”
- adding numbers on the end of a word, such as “hello39”
- adding characters to the end of the old password, such as “hello39” to “hello3900”
- repeated characters
- personal information, such as your name, birthday, or telephone number.

Maximum logon attempts and blackout period

When you logon and fail to enter the correct password you could be a valid user, or a hacker attempting to gain access. For this reason, best practices dictate to limit the number of failed attempts to logon before a blackout period where you cannot logon.

To set a maximum of five failed authentication attempts before the blackout, using the following CLI command:

```
config user setting
  set auth-invalid-max 5
end
```

To set the length of the blackout period to five minutes, or 300 seconds, once the maximum number of failed logon attempts has been reached, use the following CLI command:

```
config user setting
  set auth-blackout-time 300
end
```

Authentication protocols

When user authentication is enabled on a security policy, the authentication challenge is normally issued for any of the four protocols, HTTP, HTTPS, FTP, and Telnet, which are dependent on the connection protocol. By making selections in the Protocol Support list, the user controls which protocols support the authentication challenge. The user must connect with a supported protocol first, so that they can subsequently connect with other protocols.

For example, if you have selected HTTP, FTP, or Telnet, a username and password-based authentication occurs. The FortiGate unit then prompts network users to input their security username and password. If you have selected HTTPS, certificate-based authentication (HTTPS, or HTTP redirected to HTTPS only) occurs.

FTP and Telnet authentication replacement messages cannot be customized. For HTTP and HTTPS replacement messages see "Authentication replacement messages" on page 518.

For certificate-based authentication, you must install customized certificates on the FortiGate unit and on the browsers of network users. If you do not install certificates on the network user's web browser, the network users may see an SSL certificate warning message and have to manually accept the default FortiGate certificate. The network user's web browser may deem the default certificate as invalid.

When you use certificate authentication, if you do not specify any certificate when you create the security policy, the global settings are used. If you specify a certificate, the per-policy setting will overwrite the global setting. For more information about the use of certification authentication see "Certificate-based authentication" on page 532.

To set the authentication protocols

1. Go to *User & Device* > *Authentication* > *Settings*.
2. In *Protocol Support*, select the required authentication protocols.
3. If using HTTPS protocol support, in *Certificate*, select a Local certificate from the drop-down list.
4. Select *Apply*.

Authentication in security policies

Security policies control traffic between FortiGate interfaces, both physical interfaces and VLAN subinterfaces. Without authentication, a security policy enables access from one network to another for all users on the source network. Authentication enables you to allow access only for users who are members of selected user groups. To include authentication in a security policy, you must create an identity-based policy.

You can configure user authentication for security policies only when *Action* is set to *Accept*. If the policy is set to *Deny*, *IPsec*, or *SSL VPN* the options will be different.

The style of the authentication method varies by the authentication protocol. If you have selected HTTP, FTP or Telnet, a username and password-based authentication occurs. The FortiGate unit prompts network users to input their security username and password. If you

have selected HTTPS, certificate-based authentication (HTTPS or HTTP redirected to HTTPS only) occurs. You must install customized certificates on the FortiGate unit and on the browsers of network users, which the FortiGate unit matches.

This section includes:

Enabling authentication protocols

Users can authenticate using FTP, HTTP, HTTPS, and Telnet. However, these protocols must be enabled first.

Another authentication option is to redirect any attempts to authenticate using HTTP to a more secure channel that uses HTTPS. This forces users to a more secure connection before entering their user credentials.

To enable support for authentication protocols - web-based manager

1. Go to *User & Device* > *Authentication* > *Settings*.
2. Select one or more of HTTP, HTTPS, FTP, Telnet, or Redirect HTTP Challenge to a Secure Channel (HTTPS). Only selected protocols will be available for use in authentication.
3. Select the *Certificate* to use, for example `Fortinet_Factory`.
4. Select *Apply*.

To enable support for authentication protocols - CLI

```
config user setting
  set auth-type ftp http https telnet
  set auth-cert Fortinet_Factory
end
```

Authentication replacement messages

A replacement message is the body of a webpage containing a message about a blocked website message, a file too large message, a disclaimer, or even a login page for authenticating. The user is presented with this message instead of the blocked content.

Authentication replacement messages are the prompts a user sees during the security authentication process such as login page, disclaimer page, and login success or failure pages. These are different from most replacement messages because they are interactive requiring a user to enter information, instead of simply informing the user of some event as other replacement messages do.

Replacement messages have a system-wide default configuration, a per-VDOM configuration, and disclaimers can be customized for multiple security policies within a VDOM.

These replacement messages are used for authentication using HTTP and HTTPS. Authentication replacement messages are HTML messages. You cannot customize the security authentication messages for FTP and Telnet.

The authentication login page and the authentication disclaimer include replacement tags and controls not found on other replacement messages.

More information about replacement messages can be found in the `config system replacemsg` section of the *FortiOS CLI Reference*.

Table 21: List of authentication replacement messages

Replacement message name (CLI name)	Description
Login challenge page (auth-challenge-page)	This HTML page is displayed if security users are required to answer a question to complete authentication. The page displays the question and includes a field in which to type the answer. This feature is supported by RADIUS and uses the generic RADIUS challenge-access auth response. Usually, challenge-access responses contain a Reply-Message attribute that contains a message for the user (for example, “Please enter new PIN”). This message is displayed on the login challenge page. The user enters a response that is sent back to the RADIUS server to be verified. The Login challenge page is most often used with RSA RADIUS server for RSA SecurID authentication. The login challenge appears when the server needs the user to enter a new PIN. You can customize the replacement message to ask the user for a SecurID PIN. This page uses the %%QUESTION%% tag.
Disclaimer page (auth-disclaimer-page-1) (auth-disclaimer-page-2) (auth-disclaimer-page-3)	Prompts user to accept the displayed disclaimer when leaving protected network. The web-based manager refers to this as User Authentication Disclaimer, and it is enabled with a security policy that also includes at least one identity-based policy. When a security user attempts to browse a network through the FortiGate unit using HTTP or HTTPS this disclaimer page is displayed. The extra pages seamlessly extend the size of the page from 8 192 characters to 16 384 and 24 576 characters respectively. When configuring the disclaimer page in the web-based manager this is shown by its size being 24 576 characters. See “Disclaimer” on page 521.
Email token page (auth-email-token-page)	The page prompting a user to enter their email token. See “Email” on page 495.
FortiToken page (auth-fortitoken-page)	The page prompting a user to enter their FortiToken code. See “FortiToken” on page 497.

Table 21: List of authentication replacement messages

Replacement message name (CLI name)	Description

Keepalive page (auth-keepalive-page)	The HTML page displayed with security authentication keepalive is enabled using the following CLI command:
	`config system global`
	`set auth-keepalive enable`
	`end`
	Authentication keepalive keeps authenticated firewall sessions from ending when the authentication timeout ends. In the web-based manager, go to *User & Device* > *Authentication* > *Settings* to set the *Authentication Timeout*.
	This page includes %%TIMEOUT%%.

Login failed page (auth-login-failed-page)	The Disclaimer page replacement message does not re-direct the user to a redirect URL or the security policy does not include a redirect URL. When a user selects the button on the disclaimer page to decline access through the FortiGate unit, the Declined disclaimer page is displayed.
Login page (auth-login-page)	The authentication HTML page displayed when users who are required to authenticate connect through the FortiGate unit using HTTP or HTTPS. Prompts the user for their username and password to login. This page includes %%USERNAMEID%% and %%PASSWORDID%% tags.
Declined disclaimer page (auth-reject-page)	The page displayed if a user declines the disclaimer page. See "Disclaimer" on page 521.
SMS Token page (auth-sms-token-page)	The page prompting a user to enter their SMS token. See "SMS" on page 496.
Success message (auth-success-msg)	The page displayed when a user successfully authenticates. Prompts user to attempt their connection again (as the first was interrupted for authentication).

Access to the Internet

A policy for accessing the Internet is similar to a policy for accessing a specific network, but the destination address is set to *all*. The destination interface is the one that connects to the Internet Service Provider (ISP). For general purpose Internet access, the Service is set to ANY.

Access to HTTP, HTTPS, FTP and Telnet sites may require access to a domain name service. DNS requests do not trigger authentication. You must configure a policy to permit unauthenticated access to the appropriate DNS server, and this policy must ***precede*** the policy for Internet access. Failure to do this will result in the lack of a DNS connection and a corresponding lack of access to the Internet.

Configuring authentication security policies

To include authentication in a security policy, you must create an identity-based policy. An identity-based policy can authenticate by certificate, FSSO, and NTLM. The two exceptions to this are RADIUS SSO and FSSO Agents. See “SSO using RADIUS accounting records” on page 602, and “Introduction to FSSO agents” on page 564.

Before creating an identity-based security policy, you need to configure one or more users and firewall user groups.For more information, see “Users and user groups” on page 488.

Creating the security policy is the same as a regular security policy except you must select the action specific to your authentication method:

Table 22: Authentication methods allowed for each policy Action

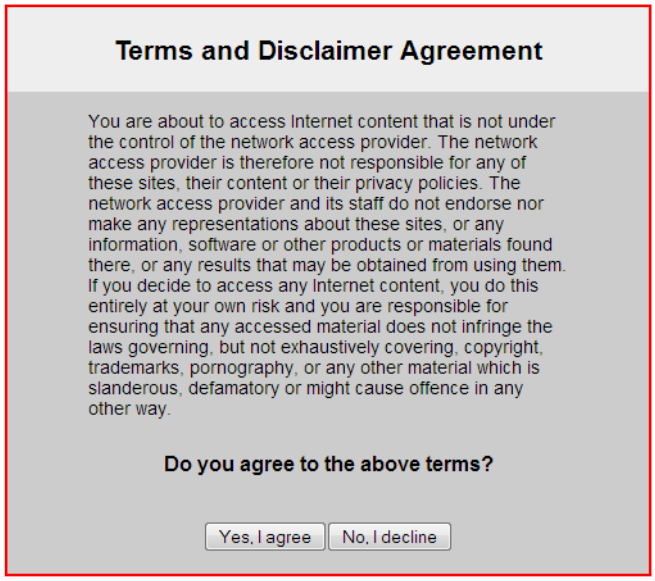
Action	Authentication method	Where authentication is used
ACCEPT	FSSO Agent or identity-based policy — FSSO	See “Agent-based FSSO” on page 563.
	identity-based policy — NTLM	See “NTLM authentication” on page 524.
	identity-based policy — Certificates	See “Configuring certificate-based authentication” on page 543.
	RADIUS SSO	See “SSO using RADIUS accounting records” on page 602.
IPSEC	IPsec Phase 1 and 2	See “Configuring authentication of remote IPsec VPN users” on page 528.
SSL-VPN	SSL certificates	See “Configuring authentication of SSL VPN users” on page 528.
DENY	none	none

Disclaimer

When configuring a User Identity authentication security policy, there is an option to enable a disclaimer. The disclaimer is a replacement message that when enabled, web traffic matching this policy will be presented with the disclaimer that the user must choose to agree or decline.

The default disclaimer contains a warning that any content the user is about to access is the responsibility of the user and not the company or owner of the network. It is presented in Figure 115. You can customize the text and the appearance as required.

Figure 115: Default disclaimer message



Customizing authentication replacement messages

Customizing disclaimers or other authentication replacement messages involves changing the text of the disclaimer message, and possibly the overall appearance of the message.

Disclaimers are useful in many situations. Often companies find it useful to brand the disclaimers with their specific company policy text, logo, and design. One example of this is at an Internet cafe where customers pay for usage and must accept terms of usage before accessing the internet. The cafe benefits from a customized disclaimer that alerts the customer to their online policies. The same is true for other authentication replacement messages such as the login page.

Changing the disclaimer at *System* > *Config* > *Replacement messages* is not the same as selecting to customize a disclaimer used in a policy. The *System* > *Config* location is the default message that all disclaimers inherit. The security policy location is a customized disclaimer that inherits the default format for the disclaimer message, but then can be customized for this policy.

To customize the disclaimer for a security policy - web-based manager

1. Go to *Policy* > *Policy* > *Policy*. Either select an existing User Identity policy or create a new one.
2. Enable *Disclaimer*, and select *Customize Authentication Messages*.
3. Select the Edit icon. You can select and edit any of the pages. Change your text or layout as needed.

Enabling security logging

There are two types of logging that relate to authentication — event logging, and security logging.

When enabled, event logging records system events such as configuration changes, and authentication. To configure event logging, go to *Log&Report* > *Log Config* > *Log Settings* and enable *Event Logging*. Select the events you want to log, such as *User activity event*.

When enabled, security logging will log UTM and security policy traffic.

You must enable logging within a security policy, as well as the options that are applied to a security policy, such as UTM features. Event logs are enabled within the Event Log page,

For more information on logging, see the *FortiOS Log and Reporting chapter*.

For more information on specific types of log messages, see the *FortiOS Log Message Reference*.

You need to set the logging severity level to *Notification* when configuring a logging location to record traffic log messages.

To enable logging within an existing security policy - web-based manager

1. Go to *Policy* > *Policy*.
2. Expand to reveal the policy list of a policy.
3. Select the security policy you want to enable logging on and then select *Edit*.
4. To log all general firewall traffic, select the check box beside *Log Allowed Traffic*.
5. On the security policy's page, select the check box beside *UTM*.
6. In *UTM Security Profiles*, select enable the UTM profiles that you want applied to the policy, then select the profile or sensor from the drop-down list as well.
7. Select *OK*.

Identity-based policy

An identity-based policy (IBP) performs user authentication in addition to the normal security policy duties. If the user does not authenticate, access to network resources is refused. This enforces Role Based Access Control (RBAC) to your organization's network and resources.

Identity-based policies also support Single Sign-On operation. The user groups selected in the policy are of the Fortinet Single Sign-On (FSSO) type.

User authentication can occur through any of the following supported protocols, including: HTTP, HTTPS, FTP, and Telnet. The authentication style depends on which of these protocols is included in the selected security services group and which of those enabled protocols the network user applies to trigger the authentication challenge.

For username and password-based authentication (HTTP, FTP, and Telnet) the FortiGate unit prompts network users to enter their username, password, and token code if two-factor authentication is selected for that user account. See "Two-factor authentication" on page 494. For certificate-based authentication, including HTTPS or HTTP redirected to HTTPS only, see "Certificate authentication" on page 525.

FortiManager does not support pushing identity based policies down to FortiGate units.

Set these commands in the CLI to see the other identity-based commands that were hidden before. In the following procedure, this is policy number 7.

```
config firewall policy
  edit 7
    set action ACCEPT
    set identity-based enable
  next
end
```

With identity-based policies, once the FortiGate unit matches the source and destination addresses, it processes the identity sub-policies for the user groups and services. This means unique security policies must be placed ***before*** an identity-based policy to be effective.

When the identity-based policy has been configured, the option to customize authentication messages is available. This allows you to change the text, style, layout, and graphics of the replacement messages associated with this firewall policy. When enabled, customizing these messages follows the same method as changing the disclaimer. See "Disclaimer" on page 521.

Types of authentication also available in identity-based policies are

- NTLM authentication
- Certificate authentication

Identity-based sub-policies

Once IBP is enabled in a policy, a table appears. Selecting *Add* allows you to configure authentication rules which are added to this table as sub-policies.

Just as with regular security policies, with these identity-based sub-policies traffic is matched from the top of the list of sub-policies down until the criteria is met. If there is no matching policy packets are dropped, even if they have been authenticated. Each sub-policy has its own UTM profile fields, traffic shaping, logging, and so on that take effect when the User Group, Service and Schedule are matched.

The order of these sub-policies is just as important as with regular security policies. For example if a user is a member of two groups, and each group has a separate sub-policy entry, the top one in the list will be matched first.

NTLM authentication

The NT LAN Manager (NTLM) protocol is used when the MS Windows Active Directory (AD) domain controller can not be contacted. NTLM uses web browsers to send and receive authentication information. See "NTLM" on page 460 and "FSSO NTLM authentication support" on page 569.

NTLM authentication is enabled when you configure FSSO and enable NTLM in the identity-based policy (IBP). There must be at least one FSSO Collector agent configured on the FortiGate. Any users and user groups associated with the security policy will use NTLM to authenticate without further configuration. However some extra configuration in the CLI may be required for certain cases including guest access, and defining NTLM enabled browsers.

If there are multiple domains, a trust relation must exist between them. This is automatic if they are in a forest. With the trust relation, only one FSSO DC agent needs to be installed. Without the trust relation, FSSO DC agents must be installed on each domain controller.

NTLM guest access - CLI

Guest profile access may be granted to users failing NTLM authentication, such as visitors who have no user credentials on the network. To allow guest users in NTLM, use the following CLI command:

```
config firewall policy
  edit 8
    set action accept
    set identity-based enable
    set ntlm enable
    set ntlm-guest enable
  next
  end
```

NTLM enabled browsers - CLI

User agent strings for NTLM enabled browsers allow the inspection of initial HTTP-User-Agent values, so that non-supported browsers are able to go straight to guest access without needlessly prompting the user for credentials that will fail. `ntlm-guest` must be enabled to use this option.

```
config firewall policy
  edit 9
    set action accept
    set identity-based enable
    set ntlm enable
    set ntlm-guest enable
    set ntlm-enabled-browsers <user_agent_string>
  next
  end
```

`<user_agent_string>` is the name of the browser that is NTLM enabled. Examples of these values include “MSIE”, “Mozilla” (which includes FireFox), and “Opera”.

Value strings can be up to 63 characters in length, and may not contain cross site scripting (XSS) vulnerability characters such as brackets. The FortiGate unit prevents use of these characters to prevent exploit of cross site scripting (XSS) vulnerabilities.

Certificate authentication

Certificates can be used as part of an identity-based policy. A customized certificate must be installed on the FortiGate unit and in the web browser, which the FortiGate unit will attempt to match.

All users being authenticated against the policy are required to have the proper certificate, which must be imported into the FortiGate unit. See “Certificate-based authentication” on page 532.

To require the user to accept a disclaimer to connect to the destination, select *Enable Disclaimer*. If the user is to be redirected after accepting the disclaimer, enter the URL in the *Redirect URL to* field. You can edit the User Authentication Disclaimer replacement message text in *System* > *Config* > *Replacement Messages*.

Certificate redirect authentication

Under *User & Device* > *Authentication* > *Settings,* select *Redirect HTTP Challenge to a Secure Channel (HTTPS)*. This forces users to use secure connections to send their authentication information.

The following steps happen during a redirect:

1. User tries to access the Internet and the HTTP traffic hits the FortiGate security policy with authentication and HTTPS redirect enabled.
2. The FortiGate redirects the user with the HTTPS port and IP address of the interface connected to the user, such as internal.
3. User authenticates over the HTTPS connection as with normal authentication.
4. On successful authentication, the FortiGate provides access to the Internet as originally requested.

Restricting number of concurrent user logons

Some users on your network may often have multiple account sessions open at one time either to the same network resource or accessing to the admin interface on the FortiGate unit.

While there are valid reasons for having multiple concurrent sessions open, hackers also do this to speed up their malicious work. Often a hacker is making multiple attempts to gain access to the internal network or the admin interface of the FortiGate unit, usually from different IP addresses to appear to the FortiGate unit as legitimate users. For this reason, the more concurrent sessions a hacker has open at once, the faster they will achieve their goal.

To help prevent this, you can disallow concurrent administrative access using the same administrator user name, but from a different IP address. This allows valid users to continue their legitimate work while limiting hackers' activity.

To disable concurrent administrator sessions - CLI

```
config system global
  set admin-concurrent disable
end
```

Limited access for unauthenticated users

When configuring User Identity policies, if you select the option *Skip this policy for unauthenticated user* the policy will only apply to users who have already authenticated with the FortiGate unit. This feature is intended for networks with two kinds of users:

- Single sign-on users who have authenticated when their devices connected to their network
- Other users who do not authenticate with the network so are "unauthenticated"

Sessions from authenticated users can match this policy and sessions from unauthenticated users will skip this policy and potentially be matched with policies further down the policy list. Typically, you would arrange a policy with *Skip this policy for unauthenticated user* at the top of a policy list.

You can also use the following CLI command to enable skipping policies for unauthenticated users:

```
config firewall policy
  edit <id>
    set identity-based enable
    set fall-through-unauthenticated enable
    next
```

Use case - allowing limited access for unauthenticated users

Consider an office with open use PCs in common areas. Staff and customers do not have to log in to these PCs and can use them for limited access to the Internet. From their desks, employees of this office log into PCs which are logged into the office network. The FortiGate unit on the office network uses single sign-on to get user credentials from the network authentication server.

The open use PCs have limited access to the Internet. Employee PCs can access internal resources and have unlimited access to the Internet.

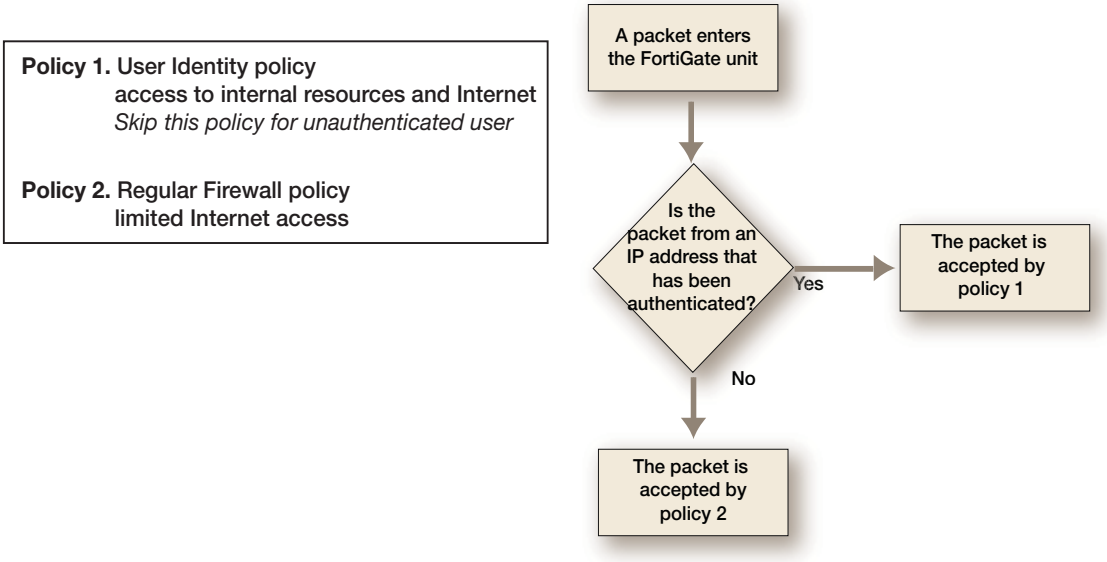
To support these different levels of access you can add a user identity policy to the top of the policy list that allows authenticated users to access internal resources and to have unlimited access to the Internet. In this policy, select *Skip this policy for unauthenticated user*.

Add a normal firewall policy below this policy that allows limited access to the Internet.

Sessions from authenticated PCs will be accepted by the User Identity policy. Sessions from unauthenticated PCs will skip the User Identity policy and be accepted by the normal firewall policy.

Figure 116 shows how the FortiGate unit handles packets received from authenticated and unauthenticated users.

Figure 116: Packet flow for authenticated and unauthenticated users



Use case - multiple levels of authentication

As a variation of the above use case, Policy 2 could be a User Identity policy and *Skip this policy for unauthenticated user* would not be selected. Sessions from unauthenticated users that are accepted by Policy2 would now require users to authenticate before traffic can connect

through the FortiGate unit. The result is different levels of authentication: Single sign on for some users and firewall authentication for others.

VPN authentication

All VPN configurations require users to authenticate. Authentication based on user groups applies to:

- SSL VPNs
- PPTP and L2TP VPNs
- an IPsec VPN that authenticates users using dialup groups
- a dialup IPsec VPN that uses XAUTH authentication (Phase 1)

You must create user accounts and user groups before performing the procedures in this section. If you create a user group for dialup IPsec clients or peers that have unique peer IDs, their user accounts must be stored locally on the FortiGate unit. You cannot authenticate these types of users using a RADIUS or LDAP server.

Configuring authentication of SSL VPN users

The general procedure for authenticating SSL VPN users is:

1. Configure user accounts.
2. Create one or more user groups for SSL VPN users.

   See “Configuring user accounts and user groups for SSL VPN” in the *FortiOS Handbook SSL VPN chapter*.
3. Enable SSL VPN.
4. Optionally, set inactivity and authentication timeouts.
5. Configure a security policy with SSL VPN action. Add an identity-based rule to allow access for the user groups you created for SSL VPN users.

   See “Configuring security policies” in the *FortiOS Handbook SSL VPN chapter*.

Configuring authentication timeout

By default, the SSL VPN authentication expires after 8 hours (28 800 seconds). You can change it only in the CLI, and the time entered must be in seconds. For example, to change this timeout to one hour, you would enter:

```
config vpn ssl settings
  set auth-timeout 3600
end
```

If you set the authentication timeout (`auth-timeout`) to 0 when you configure the timeout settings, the remote client does not have to re-authenticate unless they log out of the system. To fully take advantage of this setting, the value for `idle-timeout` has to be set to 0 also, so that the client does not time out if the maximum idle time is reached. If the `idle-timeout` is not set to the infinite value, the system will log out if it reaches the limit set, regardless of the `auth-timeout` setting.

Configuring authentication of remote IPsec VPN users

An IPsec VPN on a FortiGate unit can authenticate remote users through a dialup group. The user account name is the peer ID and the password is the pre-shared key.

Authentication through user groups is supported for groups containing only local users. To authenticate users using a RADIUS or LDAP server, you must configure XAUTH settings. See "Configuring XAuth authentication" on page 529.

To configure user group authentication for dialup IPsec - web-based manager

1. Configure the dialup users who are permitted to use this VPN. Create a user group with Type:Firewall and add them to it.

   For more information, see "Users and user groups" on page 488.
2. Go to *VPN* > *IPsec* > *Auto Key (IKE)*, select *Create Phase 1* and enter the following information.

Name	Name for group of dialup users using the VPN for authentication.
Remote Gateway	List of the types of remote gateways for VPN. Select *Dialup User*.
Authentication Method	List of authentication methods available for users. Select *Preshared Key* and enter the preshared key.
Peer Options	Select *Accept peer ID in dialup group*. Select the user group that is to be allowed access to the VPN. The listed user groups contain only users with passwords on the FortiGate unit.

3. Select *Advanced* to reveal additional parameters and configure other VPN gateway parameters as needed.
4. Select *OK*.

To configure user group authentication for dialup IPsec - CLI example

The `peertype` and `usrgrp` options configure user group-based authentication.

```
config vpn ipsec phase1
  edit office_vpn
    set interface port1
    set type dynamic
    set psksecret yORRAzltNGhzgtV32jend
    set proposal 3des-sha1 aes128-sha1
    set peertype dialup
    set usrgrp Group1
  end
```

Configuring XAuth authentication

Extended Authentication (XAuth) increases security by requiring additional user authentication information in a separate exchange at the end of the VPN Phase 1 negotiation. The FortiGate unit asks the user for a username and password. It then forwards the user's credentials (the password is encrypted) to an external RADIUS or LDAP server for verification.

XAuth can be used in addition to or in place of IPsec phase 1 peer options to provide access security through an LDAP or RADIUS authentication server. You must configure a dialup user group whose members are all externally authenticated.

To configure authentication for a dialup IPsec VPN - web-based manager

1. Configure the users who are permitted to use this VPN. Create a user group and add the users to the group.

   For more information, see "Users and user groups" on page 488.
2. Go to *VPN* > *IPsec* > *Auto Key (IKE)*.
3. Select *Create Phase 1* and configure the basic VPN phase1 settings.

   Remote Gateway must be *Dialup User*.
4. Select *Advanced* to reveal additional parameters and enter the following information.

XAuth	Select *Enable as Server*.
Server Type	Select *PAP*, *CHAP*, or *AUTO*. Use CHAP whenever possible. Use PAP with all implementations of LDAP and with other authentication servers that do not support CHAP, including some implementations of Microsoft RADIUS. Use AUTO with the Fortinet Remote VPN Client and where the authentication server supports CHAP but the XAuth client does not.
User Group	Select the user group that is to have access to the VPN. The list of user groups does not include any group that has members whose password is stored on the FortiGate unit.

5. Select *OK*.

For more information about XAUTH configuration, see the IPsec VPN chapter of this FortiOS Handbook.

To configure authentication for a dialup IPsec VPN - CLI example

The `xauthtype` and `authusrgrp` fields configure XAuth authentication.

```
config vpn ipsec phase1
  edit office_vpn
    set interface port1
    set type dynamic
    set psksecret yORRAzltNGhzgtV32jend
    set proposal 3des-sha1 aes128-sha1
    set peertype dialup
    set xauthtype pap
    set authusrgrp Group1
  end
```

Some parameters specific to setting up the VPN itself are not shown here. For detailed information about configuring IPsec VPNs, see the *FortiOS Handbook IPsec VPN chapter*.

Configuring authentication of PPTP VPN users and user groups

Configuration of a PPTP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

To configure authentication for a PPTP VPN

1. Configure the users who are permitted to use this VPN. Create a security user group and add them to it.

   For more information, see "Users and user groups" on page 488.

2. Configure the PPTP VPN in the CLI as in this example.

```
config vpn pptp
  set status enable
  set sip 192.168.0.100
  set eip 192.168.0.110
  set usrgrp PPTP_Group
end
```

   The `sip` and `eip` fields define a range of virtual IP addresses assigned to PPTP clients.

3. Configure a security policy. The source interface is the one through which the clients will connect. The source address is the PPTP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

Configuring authentication of L2TP VPN users/user groups

Configuration of a L2TP VPN is possible only through the CLI. You can configure user groups and security policies using either CLI or web-based manager.

To configure authentication for a PPTP VPN

1. Configure the users who are permitted to use this VPN. Create a user group and add them to it.

   For more information, see “Users and user groups” on page 488.

2. Configure the L2TP VPN in the CLI as in this example.

```
config vpn l2tp
  set status enable
  set sip 192.168.0.100
  set eip 192.168.0.110
  set usrgrp L2TP_Group
end
```

   The `sip` and `eip` fields define a range of virtual IP addresses assigned to L2TP clients.

3. Configure a security policy. The source interface is the one through which the clients will connect. The source address is the L2TP virtual IP address range. The destination interface and address depend on the network to which the clients will connect. The policy action is ACCEPT.

Certificate-based authentication

This section provides an overview of how the FortiGate unit verifies the identities of administrators, SSL VPN users, or IPsec VPN peers using X.509 security certificates.

The following topics are included in this section:

What is a security certificate?

A security certificate is a small text file that is part of a third-party generated public key infrastructure (PKI) to help guarantee the identity of both the user logging on and the web site they where they are logging in.

A certificate includes identifying information such as the company and location information for the web site, as well as the third-party company name, the expiry date of the certificate, and the encrypted public key.

FortiGate units use X.509 certificates to authenticate single sign-on (SSO) for users. The X.509 standard has been in use since before 2000, but has gained popularity with the Internet's increased popularity. X.509 v3 is defined in RFC 5280 and specifies standard formats for public key certificates, certificate revocation lists, and a certification path validation algorithm. The unused earlier X.509 version 1 was defined in RFC 1422.

The main difference between X.509 and PGP certificates is that where in PGP anyone can sign a certificate, for X.509 only a trusted authority can sign certificates. This limits the source of certificates to well known and trustworthy sources. Where PGP is well suited for one-on-one communications, the X.509 infrastructure is intended to be used in many different situations including one-to-many communications. Some common filename extensions for X.509 certificates are listed in Table 23.

Table 23: Common certificate filename extensions

Filetype	Format name	Description
.pem	Privacy Enhanced Mail (PEM)	Base64 encoded DER certificate, that uses "-----BEGIN CERTIFICATE-----" and "-----END CERTIFICATE-----"
.cer **.crt** **.der**	Security CERtificate	Usually binary DER form, but Base64-encoded certificates are common too.

Table 23: Common certificate filename extensions

.p7b **.p7c**	PKCS#7 SignedData	Structure without data, just certificates or CRLs. PKCS#7 is a standard for signing or encrypting (officially called “enveloping”) data.
.p12	PKCS#12	May contain certificate(s) (public) and private keys (password protected)
.pfx	personal information exchange (PFX)	Older format. Came before PKCS#12. Usually today data is in PKCS#12 format.

Certificates overview

Certificates play a major role in authentication of clients connecting to network services via HTTPS, both for administrators and SSL VPN users. Certificate authentication is optional for IPsec VPN peers.

- Certificates and protocols
- IPsec VPNs and certificates
- Certificate types on the FortiGate unit

Certificates and protocols

There are a number of protocols that are commonly used with certificates including SSL and HTTPS, and other certificate-related protocols.

SSL and HTTPS

The secure HTTP (HTTPS) protocol uses SSL. Certificates are an integral part of SSL. When a web browser connects to the FortiGate unit via HTTPS, a certificate is used to verify the FortiGate unit’s identity to the client. Optionally, the FortiGate unit can require the client to authenticate itself in return.

By default, the FortiGate unit uses a self-signed security certificate to authenticate itself to HTTPS clients. When the certificate is offered, the client browser displays two security messages.

- The first message prompts users to accept and optionally install the FortiGate unit’s self-signed security certificate. If the user does not accept the certificate, the FortiGate unit refuses the connection. When the user accepts the certificate, the FortiGate login page is displayed, and the credentials entered by the user are encrypted before they are sent to the FortiGate unit. If the user chooses to install the certificate, the prompt is not displayed again.
- Just before the FortiGate login page is displayed, a second message informs users that the FortiGate certificate distinguished name differs from the original request. This message is displayed because the FortiGate unit redirects the connection (away from the distinguished name recorded in the self-signed certificate) and can be ignored.

Optionally, you can install an X.509 server certificate issued by a certificate authority (CA) on the FortiGate unit. You can then configure the FortiGate unit to identify itself using the server certificate instead of the self-signed certificate. For more information, see the *FortiOS Handbook SSL VPN chapter*. or “Authenticating SSL VPN users with security certificates” on page 544.

After successful certificate authentication, communication between the client browser and the FortiGate unit is encrypted using SSL over the HTTPS link.

Certificate-related protocols

There are multiple protocols that are required for handling certificates. These include the Online Certificate Status Protocol (OCSP), Secure Certificate Enrollment Protocol (SCEP), and Server-based Certificate Validation Protocol (SCVP).

Online Certificate Status Protocol

Online Certificate Status Protocol (OCSP) allows the verification of X.509 certificate expiration dates. This is important to prevent hackers from changing the expiry date on an old certificate to a future date.

Normally certificate revocation lists (CRLs) are used, but OCSP is an alternate method available. However a CRL is a public list, and some companies may want to avoid the public exposure of their certificate structure even if it is only invalid certificates.

The OSCP check on the certificate's revocation status is typically carried out over HTTP with a request-response format. The authority responding can reply with a status of good, revoked, or unknown for the certificate in question.

Secure Certificate Enrollment Protocol

Secure Certificate Enrollment Protocol (SCEP) is an automated method of signing up for certificates. Typically this involves generating a request you send directly to the SCEP service, instead of generating a file request that may or may not be signed locally.

Server-based Certificate Validation Protocol

Server-based Certificate Validation Protocol (SCVP) is used to trace a certificate back to a valid root level certificate. This ensures that each step along the path is valid and trustworthy.

IPsec VPNs and certificates

Certificate authentication is a more secure alternative to preshared key (shared secret) authentication for IPsec VPN peers. Unlike administrators or SSL VPN users, IPsec peers use HTTP to connect to the VPN gateway configured on the FortiGate unit. The VPN gateway configuration can require certificate authentication before it permits an IPsec tunnel to be established. See "Authenticating IPsec VPN users with security certificates" on page 545.

Certificate types on the FortiGate unit

There are different types of certificates available that vary depending on their intended use. FortiOS supports local, remote, CA, and CRL certificates.

Local certificates

Local certificates are issued for a specific server, or web site. Generally they are very specific, and often for an internal enterprise network. For example a personal web site for John Smith at www.example.com (such as http://www.example.com/home/jsmith) would have its own local certificate.

These can optionally be just the certificate file, or also include a private key file and PEM passphrase for added security.

For information about generating a certificate request, see "Generating a certificate signing request" on page 536. For information about installing a local certificate, see "Obtaining and installing a signed server certificate from an external CA" on page 538.

Remote certificates

Remote certificates are public certificates without a private key. For dynamic certificate revocation, you need to use an Online Certificate Status Protocol (OCSP) server. The OCSP is configured in the CLI only. Installed Remote (OCSP) certificates are displayed in the Remote Certificates list. You can select *Import* to install a certificate from the management PC.

CA root certificates

CA root certificates are similar to local certificates, however they apply to a broader range of addresses or to whole company; they are one step higher up in the organizational chain. Using the local certificate example, a CA root certificate would be issued for all of www.example.com instead of just the smaller single web page.

Certificate revocation list

Certificate revocation list (CRL) is a list of certificates that have been revoked and are no longer usable. This list includes certificates that have expired, been stolen, or otherwise compromised. If your certificate is on this list, it will not be accepted. CRLs are maintained by the CA that issues the certificates and includes the date and time when the next CRL will be issued as well as a sequence number to help ensure you have the most current version of the CRL.

Certificate signing

The trust in a certificate comes from the authority that signs it. For example if VeriSign signs your CA root certificate, it is trusted by everyone. While these certificates are universally accepted, it is cumbersome and expensive to have all certificates on a corporate network signed with this level of trust.

With self-signed certificates nobody, except the other end of your communication, knows who you are and therefore they do not trust you as an authority. However this level is useful for encryption between two points — neither point may care about who signed the certificate, just that it allows both points to communicate. This is very useful for internal networks and communications.

A general rule is that CA signed certificates are accepted and sometimes required, but it is easier to self-sign certificates when you are able.

For more on the methods of certificate signing see “Generating a certificate signing request” on page 536.

Managing X.509 certificates

Managing security certificates is required due to the number of steps involved in both having a certificate request signed, and then distributing the correct files for use.

You use the FortiGate unit or CA software such as OpenSSL to generate a certificate request. That request is a text file that you send to the CA for verification, or alternately you use CA software to self-validate. Once validated, the certificate file is generated and must be imported to the FortiGate unit before it can be used. These steps are explained in more detail later in this section.

This section provides procedures for generating certificate requests, installing signed server certificates, and importing CA root certificates and CRLs to the FortiGate unit.

For information about how to install root certificates, CRLs, and personal or group certificates on a remote client browser, refer to your browser’s documentation.

This section includes:

Generating a certificate signing request

Whether you create certificates locally with a software application or obtain them from an external certificate service, you will need to generate a certificate signing request (CSR).

When you generate a CSR, a private and public key pair is created for the FortiGate unit. The generated request includes the public key of the FortiGate unit and information such as the FortiGate unit's public static IP address, domain name, or email address. The FortiGate unit's private key remains confidential on the FortiGate unit.

After you submit the request to a CA, the CA will verify the information and register the contact information on a digital certificate that contains a serial number, an expiration date, and the public key of the CA. The CA will then sign the certificate, and you install the certificate on the FortiGate unit.

The Certificate Request Standard is a public key cryptography standard (PKCS) published by RSA, specifically PKCS10 which defines the format for CSRs. This is defined in RFC 2986.

To generate a certificate request in FortiOS - web-based manager

1. Go to *System* > *Certificates* > *Local Certificates*.
2. Select *Generate*.
3. In the *Certificate Name* field, enter a unique meaningful name for the certificate request. Typically, this would be the hostname or serial number of the FortiGate unit or the domain of the FortiGate unit such as example.com.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

4. Enter values in the *Subject Information* area to identify the FortiGate unit:
   - If the FortiGate unit has a static IP address, select *Host IP* and enter the public IP address of the FortiGate unit. If the FortiGate unit does not have a public IP address, use an email address (or fully qualified domain name (FQDN) if available) instead.
   - If the FortiGate unit has a dynamic IP address and subscribes to a dynamic DNS service, use a FQDN if available to identify the FortiGate unit. If you select *Domain Name*, enter the FQDN of the FortiGate unit. Do not include the protocol specification (http://) or any port number or path names.

If a domain name is not available and the FortiGate unit subscribes to a dynamic DNS service, an "unable to verify certificate" type message may be displayed in the user's browser whenever the public IP address of the FortiGate unit changes.

- If you select *E-Mail*, enter the email address of the owner of the FortiGate unit.

5. Enter values in the *Optional Information* area to further identify the FortiGate unit.

Organization Unit	Name of your department. You can enter a series of OUs up to a maximum of 5. To add or remove an OU, use the plus (+) or minus (-) icon.
Organization	Legal name of your company or organization.
Locality (City)	Name of the city or town where the FortiGate unit is installed.
State/Province	Name of the state or province where the FortiGate unit is installed.
Country	Select the country where the FortiGate unit is installed.
e-mail	Contact email address.
Subject Alternative Name	Optionally, enter one or more alternative names for which the certificate is also valid. Separate names with a comma. A name can be: • e-mail address • IP address • URI • DNS name (alternatives to the Common Name) • directory name (alternatives to the Distinguished Name) You must precede the name with the name type. Examples: IP:1.1.1.1 email:test@fortinet.com email:my@other.address URI:http://my.url.here/

6. From the *Key Size* list, select *1024 Bit*, *1536 Bit* or *2048 Bit*. Larger keys are slower to generate but more secure.
7. In *Enrollment Method*, you have two methods to choose from. Select *File Based* to generate the certificate request, or *Online SCEP* to obtain a signed SCEP-based certificate automatically over the network. For the SCEP method, enter the URL of the SCEP server from which to retrieve the CA certificate, and the CA server challenge password.
8. Select *OK*.
9. The request is generated and displayed in the *Local Certificates* list with a status of `PENDING`.
10. Select the *Download* button to download the request to the management computer.
11. In the *File Download* dialog box, select *Save* and save the Certificate Signing Request on the local file system of the management computer.
12. Name the file and save it on the local file system of the management computer.

The certificate request is ready for the certificate to be generated.

Generating certificates with CA software

CA software allows you to generate unmanaged certificates and CA certificates for managing other certificates locally without using an external CA service. Examples of CA software include ssl-ca from OpenSSL (available for Linux, Windows, and Mac) or gensslcert from SuSE, MS Windows Server 2000 and 2003 come with a CA as part of their certificate services, and in MS Windows 2008 CA software can be installed as part of the Active Directory installation. See "Example — Generate and Import CA certificate with private key pair on OpenSSL" on page 546.

The general steps for generating certificates with CA software are

1. Install the CA software as a stand-alone root CA.
2. Provide identifying information for your self-administered CA.

While following these steps, the methods vary slightly when generating server certificates, CA certificates, and PKI certificates.

Server certificate

1. Generate a Certificate Signing Request (CSR) on the FortiGate unit.
2. Copy the CSR base-64 encoded text (PKCS10 or PKCS7) into the CA software and generate the certificate.

   PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.
3. Export the certificate as a X.509 DER encoded binary file with .CER extension
4. Upload the certificate file to the FortiGate unit Local Certificates page (type is Certificate).

CA certificate

1 Retrieve the CA Certificate from the CA software as a DER encoded file.

2 Upload the CA certificate file to the FortiGate unit CA Certificates page at *System* > *Certificates* > *CA Certificates*.

PKI certificate

1. Generate a Certificate Signing Request (CSR) on the FortiGate unit.
2. Copy the CSR base-64 encoded text (PKCS#10 or PKCS#7) into the CA software and generate the certificate.

   PKCS10 is the format used to send the certificate request to the signing authority. PKCS7 is the format the signing authority can use for the newly signed certificate.
3. Export the certificate as a X.509 DER encoded binary file with .CER extension.
4. Install the certificate in the user's web browser or IPsec VPN client as needed.

Obtaining and installing a signed server certificate from an external CA

To obtain a signed server certificate for a FortiGate unit, you must send a request to a CA that provides digital certificates that adhere to the X.509 standard. The FortiGate unit provides a way for you to generate the request.

To submit the certificate signing request (file-based enrollment)

1. Using the web browser on the management computer, browse to the CA web site.
2. Follow the CA instructions for a base-64 encoded PKCS#10 certificate request and upload your certificate request.

3. Follow the CA instructions to download their root certificate and CRL.

   When you receive the signed server certificate from the CA, install the certificate on the FortiGate unit.

To install or import the signed server certificate - web-based manager

1. On the FortiGate unit, go to *System* > *Certificates* > *Local Certificates*.
2. Select *Import*.
3. From *Type*, select *Local Certificate*.
4. Select *Browse*, browse to the location on the management computer where the certificate was saved, select the certificate, and then select *Open*.
5. Select *OK*, and then select *Return*.

Installing a CA root certificate and CRL to authenticate remote clients

When you apply for a signed personal or group certificate to install on remote clients, you can obtain the corresponding root certificate and CRL from the issuing CA. When you receive the signed personal or group certificate, install the signed certificate on the remote client(s) according to the browser documentation. Install the corresponding root certificate (and CRL) from the issuing CA on the FortiGate unit according to the procedures given below.

To install a CA root certificate

1. After you download the root certificate of the CA, save the certificate on the management computer. Or, you can use online SCEP to retrieve the certificate.
2. On the FortiGate unit, go to *System* > *Certificates* > *CA Certificates*.
3. Select *Import*.
4. Do one of the following:
   - To import using SCEP, select *SCEP*. Enter the URL of the SCEP server from which to retrieve the CA certificate. Optionally, enter identifying information of the CA, such as the filename.
   - To import from a file, select *Local PC*, then select *Browse* and find the location on the management computer where the certificate has been saved. Select the certificate, and then select *Open*.
5. Select *OK*, and then select *Return*.

The system assigns a unique name to each CA certificate. The names are numbered consecutively (CA_Cert_1, CA_Cert_2, CA_Cert_3, and so on).

To import a certificate revocation list

A Certificate Revocation List (CRL) is a list of the CA certificate subscribers paired with certificate status information. The list contains the revoked certificates and the reason(s) for revocation. It also records the certificate issue dates and the CAs that issued them.

When configured to support SSL VPNs, the FortiGate unit uses the CRL to ensure that the certificates belonging to the CA and remote peers or clients are valid. The CRL has an “effective date” and a “next update” date. The interval is typically 7 days (for Microsoft CA). FortiOS will update the CRL automatically. Also, there is a CLI command to specify an “update-interval” in seconds. Recommendation should be 24 hours (86400 seconds) but depends on company security policy.

1. After you download the CRL from the CA web site, save the CRL on the management computer.
2. Go to *System* > *Certificates* > *CRL*.
3. Select *Import*.

4. Do one of the following:
   - To import using an HTTP server, select *HTTP* and enter the URL of the HTTP server.
   - To import using an LDAP server see this KB article.
   - To import using an SCEP server, select *SCEP* and select the Local Certificate from the list. Enter the URL of the SCEP server from which the CRL can be retrieved.
   - To import from a file, select *Local PC*, then select *Browse* and find the location on the management computer where the CRL has been saved. Select the CRL and then select *Open*.
5. Select *OK*, and then select *Return*.

Troubleshooting certificates

There are times when there are problems with certificates — a certificate is seen as expired when its not, or it can't be found. Often the problem is with a third party web site, and not FortiOS. However, some problems can be traced back to FortiOS such as DNS or routing issues.

Certificate is reported as expired when it is not

Certificates often are issued for a set period of time such as a day or a month, depending on their intended use. This ensures everyone is using up-to-date certificates. It is also more difficult for hackers to steal and use old certificates.

Reasons a certificate may be reported as expired include:

- It really has expired based on the "best before" date in the certificate
- The FortiGate unit clock is not properly set. If the FortiGate clock is fast, it will see a certificate as expired before the expiry date is really here.
- The requesting server clock is not properly set. A valid example is if your certificate is 2 hours from expiring, a server more than two time zones away would see the certificate as expired. Otherwise, if the server's clock is set wrongly it will also have the same effect.
- The certificate was revoked by the issuer before the expiry date. This may happen if the issuer believes a certificate was either stolen or misused. Its possible it is due to reasons on the issuer's side, such as a system change or such. In either case it is best to contact the certificate issuer to determine what is happening and why.

A secure connection cannot be completed (Certificate cannot be found)

Everyone who uses a browser has encountered a message such as *This connection is untrusted*. Normally when you try to connect securely to a web site, that web site will present its valid certificate to prove their identity is valid. When the web site's certificate cannot be verified as valid, the message appears stating *This connection is untrusted* or something similar. If you usually connect to this web site without problems, this error could mean that someone is trying to impersonate or hijack the web site, and best practices dictates you not continue.

Reasons a web site's certificate cannot be validated include:

- The web site uses an unrecognized self-signed certificate. These are not secure because anyone can sign them. If you accept self-signed certificates you do so at your own risk. Best practices dictate that you must confirm the ID of the web site using some other method before you accept the certificate.
- The certificate is valid for a different domain. A certificate is valid for a specific location, domain, or sub-section of a domain such as one certificate for `support.example.com`

that is not valid for marketing.example.com. If you encounter this problem, contact the webmaster for the web site to inform them of the problem.

- There is a DNS or routing problem. If the web site's certificate cannot be verified, it will not be accepted. Generally to be verified, your system checks with the third party certificate signing authority to verify the certificate is valid. If you cannot reach that third party due to some DNS or routing error, the certificate will not be verified.
- Firewall is blocking required ports. Ensure that any firewalls between the requesting computer and the web site allow the secure traffic through the firewall. Otherwise a hole must be opened to allow it through. This includes ports such as 443 (HTTPS) and 22 SSH).

Online updates to certificates and CRLs

If you obtained your local or CA certificate using SCEP, you can configure online renewal of the certificate before it expires. Similarly, you can receive online updates to CRLs.

Local certificates

In the config vpn certificate local command, you can specify automatic certificate renewal. The relevant fields are:

scep-url <URL_str>	The URL of the SCEP server. This can be HTTP or HTTPS. The following options appear after you add the <URL_str>.
scep-password <password_str>	The password for the SCEP server.
auto-regenerate-days <days_int>	How many days before expiry the FortiGate unit requests an updated local certificate. The default is 0, no auto-update.
auto-regenerate-days -warning <days_int>	How many days before local certificate expiry the FortiGate generates a warning message. The default is 0, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate local
  edit mycert
    set scep-url http://scep.example.com/scep
    set scep-server-password my_pass_123
    set auto-regenerate-days 3
    set auto-regenerate-days-warning 2
  end
```

CA certificates

In the config vpn certificate ca command, you can specify automatic certificate renewal. The relevant fields are:

scep-url <URL_str>	The URL of the SCEP server. This can be HTTP or HTTPS.
auto-update-days <days_int>	How many days before expiry the FortiGate unit requests an updated CA certificate. The default is 0, no auto-update.
auto-update-days-warning <days_int>	How many days before CA certificate expiry the FortiGate generates a warning message. The default is 0, no warning.

In this example, an updated certificate is requested three days before it expires.

```
config vpn certificate ca
  edit mycert
    set scep-url http://scep.example.com/scep
    set auto-update-days 3
    set auto-update-days-warning 2
  end
```

Certificate Revocation Lists

If you obtained your CRL using SCEP, you can configure online updates to the CRL using the `config vpn certificate crl` command. The relevant fields are:

Variable	Description
`http-url <http_url>`	URL of the server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
`scep-cert <scep_certificate>`	Local certificate used for SCEP communication for CRL auto-update.
`scep-url <scep_url>`	URL of the SCEP CA server used for automatic CRL certificate updates. This can be HTTP or HTTPS.
`update-interval <seconds>`	How frequently, in seconds, the FortiGate unit checks for an updated CRL. Enter `0` to update the CRL only when it expires. Not available for http URLs.
`update-vdom <update_vdom>`	VDOM used to communicate with remote SCEP server for CRL auto-update.

In this example, an updated CRL is requested only when it expires.

```
config vpn certificate crl
  edit cert_crl
    set http-url http://scep.example.com/scep
    set scep-cert my-scep-cert
    set scep-url http://scep.ca.example.com/scep
    set update-interval 0
    set update-vdom root
  end
```

Backing up and restoring local certificates

The FortiGate unit provides a way to export and import a server certificate and the FortiGate unit's personal key through the CLI. If required (to restore the FortiGate unit configuration), you can import the exported file through the *System* > *Certificates* > *Local Certificates* page of the web-based manager.

As an alternative, you can back up and restore the entire FortiGate configuration through the *System Information* widget on the Dashboard of the web-based manager. Look for *[Backup]* and *[Restore]* in the *System Configuration* row. The backup file is created in a FortiGate-proprietary format.

To export a server certificate and private key - CLI

This procedure exports a server (local) certificate and private key together as a password protected PKCS12 file. The export file is created through a customer-supplied TFTP server. Ensure that your TFTP server is running and accessible to the FortiGate unit before you enter the command.

1. Connect to the FortiGate unit through the CLI.
2. Type the following command:

```
execute vpn certificate local export tftp <cert_name> <exp_filename>
     <tftp_ip>
```

where:

- `<cert_name>` is the name of the server certificate; typing `?` displays a list of installed server certificates.
- `<exp_filename>` is a name for the output file.
- `<tftp_ip>` is the IP address assigned to the TFTP server host interface.

3 Move the output file from the TFTP server location to the management computer for future reference.

To import a server certificate and private key - web-based manager

1. Go to *System* > *Certificates* > *Local Certificates* and select *Import*.
2. In *Type*, select *PKCS12 Certificate*.
3. Select *Browse*. Browse to the location on the management computer where the exported file has been saved, select the file, and then select *Open*.
4. In the *Password* field, type the password needed to upload the exported file.
5. Select *OK*, and then select *Return*.

To import separate server certificate and private key files - web-based manager

Use the following procedure to import a server certificate and the associated private key file when the server certificate request and private key were not generated by the FortiGate unit. The two files to import must be available on the management computer.

1. Go to *System* > *Certificates* > *Local Certificates* and select *Import*.
2. In *Type*, select *Certificate*.
3. Select the *Browse* button beside the *Certificate file* field. Browse to the location on the management computer where the certificate file has been saved, select the file, and then select *Open*.
4. Select the *Browse* button beside the *Key file* field. Browse to the location on the management computer where the key file has been saved, select the file, and then select *Open*.
5. If required, in the *Password* field, type the associated password, and then select *OK*.
6. Select *Return*.

Configuring certificate-based authentication

You can configure certificate-based authentication for FortiGate administrators, SSL VPN users, and IPsec VPN users.

In Microsoft Windows 7, you can use the certificate manager to keep track of all the different certificates on your local computer. To access certificate manager, in Windows 7 press the Windows key, enter “certmgr.msc” at the search prompt, and select the displayed match.

Remember that in addition to these system certificates, many applications require you to register certificates with them directly.

To see FortiClient certificates, open the FortiClient Console, and select VPN. The VPN menu has options for My Certificates (local or client) and CA Certificates (root or intermediary certificate authorities). Use Import on those screens to import certificate files from other sources.

Authenticating administrators with security certificates

You can install a certificate on the management computer to support strong authentication for administrators. When a personal certificate is installed on the management computer, the FortiGate unit processes the certificate after the administrator supplies a username and password.

To enable strong administrative authentication:

- Obtain a signed personal certificate for the administrator from a CA and load the signed personal certificate into the web browser on the management computer according to the browser documentation.
- Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see "Installing a CA root certificate and CRL to authenticate remote clients" on page 539).
- Create a PKI user account for the administrator.
- Add the PKI user account to a firewall user group dedicated to PKI-authenticated administrators.
- In the administrator account configuration, select *PKI* as the account *Type* and select the *User Group* to which the administrator belongs.

Authenticating SSL VPN users with security certificates

While the default self-signed certificates can be used for HTTPS connections, it is preferable to use the X.509 server certificate to avoid the redirection as it can be misinterpreted as possible session hijacking. However, the server certificate method is more complex than self-signed security certificates. Also the warning message is typically displayed for the initial connection, and future connections will not generate these messages.

X.509 certificates can be used to authenticate IPsec VPN peers or clients, or SSL VPN clients. When configured to authenticate a VPN peer or client, the FortiGate unit prompts the VPN peer or client to authenticate itself using the X.509 certificate. The certificate supplied by the VPN peer or client must be verifiable using the root CA certificate installed on the FortiGate unit in order for a VPN tunnel to be established.

To enable certificate authentication for an SSL VPN user group

1. Install a signed server certificate on the FortiGate unit and install the corresponding root certificate (and CRL) from the issuing CA on the remote peer or client.
2. Obtain a signed group certificate from a CA and load the signed group certificate into the web browser used by each user. Follow the browser documentation to load the certificates.
3. Install the root certificate and the CRL from the issuing CA on the FortiGate unit (see "Installing a CA root certificate and CRL to authenticate remote clients" on page 539).
4. Create a PKI user for each SSL VPN user. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
5. Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the SSL VPN users who are authenticated by certificate.
6. Go to *Policy* > *Policy* > *Policy*.
7. Edit the SSL-VPN security policy.

8. Select *SSL Client Certificate Restrictive*.
9. Select *OK*.

Authenticating IPsec VPN users with security certificates

To require VPN peers to authenticate by means of a certificate, the FortiGate unit must offer a certificate to authenticate itself to the peer.

To enable the FortiGate unit to authenticate itself with a certificate:

1. Install a signed server certificate on the FortiGate unit.
   See "To install or import the signed server certificate - web-based manager" on page 539.
2. Install the corresponding CA root certificate on the remote peer or client. If the remote peer is a FortiGate unit, see "To install a CA root certificate" on page 539.
3. Install the certificate revocation list (CRL) from the issuing CA on the remote peer or client. If the remote peer is a FortiGate unit, see "To import a certificate revocation list" on page 539.
4. In the VPN phase 1 configuration, set *Authentication Method* to *RSA Signature* and from the *Certificate Name* list select the certificate that you installed in Step 1.

To authenticate a VPN peer using a certificate, you must install a signed server certificate on the peer. Then, on the FortiGate unit, the configuration depends on whether there is only one VPN peer or if this is a dialup VPN that can he multiple peers.

To configure certificate authentication of a single peer

1. Install the CA root certificate and CRL.
2. Create a PKI user to represent the peer. Specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.
3. In the VPN phase 1 *Peer Options*, select *Accept this peer certificate only* and select the PKI user that you created.

To configure certificate authentication of multiple peers (dialup VPN)

1. Install the corresponding CA root certificate and CRL.

2 Create a PKI user for each remote VPN peer. For each user, specify the text string that appears in the Subject field of the user's certificate and then select the corresponding CA certificate.

3 Use the `config user peergrp` CLI command to create a peer user group. Add to this group all of the PKI users who will use the IPsec VPN.

In the VPN phase 1 *Peer Options*, select *Accept this peer certificate group only* and select the peer group that you created.

Example — Generate a CSR on the FortiGate unit

This example follows all the steps required to create and install a local certificate on the FortiGate unit, without using CA software.

The FortiGate unit is called myFortiGate60, and is located at 10.11.101.101 (a private IP address) and http://myfortigate.example.com. Mr. John Smith (john.smith@myfortigate.example.com) is the IT administrator for this FortiGate unit,a nd the unit belongs to the Sales department located in Greenwich, London, England.

To generate a certificate request on the FortiGate unit - web-based manager

1. Go to *System* > *Certificates* > *Local Certificates*.
2. Select *Generate*.

3. In the *Certificate Name* field, enter `myFortiGate60`.

Do not include spaces in the certificate name. This will ensure compatibility of a signed certificate as a PKCS12 file to be exported later on if required.

Since the IP address is private, we will use the FQDN instead.

4. Select *Domain Name*, and enter `http://myfortigate.example.com`.
5. Enter values in the *Optional Information* area to further identify the FortiGate unit.

Organization Unit	Sales
Organization	Example.com
Locality (City)	Greenwich
State/Province	London
Country	England
e-mail	john.smith@myfortigate.example.com

6. From the *Key Size* list, select *2048 Bit* or the most secure option available to you.
7. In *Enrollment Method*, select *File Based* to generate the certificate request
8. Select *OK*.

   The request is generated and displayed in the *Local Certificates* list with a status of PENDING.
9. Select the *Download* button to download the request to the management computer.
10. In the *File Download* dialog box, select *Save* and save the Certificate Signing Request on the local file system of the management computer.
11. Name the file and save it on the local file system of the management computer.

Example — Generate and Import CA certificate with private key pair on OpenSSL

This example explains how to generate a certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

Assumptions

Before starting this procedure, ensure that you have downloaded and installed OpenSSL on Windows. One source is http://www.slproweb.com/products/Win32OpenSSL.html.

Generating and importing the CA certificate and private key

The two following procedures will generate a CA certificate file and private key file, and then import it to the FortiGate unit as a local certificate.

To generate the private key and certificate

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:

   ```
   cd c:\OpenSSL-Win32\bin
   ```

2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet123.

   ```
   openssl genrsa -des3 -out fgtcapriv.key 2048
   ```

   This command generates an RSA DES3 2038-bit encryption key.

3. The following command will generate the certificate using the key from the previous step.

   ```
   openssl req -new -x509 -days 3650 -extensions v3_ca -key
        fgtcapriv.key -out fgtca.crt
   ```

   This step generates an X509 CA certificate good for 10 years that uses the key generated in the previous step. The certificate filename is `fgtca.crt`.

   You will be prompted to enter information such as PEM Pass Phrase from the previous step, Country Name, State, Organization Name, Organizational Unit (such as department name), Common Name (the FQDN), and Email Address.

To import the certificate to the FortiGate unit - web-based manager

1. Go to *System* > *Certificates* > *Local Certificates*.
2. Select *Import*.
3. Select Certificate for Type.

   Fields for Certificate file, Key file, and Password are displayed.
4. For Certificate file, enter `c:\OpenSSL-Win32\bin\fgtca.crt`.
5. For Key file, enter `c:\OpenSSL-Win32\bin\fgtcapriv.key`.
6. For Password, enter the PEM Pass Phrase you entered earlier, such as fortinet123.
7. Select OK.

The Certificate will be added to the list of Local Certificates and be ready for use. It will appear in the list as the filename you uploaded — `fgtca`.You can add comments to this certificate to make it clear where its from and how it is intended to be used. If you download the certificate from FortiOS, it is a .CER file.

It can now be used in "Authenticating IPsec VPN users with security certificates" on page 545, and "Authenticating SSL VPN users with security certificates" on page 544.

Optionally, you can install the certificate as a CA Certificate. CA certificates are used in HTTPS proxy/inspection. To do this, under *CA Certificates* select *Import*. Select *Local PC* and enter the certificate file `c:\OpenSSL-Win32\bin\fgtca.crt`. Then select *OK*. This certificate will be displayed in the CA Certificate list under the name `CA_Cert_1`.

Example — Generate an SSL certificate in OpenSSL

This example explains how to generate a CA signed SSL certificate using OpenSSL on MS Windows. OpenSSL is available for Linux and Mac OS as well, however their terminology will vary slightly from what is presented here.

This example includes:

- Assumptions
- Generating a CA signed SSL certificate
- Generating a self-signed SSL certificate
- Import the SSL certificate into FortiOS

Assumptions

- Before starting this procedure, ensure that you have downloaded and installed OpenSSL on MS Windows. One download source is http://www.slproweb.com/products/Win32OpenSSL.html.

Generating a CA signed SSL certificate

This procedure assumes:

- you have already completed "Example — Generate and Import CA certificate with private key pair on OpenSSL" on page 546 successfully.

To generate the CA signed SSL certificate

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:
   ```
   cd c:\OpenSSL-Win32\bin
   ```
2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.
   ```
   openssl genrsa -des3 -out fgtssl.key 2048
   ```
   This command generates an RSA DES3 2038-bit encryption key.
3. Create a certificate signing request for the SSL certificate. This step requires you to enter the information listed in step 3 of the previous example — "To generate the private key and certificate" on page 547. You can leave the Challenge Password blank.
   ```
   openssl req -new -key fgtssl.key -out fgtssl.csr
   ```
4. Using the CSR from the previous step, you can now create the SSL certificate using the CA certificate that was created in "Example — Generate and Import CA certificate with private key pair on OpenSSL" on page 546.
   ```
   openssl x509 -req -days 365 -in fgtssl.csr -CA fgtca.crt -CAkey
        fgtcapriv.key -set_serial 01 -out fgtssl.crt
   ```
   This will generate an X.509 certificate good for 365 days signed by the CA certificate fgtca.crt.

Generating a self-signed SSL certificate

This procedures does not require any existing certificates.

1. At the Windows command prompt, go to the OpenSSL bin directory. If you installed to the default location this will be the following command:
   ```
   cd c:\OpenSSL-Win32\bin
   ```
2. Enter the following command to generate the private key. You will be prompted to enter your PEM pass phrase. Choose something easy to remember such as fortinet.
   ```
   openssl genrsa -des3 -out fgtssl.key 2048
   openssl req -new -key fgtssl.key -out fgtssl.csr
   openssl x509 -req -days 365 -in fgtssl.csr -signkey fgtssl.key
        -out fgtssl.crt
   ```
   These commands:
   - generate an RSA 3DES 2048-bit private key,
   - generate an SSL certificate signing request, and
   - sign the CSR to generate an SSL .CRT certificate file.

Import the SSL certificate into FortiOS

To import the certificate to FortiOS- web-based manager

1. Go to *System* > *Certificates* > *Local Certificates*.
2. Select *Import*.
3. Select Certificate for Type.

   Fields for Certificate file, Key file, and Password are displayed.
4. For Certificate file, enter `c:\OpenSSL-Win32\bin\fgtssl.crt`.
5. For Key file, enter `c:\OpenSSL-Win32\bin\fgtssl.key`.
6. For Password, enter the PEM Pass Phrase you entered, such as fortinet.
7. Select OK.

The SSL certificate you just uploaded can be found under *System* > *Certificates* > *Local Certificates* under the name of the file you uploaded — `fgtssl`.

To confirm the certificate is uploaded properly - CLI

```
config vpn certificate local
  edit fgtssl
    get
  end
```

The get command will display all the certificate's information. If it is not there or the information is not correct, you will need to remove the corrupted certificate (if it is there) and upload it again from your PC.

To use the new SSL certificate - CLI

```
config vpn ssl settings
  set servercert fgtssl
end
```

This assigns the fgtssl certificate as the SSL server certificate. For more information see the *FortiOS Handbook SSL VPN chapter*.

SSO using a FortiAuthenticator unit

If you use a FortiAuthenticator unit in your network as a single sign-on agent,

- Users can authenticate through a web portal on the FortiAuthenticator unit.
- Users with FortiClient Endpoint Security installed can be automatically authenticated by the FortiAuthenticator unit through the FortiClient SSO Mobility Agent.

The FortiAuthenticator unit can integrate with external network authentication systems such as RADIUS and LDAP to gather user logon information and send it to the FortiGate unit.

User's view of FortiAuthenticator SSO authentication

There are two different ways users can authenticate through a FortiAuthenticator unit.

Users without FortiClient Endpoint Security - SSO widget

To log onto the network, the user accesses the organization's web page with a web browser. Embedded on that page is a simple logon widget, like this:

User not logged in. Click *Login* to go to the FortiAuthenticator login page.

User logged in. Name displayed. *Logout* button available.

The SSO widget sets a cookie on the user's browser. When the user browses to a page containing the login widget, the FortiAuthenticator unit recognizes the user and updates its database if the user's IP address has changed. The user will not need to re-authenticate until the login timeout expires, which can be up to 30 days.

Users with FortiClient Endpoint Security - FortiClient SSO Mobility Agent

The user simply accesses resources and all authentication is performed transparently with no request for credentials. IP address changes, such as those due to WiFi roaming, are automatically sent to the FortiAuthenticator unit. When the user logs off or otherwise disconnects from the network, the FortiAuthenticator unit is aware of this and deathenticates the user.

The FortiClient SSO Mobility Agent, a feature of FortiClient Endpoint Security v5.0, must be configured to communicate with the appropriate FortiAuthenticator unit. After that, the agent automatically provides user name and IP address information to the FortiAuthenticator unit for transparent authentication.

Administrator's view of FortiAuthenticator SSO authentication

You can configure either or both of these authentication types on your network.

SSO widget

You need to configure the Single Sign-On portal on the FortiAuthenticator unit. Go to *SSO & Dynamic Polices* > *SSO* > *Login Portal* to do this. Copy the *Embeddable login widget* code for use on your organization's home page. Identity-based security policies on the FortiGate unit determine which users or groups of users can access which network resources.

FortiClient SSO Mobility Agent

Your users must be running FortiClient Endpoint Security v5.0 to make use of this type of authentication.

On the FortiAuthenticator unit, you need to enable *FortiClient Service* when you define the unit's secret key. Go to *SSO & Dynamic Policies* > *SSO* > *Options*. You need to provide your users the FortiAuthenticator IP address and secret key so that they can configure the FortiClient SSO Mobility Agent on their computers. See "Configuring the FortiGate unit" on page 552.

Configuring the FortiAuthenticator unit

The FortiAuthenticator unit can poll FortiGate units, Windows Active Directory, RADIUS servers, LDAP servers, and FortiClients for information about user logon activity.

To configure FortiAuthenticator polling

1. Go to *SSO & Dynamic Policies* > *SSO* > *Options*.
2. In the *FortiGate* section, leave the Listening Port at 8000, unless your network requires you to change this. The FortiGate unit must allow traffic on this port to pass through the firewall.

   Optionally, you can set the Login Expiry time. This is the length of time users can remain logged in before the system logs them off automatically. The default is 480 minutes (8 hours).
3. Select *Enable Authentication* and enter the *Secret key*. Be sure to use the same secret key when configuring the FSSO Agent on FortiGate units.
4. In the *Fortinet Single Sign-On (FSSO)* section, enter

Enable Windows Active Directory domain controllers	Select for integration with Windows Active Directory.
Enable Radius accounting service	Select if you want to use a Remote LDAP server.
Use remote LDAP server for SSO groups lookup	Optionally, you can provide SSO only to certain groups. If so, enable this option and select the remote LDAP server.
Enable FortiClient service Enable Authentication	Select both options to enable single sign-on by clients running FortiClient Endpoint Security. Enter the *Secret key*. Be sure to use the same secret key in the FortiClient Single Sign-On Mobility Agent settings.

5. Select *OK*.

For more information, see the *FortiAuthenticator Administration Guide*.

Configuring the FortiGate unit

Adding a FortiAuthenticator unit as an SSO agent

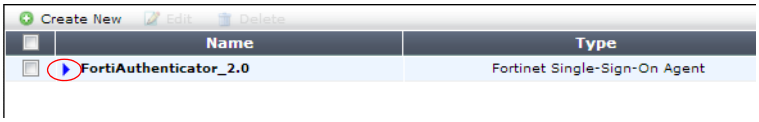
On the FortiGate unit, you need to add the FortiAuthenticator unit as a Single Sign-On agent that provides user logon information.

To add a FortiAuthenticator unit as SSO agent

1. Go to *User & Device* > *Authentication* > *Single Sign-On* and select *Create New*.
2. In *Type*, select *Fortinet Single-Sign-On Agent*.
3. Enter a *Name* for the FortiAuthenticator unit.
4. In Primary Agent IP/Name, enter the IP address of the FortiAuthenticator unit.
5. In Password, enter the secret key that you defined for the FortiAuthenticator unit.

   On the FortiAuthenticator unit, you go to *SSO & Dynamic Policies* > *SSO* > *Options* to define the secret key. Select *Enable Authentication*.
6. Select OK.

In a few minutes, the FortiGate unit receives a list of user groups from the FortiAuthenticator unit. The entry in the Single Sign-On server list shows a blue caret.



When you open the server, you can see the list of groups. You can use the groups in identity-based security policies.

Configuring an FSSO user group

You cannot use FortiAuthenticator SSO user groups directly in a security policy. Create an FSSO user group and add FortiAuthenticator SSO user groups to it. FortiGate FSSO user groups are available for selection in identity-based security policies.

To create an FSSO user group

1. Go to *User & Device* > *User* > *User Groups* and select *Create New*.
2. Enter a *Name* for the group.
3. In Type, select *Fortinet Single Sign-On (FSSO)*.
4. Add *Available Members* to the *Members* list.

   The Available Members are SSO groups provided by SSO agents.
5. Select *OK*.

Configuring security policies

You can create identity-based policies based on FSSO groups as you do for local user groups. For more information about security policies see the Firewall chapter.

Configuring the FortiClient SSO Mobility Agent

The user's device must have FortiClient Endpoint Security v5.0 installed. Only two pieces of information are required to set up the SSO Mobility Agent feature: the FortiAuthenticator unit IP address and the preshared secret.

The user needs to know the FortiAuthenticator IP address and preshared secret to set up the SSO Mobility Agent. Or, you could preconfigure FortiClient

To configure FortiClient SSO Mobility Agent

1. In FortiClient Endpoint Security, go to *File* > *Settings*.

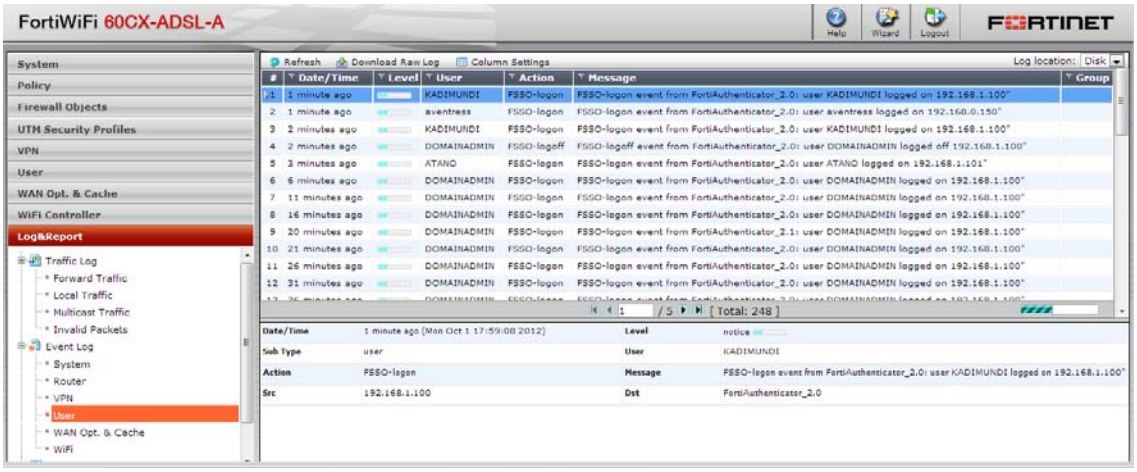
   You must run the FortiClient application as an administrator to access these settings.
2. Select *Enable single sign-on mobility agent*. Enter the FortiAuthenticator unit IP address, including the listening port number specified on the FortiAuthenticator unit.

   Example: 192.168.0.99:8001. You can omit the port number if it is 8005.
3. Enter the preshared key.

Select OK.

Viewing SSO authentication events on the FortiGate unit

User authentication events are logged in the FortiGate event log. Go to *Log & Report* > *Event Log* > *User*.



Single Sign-On to Windows AD

The FortiGate unit can authenticate users transparently and allow them network access based on their privileges in Windows AD. This means that users who have logged on to the network are not asked again for their credentials to access network resources through the FortiGate unit, hence the term “Single Sign-On”.

The following topics are included:

Introduction to Single Sign-On with Windows AD

Introduced in FortiOS 5.0, Single Sign-On (SSO) support provided by FortiGate polling of domain controllers is simpler than the earlier method that relies on agent software installed on Windows AD network servers. No Fortinet software needs to be installed on the Windows network. The FortiGate unit needs access only to the Windows AD global catalog and event log.

When a Windows AD user logs on at a workstation in a monitored domain, the FortiGate unit

- detects the logon event in the domain controller’s event log and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- uses the domain controller’s LDAP server to determine which groups the user belongs to,
- creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. The selection consist of matching the FSSO group or groups the user belongs to with the security policy or policies that match that group. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

Configuring Single Sign On to Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet Single Sign On, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet Single Sign On sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate units.

To configure your FortiGate unit to operate with either a Windows AD or a Novell eDirectory FSSO install, you

- Configure LDAP access to the Windows AD global catalog. See “Configuring LDAP server access” on page 555.
- Add Active Directory user groups to FortiGate FSSO user groups. See “Creating Fortinet Single Sign-On (FSSO) user groups” on page 557.
- Configure the LDAP Server as a Single Sign-On server. See “Configuring the LDAP Server as a Single Sign-On server” on page 557
- Create security policies for FSSO-authenticated groups. See “Creating security policies” on page 557.
- Optionally, specify a guest protection profile to allow guest access. See “Enabling guest access through FSSO security policies” on page 559.

Configuring LDAP server access

The FortiGate unit needs access to the domain controller’s LDAP server to retrieve user group information.

The LDAP configuration on the FortiGate unit not only provides access to the LDAP server, it sets up the retrieval of Windows AD user groups for you to select in FSSO. The LDAP Server configuration (in *User & Device* > *Authentication* > *LDAP Servers*) includes a function to preview the LDAP server’s response to your distinguished name query. If you already know the appropriate Distinguished Name (DN) and User DN settings, you may be able to skip some of the following steps.

To add an LDAP server - web-based manager

1. Go to *User & Device* > *Authentication* > *LDAP Servers* and select *Create New*.
2. Enter the *Server Name/IP* and *Server Port* (default 389).
3. Select the *Query distinguished name* button to the right of the *Distinguished Name* field.

   A new window opens.
4. If more than one name is listed, you might need to explore each name following the steps below to determine which one is relevant to your needs.
5. Copy the name string to the *Distinguished Name* field and select *OK*.

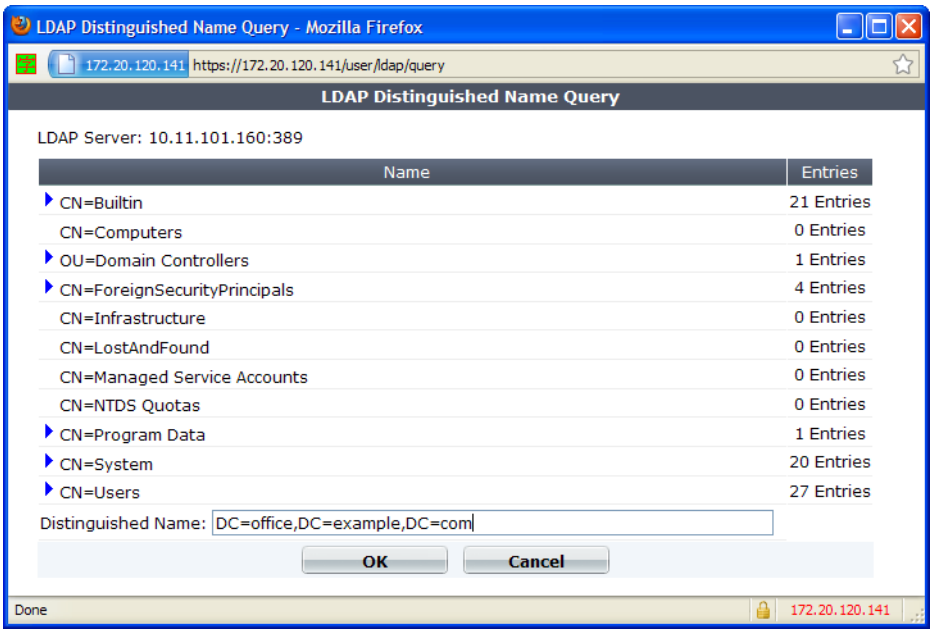
   This closes the window and copies the name string to the *Distinguished Name* field of the LDAP Server configuration.
6. Set *Bind Type* to *Regular.*
7. In the *User DN* field, enter the administrative account name that you created for FSSO.

   For example, if the account is FSSO_Admin, enter “cn=FSSO_Admin,cn=users”.
8. Make sure that the *User DN* entry ends with a comma and append the string from the *Distinguished Name* field to the end of it.

   Example: cn=FSSO_Admin,cn=users,dc=office,dc=example,dc=com
9. Enter the administrative account password in the *Password* field.
10. Select the *Query distinguished name* button again.

    The LDAP Distinguished Name Query window opens:

Figure 117: Authenticated DN query



You can expand any of the DNs that contain entries. When you select an expandable DN, the *Distinguished Name* field is updated. Look for the DN that contains the users or groups whose logon you want to monitor.

11. Select the DN that you want to monitor and then select *OK*.

    This closes the window and updates the *Distinguished Name* field of the LDAP Server configuration with the selected Domain Name Identifier (DNI).

12. Check the following fields and select OK:

Name	Enter a name to identify the LDAP server.
Common Name Identifier	The default common name identifier is `cn`. This is correct for most LDAP servers. However some servers use other identifiers such as `uid`.
Secure Connection	Optional.

To configure LDAP for FSSO - CLI example

```
config user ldap
  edit "ADserver"
    set server "10.11.101.160"
    set cnid "cn"
    set dn "cn=users,dc=office,dc=example,dc=com"
    set type regular
    set username
        "cn=administrator,cn=users,dc=office,dc=example,dc=com"
    set password set_a_secure_password
  next
end
```

Creating Fortinet Single Sign-On (FSSO) user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

To create a user group for FSSO authentication - web-based manager

1. Go to *User & Device* > *User* > *User Groups*. and select *Create New*.
   The New User Group dialog box opens.
2. In the *Name* box, enter a name for the group, FSSO_Internet_users for example.
3. In *Type*, select *Fortinet Single Sign-On (FSSO)*.
4. From the *Available Members* list, select the required *FSSO* groups.
   Using the CTRL or SHIFT keys, you can select multiple groups.
5. Select the green right arrow button to move the selected groups to the *Members* list.
6. Select *OK*.

To create the FSSO_Internet-users user group - CLI

```
config user group
  edit FSSO_Internet_users
    set group-type fsso-service
    set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
         CN=Sales,cn=users,dc=office,dc=example,dc=com
  end
```

Configuring the LDAP Server as a Single Sign-On server

The LDAP server must be added to the FortiGate Single Sign-On configuration.

To add the LDAP server as a Single Sign-On server

1. Go to *User & Device* > *Authentication* > *Single Sign-On* and select *Create New*.
2. Enter

Type	Poll Active Directory Server
Server Name/IP	Server Name or IP address of the Domain Controller
User	A Domain user name
Password	The user's password
LDAP Server	Select the LDAP server you added earlier.
Enable Polling	Select

3. Select *OK*.

Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and

requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fsso_group`, and the FSSO RADIUS server is `fsso_rad_server`.

To configure an FSSO authentication security policy - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Enter the following information.

Policy Type	Firewall
Policy subtype	User Identity
Incoming Interface	port1
Source Address	company_network
Outgoing Interface	port2
Enable NAT	Select

3. In *Configure Authentication Rules*, select *Create New*.
4. Enter

Destination Address	all
Groups	Select from the FSSO user groups that you created earlier. `FSSO_Guest_users` is a default user group enabled when FSSO is configured. It allows guest users on the network who do not have an FSSO account to still authenticate and have access to network resources. See "Enabling guest access through FSSO security policies" on page 559.
Schedule	always
Service	HTTP, HTTPS, FTP, and Telnet
Action	ACCEPT
Log Allowed Traffic	Select. Logging FSSO logon events helps troubleshoot any FSSO related issues.
UTM Security Profiles	Enable AntiVirus, IPS, Web Filter, and Email Filter default profiles.

5. Select *OK*.

   A new line of information will appear in the identity-based policy table, listing the user groups, services, schedule, UTM, and logging selected for the rule.
6. Select OK.
7. Ensure the FSSO authentication policy is higher in the policy list than more general policies for the same interfaces.

To create a security policy for FSSO authentication - CLI

```
config firewall policy
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr company_network
    set dstaddr all
    set action accept
    set identity-based enable
    set nat enable
    config identity-based-policy
      edit 1
        set schedule any
        set groups company_network FSSO_guest_users
        set service HTTP HTTPS FTP TELNET
      end
  end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to Windows AD and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `FSSO_Guest_Users`. Specify the services, schedule and UTM profiles that apply to guest users — typically guests have access to a reduced set of services. See "Creating security policies" on page 557.

FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For more information on firewall logging, see "Enabling security logging" on page 522. For more information on logging, see the *FortiOS Handbook Log and Reporting chapter*.

Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events need, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged. While this extra information is useful, you must

To enable event logging

1. Go to *Log&Report* > *Log Config* > *Log Settings*.
2. In *Event Logging*, select

System activity event	All system-related events, such as ping server failure and gateway status.
User activity event	All administration events, such as user logins, resets, and configuration updates.

Optionally you can enable any or all of the other logging event options.

3. Select *Apply*.

Figure 118: Authentication log messages

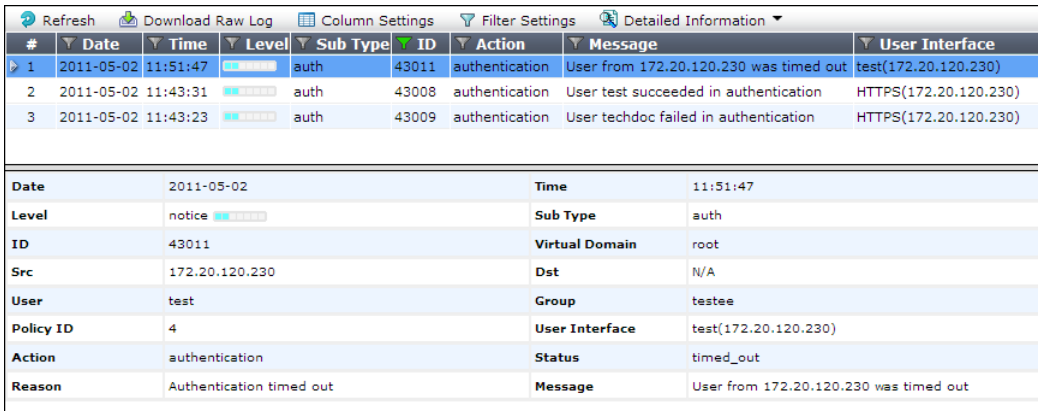


Table 24: List of FSSO related log messages

Message ID	Severity	Description
43008	Notification	Authentication was successful
43009	Notification	Authentication session failed
43010	Warning	Authentication locked out
43011	Notification	Authentication timed out
43012	Notification	FSSO authentication was successful
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the *FortiOS Handbook Log and Reporting chapter*.

Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see "Troubleshooting FSSO" on page 561.

1. Logon to one of the stations on the FSSO domain, and access an Internet resource.
2. Connect to the CLI of the FortiGate unit, and if possible log the output.
3. Enter the following command:
   ```
   diagnose debug authd fsso list
   ```
4. Check the output. If FSSO is functioning properly you will see something similar to the following:
   ```
   ----FSSO logons----
   IP: 192.168.1.230  User: ADMINISTRATOR  Groups: VLAD-AD/DOMAIN USERS
   IP: 192.168.1.240  User: ADMINISTRATOR  Groups: VLAD-AD/DOMAIN USERS
   Total number of users logged on: 2
   ----end of FSSO logons----
   ```
   The exact information will vary based on your installation.
5. Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field. For a list of FSSO log message IDs, see Table 24 on page 560.
6. To check server connectivity, run the following commands from the CLI:
   ```
   FGT# diagnose debug enable
   FGT# diagnose debug authd fsso server-status
   FGT# Server Name           Connection Status
        -----------           -----------------
        SBS-2003              connected
   ```

Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- General troubleshooting tips for FSSO
- Users on a particular computer (IP address) can not access the network
- Guest users do not have access to network

General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- Ensure all firewalls are allowing the FSSO required ports through.

  FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP).
- Ensure there is at least 64kbps bandwidth between the FortiGate unit and domain controllers. If there is insufficient bandwidth, some FSSO information might not reach the FortiGate unit. The best solution is to configure traffic shaping between the FortiGate unit and the domain controllers to ensure that the minimum bandwidth is always available.

Users on a particular computer (IP address) can not access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the authentication system to become confused and believe that the user on computer_1 is actually trying to access computer_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediate logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

Guest users do not have access to network

A group of guest users was created, but they don't have access.

Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called `FSSO_Guest_Users`. Ensure that group is part of an identity-based security policy to allow traffic.

Agent-based FSSO

FortiOS can provide single sign-on capabilities to Windows AD, Citrix, or Novell eDirectory users with the help of agent software installed on these networks. The agent software sends information about user logons to the FortiGate unit. With user information such as IP address and user group memberships from the network, FortiGate security policies can allow authenticated network access to users who belong to the appropriate user groups without requesting their credentials again.

For Windows AD networks, FortiGate units can provide SSO capability without agent software by directly polling the Windows AD domain controllers. For information about this type of SSO, see "Single Sign-On to Windows AD" on page 554.

The following topics are included:

Introduction to agent-based FSSO

Fortinet Single Sign-On (FSSO), through agents installed on the network, monitors user logons and passes that information to the FortiGate unit. When a user logs on at a workstation in a monitored domain, FSSO

- detects the logon event and records the workstation name, domain, and user,
- resolves the workstation name to an IP address,
- determines which user groups the user belongs to,
- sends the user logon information, including IP address and groups list, to the FortiGate unit
- creates one or more log entries on the FortiGate unit for this logon event as appropriate.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups associated with that policy, the connection is allowed. Otherwise the connection is denied.

FSSO can also provide NTLM authentication service for requests coming from FortiGate. SSO is very convenient for users, but may not be supported across all platforms. NTLM is not as convenient, but it enjoys wider support. See "FSSO NTLM authentication support" on page 569.

Introduction to FSSO agents

There are several different FSSO agents that can be used in an FSSO implementation.

- Domain Controller (DC) agent
- eDirectory agent
- Citrix/Terminal Server (TS) agent
- Collector (CA) agent

Consult the latest FortiOS and FSSO Release Notes for operating system compatibility information.

Domain Controller (DC) agent

The Domain Controller (DC) agent must be installed on every domain controller if you will use DC Agent mode, but is not required if you use Polling mode. See "FSSO for Windows AD" on page 565.

eDirectory agent

The eDirectory agent is installed on a Novell network to monitor user logons and send the required information to the FortiGate unit. It functions much like the Collector agent on a Windows AD domain controller.The agent can obtain information from the Novell eDirectory using either the Novell API or LDAP.

Citrix/Terminal Server (TS) agent

The Citrix/Terminal Server (TS) agent is installed on a Citrix terminal server to monitor user logons in real time. It functions much like the DC Agent on a Windows AD domain controller.

Collector (CA) agent

This agent is installed as a service on a server in the Windows AD network to monitor user logons and send the required information to the FortiGate unit. The Collector agent can collect information from

- Domain Controller agent (Windows AD)
- TS agent (Citrix Terminal Server)

In a Windows AD network, the Collector agent can optionally obtain logon information by polling the AD domain controllers. In this case, DC agents are not needed.

The Collector can obtain user group information from the DC agent or Optionally, a FortiGate unit can obtain group information directly from AD using Lightweight Directory Access Protocol (LDAP).

On a Windows AD network, the FSSO software can also serve NT LAN Manager (NTLM) requests coming from client browsers (forwarded by the FortiGate unit) with only one or more Collector agents installed. See "FSSO NTLM authentication support" on page 569.

The CA is responsible for DNS lookups, group verification, workstation checks, and as mentioned FortiGate updates of logon records. The FSSO Collector Agent sends Domain Local Security Group and Global Security Group information to FortiGate units. The CA communicates with the FortiGate over TCP port 8000 and it listens on UDP port 8002 for updates from the DC agents.

The FortiGate unit can have up to five CAs configured for redundancy. If the first on the list is unreachable, the next is attempted, and so on down the list until one is contacted. See "Configuring FSSO on FortiGate units" on page 589.

All DC agents must point to the correct Collector agent port number and IP address on domains with multiple DCs.

See "Configuring Collector agent settings" on page 577.

A FortiAuthenticator unit can act much like a Collector agent, collecting Windows AD user logon information and sending it to the FortiGate unit. It is particularly useful in large installations with several FortiGate units. For more information, see the FortiAuthenticator Administration Guide.

FSSO for Windows AD

FSSO for Windows AD requires at least one Collector agent. Domain Controller agents may also be required depending on the Collector agent working mode. There are two working modes to monitor user logon activity: DC Agent mode or Polling mode.

Table 25: Collector agent DC Agent mode versus Polling mode

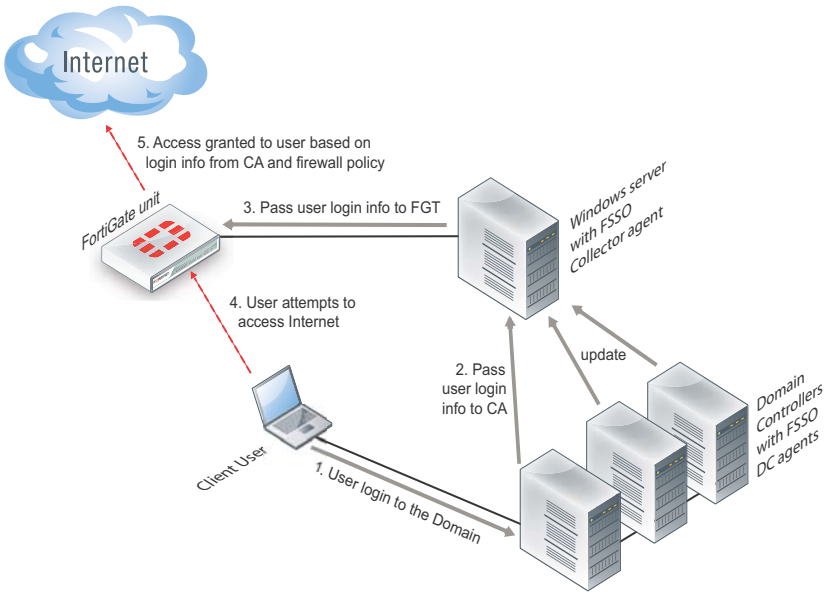
	DC Agent mode	Polling Mode
Installation	Complex — Multiple installations: one agent per DC plus Collector agent, requires a reboot	Easy — only Collector agent installation, no reboot required
Resources	Shares resources with DC system	Has own resources
Network load	Each DC agent requires minimum 64kpbs bandwidth, adding to network load	Increase polling period during busy period to reduce network load
Level of Confidence	Captures all logons	Potential to miss a login if polling period is too great

DC Agent mode

DC Agent mode is the standard mode for FSSO. In DC Agent mode (see Figure 119), a Fortinet authentication agent is installed on each domain controller. These DC agents monitor user logon events and pass the information to the Collector agent, which stores the information and sends it to the FortiGate unit.

The DC agent installed on the domain controllers is not a service like the Collector agent — it is a DLL file called `dcagent.dll` and is installed in the `Windows\system32` directory. It must be installed on all domain controllers of the domains that are being monitored.

Figure 119:FSSO in DC agent mode



DC Agent mode provides reliable user logon information, however you must install a DC agent on every domain controller. A reboot is needed after the agent is installed. Each installation requires some maintenance as well. For these reasons it may not be possible to use the DC Agent mode.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality. You can optionally configure traffic shapers on the FortiGate unit to ensure this minimum bandwidth is guaranteed for the domain controller connections.

Polling mode

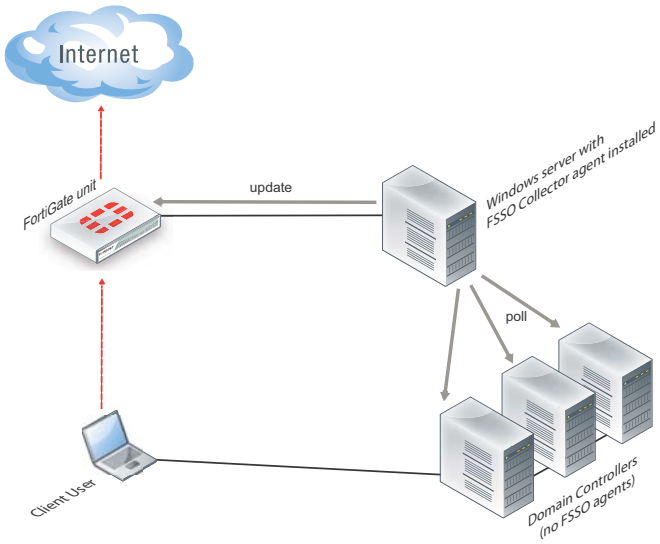
In Polling mode there are two options — NetAPI polling, and Event log polling. Both share the advantages of being transparent and agentless.

NetAPI polling is used to retrieve server logon sessions. This includes the logon event information for the Controller agent. NetAPI runs faster than Event log polling but it may miss some user logon events under heavy system load. It requires a query round trip time of less than 10 seconds.

Event log polling may run a bit slower, but will not miss events, even when the installation site has many users that require authentication. It does not have the 10 second limit or NetAPI polling. Event log polling requires fast network links. Event log polling is required if there are Mac OS users logging into Windows AD.

In Polling mode (see Figure 120), the Collector agent polls port 445 of each domain controller for user logon information every few seconds and forwards it to the FortiGate unit. There are no DC Agents installed, so the Collector agent polls the domain controllers directly.

Figure 120:FSSO in Polling mode



A major benefit of Polling mode is that no FSSO DC Agents are required. If it is not possible to install FSSO DC Agents on your domain controllers, this is the alternate configuration available to you. Polling mode results in a less complex install, and reduces ongoing maintenance. The minimum permissions required in Polling mode are to read the event log or call NetAPI. To install FSSO with minimum permissions, see "Installing FSSO without using an administrator account" on page 574.

Collector agent AD Access mode - Standard versus Advanced

The Collector agent has two ways to access Active Directory user information. The main difference between Standard and Advanced mode is the naming convention used when referring to username information.

Standard mode uses regular Windows convention: Domain\Username. Advanced mode uses LDAP convention: CN=User, OU=Name, DC=Domain.

If there is no special requirement to use LDAP— best practices suggest you set up FSSO in Standard mode. This mode is easier to set up, and is usually easier to maintain and troubleshoot.

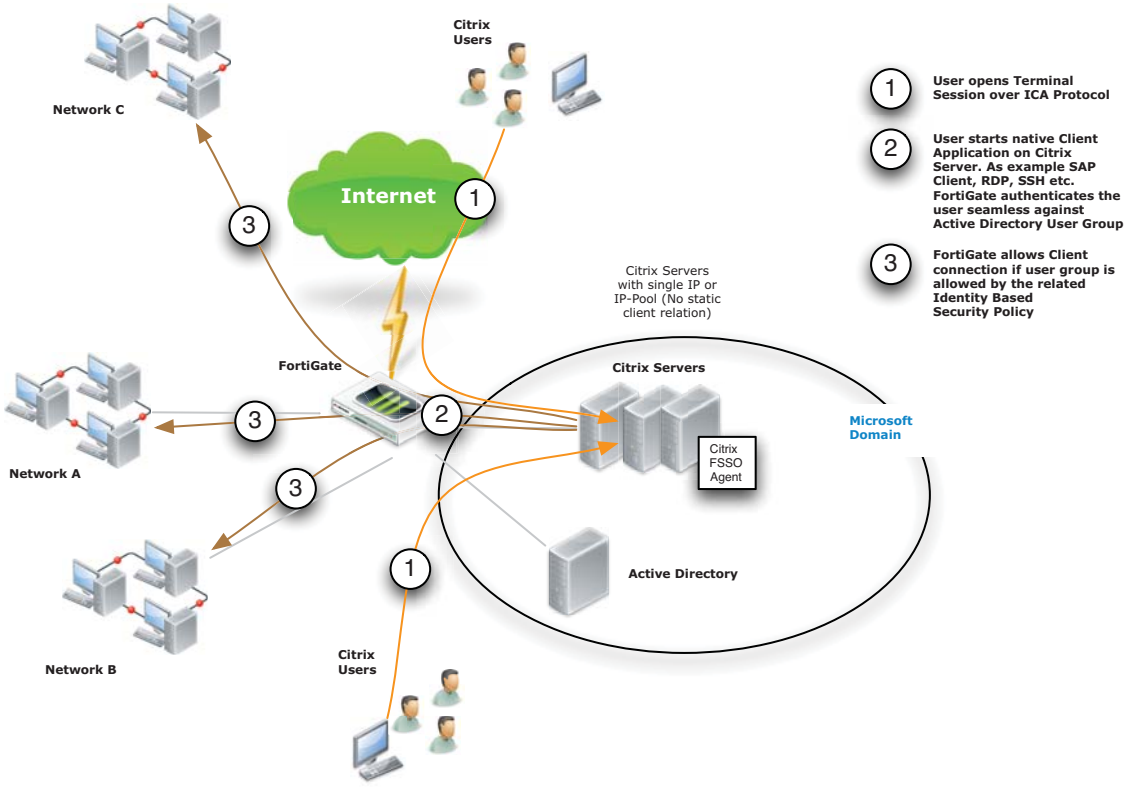
Standard and advanced modes have the same level of functionality with the following exceptions:

1. Users have to create Group filters on the Collector agent. This differs from Advanced mode where Group filters are configured from the FortiGate unit. Fortinet strongly encourages users to create filters from CA.
2. Advanced mode supports nested or inherited groups. This means that users may be a member of multiple monitored groups. Standard mode does not support nested groups so a user must be a direct member of the group being monitored.

FSSO for Citrix

Citrix users can enjoy a similar Single Sign-On experience as Windows AD users. The FSSO TS agent installed on each Citrix server provides user logon information to the FSSO Collector agent on the network. The FortiGate unit uses this information to authenticate the user in security policies.

Figure 121: Citrix SSO topology



Citrix users do not have unique IP addresses. When a Citrix user logs on, the TS agent assigns that user a range of ports. By default each user has a range of 200 ports.

FSSO for Novell eDirectory

FSSO in a Novell eDirectory environment works similar to the FSSO Polling mode in the Windows AD environment. The eDirectory agent polls the eDirectory servers for user logon information and forwards the information to the FortiGate unit. There is no need for the Collector agent.

When a user logs on at a workstation, FSSO:

- detects the logon event by polling the eDirectory server and records the IP address and user ID,
- looks up in the eDirectory which groups this user belongs to,
- sends the IP address and user groups information to the FortiGate unit.

When the user tries to access network resources, the FortiGate unit selects the appropriate security policy for the destination. If the user belongs to one of the permitted user groups, the connection is allowed.

FSSO is supported on the Novell E-Directory 8.8 operating system.

For a Novell network, there is only one FSSO component to install — the eDirectory agent. In some cases, you also need to install the Novell Client.

FSSO security issues

When the different components of FSSO are communicating there are some inherent security features.

FSSO installation requires an account with network admin privileges. The security inherent in these types of accounts helps ensure access to FSSO configurations is not tampered with.

User passwords are never sent between FSSO components. The information that is sent is information to identify a user including the username, group or groups, and IP address.

NTLM uses base-64 encoded packets, and uses a unique randomly generated challenge nonce to avoid sending user information and password between the client and the server. For more information on NTLM, see “FSSO NTLM authentication support” on page 569.

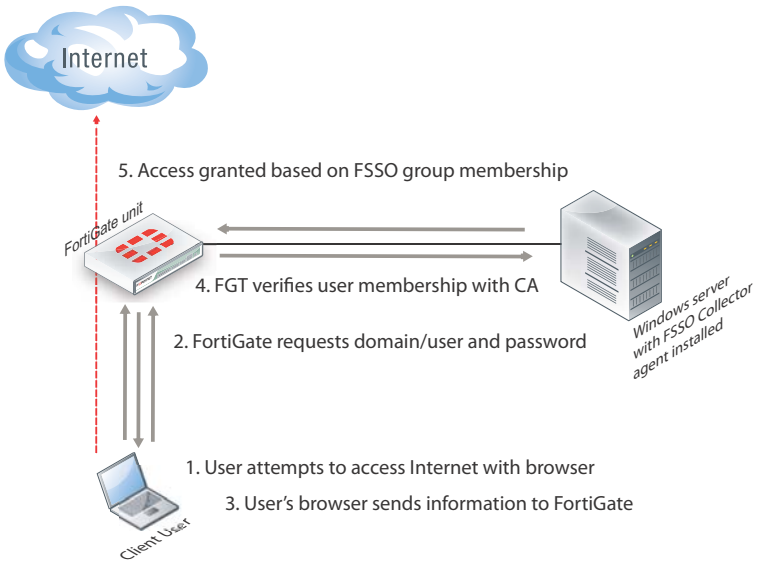
FSSO NTLM authentication support

In a Windows AD network, FSSO can also provide NTLM authentication service to the FortiGate unit. When the user makes a request that requires authentication, the FortiGate unit initiates NTLM negotiation with the client browser. The FortiGate unit does not process the NTLM packets itself. Instead, it forwards all the NTLM packets to the FSSO service to process.

NTLM has the benefit of not requiring an FSSO agent, but it is not transparent to users, and the user’s web browser must support NTLM.

The NTLM protocol protects the user’s password by not sending it over the network. Instead, the server sends the client a random number that the client must encrypt with the hash value of the user's password. The server compares the result of the client's encryption with the result of its own encryption. The two will match only if both parties used the same password.

Figure 122:NTLM authentication



If the NTLM authentication with the Windows AD network is successful, and the user belongs to one of the groups permitted in the applicable security policy, the FortiGate unit allows the connection.

Fortinet has tested NTLM authentication with Internet Explorer and Firefox browsers.

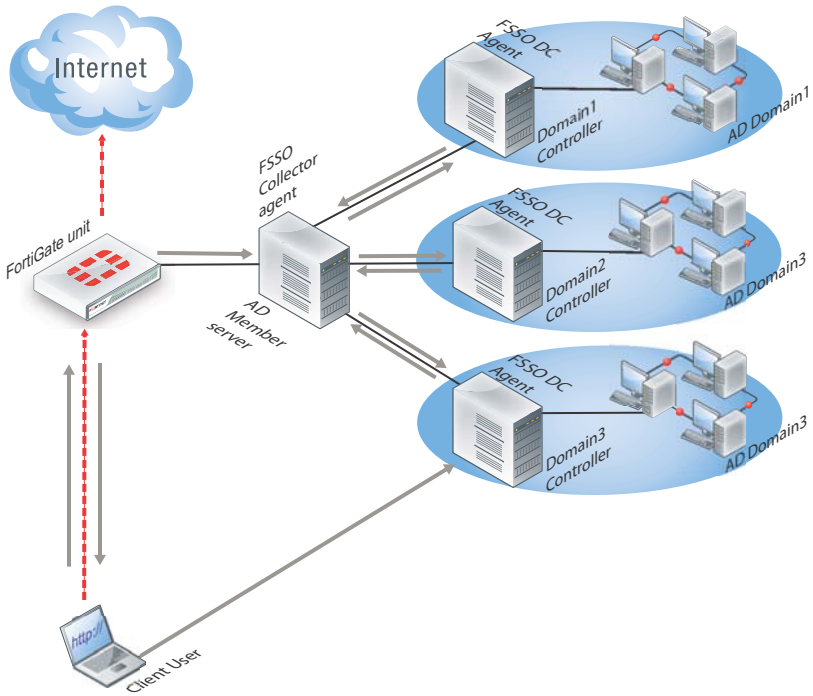
NTLM in a multiple domain environment

In a multiple domain environment for NTLM, the important factor is that there is a trust relation between the domains. In a forest, this relation is automatically created. So you can install FSSO agent on one of the domain controllers without worry.

But in case of multiple domains that are not in a forest, you need to create a trust relation between the domains. If you do not want to have a trust relation between your multiple domains, you need to use FSAE 4.0 MR1 and the DC agent needs to be installed once on each domain. Then you can use security policies to configure server access.

In Figure 123, three domains are shown connected to the FSSO Collector agent server. The Client logs on to their local Domain Controller, which then sends the user logon event information to the Collector Agent. When the Client attempts to access the Internet, the FortiGate unit contacts the Collector Agent for the logon information, sees the Client is authenticated, and allows access to the Internet. There are multiple domains each with a domain controller agent (DCagent) that sends logon information to the Collector agent. If the multiple domains have a trust relationship, only one DCagent is required instead of one per domain.

Figure 123:FSSO NTLM with multiple domains not in a forest



Understanding the NTLM authentication process

1. The user attempts to connect to an external (internet) HTTP resource. The client application (browser) on the user's computer issues an unauthenticated request through the FortiGate unit.
2. The FortiGate is aware that this client has not authenticated previously, so responds with a `401 Unauthenticated` status code, and tells the client which authentication method to reply with in the header: `Proxy-Authenticated: NTLM`. Then the initial session is dismantled.
3. The client application connects again to the FortiGate, and issues a GET-request, with a `Proxy-Authorization: NTLM <negotiate string>` header. `<negotiate-string>` is a base64-encoded NTLM Type 1 negotiation packet.

4. The FortiGate unit replies with a `401 "proxy auth required"` status code, and a `Proxy-Authenticate: NTLM <challenge string>` (a base 64-encoded NTLM Type 2 challenge packet). In this packet is the challenge nonce, a random number chosen for this negotiation that is used once and prevents replay attacks.

The TCP connection must be kept alive, as all subsequent authentication-related information is tied to the TCP connection. If it is dropped, the authentication process must start again from the beginning.

5. The client sends a new GET-request with a header: `Proxy-Authenticate: NTLM <authenticate string>`, where `<authenticate string>` is a NTLM Type 3 Authentication packet that contains:
6. username and domain
7. the challenge nonce encoded with the client password (it may contain the challenge nonce twice using different algorithms).

If the negotiation is successful and the user belongs to one of the groups permitted in the security policy, the connection is allowed, Otherwise, the FortiGate unit denies the authentication by issuing a 401 return code and prompts for a username and password. Unless the TCP connection is broken, no further credentials are sent from the client to the proxy.

If the authentication policy reaches the authentication timeout period, a new NTLM handshake occurs.

Agent installation

After reading the appropriate sections of "Introduction to agent-based FSSO" on page 563 to determine which FSSO agents you need, you can proceed to perform the necessary installations.

Ensure you have administrative rights on the servers where you are installing FSSO agents. It is best practice to install FSSO agents using the built-in local administrator account. Optionally, you can install FSSO without an admin account. See "Installing FSSO without using an administrator account" on page 574.

In Windows 2008 by default, you do not have administrative user rights if you are logged on as a user other than as the built-in administrator, even if you were added to the local Administrators group on the computer.

The FSSO installer first installs the Collector agent. You can then continue with installation of the DC agent, or you can install it later by going to *Start* > *Programs* > *Fortinet* >

Fortinet Single Sign On Agent > *Install DC Agent*. The installer will install a DC agent on the domain controllers of all of the trusted domains in your network.

Each domain controller connection needs a minimum guaranteed 64kpbs bandwidth to ensure proper FSSO functionality.Traffic shapers configured on the FortiGate can help guarantee these minimum bandwidths.

Collector agent installation

To install FSSO, you must obtain the FSSO_Setup file from the Fortinet Support web site. This is available as either an executable (.exe) or a Microsoft Installer (.msi) file. Then you follow these two installation procedures on the server that will run the Collector agent. This can be any server or domain controller that is part of your network. These procedures also installs the DC Agent on all of the domain controllers in your network.

To install the Collector agent

1. Create an account with administrator privileges and a password that does not expire. See Microsoft Advanced Server documentation for help with this task.

   To use a non-admin read only account, see "Installing FSSO without using an administrator account" on page 574.
2. Log on to the account that you created in Step 1.
3. Double-click the `FSSOSetup.exe` file.
4. The Fortinet SSO Collector Agent Setup Wizard starts.
5. Select *Next*.
6. Read and accept the license agreement. Select *Next*.
7. Optionally, you can change the installation location. Select *Next*.
8. Optionally, change the *User Name*.

   By default, the agent is installed using the currently running account. If you want FSSO to use another existing admin account, change the *User Name* using the format DomainName \ UserName. For example if the account is `jsmith` and the domain is *example_corp* you would enter `example_corp\jsmith`.
9. In the *Password* field, enter the password for the account listed in the *User Name* field.
10. Select *Next*.
11. Enable as needed:
    - *Monitor user logon events and send the information to the FortiGate unit*
    - *Serve NTLM authentication requests coming from FortiGate*

    By default, both methods are enabled. You can change these options after installation.
12. Select the access method to use for Windows Directory:
    - Select *Standard* to use Windows domain and username credentials.
    - Select *Advanced* if you will set up LDAP access to Windows Directory.

    See "Collector agent AD Access mode - Standard versus Advanced" on page 567.
13. Select *Next* and then select *Install*.
14. If you want to use DC Agent mode, ensure that *Launch DC Agent Install Wizard* is selected. This will start DC agent installation immediately after you select *Finish*.
15. Select *Finish*.

If you see an error such as Service Fortinet Single Sign On agent (service_FSAE) failed to start, there are two possible reasons for this. Verify the user account you selected has sufficient privileges to run the FSSO service. Also verify the computer system you are attempting to install on is a supported operating system and version.

DC agent installation

The FSSO_Setup file contains both the Collector agent and DC Agent installers, but the DC Agent installer is also available separately as either a .exe or .msi file named DCAgent_Setup.

To install the DC Agent

1. If you have just installed the Collector agent, the FSSO - Install DC Agent wizard starts automatically. Otherwise, go to *Start* > *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Install DC Agent*.
2. Select *Next*.
3. Read and accept the license agreement. Select *Next*.
4. Optionally, you can change the installation location. Select *Next*.
5. Enter the *Collector agent IP address*.
6. If the Collector agent computer has multiple network interfaces, ensure that the one that is listed is on your network. The listed *Collector agent listening port* is the default. Only change this if the port is already used by another service.
7. Select *Next*.
8. Select the domains to monitor and select *Next*.
9. If any of your required domains are not listed, cancel the wizard and set up the proper trusted relationship with the domain controller. Then run the wizard again by going to *Start* > *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Install DC Agent*.
10. Optionally, select users that you do not want monitored. These users will not be able to authenticate to FortiGate units using FSSO. You can also do this later. See "Configuring the FSSO Collector agent for Windows AD" on page 576.
11. Select *Next*.
12. Optionally, clear the check boxes of domain controllers on which you do not want to install the DC Agent.
13. Select the *Working Mode* as DC Agent Mode. While you can select Polling Mode here, in that situation you would not be installing a DC Agent. For more information, see "DC Agent mode" on page 565 and "Polling mode" on page 566.
14. Select *Next*.
15. Select *Yes* when the wizard requests that you reboot the computer.

If you reinstall the FSSO software on this computer, your FSSO configuration is replaced with default settings.

If you want to create a redundant configuration, repeat the procedure "To install the Collector agent" on page 572 on at least one other Windows AD server.

When you start to install a second Collector agent, cancel the Install Wizard dialog appears the second time. From the configuration GUI, the monitored domain controller list will show your domain controllers un-selected. Select the ones you wish to monitor with this Collector agent, and select *Apply*.

Before you can use FSSO, you need to configure it on both Windows AD and on the FortiGate units. "Configuring FSSO on FortiGate units" on page 589 will help you accomplish these two tasks.

Installing FSSO without using an administrator account

Normally when installing services in Windows, it is best to use the Domain Admin account, as stated earlier. This ensures installation goes smoothly and uninterrupted, and when using the FSSO agent there will be no permissions issues. However, it is possible to install FSSO with a non-admin account in Windows 2003 or 2008 AD.

The following instructions for Windows 2003 are specific to the event log polling mode only. Do not use this procedure with other FSSO configurations.

Windows 2003

There are two methods in Windows 2003 AD for installing FSSO without an admin account — add the non-admin user to the security log list, and use a non-admin account with read-only permissions. A problem with the first method is that full rights (read, write, and clear) are provided to the event log. This can be a problem when audits require limited or no write access to logs. In those situations, the non-admin account with read-only permissions is the solution.

To add the non-admin user account to the Windows 2003 security log list

1. *Go to Default Domain Controller Security Settings > Security Settings > User Rights Assignment > Manage auditing and security log*.
2. Add the user account to this list.
3. Repeat these steps on every domain controller in Windows 2003 AD.
4. A reboot is required.

To use a non-admin account with read-only permissions to install FSSO on Windows 2003

The following procedure provides the user account specified with read only access to the Windows 2003 AD Domain Controller Security Event Log which allows FSSO to function.

1. Find out the SID of the account you intend to use.

   Tools for this can be downloaded for free from http://technet.microsoft.com/en-us/sysinternals/bb897417.
2. Then create the permission string. For example:

   `(A;;0x1;;;S-1-5-21-4136056096-764329382-1249792191-1107)`

   `A` means Allow,

   `0x1` means Read, and

   `S-1-5-21-4136056096-764329382-1249792191-1107` is the SID.
3. Then, append it to the registry key

4. `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\Eventlog\Security\CustomSD`.
5. Repeat these steps on every domain controller in Windows 2003 AD.
6. A reboot is required.

Windows 2008

In Windows 2008 AD, if you do not want to use the Domain Admin account then the user account that starts the FSSO agent needs to be added to the Event Log Readers group.

When the user is added to the Event Log Readers group, that user is now allowed to have read only access to the event log and this is the minimal rights required for FSSO to work.

Citrix TS agent installation

To install the Citrix TS agent, you must obtain the TSAgent_Setup file from the Fortinet Support web site. Perform the following installation procedure on the Citrix server.

To install the FSSO TS agent

1. On the Citrix server, create an account with administrator privileges and a password that does not expire. See Citrix documentation for more information.
2. Log on to the account that you created in Step 1.
3. Double-click the TSAgent_Setup installation file.

   The Fortinet SSO Terminal Server Agent Setup Wizard starts.
4. Select *Next*.
5. Read and accept the license agreement. Select *Next*.
6. Optionally, you can change the installation location. Select *Next*.
7. Verify that *This Host IP Address* is correct.
8. In the *FSSO Collector Agent List*, enter the IP address(es) of your Collector Agents.
9. Select *Next* and then select *Install*.

   The TS agent is installed.
10. Select *Finish*.

Novell eDirectory agent installation

To install the eDirectory agent, you must obtain the FSSO_Setup_eDirectory file from the Fortinet Support web site. Perform the following installation procedure on the computer that will run the eDirectory agent. This can be any server or domain controller that is part of your network. You will need to provide some setup information in step 7.

To install the FSSO eDirectory agent

1. Create an account with administrator privileges and a password that does not expire. See Novell documentation for more information.
2. Log on to the account that you created in Step 1.
3. Double-click the FSSO_Setup_edirectory file to start the installation wizard.
4. Select *Next*.
5. Read and accept the license agreement. Select *Next*.
6. Optionally, change the installation location. Select *Next*.

7. Enter:

eDirectory Server	
Server Address	Enter the IP address of the eDirectory server.
Use secure connection (SSL)	Select to connect to the eDirectory server using SSL security.
Search Base DN	Enter the base Distinguished Name for the user search.
eDirectory Authentication	
Username	Enter a username that has access to the eDirectory, using LDAP format.
User password	Enter the password.

8. Select *Next*.
9. Select *Install*. When the installation completes, select *Finish*.

Updating FSSO agents on Windows AD

After FSSO is installed on your network, you may want to upgrade to a newer version. The following procedure helps ensure you have a trouble free upgrade. How you update FSSO depends on if you are using polling mode or DCAgent mode.

For polling mode, since there are no DC agents you only need to upgrade the Collector. However in DCAgent mode, each DC Agent must be updated as well.

To update FSSO in DC Agent mode

1. Go to the system32 directory on all DC's and rename the `dcagent.dll` file to `dcagent.dll.old`.

   This ensures the when the upgrade is pushed to the DC it does not overwrite the old file. If there are any problems this makes it easy to revert to the old version.
2. Run the FSSO setup .exe file to update the collector. When this is completed, ignore any reboot message.
3. Go to *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Install DC Agent* and push the DC agent out to all servers. All DC's will now need to be rebooted so that the new DLL file is loaded.
4. After the reboot, go to all DC's and delete the `dcagent.dll.old` files.

Configuring the FSSO Collector agent for Windows AD

On the FortiGate unit, security policies control access to network resources based on user groups. With Fortinet Single Sign On, this is also true but each FortiGate user group is associated with one or more Windows AD user groups. This is how Windows AD user groups get authenticated in the FortiGate security policy.

Fortinet Single Sign On sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate units.

To avoid this problem, you can configure the Fortinet Single Sign On Collector agent to send logon information only for groups named in the FortiGate unit's security policies. See "Configuring FortiGate group filters" on page 583.

On each server with a Collector agent, you will be

- Configuring Windows AD server user groups
- Configuring Collector agent settings, including the domain controllers to be monitored
- Configuring Directory Access settings
- Configuring the Ignore User List
- Configuring FortiGate group filters for each FortiGate unit
- Configuring FSSO ports
- Configuring alternate user IP address tracking

In some environments where user IP addresses change frequently, it might be necessary to configure the alternate IP address tracking method. For more information, see "Configuring alternate user IP address tracking" on page 585.

Configuring Windows AD server user groups

FortiGate units control network resource access at the group level. All members of a user group have the same network access as defined in FortiGate security policies.

You can use existing Windows AD user groups for authentication to FortiGate units if you intend that all members within each group have the same network access privileges.

Otherwise, you need to create new user groups for this purpose.

If you change a user's group membership, the change does not take effect until the user logs off and then logs on again.

The FSSO Agent sends only Domain Local Security Group and Global Security Group information to FortiGate units. You cannot use Distribution group types for FortiGate access. No information is sent for empty groups.

Refer to Microsoft documentation for information about creating and managing Windows AD user groups.

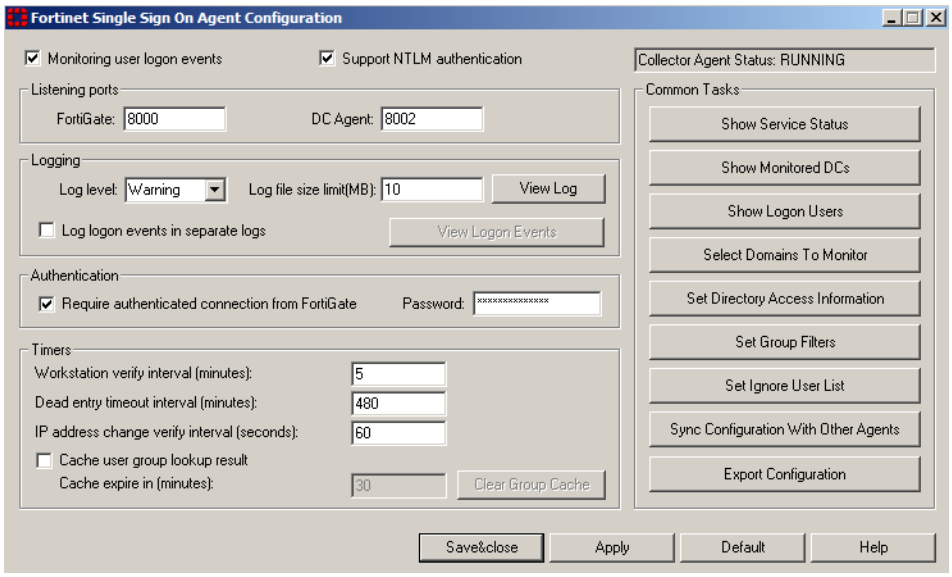
Configuring Collector agent settings

You need to configure which domain controllers the Collector agent will use and which domains to monitor for user logons. You can also alter default settings and settings you made during installation. These tasks are accomplished by configuring the FSSO Collector Agent, and selecting either Apply to enable the changes.

At any time to refresh the FSSO Agent settings, select Apply.

To configure the Collector agent

1. From the Start menu, select *Programs* > *FortiNet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.



2. Enter the following information.

Monitoring user logon events	By default, this is enabled to automatically authenticate users as they log on to the Windows domain. Disable the Monitor feature only if you have a large network where this feature will slow responses too much.
Support NTLM authentication	By default, this is enabled to facilitate logon of users who are connected to a domain that does not have the FSSO DC Agent installed. Disable NTLM authentication only if your network does not support NTLM authentication for security or other reasons.
Collector Agent Status	Shows RUNNING when Collector agent is active.
Listening ports	You can change FSSO Collector Agent related port numbers if necessary.
FortiGate	TCP port for FortiGate units. Default 8000.
DC Agent	UDP port for DC Agents. Default 8002.
Logging	
Log level	Select the minimum severity level of logged messages.
Log file size limit (MB)	Enter the maximum size for the log file in MB.
View Log	View all Fortinet Single Sign On agent logs.

Log logon events in separate logs	Record user login-related information separately from other logs. The information in this log includes • data received from DC agents • user logon/logoff information • workstation IP change information • data sent to FortiGate units
View Logon Events	If *Log logon events in separate logs* is enabled, you can view user login-related information.
Authentication	
Require authenticated connection from FortiGate	Select to require the FortiGate unit to authenticate before connecting to the Collector agent.
Password	Enter the password that FortiGate units must use to authenticate. The maximum password length is 16 characters. The default password is “fortinetcanada”.
Timers	
Workstation verify interval (minutes)	Enter the interval in minutes at which the Fortinet Single Sign On Collector agent connects to client computers to determine whether the user is still logged on. The default is every 5 minutes. The interval may be increased if your network has too much traffic. ***Note:*** This verification process creates security log entries on the client computer. If ports 139 or 445 cannot be opened on your network, set the interval to 0 to prevent checking. See “Configuring FSSO ports” on page 584.
Dead entry timeout interval	Enter the interval in minutes after which Fortinet Single Sign On Agent purges information for user logons that it cannot verify. The default is 480 minutes (8 hours). Dead entries usually occur because the computer is unreachable (such as in standby mode or disconnected) but the user has not logged off. A common reason for this is when users forget to logoff before leaving the office for the day. You can also prevent dead entry checking by setting the interval to 0.

IP address change verify interval	Fortinet Single Sign On Agent periodically checks the IP addresses of logged-in users and updates the FortiGate unit when user IP addresses change. IP address verification prevents users from being locked out if they change IP addresses, as may happen with DHCP assigned addresses. Enter the verification interval in seconds. The default is 60 seconds. You can enter 0 to prevent IP address checking if you use static IP addresses. This does not apply to users authenticated through NTLM.
Cache user group lookup result	Enable caching. Caching can reduce group lookups and increase performance.
Cache expire in (minutes)	Fortinet Single Sign On Agent caches group information for logged-in users. Enter the duration in minutes after which the cache entry expires. If you enter 0, the cache never expires. A long cache expire interval may result in more stale user group information. This can be an issue when a user's group information is changed.
Clear Group Cache	Clear group information of logged-in users. This affects all logged-in users, and may force them to re-logon.

3. You can select *Save&Close* now or leave the agent configuration window open to complete additional configuration in the following sections.

To view the version and build number information for your FSSO Collector Agent configuration, selecting the Fortinet icon in the upper left corner of the Collector agent Configuration screen and select *About Fortinet Single Sign On Agent configuration.*

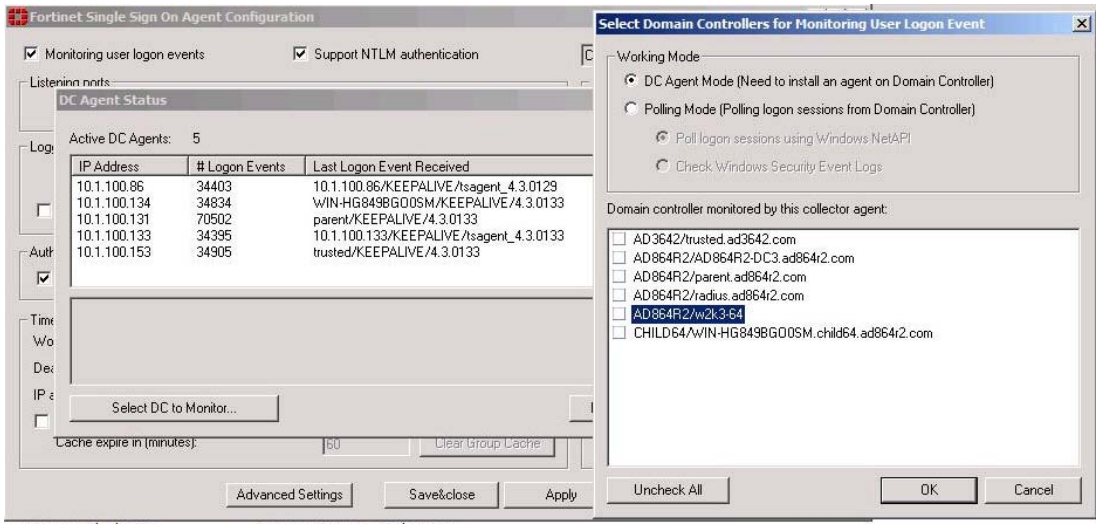
Selecting Domain Controllers and working mode for monitoring

You can change which DC agents are monitored or change the working mode for logon event monitoring between DC agent mode and polling mode.

When polling mode is selected, it will poll port 445 of the domain controller every few seconds to see who is logged on.

1. From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.
2. In the *Common Tasks* section, select *Show Monitored DCs*.

3. Select *Select DC to Monitor*.



4. Choose the *Working Mode*.
   - **DC Agent mode** — a Domain Controller agent monitors user logon events and passes the information to the Collector agent. This provides reliable user logon information, however you must install a DC agent on every domain controller in the domain.
   - **Polling mode** — the Collector agent polls each domain controller for user logon information. Under heavy system load this might provide information less reliably. However installing a DC agent on each domain controller is not required in this mode.

     You also need to choose the method used to retrieve logon information:
     - Poll logon sessions using Windows NetAPI
     - Check Windows Security Event Logs

     For more information about these options, see "Polling mode" on page 566.
5. In *Domain controller monitored by this collector agent*, select the collector agent that you installed.
6. Select *OK*. Select *Close*. Select *Save & Close*.

Configuring Directory Access settings

The FSSO Collector Agent can access Windows Active Directory in one of two modes:

- Standard — the FSSO Collector Agent receives group information from the Collector agent in the *domain\user* format. This option is available on FortiOS 3.0 and later.
- Advanced — the FSSO Collector Agent obtains user group information using LDAP. The benefit of this method is that it is possible to nest groups within groups. This is option is available on FortiOS 3.0 MR6 and later. The group information is in standard LDAP format.

If you change AD access mode, you must reconfigure your group filters to ensure that the group information is in the correct format.

To configure Directory Access settings

1. From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.

2. In the *Common Tasks* section, select *Set Directory Access Information*.
3. The *Set Directory Access Information* dialog box opens.
4. From the *AD access mode* list, select either *Standard* or *Advanced*.
5. If you selected Advanced AD access mode, select *Advanced Setting* and configure the following settings and then select *OK*:

AD server address	Enter the address of your network's global catalog server.
AD server port	The default AD server port is 3268. This must match your server port.
BaseDN	Enter the Base distinguished name for the global catalog. This is the point in the tree that will be considered the starting point by default.
Username	If the global catalog accepts your Fortinet Single Sign On Agent agent's credentials, you can leave these fields blank. Otherwise, enter credentials for an account that can access the global catalog.
Password	

BaseDN example

An example DN for Training Fortinet, Canada is `DN = ou=training, ou=canada, dc=fortinet, dc=com`. If you set the *BaseDN* to `ou=canada, dc=fortinet, dc=com` then when Fortinet Single Sign On Agent is looking up user credentials, it will only search the Canada organizational unit, instead of all the possible countries in the company. Its a short cut to entering less information and faster searches.

However, you may have problems if you narrow the BaseDN too much when you have international employees from the company visiting different offices. If someone from Fortinet Japan is visiting the Canada office in the example above, their account credentials will not be matched because they are in `DN = ou=japan, dc=fortinet, dc=com` instead of the BaseDN `ou=canada, dc=fortinet, dc=com`. The easy solution is to change the BaseDN to simply be `dc=fortinet, dc=com`. Then any search will check all the users in the company.

Configuring the Ignore User List

The Ignore User List excludes users that do not authenticate to any FortiGate unit, such as system accounts. The logons of these users are not reported to FortiGate units. This reduces the amount of required resources on the FortiGate unit especially when logging logon events to memory.

To configure the Ignore User List

1. From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.
2. In the *Common Tasks* section, select *Set Ignore User List*.

   The current list of ignored users is displayed. To view ignored usernames, expand each domain.
3. Do any of the following:
   - To remove a user from the list, select the check box beside the username and then select *Remove*. The user's login is no longer ignored.
   - To add users to be ignored, select *Add*, select the check box beside each required username, and then select *Add*.
4. Select *OK*.

Configuring FortiGate group filters

FortiGate group filters actively control which user logon information is sent to each FortiGate unit. You need to configure the group filter list so that each FortiGate unit receives the correct user logon information for the user groups that are named in its security policies. These group filters help limit the traffic sent to the FortiGate unit, and help limit the logon events logged.

The maximum number of Windows AD user groups allowed on a FortiGate depends on the model. Low end models up to 300A support 256 Windows AD user groups, where mid and high end models support 1024 groups. This is per VDOM if VDOMs are enabled on the FortiGate unit.

You do not need to configure a group filter on the Collector agent if the FortiGate unit retrieves group information from Windows AD using LDAP. In that case, the Collector agent uses the list of groups you selected on the FortiGate unit as its group filter.

The filter list is initially empty. You need to configure filters for your FortiGate units using the Add function. At a minimum, create a default filter that applies to all FortiGate units without a defined filter.

If no filter is defined for a FortiGate unit and there is no default filter, the Collector agent sends all Windows AD group and user logon events to the FortiGate unit. While this normally is not a problem, limiting the amount of data sent to the FortiGate unit improves performance by reducing the amount of memory the unit uses to store the group list and resulting logs.

To configure a FortiGate group filter

1. From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.
2. In the *Common Tasks* section, select *Set Group Filters*.

   The FortiGate Filter List opens. It has the following columns:

FortiGate SN	The serial number of the FortiGate unit to which this filter applies.
Description	An optional description of the role of this FortiGate unit.
Monitored Groups	The Windows AD user groups that are relevant to the security policies on this FortiGate unit.
Add	Create a new filter.
Edit	Modify the filter selected in the list.
Remove	Remove the filter selected in the list.
OK	Save the filter list and exit.
Cancel	Cancel changes and exit.

3. Select *Add* to create a new filter. If you want to modify an existing filter, select it in the list and then select *Edit*.

4. Enter the following information and then select *OK*.

Default filter	Select to create the default filter. The default filter applies to any FortiGate unit that does not have a specific filter defined in the list.
FortiGate Serial Number	Enter the serial number of the FortiGate unit to which this filter applies. This field is not available if Default is selected.
Description	Enter a description of this FortiGate unit's role in your network. For example, you could list the resources accessed through this unit. This field is not available if Default is selected.
Monitor the following groups	The Collector agent sends to the FortiGate unit the user logon information for the Windows AD user groups in this list. Edit this list using the Add, Advanced and Remove buttons.
Add	In the preceding single-line field, enter the Windows AD domain name and user group name, and then select Add. If you don't know the exact name, use the Advanced button instead. The format of the entry depends on the AD access mode (see "Configuring Directory Access settings" on page 581): Standard: Domain\Group Advanced: cn=group, ou=corp, dc=domain
Advanced	Select *Advanced*, select the user groups from the list, and then select *Add*.
Remove	Remove the user groups selected in the monitor list.

Configuring FSSO ports

For FSSO to function properly a small number of TCP and UDP ports must be open through all firewalls on the network. There ports listed in this section assume the default FSSO ports are used.

TCP ports for FSSO agent with client computers

Windows AD records when users log on but not when they log off. For best performance, Fortinet Single Sign On Agent monitors when users log off. To do this, Fortinet Single Sign On Agent needs read-only access to each client computer's registry over TCP port 139 or 445. Open at least one of these ports — ensure it is not blocked by firewalls.

If it is not feasible or acceptable to open TCP port 139 or 445, you can turn off Fortinet Single Sign On Agent logoff detection. To do this, set the Collector agent workstation verify interval to 0. The FSSO Collector Agent assumes that the logged on computer remains logged on for the duration of the Collector agent dead entry timeout interval — by default this is eight hours.

Configuring ports on the Collector agent computer

On the computer where you install the Collector agent, you must make sure that the firewall does not block the listening ports for the FortiGate unit and the DC Agent. By default, these are TCP port 8000 and UDP port 8002. For more information about setting these ports, see "Configuring Collector agent settings" on page 577.

Configuring alternate user IP address tracking

In environments where user IP addresses change frequently, you can configure Fortinet Single Sign On Agent to use an alternate method to track user IP address changes. Using this method, Fortinet Single Sign On Agent responds more quickly to user IP address changes because it directly queries workstation IP addresses to match users and IP addresses.

This feature requires FSAE version 3.5.27 or later, Fortinet Single Sign On Agent any version, and FortiOS 3.0 MR7 or later.

To configure alternate user IP address tracking

1. On the computer where the Collector agent is installed, go to *Start* > *Run*.
2. Enter `regedit` or `regedt32` and select *OK*.

   The Registry Editor opens.
3. Find the registry key HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\collectoragent.
4. Set the supportFSAEauth value (dword) to 00000001.

   If needed, create this new dword.
5. Close the Registry Editor.
6. From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.
7. Select *Apply*.

   The Fortinet Single Sign On Agent service restarts with the updated registry settings.

Viewing FSSO component status

It is important to know the status of both your Collector agents and DC agents.

Viewing Collector agent status

Use the *Show Service Status* to view your Collector agent information in the Status window. The Status window displays:

- the version of the software
- the status of the service
- the number of connected FortiGate units
- connected FortiGate information such as serial number, IP address, and time connected

To view Collector agent status

1. From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.
2. In the *Common Tasks* section, select *Show Service Status*.

The Fortinet Single Sign On Collector agent Status window opens.

Optionally select *Get NTLM statistics* in the Status window to display NTLM information such as number of messages received, processed, failed, in the queue.

Viewing DC agent status

Use the *Show Monitored DCs* to view the status of DC agents.

To view domain controller agent status

1. From the Start menu select *Programs* > *Fortinet* > *Fortinet Single Sign On Agent* > *Configure Fortinet Single Sign On Agent*.

2. In the *Common Tasks* section, select *Show Monitored DCs*.

   For each DC Agent, the following information is displayed:

   - IP address
   - number of logon events received
   - the last logon event
   - when last logon was received.

To change which DC agents are monitored or change the working mode for logon event monitoring, select *Select DC to Monitor*.

Configuring the FSSO TS agent for Citrix

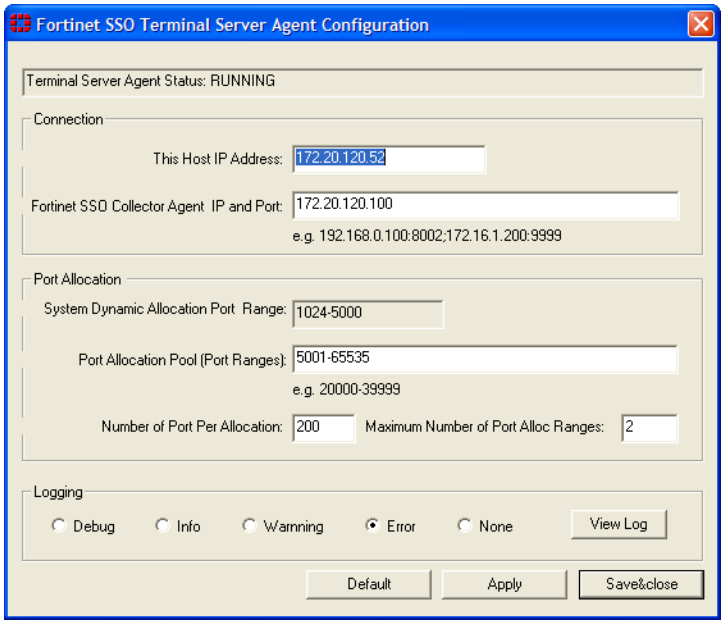
The FSSO TS agent works with the same FSSO Collector agent that is used for integration with Windows Active Directory. Install the Collector agent first. Follow the Collector agent installation procedure in "Collector agent installation" on page 572.

Configuration steps include:

- Install the Fortinet Citrix FSSO agent on the Citrix server.
- Install the Fortinet FSSO collector on a server on the network.
- Add the Citrix FSSO agent to the FortiGate Single-sign-On configuration.
- Add Citrix FSSO groups and users to an FSSO user group.
- Add an FSSO identity-based security policy that includes the Citrix FSSO user groups.

To change the TS agent configuration, select from the Start menu *Programs* > *Fortinet* > *Fortinet Single Sign-On Agent* > *TSAgent Config*. In addition to the host and Collector agent IP addresses that you set during installation, you can adjust port allocations for Citrix users. When a Citrix user logs on, the TS agent assigns that user a range of ports. By default each user has a range of 200 ports.

Figure 124: Configuring the TS agent



Configuring the FSSO eDirectory agent for Novell eDirectory

You need to configure the eDirectory agent for it to communicate with eDirectory servers. You may have provided some of this information during installation.

This section includes:

- Configuring the eDirectory agent
- Adding an eDirectory server
- Configuring a group filter

Configuring the eDirectory agent

You need to configure the eDirectory agent for it to communicate with eDirectory servers.

To configure the eDirectory agent

1. From the Start menu select *Programs* > *Fortinet* > *eDirectory Agent* > *eDirectory Config Utility*.
2. The eDirectory Agent Configuration Utility dialog opens. Enter the following information and select *OK*.

eDirectory Authentication	
Username	Enter a username that has access to the eDirectory, using LDAP format.
Password	Enter the password.
Listening port	Enter the TCP port on which Fortinet Single Sign On Agent listens for connections from FortiGate units. The default is 8000. You can change the port if necessary.
Refresh interval	Enter the interval in seconds between polls of the eDirectory server to check for new logons. The default is 30 seconds.
FortiGate Connection Authentication	
Require authenticated connection from FortiGate	Select to require the FortiGate unit to authenticate before connecting to the eDirectory Agent.
Password	Enter the password that FortiGate units must use to authenticate. The maximum password length is 16 characters. The default password is “FortinetCanada”.
User logon Info Search Method	Select how the eDirectory agent accesses user logon information: *LDAP* or *Native* (Novell API). LDAP is the default. If you select *Native*, you must also have the Novell Client installed on the PC.
Logging	
Log file size limit (MB)	Enter the maximum size for the log file in MB.
View Log	View the current log file.

Dump Session	List the currently logged-on users in the log file. This can be useful for troubleshooting.
Log level	Select *Debug, Info*, *Warning* or *Error* as the minimum severity level of message to log or select *None* to disable logging.
eDirectory Server List	If you specified an eDirectory server during installation, it appears in this list.
Add	Add an eDirectory server. See .
Delete	Delete the selected eDirectory server.
Edit	Modify the settings for the selected server.
Set Group Filters...	Select the user groups whose user logons will be reported to the FortiGate unit. This is used only if user groups are not selected on the FortiGate unit.

Adding an eDirectory server

Once the eDirectory agent is configured, you add one or more eDirectory servers.

To add an eDirectory server

1. In the eDirectory Agent Configuration Utility dialog box (see the preceding procedure, "Configuring the eDirectory agent"), select *Add*.
2. The eDirectory Setup dialog box opens. Enter the following information and select OK:

eDirectory Server Address	Enter the IP address of the eDirectory server.
Port	If the eDirectory server does not use the default port 389, clear the *Default* check box and enter the port number.
Use default credential	Select to use the credentials specified in the eDirectory Configuration Utility. See "Configuring the eDirectory agent" on page 587. Otherwise, leave the check box clear and enter a username and Password below.
User name	Enter a username that has access to the eDirectory, using LDAP format.
User password	Enter the password.
Use secure connection (SSL)	Select to connect to the eDirectory server using SSL security.
Search Base DN	Enter the base Distinguished Name for the user search.

Configuring a group filter

The eDirectory agent sends user logon information to the FortiGate unit for all user groups unless you either configure an LDAP server entry for the eDirectory on the FortiGate unit and select the groups that you want to monitor or configure the group filter on the eDirectory agent.

If both the FortiGate LDAP configuration and the eDirectory agent group filter are present, the FortiGate user group selections are used.

To configure the group filter

1. From the Start menu select *Programs* > *Fortinet* > *eDirectory Agent* > *eDirectory Config Utility*.
2. Select *Set Group Filters*.
3. Do one of the following:
   - Enter group names, then select *Add*.
   - Select *Advanced*, select groups, and then select *Add*.
4. Select *OK*.

Configuring FSSO on FortiGate units

To configure your FortiGate unit to operate with agent-based FSSO, you

- Configure any access to LDAP servers that might be necessary. Skip this step if you are using FSSO Standard mode. See "Configuring LDAP server access" on page 589.
- Specify the Collector agent or Novell eDirectory agent that will provide user logon information. See "Specifying your Collector agents or Novell eDirectory agents" on page 590.
- Add Active Directory user groups to FortiGate user groups. See "Creating Fortinet Single Sign-On (FSSO) user groups" on page 591.
- Create security policies for FSSO-authenticated groups. See "Creating security policies" on page 591.
- Optionally, specify a guest security policy to allow guest access. See "Enabling guest access through FSSO security policies" on page 594.

Configuring LDAP server access

LDAP access is required if your network has a Novell eDirectory agent or a Collector agent using Windows Advanced AD access mode. If you are using FSSO Standard mode, go to "Specifying your Collector agents or Novell eDirectory agents" on page 590.

1. Go to *User & Device* > *Authentication* > *LDAP Servers* and select *Create New*.
2. Enter a *Name* to identify this server in FortiGate configurations.
3. Enter the *Server Name/IP* of the LDAP server.
4. Enter the *Distinguished Name.*
5. Set *Bind Type* to *Regular.*
6. In the *User DN* field, enter the administrative account name that you created for FSSO.

   For example, if the account is FSSO_Admin, enter "cn=FSSO_Admin,cn=users".
7. Make sure that the *User DN* entry ends with a comma and append the string from the *Distinguished Name* field to the end of it.

   Example: cn=FSSO_Admin,cn=users,dc=office,dc=example,dc=com
8. Enter the administrative account password in the *Password* field.
9. Select the *Test* button.

   A pop-up window near the top of the window should indicate "Successful".
10. Select OK.

To configure LDAP for FSSO - CLI example

```
config user ldap
  edit "ADserver"
    set server "10.11.101.160"
    set cnid "cn"
    set dn "cn=users,dc=office,dc=example,dc=com"
    set type regular
    set username
         "cn=administrator,cn=users,dc=office,dc=example,dc=com"
    set password set_a_secure_password
  next
end
```

Specifying your Collector agents or Novell eDirectory agents

You need to configure the FortiGate unit to access at least one Collector agent or Novell eDirectory agent. You can specify up to five servers on which you have installed a Collector or eDirectory agent. The FortiGate unit accesses these servers in the order that they appear in the list. If a server becomes unavailable, the next one in the list is tried.

To specify Collector agents - web-based manager

1. Go to *User & Device* > *Authentication* > *Single Sign-On* and select *Create New*.
2. In *Type*, select *Fortinet Single-Sign-On Agent*.
3. Enter a *Name* for the Windows AD server. This name appears in the list of Windows AD servers when you create user groups.
4. Enter the following information for each of up to five collector agents and select *OK*:

Agent IP/Name	Enter the IP address or the name of the server where this agent is installed. Maximum name length is 63 characters. If the TCP port used for FSSO is not the default, 8000, you can change the setting in the CLI using the `config user fsso` command. See "Configuring Collector agent settings" on page 577 .
Password	Enter the password for the Collector agent or eDirectory agent. For the Collector agent, this is required only if you configured the agent to require authenticated access.

5. For Novell eDirectory or Windows AD with Collector agent in Advanced AD access mode
   a. select the *LDAP Server* you configured previously. See "Configuring LDAP server access" on page 589.
   b. In *Users/Groups*, select the *Edit Users/Groups* tab and then select the users or groups that you want to monitor. Select the *View Users/Groups* tab to check your selection.
6. Select OK.

To specify the FSSO Collector agent - CLI

In this example, the SSO server name is WinAD_1 and the LDAP server is ADserver.

```
config user fsso
  edit WinAD_1
    set ldap-server ADserver
    set password ENC
        G7GQV7NEqilCM9jKmVmJJFVvhQ2+wtNEe9T0iYA5Sa+EqT2J8zhOrbkJFD
        r0RmY3c4LaoXdsoBczA1dONmcGfthTxxwGsigzGpbJdC71spFlQYtj
    set server 10.11.101.160
    set port 8000
  end
config user adgrp
  edit
```

Creating Fortinet Single Sign-On (FSSO) user groups

You cannot use Windows or Novell groups directly in FortiGate security policies. You must create FortiGate user groups of the FSSO type and add Windows or Novell groups to them.

To create a user group for FSSO authentication - web-based manager

1. Go to *User & Device* > *User* > *User Groups*.
2. Select *Create New*.

   The New User Group dialog box opens.
3. In the *Name* box, enter a name for the group, FSSO_Internet_users for example.
4. In *Type*, select *Fortinet Single Sign-On (FSSO)*.
5. From the *Available Members* list, select the required *FSSO* groups.

   Using the CTRL or SHIFT keys, you can select multiple groups.
6. Select the green right arrow button to move the selected groups to the *Members* list.
7. Select *OK*.

To create the FSSO_Internet-users user group - CLI

```
config user group
  edit FSSO_Internet_users
    set group-type fsso-service
    set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
        CN=Sales,cn=users,dc=office,dc=example,dc=com
  end
```

Creating security policies

Policies that require FSSO authentication are very similar to other security policies. Using identity-based policies, you can configure access that depends on the FSSO user group. This allows each FSSO user group to have its own level of access to its own group of services

In this situation, Example.com is a company that has its employees and authentication servers on an internal network. The FortiGate unit intercepts all traffic leaving the internal network and requires FSSO authentication to access network resources on the Internet. The following procedure configures the security policy for FSSO authentication. FSSO is installed and configured including the RADIUS server, FSSO Collector agent, and user groups on the FortiGate

For the following procedure, the internal interface is `port1` and the external interface connected to the Internet is `port2`. There is an address group for the internal network called `company_network`. The FSSO user group is called `fsso_group`, and the FSSO RADIUS server is `fsso_rad_server`.

To configure an FSSO authentication security policy - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Enter the following information.

Policy Type	Firewall
Policy subtype	User Identity
Incoming Interface	port1
Source Address	company_network
Outgoing Interface	port2
Enable NAT	Select

3. In *Configure Authentication Rules*, select *Create New*.
4. Enter

Destination Address	all
Groups	Select from the FSSO user groups that you created earlier. `FSSO_Guest_users` is a default user group enabled when FSSO is configured. It allows guest users on the network who do not have FSSO account to still authenticate and have access to network resources. See "Enabling guest access through FSSO security policies" on page 594.
Schedule	always
Service	HTTP, HTTPS, FTP, and Telnet
Action	ACCEPT
Logging Options	Select Log all Sessions. Logging FSSO logon events helps troubleshoot any FSSO related issues.
UTM Security Profiles	Enable AntiVirus, IPS, Web Filter, and Email Filter default profiles.

5. Select *OK*.

   A new line of information will appear in the identity-based policy table. The table lists the ID, user group or groups, the service or services, schedule, UTM, and logging selected for the rule. Use this display to verify your information was entered correctly.
6. Select OK.
7. Ensure the FSSO authentication policy is at the top of the list so it will be attempted to be matched before any other policy.

To create a security policy for FSSO authentication - CLI

```
config firewall policy
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr company_network
    set dstaddr all
    set action accept
    set identity-based enable
    set nat enable
    config identity-based-policy
      edit 1
        set schedule any
        set groups company_network FSSO_guest_users
        set service HTTP HTTPS FTP TELNET
      end
  end
```

Here is an example of how this FSSO authentication policy is used. Example.com employee on the internal company network logs on to the internal network using their RADIUS username and password. When that user attempts to access the Internet, which requires FSSO authentication, the FortiGate authentication security policy intercepts the session, checks with the FSSO Collector agent to verify the user's identity and credentials, and then if everything is verified the user is allowed access to the Internet.

Users belonging to multiple groups

Before FSSO 4.0 MR3, if a user belonged to multiple user groups, the first security policy to match any group that user belonged too was the only security policy applied. If that specific group did not have access to this protocol or resource where another group did, the user was still denied access. For example, `test_user` belongs to `group1` and `group2`. There are two FSSO authentication policies — one matches `group1` to authenticate FTP traffic and one matches `group2` to authenticate email traffic. The `group1` policy is at the top of the list of policies. If `test_user` wants to access an email server, the first policy encountered for a group `test_user` belongs to is the `group1` policy which does not allow email access and `test_user` is denied access. This is despite the next policy allowing access to email. If the order was reversed in this case, the traffic would be matched and the user's traffic would be allowed through the firewall. However if the policy order was reversed, FTP traffic would not be matched.

As of FSSO 4.0 MR3, if a user belongs to multiple groups multiple then attempts to match the group are attempted if applicable. Using the above example, when the attempt to match the `group1` policy is made and fails, the next policy with a group that `test_user` is a member of is attempted. In this case, the next policy is matched and access is granted to the email server.

When configuring this example the only difference between the policies is the services that are listed and the FSSO user group name.

Authenticating through multiple groups allows administrators to assign groups for specific services, and users who are members of each group have access to those services. For example there could be an FTP group, an email group, and a Telnet group.

Enabling guest access through FSSO security policies

You can enable guest users to access FSSO security policies. Guests are users who are unknown to the Windows AD or Novell network and servers that do not logon to a Windows AD domain.

To enable guest access in your FSSO security policy, add an identity-based policy assigned to the built-in user group `FSSO_Guest_Users`. Specify the services, schedule and protection profile that apply to guest users — typically guests receive reduced access to a reduced set of services. See "Creating security policies" on page 591.

FortiOS FSSO log messages

There are two types of FortiOS log messages — firewall and event. FSSO-related log messages are generated from authentication events. These include user logon and log off events, and NTLM authentication events. These log messages are central to network accounting policies, and can also be useful in troubleshooting issues. For more information on firewall logging, see "Enabling security logging" on page 522. For more information on logging, see the *FortiOS Handbook Log and Reporting chapter*.

Enabling authentication event logging

For the FortiGate unit to log events, that specific type of event must be enabled under logging.

When VDOMs are enabled certain options may not be available, such as CPU and memory usage events. You can enable event logs only when you are logged on to a VDOM; you cannot enable event logs globally.

To ensure you log all the events need, set the minimum log level to Notification or Information. Firewall logging requires Notification as a minimum. The closer to Debug level, the more information will be logged. While this extra information is useful, you must

To enable event logging

1. Go to *Log&Report* > *Log Config* > *Log Settings*.
2. In *Event Logging*, select

System activity event	All system-related events, such as ping server failure and gateway status.
User activity event	All administration events, such as user logins, resets, and configuration updates.

   Optionally you can enable any or all of the other logging event options.
3. Select *Apply*.

Figure 125: Authentication log messages

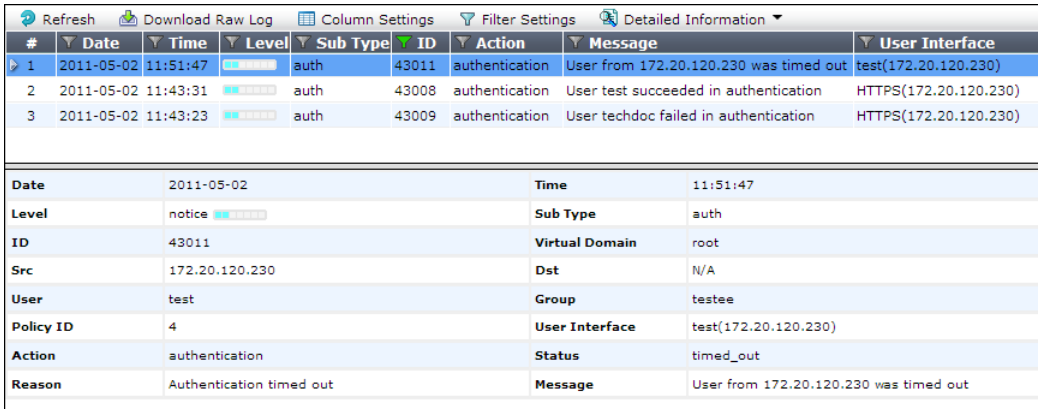


Table 26: List of FSSO related log messages

Message ID	Severity	Description
43008	Notification	Authentication was successful
43009	Notification	Authentication session failed
43010	Warning	Authentication locked out
43011	Notification	Authentication timed out
43012	Notification	FSSO authentication was successful
43013	Notification	FSSO authentication failed
43014	Notification	FSSO user logged on
43015	Notification	FSSO user logged off
43016	Notification	NTLM authentication was successful
43017	Notification	NTLM authentication failed

For more information on logging, see the *FortiOS Handbook Log and Reporting chapter*.

Testing FSSO

Once FSSO is configured, you can easily test to ensure your configuration is working as expected. For additional FSSO testing, see "Troubleshooting FSSO" on page 596.

1. Logon to one of the stations on the FSSO domain, and access an Internet resource.
2. Connect to the CLI of the FortiGate unit, and if possible log the output.
3. Enter the following command:

```
diagnose debug authd fsso list
```

4. Check the output. If FSSO is functioning properly you will see something similar to the following:

```
----FSSO logons----
IP: 192.168.1.230  User: ADMINISTRATOR  Groups: VLAD-AD/DOMAIN USERS
IP: 192.168.1.240  User: ADMINISTRATOR  Groups: VLAD-AD/DOMAIN USERS
Total number of users logged on: 2
----end of FSSO logons----
```

   The exact information will vary based on your installation.

5. Check the FortiGate event log, for FSSO-auth action or other FSSO related events with FSSO information in the message field. For a list of FSSO log message IDs, see Table 26 on page 595.

6. To check server connectivity, run the following commands from the CLI:

```
FGT# diagnose debug enable
FGT# diagnose debug authd fsso server-status
FGT# Server Name           Connection Status
     -----------           -----------------
     SBS-2003              connected
```

Troubleshooting FSSO

When installing, configuring, and working with FSSO some problems are quite common. A selection of these problems follows including explanations and solutions.

Some common Windows AD problems include:

- General troubleshooting tips for FSSO
- User status “Not Verified” on the Collector agent
- After initial configuration, there is no connection to the Collector agent
- FortiGate performance is slow on a large network with many users
- Users from the Windows AD network are not able to access the network
- Users on a particular computer (IP address) can not access the network
- Guest users do not have access to network
- Can’t find the DCagent service
- User logon events not received by FSSO Collector agent
- User list from Windows AD is empty
- Mac OS X users can’t access external resources after waking from sleep mode

General troubleshooting tips for FSSO

The following tips are useful in many FSSO troubleshooting situations.

- To help locate the problem, configure a sniffer policy to capture FSSO logon messages along with other information.

  If FSSO is in use the log messages captured by a sniffer policy will include a user name if the IP address in the log message corresponds to the IP address if a user who has been authenticated with FSSO.
- Ensure all firewalls are allowing the FSSO required ports through.

  FSSO has a number of required ports that must be allowed through all firewalls or connections will fail. These include: ports 139, 389 (LDAP), 445, 636 (LDAP) 8000, and 8002.
- Ensure the Collector agent has at least 64kbps bandwidth to the FortiGate unit.

  If not the Collector agent does not have this amount of bandwidth, information FSSO information may not reach the FortiGate unit resulting in outages. The best solution is to configure traffic shaping between the FortiGate unit and the Collector agent to ensure that minimum bandwidth is always available.

User status “Not Verified” on the Collector agent

When selecting “Show logon Users” in the Collector agent, some users may have their status set as “Not Verified”.

The Collector agent receives logon events for users from the DC agents, but Windows does not generate log out events. As such, the Collector agent needs to verify that the user is still logged on by checking the registry on that host.

If the Collector agent cannot connect to the host on ports 139 and 445 to perform this check, the host status is set to “Not Verified” and a log entry will be added to the Collector agent logs:

```
"01/01/2010 01:23:45 [ 1884] name_ip_match: failed to connect to
     workstation: <Workstation Name> (192.168.1.1)"
```

Solution

There are a few things that can cause the Collector agent not to be able to connect to the user's work station. Below is a list of the most common causes:

- Most commonly, a host firewall on the user's workstation or a router on the network prevents remote access on ports 139 and/or 445. Try opening the ports on the host firewall.
- If the remote registry service is not running on the user's workstation, the Collector agent will not be able to connect to the registry remotely. Make sure the remote registry service is running.
- This problem may also be caused by a known MS upgrade issue.

  Using `Regedit.exe`, edit “`HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\SecurePipeServers`”, set permissions for winreg and allow Local Service with R and W permissions.

After initial configuration, there is no connection to the Collector agent

The Collector Agent has been configured but now cannot be contacted. This may be a regular connectivity problem. The section *Troubleshooting Connectivity* in the *FortiOS Handbook Troubleshooting chapter* will help locate and identify any network problems. Other solutions specific to FSSO are listed here.

Solution

If there are no network problems that can be identified, try the following solutions.

- The Windows AD network must be configured before configuring the FortiGate unit. This includes the domain controller agents, and Collector agents.
- Ensure the DC agents point to the correct collector agent port and IP address.
- Ensure that TCP port 8000, and UDP port 8002 are not blocked.
- FSSO is very dependent on DNS, ensure the forward DNS zone has no stale records and after adding it to the domain if the DNS entry is not in the zone add it.
- An error in the DNI field on the FortiGate unit will prevent connections. Select the browse button next to the field to confirm it can connect correctly to the Windows AD server and return information. See
- If the secure check box is selected, ensure that LDAP v3 is being used since earlier LDAP does not support secure TLS connections.
- Ensure that the default LDAP ports are not being blocked on the network. These ports include port 389, and port 636. If you change the default ports, ensure both the FortiGate unit and the Windows AD server are using the same port numbers and that those ports are allowed through all firewalls on your network.
- If you are using FSSO in polling mode, ensure that port 445 is not blocked by firewalls.

Collector Agent service freezing and shutting down

FSSO problem.

Solution

- Reinstall FSSO.

FortiGate performance is slow on a large network with many users

FSSO sends information about Windows user logons to FortiGate units. If there are many users on your Windows AD domains, the large amount of information might affect the performance of the FortiGate units. Logon tracking is logged to memory, and may reduce performance in extreme situations.

To avoid this problem, you can configure the Collector agent to send logon information only for groups named in the FortiGate unit's security policies. Also you can configure the Ignore User list on the FortiGate unit to avoid tracking unnecessary logons.

Also logging to memory can consume large amounts of FortiGate system memory. To lessen the memory used, change the logging from the default level of Information to a less frequent level such as Error or Warning. This results in less information being logged and frees system memory to improve overall FortiGate system performance. However, if you are trying to troubleshoot a problem one of the first things to do is to change the logging severity to Information or possibly even Debug to provide you with additional information while solving your problem.

Solution

Add users to the Ignore User list. This a best practice for admin accounts whose logon information will not be sent to the FortiGate unit. This is useful for automated accounts that may logon many times. Examples of accounts in this category include:

- IIS services
- AV
- other system accounts

For more information on configuring the Ignore users list, see "Configuring the Ignore User List" on page 582.

Users from the Windows AD network are not able to access the network

If nobody can access the network and your network has only one Collector agent, when it goes offline no users will have access. However if only some users can not access the network, it is likely that user group changes were made recently that are causing the problems.

Solutions

- If there is only one Collector agent, configure additional Collector agents in the domain to act as backups. They will provide the redundancy required if the original collector goes offline. Remember to add them to the Fortinet Single Sign-On Agent entry under *User & Device* > *Authentication* > *Single Sign-On* on the web-based manager or `config user fsso` in the CLI. If the server and port for the new agent are not in the list, it will not be contacted.
- Ensure the Collector agent has at least 64kbps bandwidth to the FortiGate unit. If not, information FSSO information may not reach the FortiGate unit resulting in outages. The best solution is to configure traffic shaping between the FortiGate unit and the Collector agent to ensure that minimum bandwidth is always available.
- If some users can not connect, verify their Windows AD records to find groups in common, and investigate the state of those groups focusing on any recent changes. It may be a group or permission change is the reason.
- There may be a a problem with the user list. See "User list from Windows AD is empty" on page 600.

Users on a particular computer (IP address) can not access the network

Windows AD Domain Controller agent gets the username and workstation where the logon attempt is coming from. If there are two computers with the same IP address and the same user trying to logon, it is possible for the authentication system to become confused and believe that the user on computer_1 is actually trying to access computer_2.

Windows AD does not track when a user logs out. It is possible that a user logs out on one computer, and immediate logs onto a second computer while the system still believes the user is logged on the original computer. While this is allowed, information that is intended for the session on one computer may mistakenly end up going to the other computer instead. The result would look similar to a hijacked session.

Solutions

- Ensure each computer has separate IP addresses.
- Encourage users to logout on one machine before logging onto another machine.
- If multiple users have the same username, change the usernames to be unique.
- Shorten timeout timer to flush inactive sessions after a shorter time.

Guest users do not have access to network

A group of guest users was created, but they don't have access.

Solution

The group of the guest users was not included in a policy, so they do not fall under the guest account. To give them access, associate their group with a security policy.

Additionally, there is a default group called `FSSO_Guest_Users`. Ensure that group is part of an identity-based security policy to allow traffic.

Can't find the DCagent service

The DCagent service can't be found in the list of regular windows services. This is because it has no associated Windows service.

Instead DCagent is really `dcagent.dll` and is located in the `Windows\system32` folder. This DLL file is loaded when windows boots up and it intercepts all logon events processed by the domain controller to send these events to the Collector agent (CA).

Solution

To verify that the DCagent is installed properly

1. Check that DCagent.dll exists in `%windir%\system32` folder.
2. Check that the registry key exists:
   `[HKEY_LOCAL_MACHINE\SOFTWARE\Fortinet\FSAE\dcagent]`

If both exist, the DCagent is properly installed.

User logon events not received by FSSO Collector agent

When a a warning dialog is present on the screen on the Collector agent computer, the Collector agent will not receive any logon events. Once the dialog has been closed normal operation will resume.

If polling mode is enabled, it is possible the polling interval is too large. Use a shorter polling interval to ensure the collector agent is capturing all logon events.

If NetAPI polling mode is enabled, consider switching to Event log polling as it provides letter accuracy.

User list from Windows AD is empty

FSSO server is configured. I have received a list of windows AD groups. However, a user list is empty.

Solution

There could be 2 problems:

In most cases, the FortiGate receives login information, but can't translate the Windows AD group into the protection profile. Make sure that all the required Windows AD groups are included in the FortiGate user groups and that all FortiGate user groups are included into the authentication security policy.

There may be a problem with AD FSSO service running on the Windows AD server.

To ensure the problem is on windows side

1. Go to *Log&Report* > *Log Config*.
2. Enable firewall authentication event logging and debug level logging on the FortiGate.
3. Ask one or more users to log in into windows.
4. Check the FortiGate logs for the logon event from the Windows AD server.

If there is no new logon event entry in the logs, the problem is with Windows side. Use MS Windows AD documentation to troubleshoot the problem.

Mac OS X users can’t access external resources after waking from sleep mode

When client computers running Mac OS X (10.6.X and higher) wake up from sleep mode, the user must authenticate again to be able to access external resources. If the user does not re-authenticate, the user will maintain access to internal web sites, but will be unable to access any external resources.

This issue is caused by Mac OS X not providing sufficient information to the FSAE. This results in the FortiGate blocking access to the user because they cannot be authenticated.

Solution

The security settings on client computer(s) must be configured to require that a username and password be entered when exiting sleep mode or screen saver. With this feature enabled in Mac OS X, the FortiGate will receive the authentication information it requires to authenticate the user and allow them access.

Note that if the user reverts their settings to disable the password requirement, this will cause the issue to reappear.

SSO using RADIUS accounting records

A FortiGate unit can authenticate users transparently who have already authenticated on an external RADIUS server. Based on the user group to which the user belongs, the security policy applies the appropriate UTM profiles. RADIUS SSO is relatively simple because the FortiGate unit does not interact with the RADIUS server, it only monitors RADIUS accounting records that the server emits. These records include the user's IP address and user group.

After the initial set-up, changes to the user database, including changes to user group memberships, are made on the external RADIUS server, not on the FortiGate unit.

This section describes:

User's view of RADIUS SSO authentication

For the user, RADIUS SSO authentication is simple:

- The user connects to the RADIUS server and authenticates.
- The user attempts to connect to a network resource that is reached through a FortiGate unit. Authentication is required for access, but the user connects to the destination without being asked for logon credentials because the FortiGate unit knows that the user is already authenticated. FortiOS applies UTM features appropriate to the user groups that the user belongs to.

Configuration Overview

The general steps to implement RADIUS Single Sign-On are:

1. If necessary, configure your RADIUS server. The user database needs to include user group information and the server needs to send accounting messages.
2. Create the FortiGate RADIUS SSO agent.
3. Define local user groups that map to RADIUS groups.
4. Create an identity-based security policy and create authentication rules as appropriate for the different user groups that are permitted access.

Configuring the RADIUS server

You can configure FortiGate RSSO to work with most RADIUS-based accounting systems. In most cases, you only need to do the following to your RADIUS accounting system:

- Add a user group name field to customer accounts on the RADIUS server so that the name is added to the RADIUS Start record sent by the accounting system to the FortiOS unit. User group names do not need to be added for all users, only to the accounts of users who will use RSSO feature on the FortiGate unit.
- Configure your accounting system to send RADIUS Start records to the FortiOS unit. You can send the RADIUS Start records to any FortiGate network interface. If your FortiGate unit is operating with virtual domains (VDOMs) enabled, the RADIUS Start records must be sent to a network interface in the management VDOM.

Creating the FortiGate RADIUS SSO agent

Once you define a RADIUS SSO (RSSO) agent, the FortiGate unit will accept user logon information from any RADIUS server that has the same shared secret. You can create only one RSSO agent in each VDOM.

Before you create the RSSO agent, you need to allow RADIUS accounting information on the interface that connects to the RADIUS server.

To enable RADIUS access on the interface - web-based manager

1. Go to *System* > *Network* > *Interfaces* and edit the interface to which the RADIUS server connected.
2. Select *Listen for RADIUS Accounting Messages*.
3. Select *OK*.

To enable RADIUS access on the interface - CLI

In this example, the port2 interface is used.

```
config system interface
  edit port2
    append allowaccess radius-acct
  end
```

To create a RADIUS SSO agent

1. Go to *User & Device* > *Authentication* > *Single Sign-On* and select *Create New*.
2. In *Type*, select *RADIUS Single-Sign-On Agent*.
3. Select *Use RADIUS Shared Secret* and enter the RADIUS server shared secret.
4. Select *Send RADIUS Responses*.
5. Select *OK*.

The Single Sign-On agent is named RSSO_Agent.

To create a RADIUS SSO agent - CLI

In this example, the RADIUS server secret is “fortinet”.

```
config user radius
  edit RSSO_Agent
    set rsso enable
    set rsso-validate-request-secret enable
    set rsso-secret fortinet
    set rsso-radius-response enable
  end
```

When the RSSO agent is created in the web-based manager, it is automatically named RSSO_Agent. You can use any name when creating the agent in the CLI.

Selecting which RADIUS attributes are used for RSSO

For RADIUS SSO to work, FortiOS needs to know the user’s endpoint identifier (usually IP address) and RADIUS user group. There are default RADIUS attributes where FortiOS expects this information, but you can change these attributes in the `config user radius` CLI command.

Table 27: RSSO information and RADIUS attribute defaults

RSSO Information	RADIUS Attribute	CLI field
Endpoint identifier	Calling-Station-ID	`rsso-endpoint-attribute`
Endpoint block attribute	Called-Station-ID	`rsso-endpoint-block-attribute`
User group	Class	`sso-attribute`

The Endpoint block attribute can be used to block a user. If the attribute value is “Block”, FortiOS blocks all traffic from that user’s IP address. The RSSO fields are visible only when `rsso` is set to `enable`.

Configuring logging for RSSO

In the `config user radius` CLI command, you can set the following flags in the `rsso-log-flags` field to determine which types of RSSO-related events are logged:

`accounting-event` — FortiOS did not find the expected information in a RADIUS record.

`accounting-stop-missed` — a user context entry expired without FortiOS receiving a RADIUS Stop message.

`context-missing` — FortiOS was not able to match a communication session with a user.

`endpoint-block` — FortiOS blocked a user because the RADIUS record’s endpoint block attribute had the value “Block”.

`profile-missing` — FortiOS cannot find a user group name in a RADIUS start message that matches the name of an RSSO user group in FortiOS.

`protocol-error` — A RADIUS protocol error occurred.

`radiusd-other` — Other events, described in the log message.

Defining local user groups for RADIUS SSO

You cannot use RADIUS user groups directly in security policies. Instead, you create locally-defined user groups on the FortiGate unit and associate each of them with a RADIUS user group.

To define local user groups for RADIUS SSO

1. Go to *User & Device* > *User* > *User Groups* and select *Create New*.
2. Enter a Name for the user group.
3. In *Type*, select *RADIUS Single Sign-On (RSSO)*.
4. In *RADIUS Attribute Value*, enter the name of the RADIUS user group this local user group represents.
5. Select *OK*.

To define local user groups for RADIUS SSO

This example creates an RSSO user group called RSSO-1 that is associated with RADIUS user group “student”.

```
config user group
  edit RSSO-1
    set group-type rsso
    set sso-attribute-value student
  end
```

Creating security policies

RADIUS SSO uses regular identity-based security policies. The RSSO user group you specify determines which users are permitted to use the policy. You can create multiple authentication rules so that various user groups can have different UTM features enabled, different permitted services, schedules, and so on.

To create a security policy for RSSO - web-based manager

1. Go to *Policy* > *Policy* > *Policy*.
2. Select *Create New*.
3. Enter the following information.

Policy Type	Firewall
Policy Subtype	User Identity
Incoming Interface **Source Address** **Outgoing Interface**	as needed
Enable NAT	Selected

4. In *Configure Authentication Rules*, select *Create New* and enter:

Destination Address	all
Group(s)	Select the user groups you created for RSSO. See "Defining local user groups for RADIUS SSO" on page 605.
User(s)	not used
Schedule **Service**	as needed
Action	ACCEPT
UTM Security Profiles	Select UTM security profiles appropriate for the user group.

5. Select *OK*.
6. Repeat steps 4 and 5 for each user group that is allowed to use this security policy. Schedule, Service, and UTM profiles can be different for each group.
7. Select *OK*.

To ensure an RSSO-related policy is matched first, the policy should be placed higher in the security policy list than more general policies for the same interfaces.

To create a security policy for RSSO - CLI

In this example, an internal network to Internet policy enables web access for members of a student group and activates the appropriate UTM profiles.

```
config firewall policy
  edit 0
    set srcintf internal
    set dstintf wan1
    set srcaddr all
    set action accept
    set rsso enable
    set identity-based enable
    set nat enable
    config identity-based-policy
      edit 1
        set schedule always
        set utm-status enable
        set groups "RSSO-student"
        set dstaddr "all"
        set service HTTP HTTPS
        set av-profile students
        set webfilter-profile students
        set spamfilter-profile students
        set dlp-sensor default
        set ips-sensor default
        set application-list students
        set profile-protocol-options "default"
      end
    end
```

Example: webfiltering for student and teacher accounts

The following example uses RADIUS SSO to apply web filtering to students, but not to teachers. Assume that the RADIUS server is already configured to send RADIUS Start and Stop records to the FortiGate unit. There are two RADIUS user groups, *students* and *teachers*, recorded in the default attribute *Class*. The workstations are connected to port1, port2 connects to the RADIUS server, and port3 connects to the Internet.

Configure the student web filter profile

1. Go to *Security Profiles* > *Web Filter* > *Profiles* and select *Create New*.
2. Enter the following and select *Apply*.

Name	student
Inspection Mode	Proxy
FortiGuard Categories	Enable. Right-click the *Potentially Liable* category and select *Block*. Repeat for *Adult/Mature Content* and *Security Risk*.

Enable RADIUS access on the port2 interface

1. Go to *System* > *Network* > *Interfaces* and edit the port2 interface.
2. Select *Listen for RADIUS Accounting Messages*.
3. Select *OK*.

Create the RADIUS SSO agent

1. Go to *User & Device* > *Authentication* > *Single Sign-On* and select *Create New*.
2. In *Type*, select *RADIUS Single-Sign-On*.
3. Select *Use RADIUS Shared Secret* and enter the RADIUS server shared secret.
4. Select *Send RADIUS Responses*.
5. Select *OK*.

The Single Sign-On agent is named RSSO_Agent.

Define local user groups associated with the RADIUS SSO user groups

1. Go to *User & Device* > *User* > *User Groups* and select *Create New*.
2. Enter the following and select *OK*.

Name	RSSO-students
Type	RADIUS Single Sign-On (RSSO)
RADIUS Attribute Value	students

3. Select Create New, enter the following and select *OK*.

Name	RSSO-teachers
Type	RADIUS Single Sign-On (RSSO)
RADIUS Attribute Value	teachers

Create a security policy for RSSO

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Enter

Policy Type	Firewall
Policy Subtype	User Identity
Incoming Interface	port1
Source Address	all
Outgoing Interface	port3
Enable NAT	Selected

3. In *Configure Authentication Rules*, select *Create New* and enter:

Destination Address	all
Group(s)	RSSO-students
Schedule	always
Service	HTTP, HTTPS
Action	ACCEPT
UTM Security Profiles	Enable AntiVirus, Web Filter, IPS. In Web Filter, select the *student* profile.

4. Select *OK*.
5. In *Configure Authentication Rules*, select *Create New* and enter:

Destination Address	all
Group(s)	RSSO-teachers
Schedule	always
Service	ALL
Action	ACCEPT
UTM Security Profiles	Enable AntiVirus and IPS.

6. Select *OK*.
7. Select *OK* to save the policy.
8. Repeat steps 4 and 5 for each user group that is allowed to use this security policy. Schedule, Service, and UTM profiles can be different for each group.
9. Select *OK*.

Monitoring authenticated users

This section describes how to view lists of currently logged-in firewall and VPN users. It also describes how to disconnect users.

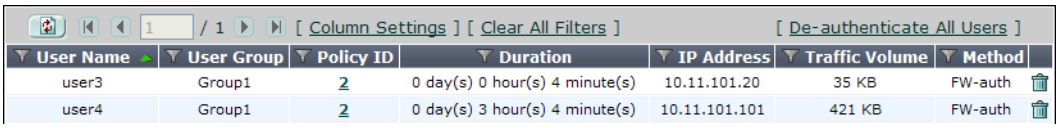
The following topics are included in this section:

- Monitoring firewall users
- Monitoring SSL VPN users
- Monitoring IPsec VPN users

Monitoring firewall users

To monitor firewall users, go to *User & Device* > *Monitor* > *Firewall.*

Figure 126: Firewall users listed in monitor



You can de-authenticate a user by selecting the Delete icon for that entry.

You can filter the list of displayed users either by selecting the funnel icon for one of the column titles or selecting *Filter Settings*.

Select *Column Settings* to add or remove columns to the display, or rearrange the order of the columns displayed.

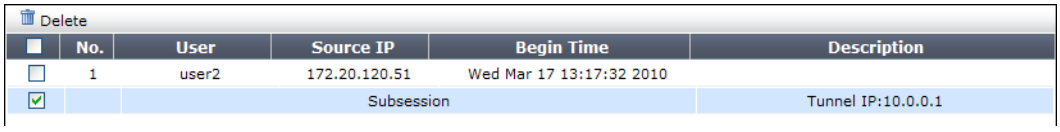
Optionally, you can select *De-authenticate all users*. Best practices dictate that this only be used in extreme cases since all users will momentarily loose their network resource connections.

Monitoring SSL VPN users

You can monitor web-mode and tunnel-mode SSL VPN users by username and IP address.

To monitor SSL VPN users, go to *VPN* > *Monitor* > *SSL-VPN Monitor*. To disconnect a user, select the user and then select the *Delete* icon.

Figure 127: Monitoring SSL VPN users



The first line, listing the username and IP address, is present for a user with either a web-mode or tunnel-mode connection. The Subsession line is present only if the user has a tunnel mode connection. The *Description* column displays the virtual IP address assigned to the user's tunnel-mode connection.

For more information about SSL VPN, see the *FortiOS Handbook SSL VPN chapter.*

To monitor SSL VPN users - CLI

To list all of the SSL VPN sessions and their index numbers:

```
execute vpn sslvpn list
```

The output looks like this:

```
SSL-VPN Login Users:
 Index   User   Auth Type     Timeout        From     HTTPS in/out
 0       user1  1              256    172.20.120.51   0/0

SSL-VPN sessions:
 Index   User    Source IP      Tunnel/Dest IP
 0       user2   172.20.120.51  10.0.0.1
```

You can use the Index value in the following commands to disconnect user sessions:

To disconnect a tunnel-mode user

```
execute vpn sslvpn del-tunnel <index>
```

To disconnect a web-mode user

```
execute vpn sslvpn del-web <index>
```

You can also disconnect multiple users:

To disconnect all tunnel-mode SSL VPN users in this VDOM

```
execute vpn ssl del-all tunnel
```

To disconnect all SSL VPN users in this VDOM

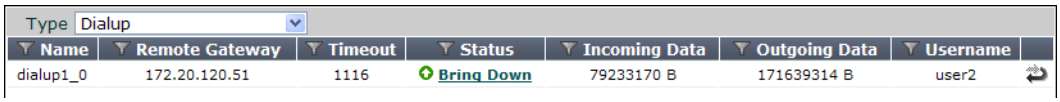
```
execute vpn ssl del-all
```

Monitoring IPsec VPN users

To monitor IPsec VPN tunnels in the web-based manager, go to *VPN* > *Monitor* > *IPsec Monitor*. user names are available only for users who authenticate with XAuth.

You can close a tunnel by selecting its *Bring Down* link in the *Status* column.

Figure 128: Monitoring dialup VPN users



For more information, see the *FortiOS Handbook IPsec chapter*.

Monitoring banned users

The Banned User list shows all IP addresses and interfaces blocked by NAC quarantine. The list also shows all IP addresses, authenticated users, senders, and interfaces blocked by Data Leak Prevention (DLP). The system administrator can selectively release users or interfaces from quarantine or configure quarantine to expire after a selected time period.

All sessions started by users or IP addresses on the Banned User list are blocked until the user or IP address is removed from the list. All sessions to an interface on the list are blocked until the interface is removed from the list.

You can configure NAC quarantine to add users or IP addresses to the Banned User list under the following conditions:

- **Users or IP addresses that originate attacks detected by IPS** - To quarantine users or IP addresses that originate attacks, enable and configure *Quarantine Attackers* in an IPS Sensor Filter.
- **IP addresses or interfaces that send viruses detected by virus scanning** - To quarantine IP addresses that send viruses or interfaces that accept traffic containing a virus, enable *Quarantine Virus Sender* in an antivirus profile.
- **Users or IP addresses that are banned or quarantined by Data Leak Prevention** -Set various options in a DLP sensor to add users or IP addresses to the Banned User list.

For more information, see *FortiOS Handbook UTM chapter*.

Banned users are viewed from *User & Device* > *Monitor* > *Banned User.*

Banned User page Lists all banned users.	
Page Controls	Use to navigate through the list.
Clear	Removes all users and IP addresses from the Banned User list.
#	The position number of the user or IP address in the list.
Ban key	The Ban key.
Application Protocol	The protocol that was used by the user or IP address added to the Banned User list.
Cause or rule	The Fortinet function that caused the user or IP address to be added to the Banned User list. *Cause or rule* can be IPS, Antivirus, or Data Leak Prevention.
Created	The date and time the user or IP address was added to the Banned User list.
Expires	The date and time the user or IP address will be automatically removed from the Banned User list. If *Expires* is *Indefinite*, you must manually remove the user or host from the list.
Delete	Removes the selected user or IP address from the Banned User list.

Monitoring IM users

User lists can be managed to allow or block certain users. Each user can be assigned a policy to allow or block activity for each IM protocol. Each IM function can be individually allowed or blocked providing the administrator the granularity to block the more bandwidth consuming features such as voice chat while still allowing text messaging. The IM user monitor list displays information about instant messaging users who are currently connected. The list can be filtered by protocol. After IM users connect through the firewall, the unit displays which users are

connected. You can analyze the list and decide which users to allow or block. A policy can be configured to handle unknown users.

Active IM users are viewed from *User & Device* > *Monitor* > *IM*.

IM users who are already logged on before changes are made to the IM user profile will not be affected until their next login. You cannot disconnect users who have already logged on by enabling logon blocking.

IM page Lists all active IM users that are currently active. This page allows you to view blocked users as well as users that are currently using a particular IM protocol, such as MSN.	
Protocol	Filter the list by selecting the protocol for which to display current users: AIM, ICQ, MSN, or Yahoo. All current users can also be displayed.
#	The position number of the IM user in the list.
Protocol	The protocol being used.
User Name	The name selected by the user when registering with an IM protocol. The same user name can be used for multiple IM protocols. Each user name/protocol pair appears separately in the list.
Source IP	The IP address where the user initiated the IM session from.
Last Login	The last time the current user used the protocol.
Block	Select to add the user name to the permanent black list. Each user name/protocol pair must be explicitly blocked by the administrator.

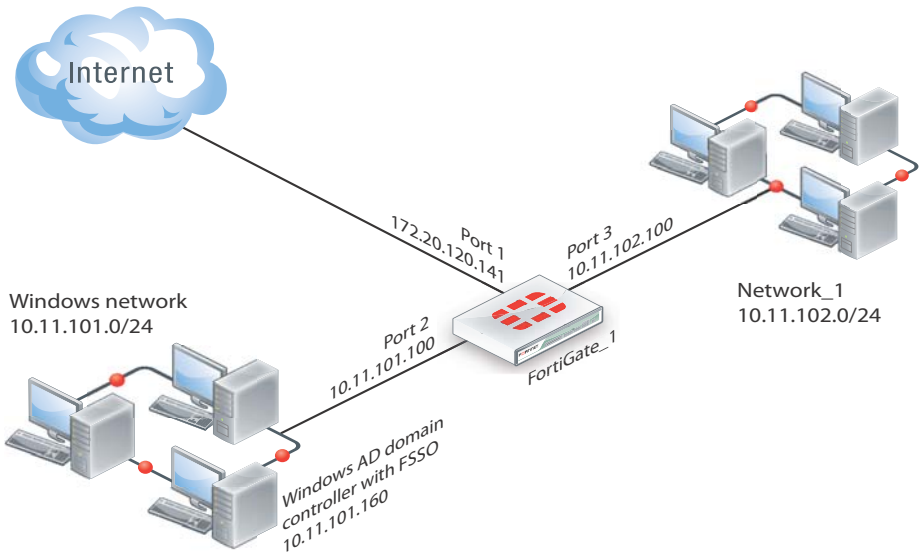
Examples and Troubleshooting

This chapter provides an example of a FortiGate unit providing authenticated access to the Internet for both Windows network users and local users.

The following topics are included in this section:

Firewall authentication example

Figure 129: Example configuration



Overview

In this example, there is a Windows network connected to Port 2 on the FortiGate unit and another LAN, Network_1, connected to Port 3.

All Windows network users authenticate when they logon to their network. Members of the Engineering and Sales groups can access the Internet without entering their authentication credentials again. The example assumes that the Fortinet Single Sign On (FSSO) has already been installed and configured on the domain controller.

LAN users who belong to the Internet_users group can access the Internet after entering their username and password to authenticate. This example shows only two users, User1 is authenticated by a password stored on the FortiGate unit, User2 is authenticated on an external authentication server. Both of these users are referred to as local users because the user account is created on the FortiGate unit.

Creating a locally-authenticated user account

User1 is authenticated by a password stored on the FortiGate unit. It is very simple to create this type of account.

To create a local user - web-based manager

1. Go to *User & Device* > *User* > *User Definition* and select *Create New*.
2. Enter the following information: username, Password.

username	User1
Password	hardtoguess

3. Select *OK*.

To create a local user - CLI

```
config user local
  edit user1
    set type password
    set passwd hardtoguess
  end
```

Creating a RADIUS-authenticated user account

To authenticate users using an external authentication server, you must first configure the FortiGate unit to access the server.

To configure the remote authentication server - web-based manager

1. Go to *User & Device* > *Authentication* > *RADIUS Servers* and select *Create New*.
2. Enter the following information and select *OK*:

Name	OurRADIUSsrv
Primary Server Name/IP	10.11.101.15
Primary Server Secret	OurSecret
Authentication Scheme	Select *Use Default Authentication Scheme*.

To configure the remote authentication server - CLI

```
config user radius
  edit OurRADIUSsrv
    set server 10.11.102.15
    set secret OurSecret
    set auth-type auto
  end
```

Creation of the user account is similar to the locally-authenticated account, except that you specify the RADIUS authentication server instead of the user's password.

To configure a remote user - web-based manager

1. Go to *User & Device* > *User* > *User Definition* and select *Create New*.

2. Enter the following information and select *OK*:

User Name	User2
Match user on RADIUS server	Select this option and then select OurRADIUSsrv from the list.

To configure a remote user - CLI

```
config user local
  edit User2
    set name User2
    set type radius
    set radius-server OurRADIUSsrv
  end
```

Creating user groups

There are two user groups: an FSSO user group for FSSO users and a firewall user group for other users. It is not possible to combine these two types of users in the same user group.

Creating the FSSO user group

For this example, assume that FSSO has already been set up on the Windows network and that it uses Advanced mode, meaning that it uses LDAP to access user group information. You need to

- configure LDAP access to the Windows AD global catalog
- specify the collector agent that sends user logon information to the FortiGate unit
- select Windows user groups to monitor
- select and add the Engineering and Sales groups to an FSSO user group

To configure LDAP for FSSO - web-based manager

1. Go to *User & Device* > *Authentication* > *LDAP Servers* and select *Create New*.
2. Enter the following information:

Name	ADserver
Server Name / IP	10.11.101.160
Distinguished Name	dc=office,dc=example,dc=com
Bind Type	Regular
User DN	cn=FSSO_Admin,cn=users,dc=office,dc=example,dc=com
Password	set_a_secure_password

   Leave other fields at their default values.
3. Select *OK*.

To configure LDAP for FSSO - CLI

```
config user ldap
  edit "ADserver"
    set server "10.11.101.160"
    set dn "cn=users,dc=office,dc=example,dc=com"
    set type regular
    set username
        "cn=administrator,cn=users,dc=office,dc=example,dc=com"
    set password set_a_secure_password
    next
  end
```

To specify the collector agent for FSSO - web-based manager

1. Go to *User & Device* > *Authentication* > *Single Sign-On.*
2. Select *Fortinet Single Sign-On Agent*.
3. Enter the following information:

Name	WinGroups
Primary Agent IP/Name	10.11.101.160
Password	fortinet_canada
LDAP Server	ADserver

4. Select *Apply & Refresh*.

   In a few minutes, the FortiGate unit downloads the list of user groups from the server.

To specify the collector agent for FSSO - CLI

```
config user fsso
  edit "WinGroups"
    set ldap-server "ADserver"
    set password ENC
        G7GQV7NEqilCM9jKmVmJJFVvhQ2+wtNEe9T0iYA5Sa+EqT2J8zhOrbkJFD
        r0RmY3c4LaoXdsoBczA1dONmcGfthTxxwGsigzGpbJdC71spFlQYtj
    set server "10.11.101.160"
  end
```

To create the FSSO_Internet-users user group - web-based manager

1. Go to *User & Device* > *User* > *User Groups* and select *Create New*.
2. Enter the group name, FSSO_Internet_users.
3. Select *Fortinet Single Sign-On (FSSO)*.
4. In the *Available Members* list, select the Engineering and Sales groups and then select the right arrow button to move them to the *Members* list.
5. Select *OK*.

To create the FSSO_Internet-users user group - CLI

```
config user group
  edit FSSO_Internet_users
    set group-type fsso-service
    set member CN=Engineering,cn=users,dc=office,dc=example,dc=com
         CN=Sales,cn=users,dc=office,dc=example,dc=com
  end
```

Creating the Firewall user group

The non-FSSO users need a user group too. In this example, only two users are shown, but additional members can be added easily.

To create the firewall user group - web-based manager

1. Go to *User & Device* > *User* > *User Groups* and select *Create New*.
2. Enter the following information and then select *OK*:

Name	Internet_users
Type	Firewall
Members	User1, User2

To create the firewall user group - CLI

```
config user group
  edit Internet_users
    set group-type firewall
    set member User1 User2
  end
```

Defining policy addresses

Go to *Firewall Objects* > *Address* > *Addresses* and create the following addresses:

Address Name	Internal_net
Type	Subnet
Subnet / IP Range	10.11.102.0/24
Interface	Port 3

Address Name	Windows_net
Type	Subnet
Subnet / IP Range	10.11.101.0/24
Interface	Port 2

Creating security policies

Two security policies are needed: one for firewall group who connect through port3 and one for FSSO group who connect through port2.

To create a security policy for FSSO authentication - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. Enter the following information:

Policy Type	Firewall
Policy Subtype	User Identity
Incoming Interface	Port2
Source address	Windows_net
Outgoing Interface	Port1
Enable NAT	Select

3. In Configuration *Authentication Rules*, select *Create New*.
   In the *New Authentication Rule* window, enter the following information, and then select OK:

Destination Address	all
Group(s)	FSSO_Internet_users
Schedule	always
Service	ALL
UTM Security Profiles	Optionally, enable UTM profiles.

4 Select OK.

To create a security policy for FSSO authentication - CLI

```
config firewall policy
  edit 0
    set srcintf port2
    set dstintf port1
    set srcaddr Windows_net
    set dstaddr all
    set action accept
    set identity-based enable
    set nat enable
    config identity-based-policy
      edit 1
        set schedule always
        set groups FSSO_Internet_users
        set service ANY
      end
  end
```

To create a security policy for local user authentication - web-based manager

1. Go to *Policy* > *Policy* and select *Create New*.
2. Enter the following information:

Policy Type	Firewall
Policy Subtype	User Identity
Incoming Interface	Port3
Source address	Internal_net
Outgoing Interface	Port1
Enable NAT	Select

3. In Configuration *Authentication Rules*, select *Create New*.
   In the *New Authentication Rule* window, enter the following information, and then select OK:

Destination Address	all
Group(s)	Internet_users
Schedule	always
Service	ALL
UTM Security Profiles	Optionally, enable UTM profiles.

4 Select OK.

To create a security policy for local user authentication - CLI

```
config firewall policy
  edit 0
    set srcintf port3
    set dstintf port1
    set srcaddr internal_net
    set dstaddr all
    set action accept
    set identity-based enable
    set nat enable
    config identity-based-policy
      edit 1
        set schedule always
        set groups Internet_users
        set service ANY
      end
  end
```

LDAP Dial-in using member-attribute

In this example, users defined in MicroSoft Windows Active Directory (AD) are allowed to set up a VPN connection simply based on an attribute that is set to TRUE, instead of based on their user group. In AD the "Allow Dialin" property is activated in the user properties, and this sets the `msNPAllowDialin` attribute to "TRUE".

This same procedure can be used for other member attributes, as your system requires.

To accomplish this with a FortiGate unit, member-attribute must be set. This can only be accomplished through the CLI - the option is not available through the web-based manager.

Before configuring the FortiGate unit, ensure the AD server has the `msNPAllowDialin` attribute set to "TRUE" for the users in question. If not, those users will not be able to authenticate.

To configure user LDAP member-attribute settings - CLI

```
config user ldap
  edit "ldap_server"
    set server "192.168.201.3"
    set cnid "sAMAccountName"
    set dn "DC=fortilabanz,DC=com,DC=au"
    set type regular
    set username "fortigate@sample.com"
    set password ******
    set member-attr "msNPAllowDialin"
  next
end
```

To configure LDAP group settings - CLI

```
config user group
  edit "ldap_grp"
    set member "ldap"
    config match
      edit 1
        set server-name "ldap"
        set group-name "TRUE"
      next
    end
  next
  end
```

Once these settings are in place, users that are a member of the `ldap` user group will be able to authenticate.

To ensure your settings are correct, here is the sample output from a diag debug command that shows the authentication process.

When the "Allow Dial-in" attribute is set to "TRUE" the following will likely be in the output:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='TRUE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Passed group matching
```

If the attribute is not set but it is expected, the following will likely be in the output:

```
get_member_of_groups-Get the memberOf groups.
get_member_of_groups- attr='msNPAllowDialin', found 1 values
get_member_of_groups-val[0]='FALSE'
fnbamd_ldap_get_result-Auth accepted
fnbamd_ldap_get_result-Going to DONE state res=0
fnbamd_auth_poll_ldap-Result for ldap svr 192.168.201.3 is SUCCESS
fnbamd_auth_poll_ldap-Failed group matching
```

The only difference between these two outputs is the last line which is either passed or failed based on if the member-attribute is set to the expected value or not.

RADIUS SSO example

A common RADIUS SSO topology involves a medium sized company network of users connecting to the Internet through the FortiGate unit, and authenticating with a RADIUS server. RADIUS SSO authentication was selected because it is fast and relatively easy to configure.

This section includes:

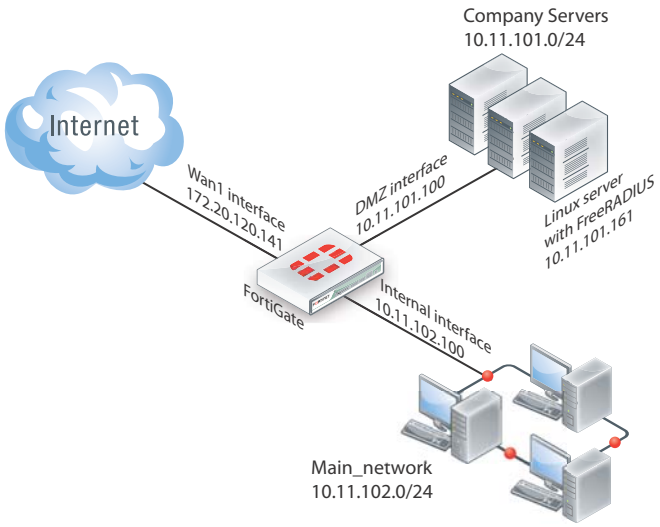
Assumptions

- VDOMs are not enabled
- The admin super_admin administrator account will be used for all FortiGate unit configuration.
- Any other devices on the network do not affect the topology of this example, and therefore are not included.
- Anywhere settings are not described, they are assumed to be default values.
- A RADIUS server is installed on a server or FortiAuthenticator unit and uses default attributes.
- BGP is used for any dynamic routing.
- Authentication event logging under Log&Report has been configured.

Topology

Example.com has an office with 20 users on the internal network. These users need access to the Internet to do their jobs. The office network is protected by a FortiGate-60C unit with access to the Internet through the wan1 interface, the user network on the internal interface, and all the servers are on the DMZ interface. This includes an Ubuntu Linux server running FreeRADIUS. For this example only two users will be configured — Pat Lee with an account name `plee`, or `plee@example.com`, and Kelly Green with an account name `kgreen`, or `kgreen@example.com`.

Figure 130:RADIUS SSO topology



General configuration

1. Configuring RADIUS with users, user group, and FortiGate information.
2. Configuring FortiGate interfaces
3. Configuring FortiGate regular and RADIUS SSO security policies

Configuring RADIUS

Configuring RADIUS includes configuring the RADIUS server such as FreeRADIUS, a radius client on user's computers, and configuring users in the system. For this example the two users will be Pat Lee, and Kelly Green. They belong to a group called `exampledotcom_employees`. When it is all configured, the RADIUS daemon needs to started.

The users have a RADIUS client installed on their PCs that allows them to authenticate through the RADIUS server.

FreeRADIUS can be found on the freeradius.org website. For any problems installing FreeRADIUS, see the FreeRADIUS documentation.

Configuring FortiGate interfaces

Before configuring the RADIUS SSO security policy, configure FortiGate interfaces. This includes defining a DHCP server for the internal network as this type of network typically uses DHCP. The wan1 and dmz interfaces are assigned static IP addresses and do not need a DHCP server.

Table 28: FortiGate interfaces used in this example

Interface	Subnet	Act as DHCP Server	Devices
wan1	172.20.120.141	No	Internet Service Provider
dmz	10.11.101.100	No	Servers, including RADIUS server
internal	10.11.102.100	Yes: x.x.x.110-.250	Internal user network

To configure FortiGate interfaces - web-based manager

1. Go to *System* > *Network* > *Interfaces*.
2. Select wan1 to edit.
3. Enter the following information and select OK.

Alias	Internet
Addressing Mode	Manual
IP/Network Mask	172.20.120.141/255.255.255.0
Administrative Access	HTTPS, SSH
Enable DHCP Server	Not selected
Comments	Internet
Administrative Status	Up

4. Select dmz to edit.
5. Enter the following information and select OK.

Alias	Servers
Addressing Mode	Manual
IP/Network Mask	10.11.101.100/255.255.255.0
Administrative Access	HTTPS, SSH, PING, SNMP
Enable DHCP Server	Not selected
Listen for RADIUS Accounting Messages	Select
Comments	Servers
Administrative Status	Up

6. Select internal to edit.

7. Enter the following information and select OK.

Alias	Internal network
Addressing Mode	Manual
IP/Network Mask	10.11.102.100/255.255.255.0
Administrative Access	HTTPS, SSH, PING
Enable DHCP Server	Select
Address Range	10.11.102.110 - 10.11.102.250
Netmask	255.255.255.0
Default Gateway	Same as Interface IP
DNS Server	Same as System DNS
Comments	Internal network
Administrative Status	Up

Configuring a RADIUS SSO Agent on the FortiGate unit

To create a RADIUS SSO agent

1. Go to *User & Device* > *Authentication* > *Single Sign-On* and select *Create New*.
2. In *Type*, select *RADIUS Single-Sign-On Agent*.
3. Select *Use RADIUS Shared Secret* and enter the RADIUS server shared secret.
4. Select *Send RADIUS Responses*.
5. Select *OK*.

The Single Sign-On agent is named RSSO_Agent.

Creating a RADIUS SSO user group

To define a local user group for RADIUS SSO

1. Go to *User & Device* > *User* > *User Groups* and select *Create New*.
2. Enter a Name for the user group.
3. In *Type*, select *RADIUS Single Sign-On (RSSO)*.
4. In *RADIUS Attribute Value*, enter the name of the RADIUS user group this local user group represents.
5. Select *OK*.

Configuring FortiGate regular and RADIUS SSO security policies

With the RADIUS server and FortiGate interfaces configured, security policies can be configured. This includes both RADIUS SSO and regular policies, as well as addresses and address groups. All policies require NAT to be enabled.

Table 29: security policies needed for RADIUS SSO

Seq. No.	From -> To	Type	Schedule	Description
1	internal -> wan1	RADIUS SSO	business hours	Authenticate outgoing user traffic.
2	internal -> wan1	regular	always	Allow essential network services and VoIP.
3	dmz -> wan1	regular	always	Allow servers to access Internet.
4	internal -> dmz	regular	always	Allow users to access servers.
5	any -> any	deny	always	Implicit policy denying all traffic that hasn't been matched

The RADIUS SSO policy must be placed at the top of the policy list so it is matched first. The only exception to this is if you have a policy to deny access to a list of banned users. In this case, that policy must go at the top so the RADIUS SSO does not mistakenly match a banned user or IP address.

This section includes:

- Schedules, address groups, and services groups
- Configuring regular security policies
- Configuring RADIUS SSO security policy

Schedules, address groups, and services groups

This section lists the lists that need to be configured before security policies are created. Creating these lists is straight forward, so the essential information has been provided here but not step by step instructions. For more information on firewall related details, see

Schedules

Only one schedule needs to be configured — `business_hours`. This is a fairly standard Monday to Friday 8am to 5pm schedule, or whatever days and hours covers standard work hours at the company.

Address groups

The following address groups need to be configured before the security policies.

Table 30:

Address group Name	Inter face	Address range included

Table 30:

internal_network	internal	10.11.102.110 to 10.11.102.250
company_servers	dmz	10.11.101.110 to 10.11.101.250

Service groups

The following service groups need to be configured before the security policies. Note that the services listed are suggestions and may include more or less as required.

Table 31:

Service group Name	Interface	Description of services to be included
essential_network_services	internal	Any network protocols required for normal network operation such as DNS, NTP, BGP.
essential_server_services	dmz	All the protocols required by the company servers such as BGP, HTTP, HTTPS, FTP, IMAP, POP3, SMTP, IKE, SQL, MYSQL, NTP, TRACEROUTE, SOCKs, and SNMP.
user_services	internal	Any protocols required by users HTTP, HTTP, FTP,

The following security policy configurations are basic and only include logging, and default AV and IPS.

Configuring regular security policies

Regular security policies allow or deny access for non-RADIUS SSO traffic. This is essential as there are network services—such as DNS, NTP, and FortiGuard—that require access to the Internet.

To configure regular security policies - web-based manager

1. Go to *Policy* > *Policy*, and select Create New.
2. Enter the following information, and select OK.

Source Interface/Zone	Internal
Source Address	internal_network
Destination Interface/Zone	wan1
Destination Address	all
Schedule	always
Service	essential_network_services
Action	ACCEPT
Log Allowed Traffic	enable
Enable NAT	enable
UTM	enable

Enable Antivirus	enable Default
Enable IPS	enable Default
Enable VoIP	enable Default
Comments	Essential network services

3. Select Create New, enter the following information, and select OK.

Source Interface/Zone	dmz
Source Address	company_servers
Destination Interface/Zone	wan1
Destination Address	all
Schedule	always
Service	essential_server_services
Action	ACCEPT
Log Allowed Traffic	enable
Enable NAT	enable
UTM	enable
Enable Antivirus	enable Default
Enable IPS	enable Default
Comments	Company servers accessing the Internet

4. Select Create New, enter the following information, and select OK.

Source Interface/Zone	Internal
Source Address	internal_network
Destination Interface/Zone	dmz
Destination Address	company_servers
Schedule	always
Service	all
Action	ACCEPT
Log Allowed Traffic	enable
Enable NAT	enable
UTM	enable

Enable Antivirus	enable Default
Enable IPS	enable Default
Comments	Access company servers

Configuring RADIUS SSO security policy

The RADIUS SSO policy allows access for members of specific RADIUS groups.

To configure RADIUS SSO security policy

1. Go to *Policy* > *Policy* > *Policy*.
2. Select *Create New*.
3. Enter the following information.

Policy Type	Firewall
Policy Subtype	User Identity
Incoming Interface	Internal
Source Address	internal_network
Outgoing Interface	wan1
Enable NAT	Selected

4. In *Configure Authentication Rules*, select *Create New* and enter:

Destination Address	all
Group(s)	Select the user groups you created for RSSO.
User(s)	not used
Schedule	business_hours
Service	ALL
Action	ACCEPT
UTM Security Profiles	Enable AntiVirus, WebFilter, IPS, and Email Filter. In each case, select the default profile.

5. Select *OK*.
6. Repeat steps 4 and 5 for each user group that is allowed to use this security policy. Schedule, Service, and UTM profiles can be different for each group.
7. Select *OK*.

To ensure an RSSO-related policy is matched first, the policy should be placed higher in the security policy list than more general policies for the same interfaces.

Testing

Once configured, a user only needs to logon to their PC using their RADIUS account. After that when they attempt to access an Internet website, the FortiGate unit will use their session

information to get their RADIUS information. Once the user is verified, they are allowed access to the website.

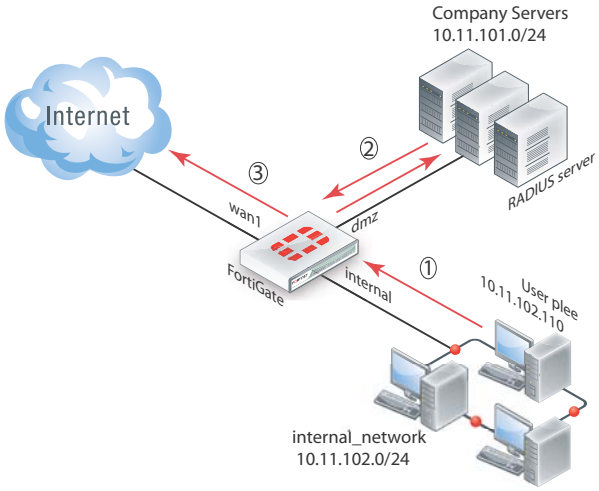
To test the configuration perform the following steps.

1. Have user plee logon to their PC, and try to access an Internet website.
2. The FortiGate unit will contact the RADUS server for user plee's information.
3. Once confirmed, plee will have access to the website.

Each step generates log entries that enable you to verify that each step was successful.

If a step is unsuccessful, confirm your configuration is correct and see "Troubleshooting dynamic profiles" on page 230.

Figure 131:RADIUS SSO test



Troubleshooting

In the web-based manager, a good tool for troubleshooting is the packet counter column on the security policy page (*Policy* > *Policy*). This column displays the number of packets that have passed through this security policy. Its value when you are troubleshooting is that when you are testing your configuration (end to end connectivity, user authentication, policy use) watching the packet count for an increase confirms any other methods you may be using for troubleshooting. It provides the key of which policy is allowing the traffic, useful information if you expect a user to require authentication and it never happens. For more information about authentication security policies, see "Authentication in security policies" on page 517.

This section addresses how to get more information from the CLI about users and user authentication attempts to help troubleshoot failed authentication attempts.

`diag firewall iprope authuser`

Shows the IP of where your computer is connected from. This is useful to confirm authorization and VPN settings.

`diag firewall iprope resetauth`

Clear all authorized users from the current list. Useful to force users to re-authenticate after system or group changes. However, this command may easily result in many users having to re-authenticate, so use carefully.

```
diag firewall auth list
```

List all the authorized users on this system.

```
diag rsso query ip
diag rsso query rsso-key
```

Queries the RSSO database.

For more information on troubleshooting specific features, go to that section of this document. Most sections have troubleshooting information at the end of the section. In addition to that information, see the *FortiOS Handbook Troubleshooting chapter* for general troubleshooting information.

Chapter 4 FortiOS Carrier

This FortiOS Handbook chapter contains the following sections:

Overview of FortiOS Carrier features provides an overview of the three major topics for FortiOS Carrier — Dynamic Profiles, MMS, and GTP.

Carrier web-based manager settings describes the web-based manager interface of FortiOS Carrier specific features.

MMS Security features describes FortiOS security features as they apply to MMS including MMS virus scanning, MMS file filtering, MMS content-based Antispam protection, and MMS DLP archiving.

Message flood protection describes setting thresholds to protect your MMS servers from receiving too many messages from the same sender.

Duplicate message protection describes setting thresholds to protect your MMS servers from receiving the same message from more than one sender.

Configuring GTP on FortiOS Carrier explains configuration of the more basic FortiOS Carrier GTP features.

GTP message type filtering explains this feature, and how to configure it on FortiOS Carrier.

GTP identity filtering explains this feature, and how to configure it on FortiOS Carrier.

Troubleshooting provides answer to common FortiOS Carrier GTP issues.

Overview of FortiOS Carrier features

FortiOS Carrier specific features include Multimedia messaging service (MMS) protection, and GPRS Tunneling Protocol (GTP) protection.

All FortiGate units, carrier-enabled or not, are capable of handling Stream Control Transmission Protocol (SCTP) traffic, which is a protocol designed for and primarily used in Carrier networks.

This section includes:

Overview

FortiOS Carrier provides all the features found on FortiGate units plus added features specific to carrier networks: MMS and GTP.

MMS

MMS is a standard for sending messages that include multimedia content between mobile phones. MMS is also popular as a method of delivering news and entertainment content including videos, pictures, and text. Carrier networks include four different MMS types of messages — MM1, MM3, MM4, and MM7. See "MMS background" on page 633.

GTP

The GPRS Tunneling Protocol (GTP) runs on GPRS carrier networks. GPRS is a GSM packet radio standard. It provides more efficient usage of the radio interface so that mobile devices can share the same radio channel. FortiOS supports GTPv1 release 7.15.0 and GTPv1 release 8.12.0.

GPRS provides direct connections to the Internet (TCP/IP) and X.25 networks for point-to-point services (connection-less/connection oriented) and point-to-multipoint services (broadcast).

GPRS currently supports data rates from 9.6 kbps to more than 100 kbps, and it is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based) that converts the message from radio to

wired, and sends the message to the carrier network and eventually the Internet (wired carrier network). See “GTP basic concepts” on page 645.

Registering FortiOS Carrier

In FortiOS 5.0, the Carrier registration process has changed. Devices are no longer shipped with Carrier functions built-in, so that administrators will have more leeway in configuring Carrier functions on existing devices.

A license is purchased from Fortinet, and is delivered by mail as a scratch card. The contained registration code is entered into the CLI according to the instructions on the card. The FortiGate will then factory reset itself into Carrier mode.

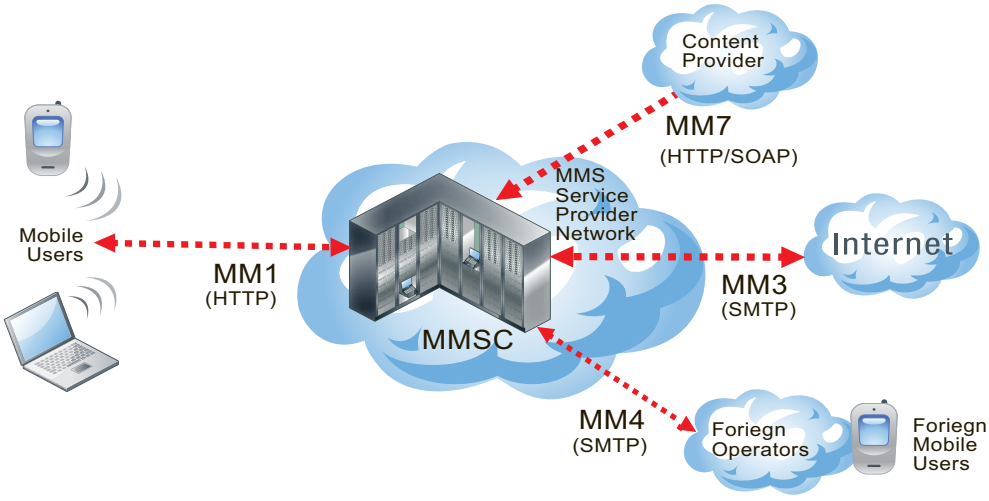
Only certain models support Carrier mode. Contact Fortinet Support for more information and firmware images.

MMS background

MMS is a common method for mobile users to send and receive multimedia content. A Carrier network supports MMS across its network. This makes up the MMS Service Provider Network (MSPN).

Messages can be sent or received between the MMSC and a number of other services including the Internet, content providers, or other carriers. Each of these different service connections uses different MMS formats including MM1 and MM7 messages (essentially HTTP format), and MM3 and MM4 messages (SMTP formatted). These different formats reflect the different purposes and content for each type of MMS message.

Figure 132:MMS content interfaces



MMS content interfaces

MMS messages are sent from devices and servers to other devices and servers using MMS content interfaces

There are eight interfaces defined for the MMS standard, referred to as MM1 through MM8. The most important of these interfaces for the transfer of data is the MM1 interface, as this defines how mobile users communicate from the mobile network to the Multimedia Message Service

Center (MMSC). MMS content to be monitored and controlled comes from these mobile users and is going to the provider network.

Other MMS content interfaces that connect a service provider network to other external sources can pose threats as well. MM3 handles communication between the Internet and the MMSC and is a possible source of viruses and other content problems from the Internet. MM4 handles communication between different content provider MMSCs. Filtering MM4 content protects the service provider network from content sent from foriegn service providers and their subscribers. Finally MM7 is used for communication between content providers and the MMSC. Filtering MM3 content can also keep harmful content off of the service provider network.

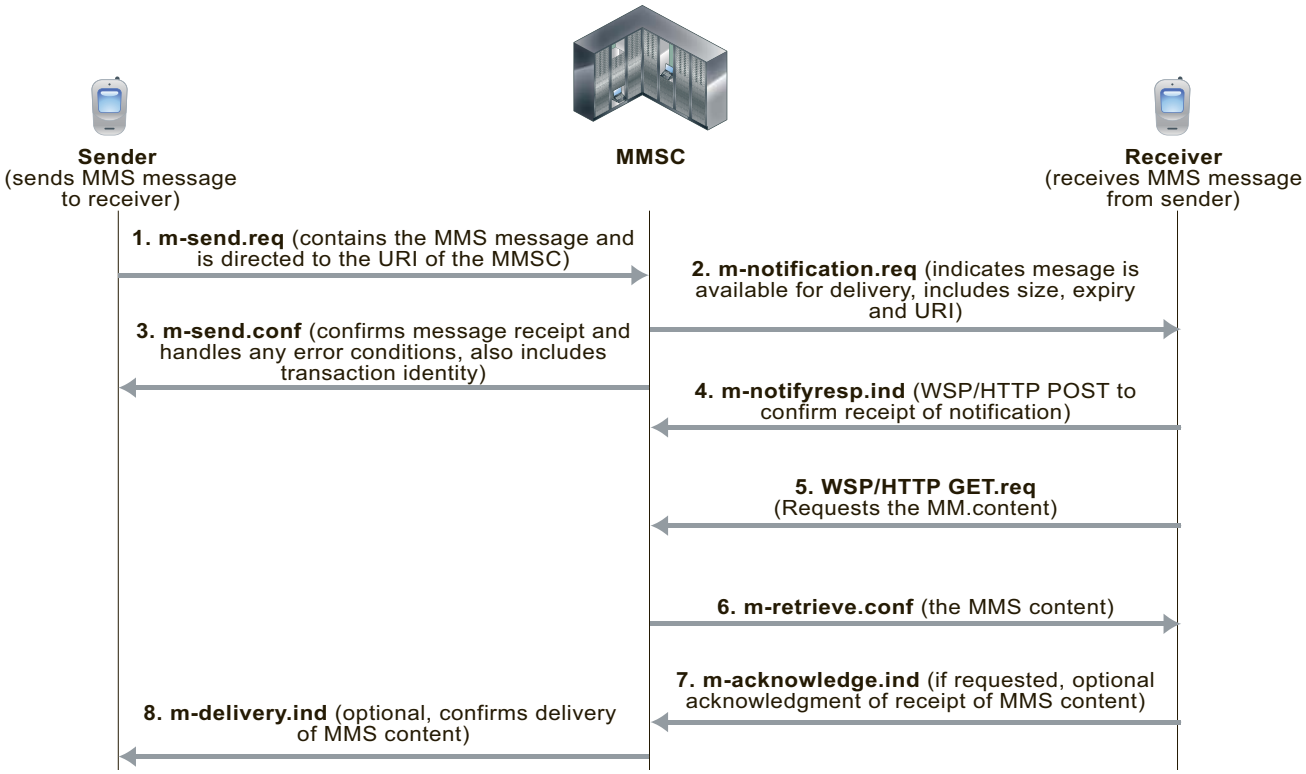
Table 32: MMS content interfaces

Type	Transaction	Similar to
MM 1	Handset to MMSC	HTTP
MM 3	Between MMSC and Internet	SMTP
MM 4	Between Operator MMSCs	SMTP
MM 7	Content Providers to MMSC	HTTP and SOAP

How MMS content interfaces are applied

As shown in Figure 133, the sender's mobile device encodes the MMS content in a form similar to MIME email message (MMS MIME content formats are defined by the MMS Message Encapsulation specification). The encoded message is then forwarded to the service provider's MMSC. Communication between the sending device and the MMSC uses the MM1 content interface. The MM1 content interface establishes a connection and sends an MM1 send request (`m-send.req`) message that contains the MMS message. The MMSC processes this request and sends back an MM1 send confirmation (`m-send.conf`) HTTP response indicating the status of the message — accepted or an error occurred, for example.

Figure 133:MM1 transactions between senders and receivers and the MMSC

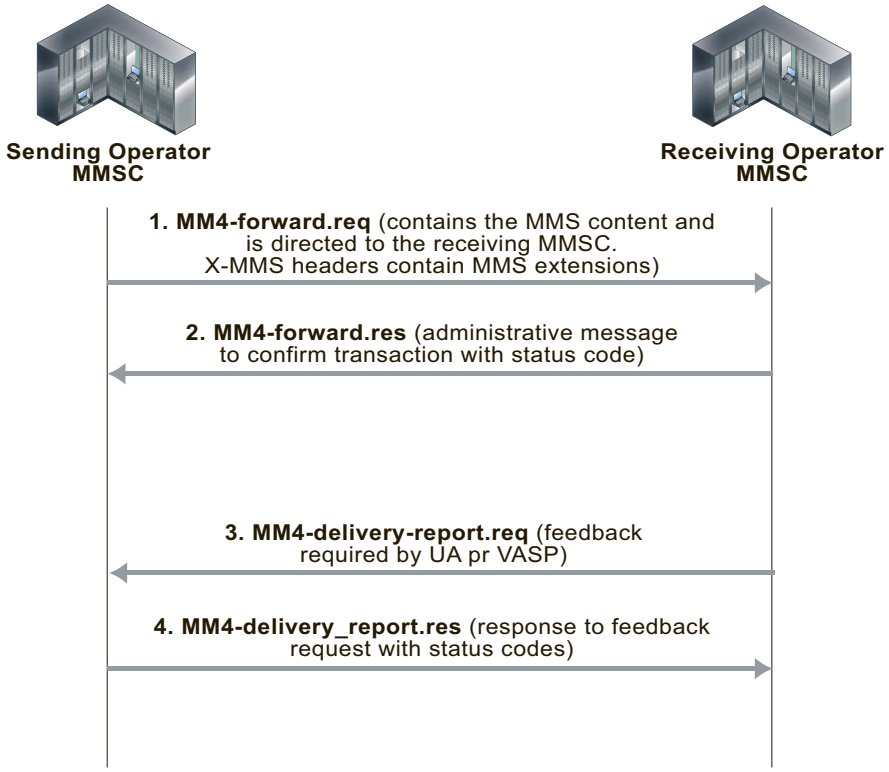


If the recipient is on another carrier, the MMSC forwards the message to the recipient's carrier. This forwarding uses the MM4 content interface for forwarding content between operator MMSCs (see Figure 134).

Before the MMSC can forward the message to the final recipient, it must first determine if the receiver's handset can receive MMS messages using the MM1 content interface. If the recipient can use the MM1 content interface, the content is extracted and sent to a temporary storage server with an HTTP front-end.

To retrieve the message, the receiver's handset establishes a connection with the MMSC. An HTTP get request is then sent from the recipient to the MMSC.This message contains the URL where the content of the message is stored. The MMSC responds with a retrieve confirmation (`m-retrieve.conf`) HTTP response that contains the message.

Figure 134:MM4 messages sent between operator MMSCs



This causes the receiver's handset to retrieve the content from the embedded URL. Several messages are exchanged to indicate status of the delivery attempt. Before delivering content, some MMSCs also include a content adaptation service that attempts to modify the multimedia content into a format suitable for the recipient's handset.

If the receiver's handset is not MM1 capable, the message can be delivered to a web based service and the receiver can view the content from a normal Internet browser. The URL for the content can be sent to the receiver in an SMS text message. Using this method, non-MM1 capable recipients can still receive MMS content.

The method for determining whether a handset is MMS capable is not specified by the standards. A database is usually maintained by the operator, and in it each mobile phone number is marked as being associated with a legacy handset or not. It can be a bit hit and miss since customers can change their handset at will and this database is not usually updated dynamically.

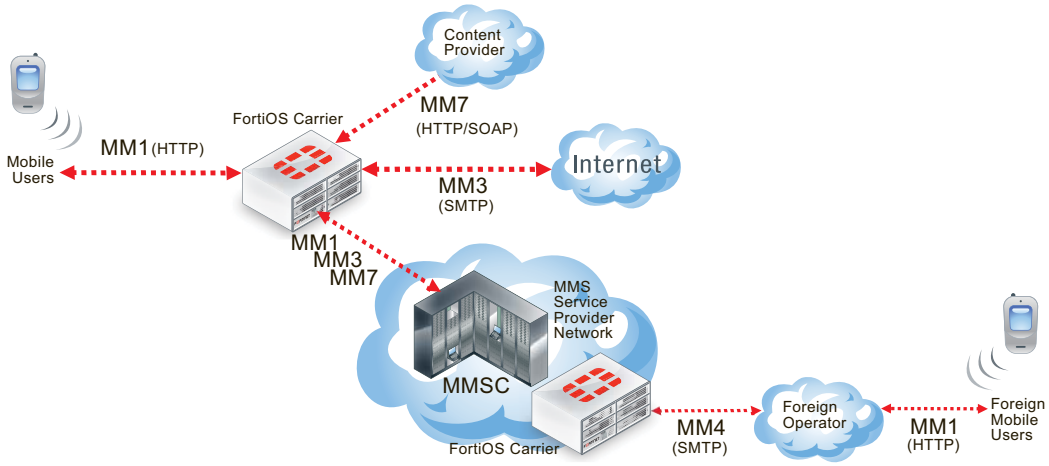
Email and web-based gateways from MMSC to the Internet use the MM3 content interface. On the receiving side, the content servers can typically receive service requests both from WAP and normal HTTP browsers, so delivery via the web is simple. For sending from external sources to handsets, most carriers allow MIME encoded message to be sent to the receiver's phone number with a special domain.

How FortiOS Carrier processes MMS messages

MMS messages can be vectors for propagating undesirable content such as spam and viruses. FortiOS Carrier can scan MMS messages sent using the MM1, MM3, MM4, and MM7 content interfaces. You can configure FortiOS Carrier to scan MMS messages for spam and viruses by configuring and adding MMS protection profiles and adding the MMS protection profiles to security policies. You can also use MMS protection profiles to apply content blocking, carrier

endpoint filtering, MMS address translation, sending MMS notifications, DLP archiving of MMS messages, and logging of MMS message activity.

Figure 135: FortiOS Carrier MMS processing



FortiOS Carrier can send MMS messages to senders informing those senders that their devices are infected. FortiOS Carrier can also send MMS notifications to administrators to inform them of suspicious activity on their networks.

For message floods and duplicate messages, FortiOS Carrier does not send notifications to message senders but does send notifications to administrators and sends messages to sender handsets to complete MM1 and MM4 sessions.

Where MMS messaging uses the TCP/IP set of protocols, SMS text messaging uses the Signaling System Number 7 (SS7) set of protocols, which is not supported by FortiOS.

FortiOS Carrier and MMS content scanning

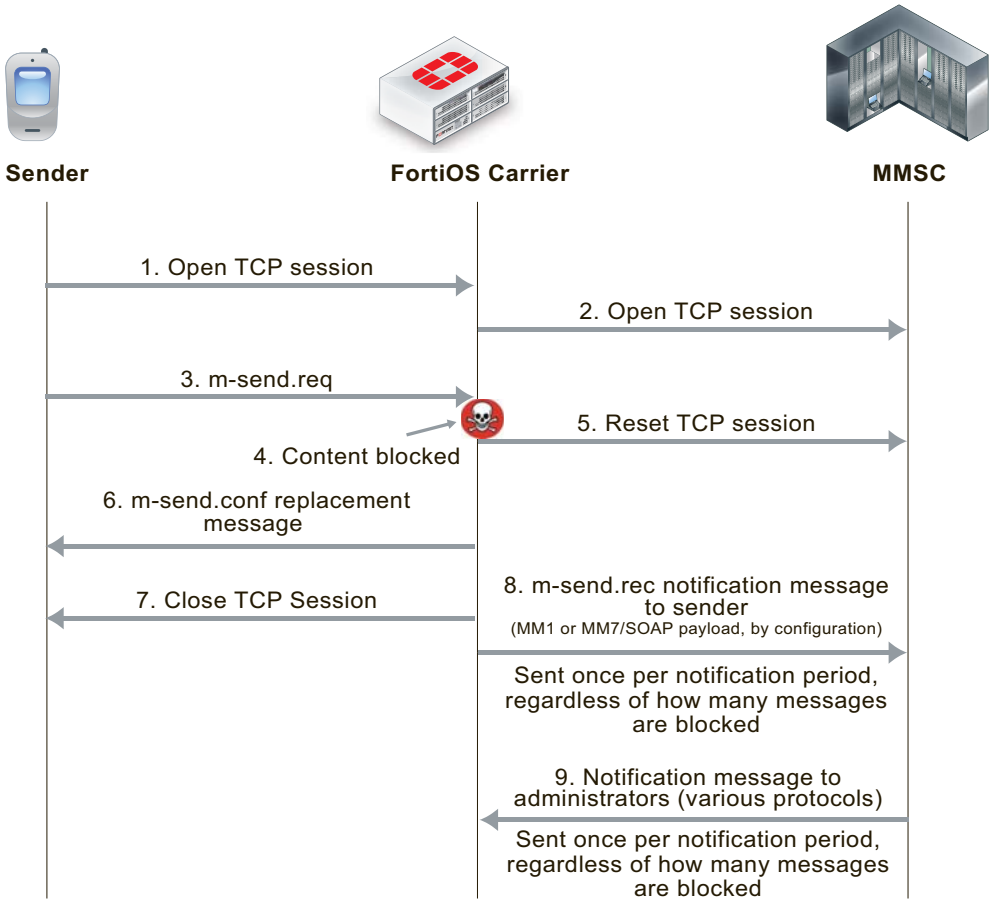
The following section applies to MMS content scanning, including virus scanning, file filtering, content spam filtering, carrier endpoint filtering, and MMS content checksum filtering.

MM1 Content Scanning

During MM1 content scanning a message is first transmitted from the sender, establishing a connection with the MMSC. FortiOS Carrier intercepts this connection and acts as the endpoint. FortiOS Carrier then establishes its own connection to the MMSC. Once connected, the client transmits its `m-send.req` HTTP post request to FortiOS Carrier which scans it according to the MMS protection profile settings. If the content is clean, the message is forwarded to the MMSC. The MMSC returns `m-send.conf` HTTP response through FortiOS Carrier to the sender.

If FortiOS Carrier blocks the message (for example because a virus was found, see Figure 136), FortiOS Carrier resets the connection to the MMSC and sends `m-send.conf` HTTP response back to the sender. The response message can be customized using replacement messages. FortiOS Carrier then terminates the connection. Sending back an `m-send.conf` message prevents the sender from trying to send the message again.

Figure 136:MM1 MMS scanning of message sent by sender (blocking m.send.req messages)



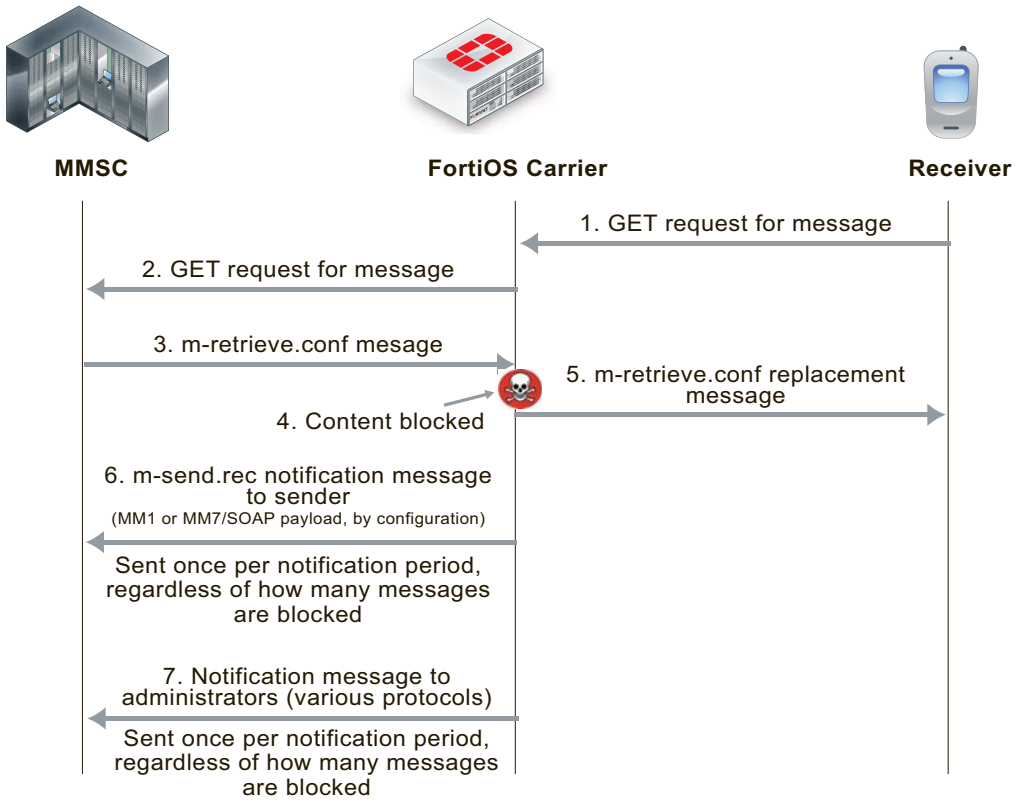
FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the sender to notify them of blocked messages.

Filtering message retrieval

FortiOS Carrier intercepts the connection to the MMSC, and the m-retrieve.conf HTTP response from the MMSC is scanned according to the MMS content scanning settings. If the content is clean, the response is forwarded back to the client. If the content is blocked, FortiOS Carrier drops the connection to the MMSC. It then builds an m-retrieve.conf message from the associated replacement message and transmits this back to the client.

FortiOS Carrier also sends `m-send.rec` notifications messages to the MMSC that are then forwarded to the receiver to notify them of blocked messages.

Figure 137:MM1 MMS scanning of messages received by receiver (blocking m.retrieve.conf messages)



Filtering MM3 and MM4 messages works in an similar way to MM1 (see Figure 138 and Figure 139). FortiOS Carrier intercepts connections to the MMSC, and scans messages as configured. When messages are blocked, FortiOS Carrier closes sessions as required, sends confirmation messages to the sender, notifies administrators, and notifies senders and receivers of messages.

Figure 138:MM3 MMS scanning of messages sent from a sender on the Internet to an MMSC

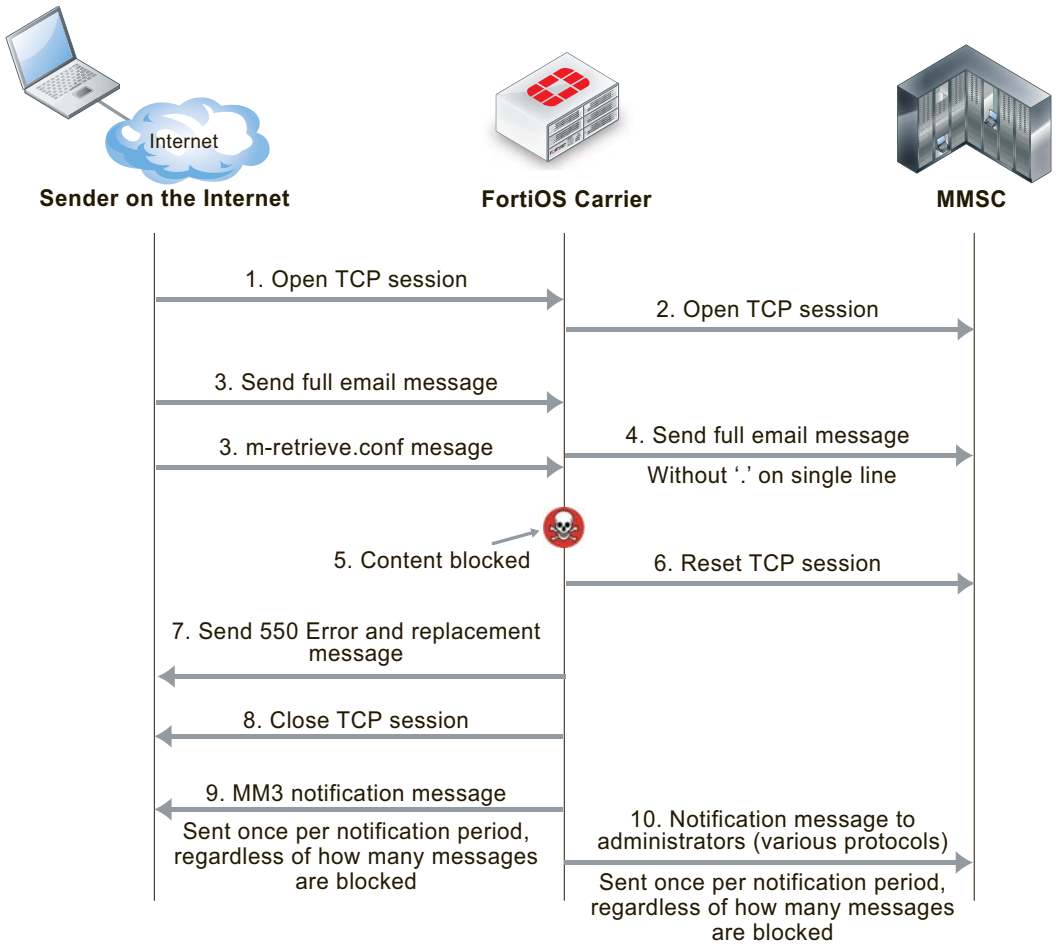


Figure 139:MM4 MMS scanning of messages sent between operator MMSCs

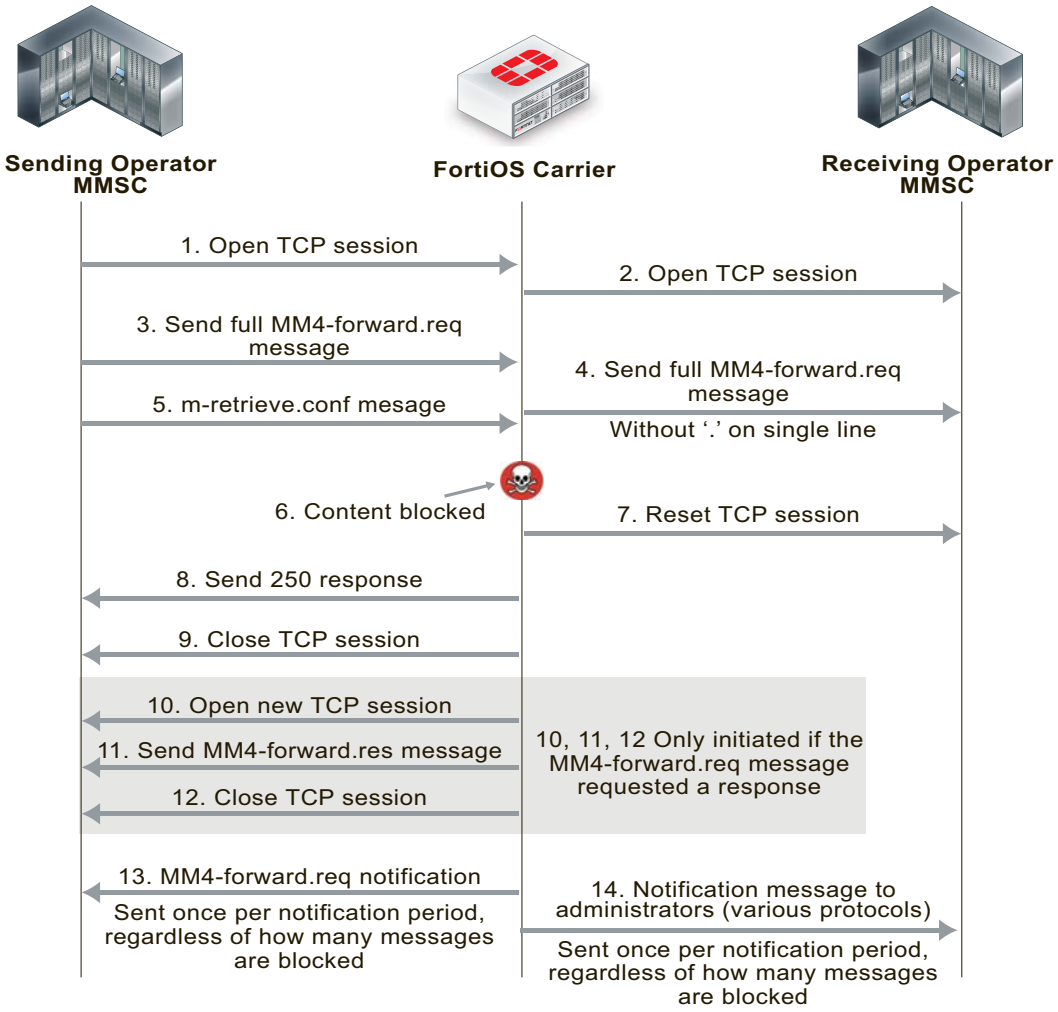

Figure 140:MM7 MMS scanning of messages sent between a VASP and an MMSC

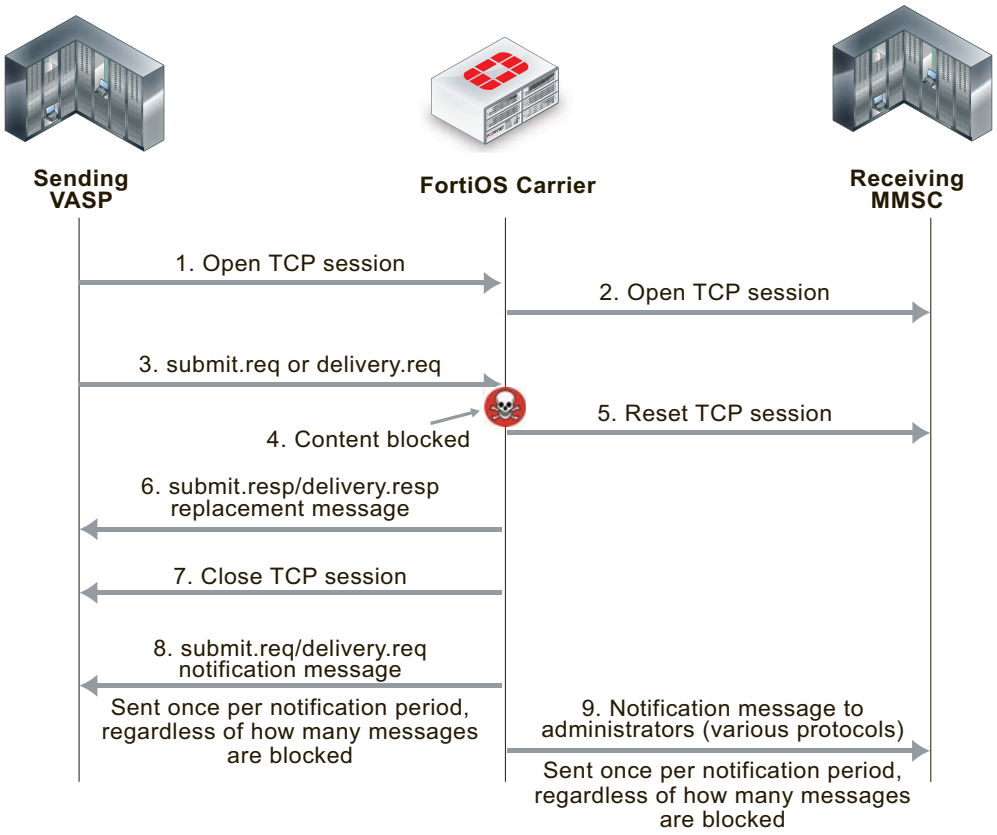

FortiOS Carrier and MMS duplicate messages and message floods

FortiOS Carrier detects duplicate messages and message floods for the MM1 and MM4 interfaces. How FortiOS Carrier detects and responds to duplicate messages and message floods is different from how FortiOS Carrier detects and responds to viruses and other MMS scanning protection measures.

For message floods and duplicate messages, the sender does not receive notifications about floods or duplicate messages, as if the sender is an attacker they can gain useful information about flood and duplicate thresholds. Plus, duplicate messages and message floods are usually a result of a large amount of messaging activity and filtering of these messages is designed to reduce the amount of unwanted messaging traffic. Adding to the traffic by sending notifications to senders and receivers could result in an increase in message traffic.

You can create up to three thresholds for detecting duplicate messages and message floods. For each threshold you can configure the FortiOS Carrier unit to respond by logging the activity, archiving or quarantining the messages, notifying administrators of the activity, and by blocking the messages. In many cases you may only want to configure blocking for higher activity thresholds, and to just monitor and send administrator notifications at lower activity thresholds.

When a block threshold is reached for MM1 messages, FortiOS Carrier sends m-send.conf or m-retrieve.conf messages to the originator of the activity. These messages are sent to end the MM1 sessions, otherwise the originator would continue to re-send the blocked message. When a block threshold is reached for MM4, FortiOS Carrier sends a `MM4-forward.res` message to close the MM4 session. An MM4 message is sent only if initiated by the originating `MM4-forward.req` message.

Figure 141:MM1 message flood and duplicate message blocking of sent messages

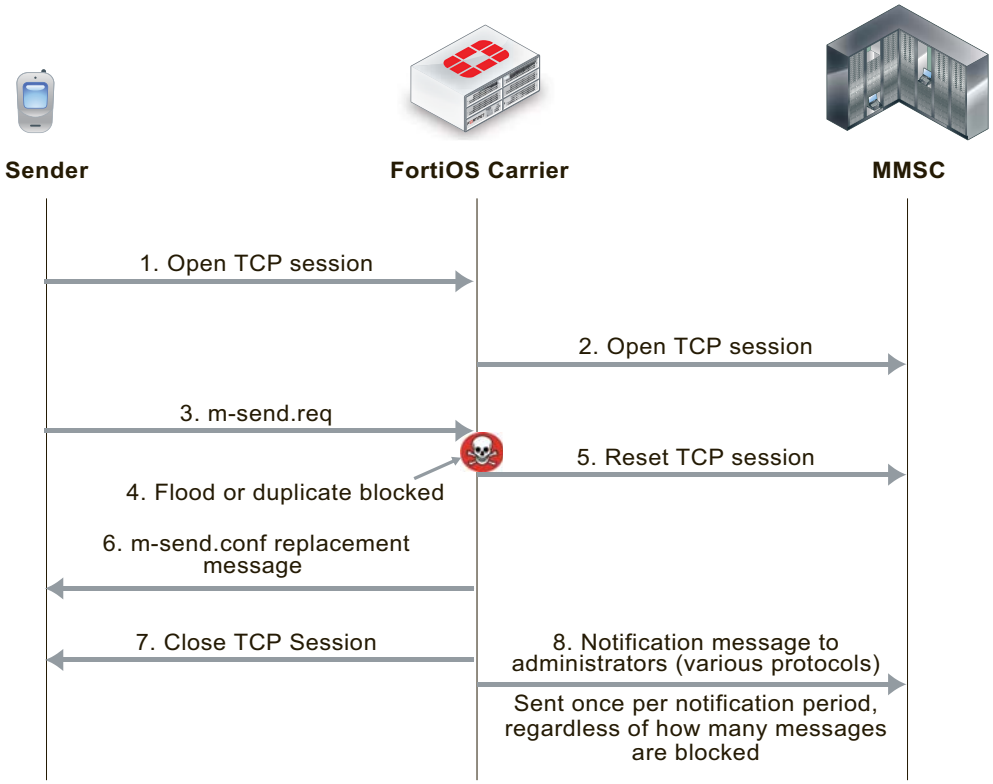

Figure 142:MM1 message flood and duplicate message blocking of received messages

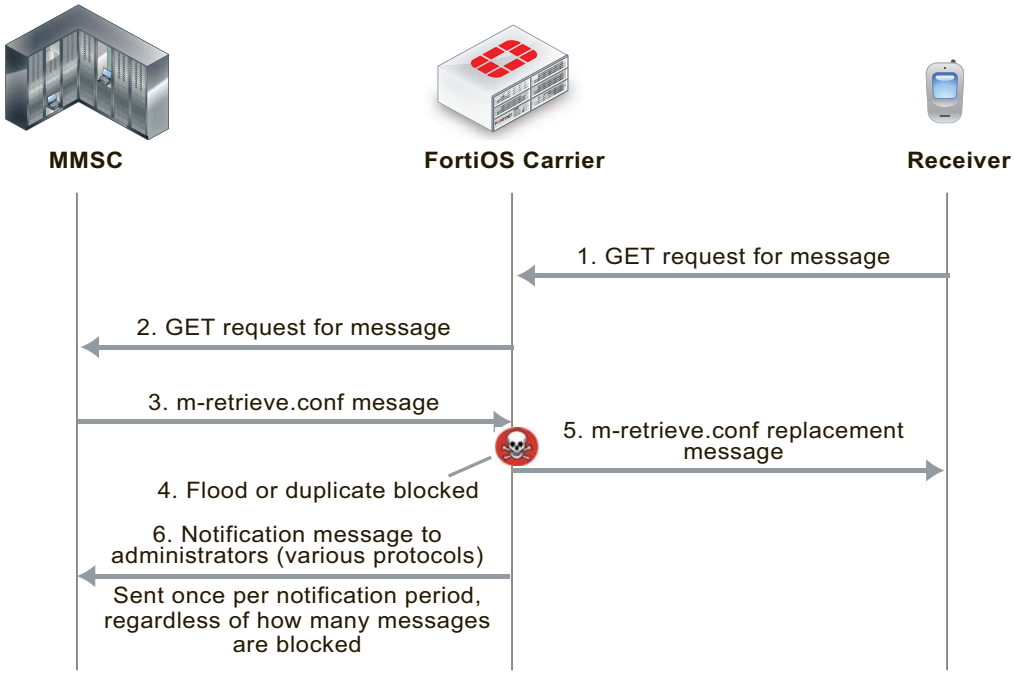

Figure 143:MM4 message flood and duplicate message blocking

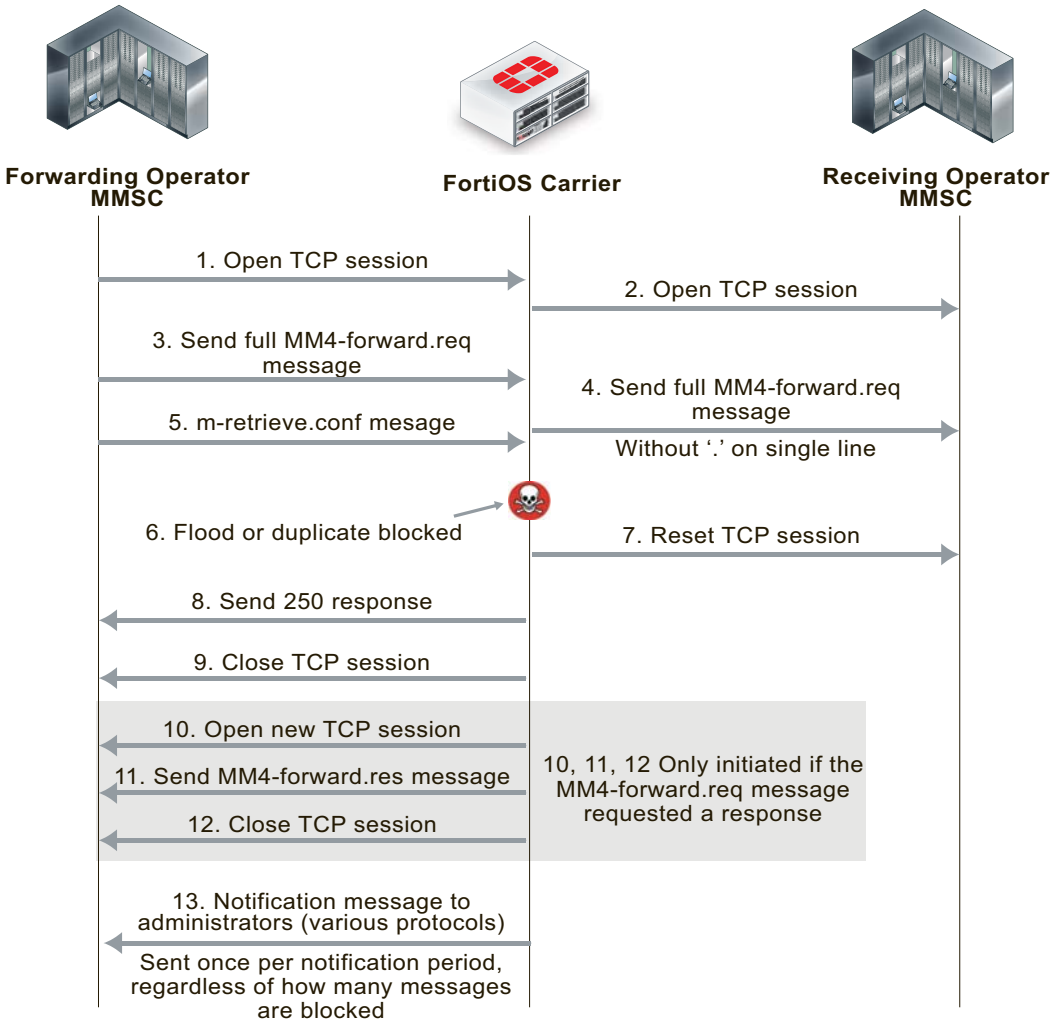

MMS protection profiles

An MMS protection profile is a group of settings that you can apply to an MMS session matched by a security policy.

MMS protection profiles are easy to configure and can be used by more than one security policy. You can configure a single MMS protection profile for the different traffic types handled by a set of security policies that require identical protection levels and types. This eliminates the need to repeatedly configure those same MMS protection profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need only moderate protection. You would configure two separate MMS protection profiles to provide the different levels of protection: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS Protection Profile, you need to add it to a security policy to apply the profile to MMS traffic.

See "MMS Security features" on page 701.

Bypassing MMS protection profile filtering based on carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from MMS protection profile filtering. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns. If you add a carrier endpoint pattern to a filter list and set the action to exempt from all scanning, all messages from matching carrier endpoints bypass MMS protection profile filtering. See "Bypassing message flood protection based on user's carrier endpoints" on page 727.

Applying MMS protection profiles to MMS traffic

To apply an MMS protection profile you must first create the MMS protection profile and then add the MMS protection profile to a security policy by enabling the Carrier security profile. The MMS protection profile then applies itself to the traffic accepted by that security policy.

MMS protection profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS protection profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS protection profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS protection profile.

To add an MMS protection profile to a security policy

1. Go to *Security Profiles* > *Carrier* > *MMS Profile*.
2. Select *Create New* to add an MMS protection profile.
3. Configure as needed, and save.
4. Go to *Policy*.
5. Select *Create New* to add a security policy, or select an existing policy and *Edit* to add the MMS profile.
6. Configure the security policy as required.
7. Enable *MMS Profile*, and select the MMS profile to add to the security policy.
8. Select *OK*.

GTP basic concepts

GPRS currently supports data rates from 9.6kbps to more than 100 kbps, and is best suited for burst forms of traffic. GPRS involves both radio and wired components. The mobile phone sends the message to a base station unit (radio based), and the base station unit sends the message to the carrier network and eventually the Internet (wired carrier network).

The network system then either sends the message back to a base station and to the destination mobile unit, or forwards the message to the proper carrier's network where it gets routed to the mobile unit.

This section includes:

- PDP Context
- GPRS security

PDP Context

The packet data protocol (PDP) context is a connection between a mobile station and the end address that goes through the SGSN and GGSN. It includes identifying information about the

mobile customer used by each server or device to properly forward the call data to the next hop in the carrier network, typically using a GTP tunnel between the SGSN and GGSN.

When a mobile customer has an active voice or data connection open, both the SGSN and GGSN have the PDP context information for that customer and session.

When a mobile phone attempts to communicate with an address on an external packet network, either an IP or X.25 address, the mobile station that phone is connected to opens a PDP context through the SGSN and GGSN to the end address. Before any traffic is sent, the PDP context must first be activated.

The information included in the PDP context includes the customer's IP address, the IMSI number of the mobile handset, and the tunnel endpoint ID for both the SGSN and GGSN. The ID is a unique number, much like a session ID on a TCP/IP firewall. All this information ensures a uniquely identifiable connection is made.

Since one mobile device may have multiple connections open at one time, such as data connections to different Internet services and voice connections to different locations, there may be more than one PDP context with the same IP address making the extra identifying information required.

The endpoint that the mobile phone is connecting to only knows about the GGSN — the rest of the GPRS connection is masked by the GGSN.

Along the PDP context path, communication is accomplished in using three different protocols.

- The connection between the Mobile Station and SGSN uses the SM protocol.
- Between SGSN and GGSN GTP is used.
- Between GGSN and the endpoint either IP or X.25 is used.

FortiOS Carrier is concerned with the SGSN to GGSN part of the PDP context — the part that uses GTP.

For more about PDP context, see "Tunnel Management Messages" on page 745.

Creating a PDP context

While FortiOS Carrier is concerned mostly with the SGSN to GGSN part of the PDP Context, knowing the steps involved in creating a PDP context helps understand the role each device, protocol, and message type plays.

Both mobile stations and GGSNs can create PDP contexts.

A Mobile Station creates a PDP context

1. The Mobile Station (MS) sends a `PDP activation request` message to the SGSN including the MS PDP address, and APN.
2. Optionally, security functions may be performed to authenticate the MS.
3. The SGSN determines the GGSN address by using the APN identifier.
4. The SGSN creates a downlink GTP tunnel to send IP packets between the GGSN and SGSN.
5. The GGSN creates an entry in its PDP context table to deliver IP packets between the SGSN and the external packet switching network.
6. The GGSN creates an uplink GTP tunnel to route IP-PDU from SGSN to GGSN.
7. The GGSN then sends back to the SGSN the result of the PDP context creation and if necessary the MS PDP address.
8. The SGSN sends an `Activate PDP context accept` message to the MS by returning negotiated the PDP context information and if necessary the MS PDP address.
9. Now traffic can pass from the MS to the external network endpoint.

A GGSN creates a PDP context

1. The network receives an IP packet from an external network.
2. The GGSN checks if the PDP Context has already been created.
3. If not, the GGSN sends a `PDU notification request` to the SGSN in order to initiate a PDP context activation.
4. The GGSN retrieves the IP address of the appropriate SGSN address by interrogating the HLR from the IMSI identifier of the MS.
5. The SGSN sends to the MS a request to activate the indicated PDP context.
6. The PDP context activation procedure follows the one initiated by the MS. See "A Mobile Station creates a PDP context" on page 646.
7. When the PDP context is activated, the IP packet can be sent from the GGSN to the MS.

Terminating a PDP context

A PDP context remains open until it is terminated. To terminate the PDP context an MS sends a `Deactivate PDP context` message to the SGSN, which then sends a `Delete PDP Context` message to the GGSN. When the SGSN receives a PDP context deletion acknowledgment from the GGSN, the SGSN confirms to the MS the PDP context deactivation. The PDP can be terminated by the SGSN or GGSN as well with a slight variation of the order of the messages passed.

When the PDP Context is terminated, the tunnel it was using is deleted as well. If this is not completed in a timely manner, it is possible for someone else to start using the tunnel before it is deleted. This hijacking will result in the original customer being overbilled for the extra usage. Anti-overbilling helps prevent this. See "Configuring Anti-overbilling in FortiOS Carrier" on page 742.

GPRS security

The GPRS network has some built-in security in the form of GPRS authentication. However this is minimal, and is not sufficient for carrier network security needs. A GTP firewall, such as FortiOS Carrier, is required to secure the Gi, Gn, and Gp interfaces.

GPRS authentication

GPRS authentication is handled by the SGSN to prevent unauthorized GPRS calls from reaching the GSM network beyond the SGSN (the base station system, and mobile station). Authentication is accomplished using some of the customer's information with a random number and uses two algorithms to create ciphers that then allow authentication for that customer.

User identity confidentiality ensures that customer information stays between the mobile station and the SGSN — no identifying information goes past the SGSN. Past that point other numbers are used to identify the customer and their connection on the network.

Periodically the SGSN may request identity information from the mobile station to compare to what is on record, using the IMEI number.

Call confidentiality is achieved through the use of a cipher, similar to the GPRS authentication described earlier. The cipher is applied between the mobile station and the SGSN. Essentially a cipher mask is XORd with each outgoing frame, and the receiving side XORs with its own cipher to result in the original frame and data.

Parts of a GTPv1 network

A sample GTP network consists of the end handset sender, the sender's mobile station, the carrier's network including the SGSN and GGSN, the receiver's mobile station, and the receiver handset.

When a handset moves from one mobile station and SGSN to another, the handset's connection to the Internet is preserved because the tunnel the handset has to the Internet using GTP tracks the user's location and information. For example, the handset could move from one cell to another, or between countries.

The parts of a GPRS network can be separated into the following groups according to the roles of the devices:

- Radio access to the GPRS network is accomplished by mobile phones and mobile stations (MS). See "Radio access" on page 649.
- Transport the GPRS packets across the GPRS network is accomplished by SGSNs and GGSNs, both local and remote, by delivering packets to the external services. See "Transport" on page 649.
- Billing and records are handled by CDF, CFR, HLR, and VLR devices. See "Billing and records" on page 652.

GPRS networks also rely on access points and PDP contexts as central parts of the communication structure. These are not actual devices, but they are still critical .

For more information on APN, see "Access Point Number (APN)" on page 753. For more information on PDP Context, see "PDP Context" on page 645.

These devices, their roles, neighboring devices, the interfaces and protocols they use are outlined in the following table. These devices and their connections can be viewed in the "Packet flow through the GPRS network" on page 654.

Figure 144: Carrier network showing the interfaces used (GTPv1)

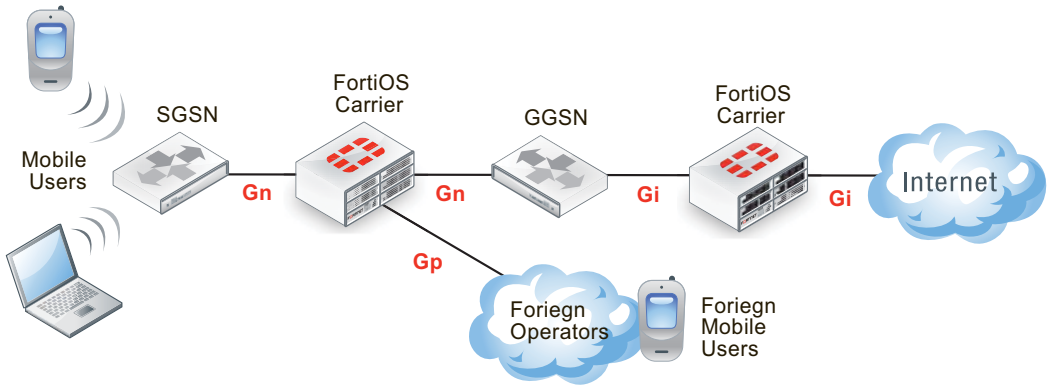

Table 33: Devices on a GTPv1 network

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	
Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay

Table 33: Devices on a GTPv1 network

SGSN (local)	**MS, SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR**	Ga, Gb, Gn, Gp, Gz	IP, Frame Relay, GTP, GTP'
SGSN (remote)	**SGSN (local)**	Gn	GTP
GGSN (local)	SGSN (local or remote), GGSN (local and remote), CDR, CFR, HLR, VLR	Ga, Gi, Gn, Gp, Gz	IP, GTP, GTP'
GGSN (remote)	SGSN (local), WAP gateway, Internet, other external services	Gi, Gp	IP, GTPv1
CDR, CFR	SGSN (local), GGSN (local)	Ga, Gz	GTP'
HLR, VLR	SGSN (local), GGSN (local)	Ga, Gz	GTP'

Radio access

For a mobile phone to access the GPRS core network, it must first connect to a mobile station. This is a cellular tower that is connected to the carrier network.

How the mobile phone connects to the mobile station (MS) is determined by what Radio Access Technologies (RATs) are supported by the MS.

Transport

Transport protocols move data along the carrier network between radio access and the Internet or other carrier networks.

FortiOS Carrier should be present where information enters the Carrier network, to ensure the information entering is correct and not malicious. This means a Carrier-enabled FortiGate unit intercepts the data coming from the SGSN or foreign networks destined for the SSGN or GGSN onto the network, and after the GGSN as the data is leaving the network.

GTP

GPRS Tunnelling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over their network via tunneling. This tunneling allows users to move between SGSNs and still maintain connection to the the Internet through the GGSN.

GTP has three versions version 0, 1, and 2. GTP1 and GTP2 are supported by FortiOS Carrier. The only GTP commands that are common to all forms of GTP are the echo request/response commands that allow GSNs to verify up to once every 60 seconds that neighboring GSNs are alive.

GTPv0

There have been three versions of GTP to date. The original version of GTP (version 0) has the following differences from version GTPv1.

- the tunnel identification is not random
- there are options for transporting X.25
- the fixed port number 3386 is used for all functions, not just charging
- optionally TCP is allowed as a transport instead of UDP
- not all message types are supported in version 0

GTPv1

On a GPRS network, Packet Data Protocol (PDP) context is a data structure used by both the Serving GPRS Support Node (SGSN) and the Gateway GPRS Support Node (GGSN). The PDP context contains the subscribers information including their access point, IP address, IMSI number, and their tunnel endpoint ID for each of the SGSN and GGSN.

The Serving GPRS Support Node (SGSN) is responsible for the delivery of data packets from and to the mobile stations within its geographical service area. Its tasks include packet routing and transfer, mobility management (attach/detach and location management), logical link management, and authentication and charging functions. The location register of the SGSN stores location information (e.g., current cell, current VLR) and user profiles (e.g., IMSI, address(es) used in the packet data network) of all GPRS users registered with this SGSN.

GTPv1-C

GTPv1-C refers to the control layer of the GPRS Transmission network. This part of the protocol deals with network related traffic.

FortiOS Carrier handles GTPv1-C in GTPv1 by using the Tunnel Endpoint IDentifier (TEID), IP address and a Network layer Service Access Point Identifier (NSAPI), sometimes called the application identifier, as an integer value that is part of the PDP context header information used to identify a unique PDP context in a mobile station, and SGSN.

For more information on GTPv1-C, see “GTP-C messages” on page 745.

GTPv1-U

GTPv1-U is defined in 3GPP TS 29.281 and refers to the user layer of the GPRS Tunneling network. This part of the protocol deals with user related traffic, user tunnels, and user administration issues.

A GTPv1-U tunnel is identified by a TEID, an IP address, and a UDP port number. This information uniquely identifies the limb of a GTPv1 PDP context. The IP address and the UDP port number define a UDP/IP path, a connectionless path between two endpoints (i.e. SGSN or GGSN). The TEID identifies the tunnel endpoint in the receiving GTPv1-U protocol entity; it allows for the multiplexing and demultiplexing of GTP tunnels on a UDP/IP path between a given GSN-GSN pair. For more information on GTPv1-U, see “GTP-U messages” on page 746.

The GTP core network consists of one or more SGSNs and GGSNs.

GGSN

The Gateway GPRS Support Node (GGSN) connects the GPRS network on one side via the SGSN to outside networks such as the Internet. These outside networks are called packet data networks (PDNs). The GGSN acts as an edge router between the two different networks — the GGSN forwards incoming packets from the external PDN to the addressed SGSN and the

GGSN also forwards outgoing packets to the external PDN. the GGSN also converts the packets from the GPRS packets with SGSN to the external packets, such as IP or X.25.

SGSN

The Serving GPRS Support Node (SGSN) connects the GPRS network to GTPv1 compatible mobile stations, and mobile units (such as UTRAN and ETRAN) on one side and to the gateway node (GGSN), which leads to external networks, on the other side. Each SGSN has a geographical area, and mobile phones in that area connect to the GPRS network through this SGSN. The SGSN also maintains a location register that contains customer's location and user profiles until they connect through a different SGSN at which time the customer information is moved to the new SGSN. This information is used for packet routing and transfer, mobility management also known as location management, logical link management, and authentication and billing functions.

GTPv2

GTPv2, defined in 3GPP TS 29.274, is dramatically differnet from GTPv1, defined in 3GPP TS 29.060. Where in GTPv1 the tunnel is between the SGSN and the GGSN, in GTPv2 The SGSN is between the MME and the LTE Serving Gateway (S-GW), beyond which is the PDN gateway (P-GW). Even tunnel management messages have changed significantly.

Figure 145: Network diagram for GTPv2

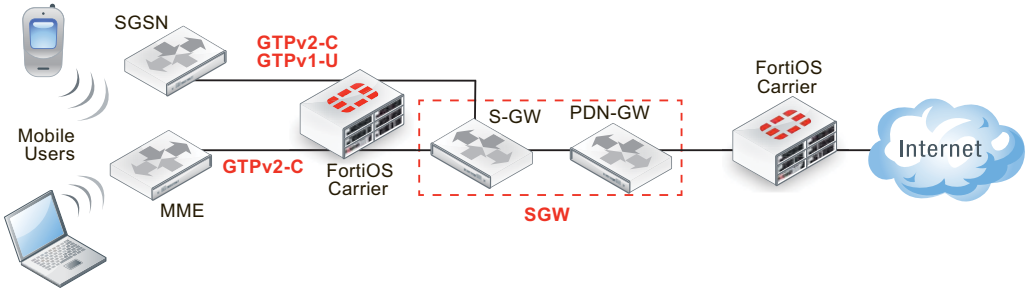

Table 34: Device roles on a GTPv2 network

Device role	Neighboring Devices	Interfaces used	Protocols used
Mobile Users	Mobile Stations (MS)	Radio Access Technology (RAT)	--
GTPv1 Mobile Stations (MS)	Mobile Users, SGSN	Gb	IP, Frame Relay
GTPv2 Mobile Stations (MS)	Mobile Users, MME	???	IP, Frame Relay
SGSN (local)	**GTPv1 MS, SGSN, S-GW**	???	IP, Frame Relay, GTPv1, GTP'

Table 34: Device roles on a GTPv2 network

S-GW	SGSN, MME, P-GW	???	IP, GTPv2, GTP’
P-GW	S-GW, Internet, other external services	???	IP, GTPv2

GTPv2-C

GTPv2-C is the control layer messaging for GTPv2. It is used by LTE mobile stations, SGSN units for backwards compatibility, and SGWs that are the gateway to other networks. The messaging is very different from GTPv1. GTPv2-C is required to communicate with the Mobility Management Entity (MME) to create, change and delete EPS bearers when handover events happen, and to create Forwarding tunnels. The protocol is also used to communicate with the Serving Gateway (SGW) which has the S-GW and PDN-GW interfaces, and the Serving GPRS Support Node (SGSN).

MME

MME essentially fills the role of the SGSN in a GTPv1 network — it is how the mobile stations gain access to the Carrier network. GTPv2 supports different mobile stations than GTPv1, so MME handles the GTPv2 MSes and SGSN handles the GTPv1 MSes

Billing and records

A major part of the GPRS network is devoted to billing. Customer billing requires enough information to identify the customer, and then billing specific information such as connection locations and times, as well as amount of data transferred. A modified form of GTP called GTP’ is used for billing. The home location records and visitor location records store information about customers that is critical to billing.

GTP’ (GTP prime)

GTP is used to handle tunnels of user traffic between SGSNs and GGSNs. However for billing purposes, other devices that are not supported by GTP are required. GTP’ (GTP prime) is a modified form of GTP and is used to communicate with these devices such as the Charging Data Function (CDF) that communicates billing information to the Charging Gateway Function (CGF). In most cases, GTP‘ transports user records from many individual network elements, such as the GGSNs, to a centralised computer which then delivers the charging data more conveniently to the network operator's billing center, often through the CGF. The core network sends charging information to the CGF, typically including PDP context activation times and the quantity of data which the end user has transferred.

GTP’ is used by the Ga and Gz interfaces to transfer billing information. GTP’ uses registered UDP/TCP port 3386. GTP’ defines a different header, additional messages, field values, as well as a synchronisation protocol to avoid losing or duplicating CDRs on CGF or SGSN/GGSN failure. Transferred CDRs are encoded in ASN.1.

HLR

The Home Location Register (HLR) is a central database that contains details of each mobile phone subscriber that is authorized to use the GSM core network. There can be several logical, and physical, HLRs per public land mobile network (PLMN), though one international mobile subscriber identity (IMSI)/MSISDN pair can be associated with only one logical HLR (which can span several physical nodes) at a time. The HLRs store details of every SIM card issued by the mobile phone operator. Each SIM has a unique identifier called an IMSI which is the primary key to each HLR record.

VLR

The Visitor Location Register (VLR) is a database which stores information about all the mobile devices that are currently under the jurisdiction of the Mobile Switching Center which it serves. Of all the information the VLR stores about each Mobile Station, the most important is the current Location Area Identity (LAI). This information is vital in the call setup process.

Whenever an MSC detects a new MS in its network, in addition to creating a new record in the VLR, it also updates the HLR of the mobile subscriber, informing it of the new location of that MS.

For more information on GTP‘, see “GTP-U and Charging Management Messages” on page 746.

GPRS network common interfaces

There are interfaces for each connection on the GPRS network. An interface is an established standard form of communication between two devices. Consider a TCP/IP network. In addition to the transport protocol (TCP) there are other protocols on that network that describe how devices can expect communications to be organized, just like GPRS interfaces.

Interfaces between devices on the network

There are a series of interfaces that define how different devices on the carrier network communicate with each other. There interfaces are called Ga to Gz, and each one defines how a specific pair of devices will communicate. For example Gb is the interface between the base station and the SGSN, and Gn is one possible interface between the SGSN and GGSN.

The SGSN and GGSN keep track of the CDR information and forward it to the Charging Data Function (CDF) using the Gr interface between the SGSN and home location register (HLR), Gs interface between the SGSN and MSC (VLR), Gx interface between the GGSN and the Charging Rules Function (CRF), Gy between the GGSN and online charging system (OCS), and finally Gz which is the off-line (CDR-based) charging interface between the GSN and the CG that uses GTP'.

Each of these interfaces on the GPRS network is has a name in the format of `Gx` where `x` is a letter of the alphabet that determines what part of the network the interface is used in. It is common for network diagrams of GPRS networks to include the interface name on connections between devices. See “Packet flow through the GPRS network” on page 654.

The Carrier-enabled FortiGate unit only provides protection on the Gn, Gp, and Gi interfaces.

Table 35: GPRS network interfaces, their roles, and billing

Name	Device connections that use this interface	Traffic Protocol used	Its role or how it affects billing
Ga	CDR and GSN (SGSNs and GGSNs)	GTP‘ - GTP modified to include CDR role	CDR have the accounting records, that are compiled in the GSN and then sent to the Charging Gateway (CG)

Table 35: GPRS network interfaces, their roles, and billing

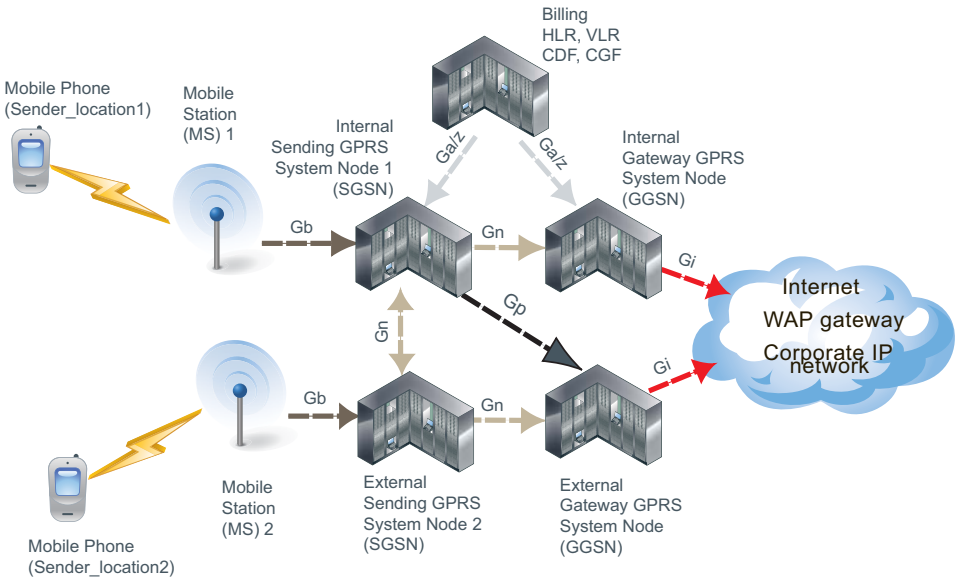
Gb	MS and SGSN	Frame Relay or IP	When an IP address moves to a new MS, the old MS may continue to use and bill that IP address.
Gi	GGSN and public data networks (PDNs)	IP based	This is the connection to the Internet. If the GTP tunnel is deleted without notifying the Gi interface, the connection may remain open incurring additional charges. FortiOS Carrier adds this interface to a firewall. See "Anti-overbilling with FortiOS Carrier" on page 742.
Gn	SGSN and external SGSNs and internal GGSNs	GTP	When the GTP tunnel is deleted, need to inform other interfaces immediately to prevent misuse of connections remaining open. FortiOS Carrier adds this interface to a firewall.
Gp	Internal SGSN and external GGSNs	GTP	
Gz	GSN (SGSN and GGSN) and the charging gateway (CG)	GTP'	Used for the offline charging interface. Ga is used for online charging.

Corporate customers may have a direct connection to the Gi interface for higher security. The Gi interface is normally an IP network, though a tunnelling protocol such as GRE or IPsec may be used instead.

Packet flow through the GPRS network

To better understand the GPRS network, we will follow the path data takes for a normal connection. For this example a call placed from a mobile phone involves accessing services on the Internet.

Figure 146: Sample GPRS network topology



1 A mobile phone places a call using a mobile station (MS). This connection between the mobile phone and the MS is a radio connection using one of the radio access technologies. See “Radio Access Technology (RAT) type” on page 753.

2. The MS connects to a GPRS System Node (GSN) specifically a Sending GSN. This connection uses the Gb interface and typically uses IP address or Frame Relay.
3. The SGSN checks the mobile phone information located in the home location register (HLR) or visitor location register (VLR) to ensure there is subscriber information for that phone. If this mobile phone is from another network, the SGSN uses the VLR and updates its home carrier’s information with its current location and information. This connection involves the Ga or Gz interfaces, and uses the GTP’ protocol for communication.
4. The SGSN checks to make sure the phone did not transfer this connection from a different MS. If it did, the connection has already been established (along with the billing) and is handed off to this SGSN. If the call is being handed over from another SGSN, it will use the Gn interface between the two SGSNs.
5. The SGSN sends GTP messages to the local external Gateway GSN (GGSN) to create a GTP tunnel for this PDP context to access the Internet. It is possible that a remote GGSN has access to a service, such as a WAP gateway, that the local GGSN is missing. In this situation, the local SGSN uses the Gp interface to connect to the remote GGSN. Both the Gn and Gp interfaces use GTP.
6. The both the local and remote GGSNs connect to external services outside the GPRS network. These services can include a WAP gateway, a corporate IP network directly connected to the GPRS network, or the Internet. The connection from the GGSN to the external services uses the Gi interface.

SCTP

As of FortiOS version 5.0, the FortiGate can now natively handle SCTP (Stream Control Transport Protocol) traffic, as an alternative to TCP and UDP for use in Carrier networks. The FortiGate handles SCTP as if it would any other traffic.

Overview

SCTP is a connection-oriented transport protocol that overcomes some of the limitations of both TCP and UDP that prevent reliable transfer of data over IP-based networks (such as those used by telephony systems and carrier networks). The 'Stream' in SCTP refers to the sequence of user messages or packets that are considered at the same time to be individual objects and also treated as a whole by networked systems. SCTP is less vulnerable to congestion and flooding due to more advanced error handling and flood protection built into the protocol.

Table 36: SCTP features as compared to TCP and UDP

Feature	SCTP	TCP	UDP
State required at each endpoint	yes	yes	no
Reliable data transfer	yes	yes	no
Congestion control and avoidance	yes	yes	no
Message boundary conservation	yes	no	yes
Path MTU discovery and message fragmentation	yes	yes	no
Message bundling	yes	yes	no
Multi-homed hosts support	yes	no	no
Multi-stream support	yes	no	no
Unordered data delivery	yes	no	yes
Security cookie against SYN flood attack	yes	no	no
Built-in heartbeat (reachability check)	yes	no	N/A

All of these features are built into the design of the Protocol, and the structure of SCTP packets and networks. The FortiGate unit interprets the traffic and provides the necessary support for maintenance and verification features, but the features are not FortiGate specific. These features are documented in greater detail below.

State required at each endpoint

Constant back and forth acknowledgement and content verification messages are sent between all SCTP peer endpoints, and all endpoints' state machine actions must be synchronized for traffic to flow.

Reliable data transfer

SCTP places data and control information (eg. source, destination, verification) into separate messages, both sharing the same header in the same SCTP packet. This allows for constant verification of the contained data at both ends and along the path, preventing data loss or fragmentation. As well, data is not sent in an interruptible stream as in TCP. See Message bundling below for more information.

Congestion control and avoidance

Built-in, constantly updating path detection and monitoring automatically redirect packets along alternate paths in case of traffic congestion or inaccessible destinations. For deliberate/malicious congestion control, see Security cookie against SYN flood attack below.

Message boundary conservation

SCTP is designed in such a way that no matter how messages are divided, redirected, or fragmented, the message boundaries will be maintained within the packets, and all messages cannot be appended without tripping verification mechanisms.

Path MTU discovery and message fragmentation

SCTP is capable of Path Maximum Transmission Unit discovery, as outlined in RFC4821. Two specific alterations have been made to how SCTP handles MTU. First, that endpoints will have separate MTU estimates for each possible multi-homed endpoint. Second, that bundled message fragments (as explained below) will be directed based on MTU calculations, so that retransmissions (if necessary) will be sent without delay to alternate addresses.

Message bundling

SCTP is a message-oriented protocol, which means that despite being a streaming data protocol, it transports a sequence of specific messages, rather than transporting a stream of bytes (like TCP). Since some data transmissions are small enough to not require a complete message's worth of content, so multiple pieces of content will be transmitted simultaneously within the messages.

Multi-homed hosts support

SCTP supports multi-homing, which is a network structure in which one or multiple sources/destinations has more than one IP address. SCTP can adapt to multi-homing scenarios and redirect traffic to alternate IP addresses in case of failure.

Multi-stream support

Due to the message bundling feature allowing for multiple pieces of content to be sent in messages at once, SCTP can 'multi-stream' content, by deliberately dividing it among messages at a fixed rate, so that multiple types of content (eg. both images and text) can be loaded at once, at the same pace.

Unordered data delivery

With control messages in every packet to provide verification of any packet's data and its place in the stream, the data being transmitted can actually arrive in any order, and verify that all has arrived or that some is missing.

Security cookie against SYN flood attack

Since every packet contains verification of its place in the stream, it makes it easy for the protocol to detect when redundant, corrupted or malicious packets flood the path, and they are automatically dropped when necessary.

Built-in heartbeat (reachability check)

Endpoints automatically send specific control chunks among the other SCTP packet information to peer endpoints, to determine the reachability of the destination. Hearthbeat acknowledgement packets are returned if the destination is available.

SCTP Firewall

FortiGate stateful firewalls will protect and inspect SCTP traffic, according to RFC4960. SCTP over IPSec VPN is also supported. The FortiGate device is inserted as a router between SCTP endpoints. It checks SCTP Syntax for the following information:

- Source and destination port
- Verification Tag
- Chunk type, chunk flags, chunk length
- Sequence of chunk types
- Associations

The firewall also oversees and maintains several SCTP security mechanisms:

- SCTP four-way handshake
- SCTP heartbeat
- NAT over SCTP

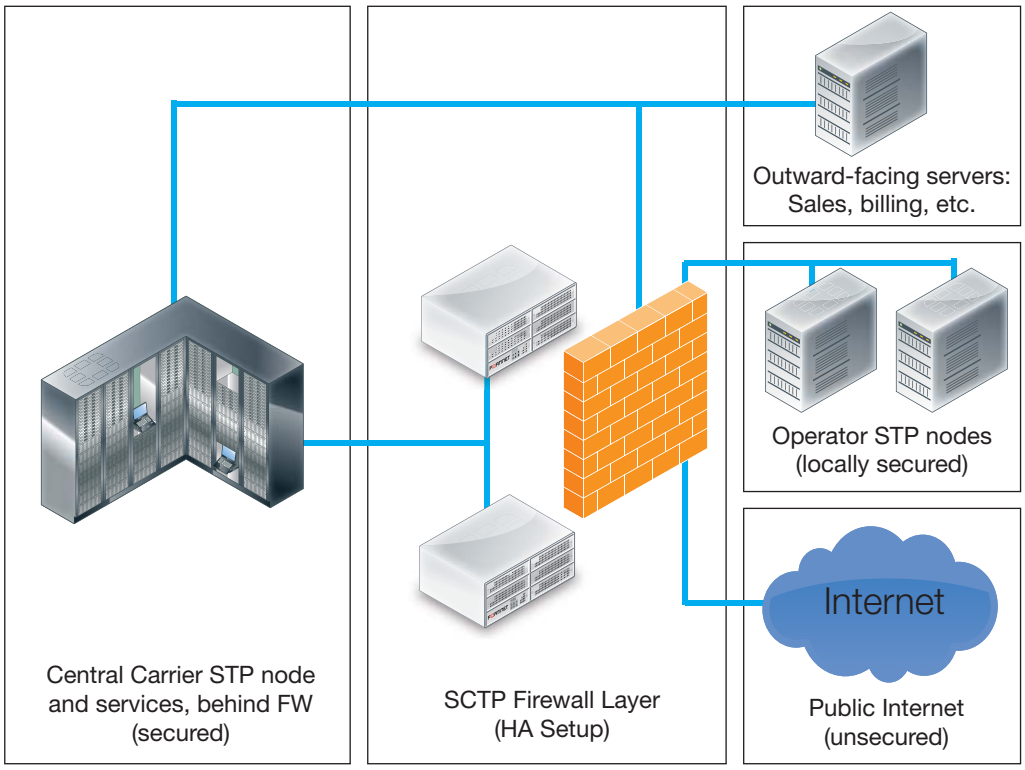
The firewall has IPS DoS protection against known threats to SCTP traffic, including INIT/ACK flood attacks, and SCTP fuzzing.

SCTP example scenario

An ideal SCTP configuration for a Carrier serving multiple operators/service providers involves a unified Firewall, securing all incoming and outgoing traffic over the Carrier network, whether it be standard web traffic, GTP or other carrier traffic, or corporate traffic for the Carrier company.

One best practice method to provide a unified firewall with built-in redundancy is to make use of multiple FortiGate units, connected in a High Availability cluster. Also, there are additional methods that can be applied to ease the complexity of managing multiple services, functions, and traffic types across multiple devices.

Figure 147: Sample SCTP Network Topology

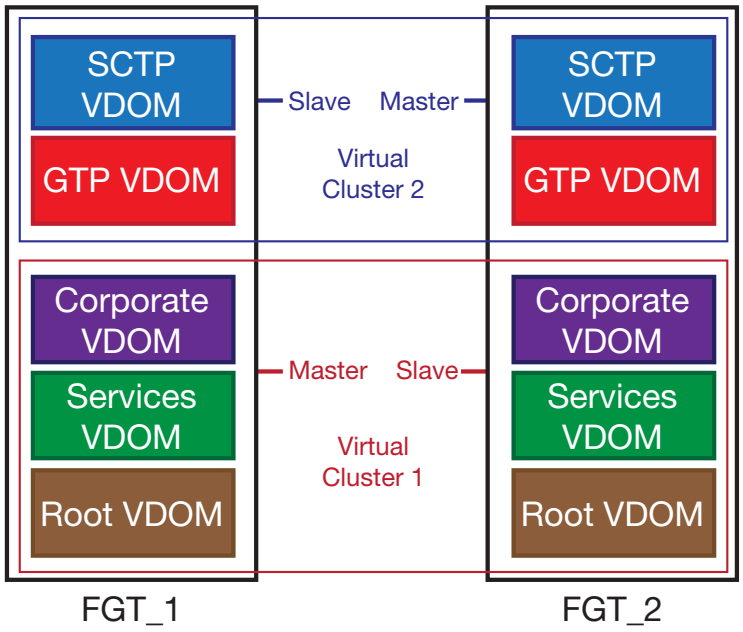


In this example, the firewall layer is configured with two FortiGate devices to act as an HA cluster, providing automatic load balancing and failover detection for the main firewall.

The two devices together make up the firewall, through which all traffic passes. Virtual Domains are created within the FortiGate units, distributing services and traffic into individual VDOMs, allowing them to be monitored and secured individually, to help mitigate possible threats to Carrier networks that target specific services. Individual departments or administrators can manage specific VDOMs, or the FortiGates can be collectively managed centrally by network administrators.

The VDOMs are distributed as below:

Figure 148:VDOM distribution between SCTP Firewall Layer FortiGate units



One FortiGate handles basic FortiGate services and non-Carrier traffic. Configuring virtual clustering across the two FortiGates allows one to mirror its VDOMs across to the other unit.

The second FortiGate can then primarily provide Carrier-specific services and handle SCTP, Gi and GTP traffic, using the first FortiGate as the slave unit in a second virtual cluster.

Carrier web-based manager settings

The Carrier menu provides settings for configuring FortiOS Carrier features within the Security Profiles menu. These features include MMS and GTP profiles.

In *Security Profiles* > *Carrier*, you can configure profiles and settings for MMS and GTP. In the Carrier menu, you can configure an MMS profile and then apply it to a security policy. You can also configure GTP profiles and apply those to security policies as well.

This topic includes the following:

MMS profiles

Since MMS profiles can be used by more than one security policy, you can configure one profile for the traffic types handled by a set of security policies requiring identical protection levels and types, rather than repeatedly configuring those same profile settings for each individual security policy.

If the security policy requires authentication, do not select the MMS profile in the security policy. This type of profile is specific to the authenticating user group. For details on configuring the profile associated with the user group, see User Groups in the *User Authentication guide*.

For example, while traffic between trusted and untrusted networks might need strict protection, traffic between trusted internal addresses might need moderate protection. To provide the different levels of protection, you might configure two separate protection profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Once you have configured the MMS profile, you can then apply the profile to MMS traffic by applying it to a security policy.

MMS profiles can contain settings relevant to many different services. Each security policy uses the subset of the MMS profile settings that apply to the sessions accepted by the security policy. In this way, you might define just one MMS profile that can be used by many security policies, each policy using a different or overlapping subset of the MMS profile.

The MMS Profile page contains options for each of the following:

- MMS scanning
- MMS Bulk Email Filtering Detection
- MMS Address Translation
- MMS Notifications
- DLP Archive
- Logging

MMS profile configuration settings

The following are MMS profile configuration settings in *Security Profiles* > *Carrier* > *MMS Profile*.

MMS Profile page Lists each individual MMS profile that you created. On this page, you can edit, delete or create an MMS profile.	
Create New	Creates a new MMS profile. When you select *Create New*, you are automatically redirected to the New MMS Profile page.
Edit	Modifies settings within an MMS profile. When you select *Edit*, you are automatically redirected to the Edit MMS Profile.
Delete	Removes an MMS profile from the list on the MMS Profile page. To remove multiple MMS profiles from within the list, on the MMS Profile page, in each of the rows of the profiles you want removed, select the check box and then select *Delete*. To remove all MMS profiles from the list, on the MMS Profile page, select the check box in the check box column, and then select *Delete*.
Name	The name of the MMS profile.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*Security Profiles* > *Antivirus* > *Profiles*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New MMS Profile page Provides settings for configuring an MMS profile. This page also provides settings for configuring DLP archives and logging.	
Profile Name	Enter a name for the profile.

Comments	Enter a description about the profile. This is optional.
MMS Scanning	Configure MMS Scanning options. See “MMS scanning options” on page 663.
MMS Bulk Email Filtering Detection	Configure MMS Bulk Email options. See “MMS bulk email filtering options” on page 665.
MMS Address Translation	Configure MMS Address Translation options. See “MMS Address Translation options” on page 668
MMS Notifications	Configure MMS Notification options. “MMS Notifications” on page 669.
DLP Archive	Configure DLP archive option. See “DLP Archive options” on page 672
Logging	Configure logging options. See “Logging” on page 673.

MMS scanning options

You can configure MMS scanning protection profile options to apply virus scanning, file filtering, content filtering, carrier endpoint blocking, and other scanning to MMS messages transmitted using the MM1, MM3, MM4 and MM7 protocols.

The following are the MMS Scanning options that are available within an MMS profile. You can create an MMS profile in *Security Profiles* > *Carrier* > *MMS Profile* or edit an existing one. You must expand MMS Scanning to access the following options.

MMS Scanning section of the New MMS Profile page	
Monitor Only	Select to cause the unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Select this option to be able to report on viruses and other problems in MMS traffic without affecting users. **Tip:** Select *Remove Blocked* if you want the unit to actually remove content intercepted by MMS scanning options.
Virus Scan	Select to scan attachments in MMS traffic for viruses. Since MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configuration also applies to MM1 and MM7 scanning. MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configuration also applies to MM3 and MM4 scanning.
Scan MM1 message retrieval	Select to scan message retrievals that use MM1. If you enable *Virus Scan* for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.

Quarantine	Select to quarantine the selected MMS traffic
Remove Blocked	Select to remove blocked content from each protocol and replace it with the replacement message. Select *Constant* if the unit is to preserve the length of the message when removing blocked content, as may occur when billing is affected by the length of the message. **Tip:** If you only want to monitor blocked content, select *Monitor Only*.
Content Filter	Select to filter messages based on matching the content of the message with the words or patterns in the selected web content filter list. For information about adding a web content filter list, see the *FortiGate CLI Reference*.
Carrier Endpoint Block	Select to add *Carrier Endpoint Filtering* in this MMS profile. Select the carrier endpoint filter list to apply it to the profile. For information about carrier endpoint filtering, see "Carrier Endpoint Filter Lists" on page 681.
MMS Content Checksum	Select to add MMS Content Checksum in this MMS profile. Select the MMS content checksum list to apply it to the profile.
Pass Fragmented Messages	Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 message are blocked.
Comfort Clients	Select client comforting for MM1 and MM7 sessions. Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.
Comfort Servers	Select server comforting for each protocol. Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for the unit to buffer and scan large POST requests from slow clients.
Interval (1-900 seconds)	Enter the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.
Amount (1-10240 bytes)	The number of bytes sent by client or server comforting at each interval.

Oversized MMS Message		Select *Block* or *Pass* for files and email messages exceeding configured thresholds for each protocol. The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.
	Threshold (1KB - 800 MB)	Enter the oversized file threshold and select KB or MB. If a file is larger than the threshold the file is passed or blocked depending on the *Oversized MMS Message* setting. The web-based manager displays the allowed threshold range. The threshold maximum is 10% of the unit's RAM.

MMS bulk email filtering options

You can use the MMS bulk email filtering options to detect and filter MM1 and MM4 message floods and duplicate messages. You can configure three thresholds that define a flood of message activity and three thresholds that define excessive duplicate messages. The configuration of each threshold includes the response actions for the threshold.

The configurable thresholds for each of the flood and duplicate sensors and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

You can also add MSISDN to the bulk email filtering configuration and select a subset of the bulk email filtering options to applied to these individual MSISDNs.

You must first select MM1 and/or MM4 to detect excessive message duplicates. If excessive message duplicates are detected, the unit will perform the *Duplicate Message Action* for the specified duration.

You can configure three duplicate message thresholds and enable them with separate values and actions. They are labeled Duplicate Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Duplicate Threshold 1 and Duplicate Threshold 2, but you cannot disable Duplicate Threshold 1 and enable Duplicate Threshold 2.

When traffic accepted by a security policy that contains an MMS profile with duplicate message configured receives MM1 or MM4 duplicate messages that match a threshold configured in the MMS protection profile, the unit performs the duplicate message action configured for the matching threshold.

You can configure three message flood thresholds and enable them with separate values and actions. They are labeled Flood Threshold 1 through 3 and must be enabled in sequence. For example, you can enable Flood Threshold 1 and Flood Threshold 2, but you cannot disable Flood Threshold 1 and enable Flood Threshold 2.

When traffic accepted by a security policy that contains an MMS protection profile with message flooding configured experiences MM1 or MM4 message flooding that matches a threshold configured in the MMS profile, the unit performs the message flood action configured for the matching threshold.

MMS Bulk Email Filtering Detection section of the New MMS Profile page **This section of the New MMS Profile page contains numerous sections where you can configure specific settings for flood threshold, duplicate threshold and recipient MSISDNs.**		
Message Flood section of the new MMS Profile page The message flood settings for each flood threshold. Expand each to configure settings for a threshold.		
Flood Threshold 1		Expand to reveal the flood threshold settings for Flood Threshold 1. The settings for Flood Threshold 1 are the same for Flood Threshold 2 and 3.
	Enable	Select to apply Flood Threshold 1 to the MSISDN exception.
	Message Flood Window	Enter the period of time during which a message flood will be detected if the *Message Flood Limit* is exceeded. The message flood window can be 1 to 2880 minutes (48 hours).
	Message Flood Limit	Enter the number of messages which signifies a message flood if exceeded within the *Message Flood Window*.
	Message Flood Block Time	Enter the amount of time during which the unit performs the *Message Flood Action* after a message flood is detected.
	Message Flood Action	Select one or more actions that the unit is to perform when a message flood is detected.
Flood Threshold 2 **Flood Threshold 3**		Expand to configure settings for Flood Threshold 2 or 3 respectively.
Duplicate Message section of the new MMS Profile page **The duplicate message threshold settings. Expand each to configure settings for a threshold.**		
MM1 Retrieve Duplicate Enable		Select to scan MM1 `mm1-retr` messages for duplicates. By default, `mm1-retr` messages are not scanned for duplicates as they may often be the same without necessarily being bulk or spam.
	Enable	Select to enable the selected duplicate message threshold and to make the rest of the options available for configuration.
	Duplicate Message Window	Enter the period of time during which excessive message duplicates will be detected if the Duplicate message Limit it exceeded. The duplicate message window can be 1 to 2880 minutes (48 hours).
	Duplicate Message Limit	Enter the number of messages which signifies excessive message duplicates if exceeded within the Duplicate Message Window.

	Duplicate Message Block Time	Enter the amount of time during which the unit will perform the Duplicate Message Action after a message flood is detected.
	Duplicate Message Action	Select one or more actions that the unit is to perform when excessive message duplication is detected.
Duplicate Threshold 2 **Duplicate Threshold 3**		Expand to configure settings for Duplicate Threshold 2 or 3 respectively.
Recipient MSISDN section of the New MMS Profile page The recipient Mobile Subscriber Integrated Services Digital Network Number (MSISDN) settings for each recipient MSISDN. When you select *Create New*, you are automatically redirected to the New MSISDN page. You need to save the profile before you can add MSISDNs.		
Recipient MSISDN		The recipient MSISDN.
Flood Threshold 1		Check to enable Flood Threshold 1 settings for this MSISDN.
Flood Threshold 2		ICheck to enable Flood Threshold 2 settings for this MSISDN..
Flood Threshold 3		ICheck to enable Flood Threshold 3 settings for this MSISDN..
Duplicate Threshold 1		Check to enable Duplicate Threshold 1 settings for this MSISDN..
Duplicate Threshold 2		Check to enable Duplicate Threshold 2 settings for this MSISDN..
Duplicate Threshold 3		Check to enable Duplicate Threshold 3 settings for this MSISDN..
Edit		Modifies the settings of a Recipient MSISDN in the Recipient MSISDN list. When you select *Edit*, you are automatically redirected to the New MSISDN page.
Delete		Removes a Recipient MSISDN in the Recipient MSISDN list within the Recipient MSISDN section of the page.
New MSISDN page		
Create New		Creates a new Recipient MSISDN. When you select *Create New*, you are automatically redirected to the New MSISDN page.
Recipient MSISDN		Enter a name for the recipient MSISDN.
Flood Threshold 1		Select to apply Flood Threshold 1 to the MSISDN exception.
Flood Threshold 2		Select to apply Flood Threshold 2 to the MSISDN exception.

Flood Threshold 3	Select to apply Flood Threshold 3 to the MSISDN exception.
Duplicate Threshold 1	Select to apply Duplicate Threshold 1 to the MSISDN exception.
Duplicate Threshold 2	Select to apply Duplicate Threshold 2 to the MSISDN exception.
Duplicate Threshold 3	Select to apply Duplicate Threshold 3 to the MSISDN exception.

MMS Address Translation options

The sender's carrier endpoint is used to provide logging and reporting details to the mobile operator and to identify the sender of infected content.

When MMS messages are transmitted, the *From* field may or may not contain the sender's address. When the address is not included, the sender information will not be present in the logs and the unit will not be able to notify the user if the message is blocked unless the sender's address is made available elsewhere in the request.

The unit can extract the sender's address from an extended HTTP header field in the HTTP request. This field must be added to the HTTP request before it is received by the unit. If this field is present, it will be used instead of the sender's address in the MMS message for logging and notification. If this header field is present when a message is retrieved, it will be used instead of the *To* address in the message. If this header field is not present the content of the *To* header field is used instead.

Alternatively, the unit can extract the sender's address from a cookie.

You can configure MMS address translation to extract the sender's carrier endpoint so that it can be added to log and notification messages. You can configure MMS address translation settings to extract carrier endpoints from HTTP header fields or from cookies. You can also configure MMS address translation to add an endpoint prefix to the extracted carrier endpoints. For more information, see Dynamic Profiles and Endpoints in the *User Authentication guide*.

MMS Address Translation section of the New MMS Profile page	
Sender Address Source	Select to extract the sender's address from the *HTTP Header Field* or a *Cookie*. You must also specify the identifier that contains the carrier endpoint.

Sender Address Identifier		Enter the sender address identifier that includes the carrier endpoint. The default identifier is `x-up-calling-line-id`.
		If the *Sender Address Source* is *HTTP Header Field*, the address and its identifier in the HTTP request header takes the format:
		`<Sender Address Identifier>: <MSISDN_value>`
		Where the `<MSISDN_value>` is the carrier endpoint. For example, the HTTP header might contain:
		`x-up-calling-line-id: 6044301297`
		where `x-up-calling-line-id` would be the Sender Address Identifier.
		If the *Sender Address Source* is Cookie, the address and its identifier in the HTTP request header's `Cookie` field takes the format of attribute-value pairs:
		`Cookie: id=<cookie-id>;`
		`<Sender Address Identifier>=<MSISDN Value>`
		For example, the HTTP request headers might contain:
		`Cookie:`
		`id=0123jf!a;x-up-calling-line-id=6044301297`
		where `x-up-calling-line-id` would be the *Sender Address Identifier*.

Convert Sender Address From / To HEX		Select to convert the sender address from ASCII to hexadecimal or from hexadecimal to ASCII. This is required by some applications.
Add Carrier Endpoint Prefix for Logging / Notification		Select the following to enable adding endpoint prefixes for logging and notification.
	Enable	Select to enable adding the country code to the extracted carrier endpoint, such as the MSISDN, for logging and notification purposes. You can limit the number length for the test numbers used for internal monitoring without a country code.
	Prefix	Enter a carrier endpoint prefix to be added to all carrier endpoints. Use the prefix to add extra information to the carrier endpoint in the log entry.
	Minimum Length	Enter the minimum length of the country code information being added. If this and Maximum Length are set to zero (`0`), length is not limited.
	Maximum Length	Enter the maximum length of the country code information being added. If this and Minimum Length are set to zero (`0`), length is not limited.

MMS Notifications

MMS notifications are messages that a unit sends when an MMS profile matches content in an MM1, MM3, MM4 or MM7 session. For example, the MMS profile detects a virus or uses

content blocking to block a web page, text message or email. You can send notifications to the sender of the message using same protocol and the addressing headers in the original message. You can also configure MMS notifications to send notification messages to another destination (such as a system administrator) using the MM1, MM3, MM4 or MM7 protocol.

You need to enable one or more *Notification Types* or you can add an *Antivirus Notification List* to enable sending notifications,.

You can also use MMS notifications options to configure how often notifications are sent. The unit sends notification messages immediately for the first event, then at a configurable interval if events continue to occur. If the interval does not coincide with the window of time during which notices may be sent, the unit waits to send the notice in the next available window. Subsequent notices contain a count of the number of events that have occurred since the previous notification.

There are separate notifications for each notification type, including virus events. Virus event notifications include the virus name. Up to three viruses are tracked for each user at a time. If a fourth virus is found, one of the existing tracked viruses is removed from the list.

The notifications are MM1 `m-send-req` messages sent from the unit directly to the MMSC for delivery to the client. The host name of the MMSC, the URL to which `m-send-req` messages are sent, and the port must be specified.

MMS Notification section of the New MMS Profile page	
Antivirus Notification List	Optionally select an antivirus notification list to select a list of virus names to send notifications for. The unit sends a notification message whenever a virus name or prefix in the antivirus notification list matches the name of a virus detected in a session scanned by the MMS protection profile. Select *Disabled* if you do not want to use a notification list. To create an antivirus notification list, see "Notification List" on page 675. Instead of selecting a notification list you can configure the *Virus Scan Notification Type* to send notifications for all viruses.
Message Protocol	In each column, select the protocol used to send notification messages. You can use a different protocol to send the notification message than the protocol on which the violation was sent. The MMS Notifications options change depending on the message protocol that you select. If you select a different message protocol, you must also enter the User Domain. If selecting MM7 you must also enter the Message Type.
Message Type	Select the MM7 message type to use if sending notifications using MM7. Options include deliver.REQ and submit.REQ

Detect Server Details	Select to use the information in the headers of the original message to set the address of the notification message. If you do not select this option, you can enter the required addressing information manually. You cannot select *Detect Server Details* if you are sending notification messages using a different message protocol. If you select *Detect Server Details*, you cannot change the *Port* where the notification is being sent.
Hostname	Enter the FQDN or the IP address of the server where the notifications will be sent.
URL	Enter the URL of the server. For example if the notificaiton is going to www.example.com/home/alerts , the URL is /home/alerts. This option is available only when *Message Protocol* is *mm1* or *mm7*.
Port	Enter the port number of the server. You cannot change the *Port* if *Detect Server Details* is enabled.
Username	Enter the user name required for sending messages using this server (optional). This option is available only when *Message Protocol* is *mm7*.
Password	Enter the password required for sending messages using this server (optional). This option is available only when *Message Protocol* is *mm7*.
VASP ID	Enter the value-added-service-provider (VASP) ID to be used when sending a notification message. If a VAS is not offered by the mobile provider, it is offered by a third party or a VAS provider or content provider (CP). This option is available only when *Message Protocol* is *mm7*.
VAS ID	Enter the value-added-service (VAS) ID to be used when sending a notification message. A VAS is generally any service beyond voice calls and fax. This option is available only when *Message Protocol* is *mm7*.
All Notification Types	In each column, select notification for all MMS event types for that MMS protocol, then enter the amount of time and select the time unit for notice intervals. Alternatively, expand *All Notification Types*, and then select notification for individual MMS event types for each MMS protocol. Then enter the amount of time and select the time unit for notice intervals. Not all event types are available for all MMS protocols.

	Content Filter	In each column, select to notify when messages are blocked by the content filter, then enter the amount of time and select the time unit for notice intervals.
	File Block	In each column, select to notify when messages are blocked by file block, then enter the amount of time and select the time unit for notice intervals.
	Carrier Endpoint Block	In each column, select to notify when messages are blocked, then enter the amount of time and select the time unit for notice intervals.
	Flood	In each column, select to notify when message flood events occur, then enter the amount of time and select the time unit for notice intervals.
	Duplicate	In each column, select to notify when duplicate message events occur, then enter the amount of time and select the time unit for notice intervals.
	MMS Content Checksum	In each column, select to notify when the content within an MMS message is scanned and banned because of the checksum value that was matched.
	Virus Scan	In each column, select to notify when the content within an MMS message is scanned for viruses.
Notifications Per Second Limit		For each MMS protocol, enter the number of notifications to send per second. If you enter zero `(0)`, the notification rate is not limited.
Day of Week		For each MMS protocol, select the days of the week the unit is allowed to send notifications.
Window Start Time		For each MMS protocol, select the time of day to begin the message alert window. By default, the message window starts at 00:00. You can change this if you want to start the message window later in the day. When configured, notification outside this window will not be sent.
Window Duration		For each MMS protocol, select the time of day at which to end the message alert window. By default, the message window ends at 00:24. You can change this if you want to end the message window earlier in the day. When configured, notification outside this window will not be sent

DLP Archive options

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. In addition to the MMS profile's DLP archive options, you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select *DLP archiving* for carrier endpoint patterns in a *Carrier Endpoint List* and select the *Carrier Endpoint Block* option in the *MMS Scanning* section of an MMS Profile

The unit only allows one sixteenth of its memory for transferring content archive files. For example, for units with 128MB RAM, only 8MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

DLP Archive section of the New MMS Profile page

Display DLP meta-information on the system dashboard	Select each required protocol to display the content archive summary in the Log and Archive Statistics dashboard widget on the System Dashboard.
Archive to FortiAnalyzer/FortiGuard	Select the type of archiving that you want for the protocol (MM1, MM3, MM4, and MM7). You can choose from Full, Summary or None. **None —** Do not send content archives. **Summary —** Send content archive metadata only. Includes information such as date and time, source and destination, request and response size, and scan result. **Full —** Send content archive both metadata and copies of files or messages. In some cases, FortiOS Carrier may not archive content, or may make only a partial content archive, regardless of your selected option. This behavior varies by prerequisites for each protocol. This option is available only if a FortiAnalyzer unit or FortiGuard Analysis and Management Service is configured.

Logging

You can enable logging in an MMS profile to write event log messages when the MMS profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS profile logging options to write an event log message every time a virus is detected.

You must first configure how the unit stores log messages so that you can then record these logs messages. For more information, see the *FortiOS Handbook Logging and Reporting chapter*.

Logging section of the New MMS Profile page		
MMS-Antivirus		If antivirus settings are enabled for this MMS profile, select the following options to record *Antivirus Log* messages.
	Viruses	Record a log message when this MMS profile detects a virus.
	Blocked Files	Record a log message when antivirus file filtering enabled in this MMS profile blocks a file.

	Intercepted Files	Record a log message when this MMS profile intercepts a file.
	Oversized Files/Emails	Record a log message when this MMS profile encounters an oversized file or email message. Oversized files and email messages cannot be scanned for viruses.
MMS Scanning		If MMS scanning settings are enabled for this MMS profile, select the following options to record *Email Filter Log* messages.
	Notification Messages	Select to log the number of MMS notification messages sent.
	Bulk Messages	Select to log MMS Bulk AntiSpam events. You must also select which protocols to write log messages for in the MMS bulk email filtering part of the MMS profile. For more information, see "MMS bulk email filtering options" on page 665.
	Carrier Endpoint Filter Block	Select to log MMS carrier endpoint filter events, such as MSISDN filtering.
	MMS Content Checksum	Select to log MMS content checksum activity.
	Content Block	Select to log content blocking events.

MMS Content Checksum

The MMS Content Checksum menu allows you to configure content checksum lists.

Configure MMS content checksum lists in *Security Profiles* > *Carrier* > *MMS Content Checksum* using the following table.

MMS Content Checksum page

Lists each individual content checksum list that you created. On this page, you can edit, delete or create a content checksum list.

Create New	Creates a new MMS content checksum list. When you select *Create New*, you are automatically redirected to the New List. This page provides a name field and comment field. You must enter a name to go to MMS Content Checksum Settings page.
Edit	Modifies settings to a MMS content checksum. When you select *Edit*, you are automatically redirected to the MMS Content Checksum Settings page.

Delete	Removes an MMS content checksum from the page. To remove multiple content checksum lists from within the list, on the MMS Content Checksum page, in each of the rows of the content checksum lists you want removed, select the check box and then select *Delete*. To remove all content checksum lists from list, on the MMS Content Checksum page, select the check box in the check box column and then select *Delete*.
Name	The name of the MMS content checksum list that you created.
# Entries	The number of checksums that are included in the content checksum list.
MMS Profiles	The MMS profile or profiles that have the MMS content checksum list applied. For example if two different MMS profiles use this content checksum list, they will both be listed here.
Comments	A description given to the MMS content checksum.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*Security Profiles* > *AntiVirus* > *Profiles*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.

Notification List

The Notification List menu allows you to configure a list of viruses. This virus list provides a list for scanning viruses in MMS messages. You can use one virus list in multiple MMS profiles, and configure multiple virus lists.

Notification list configuration settings

The following are notification list configuration settings in *Security Profiles* > *Carrier* > *Notification List*.

Notification List page Lists all the notification lists that you created. On this page you can edit, delete or create a new notification list.	
Create New	Creates a new notification list. When you select *Create New*, you are automatically redirected to the New List page. You must enter a name to go to the Notification List Settings page.
Edit	Modifies settings within the notification list. When you select *Edit*, you are automatically redirected to the Notification List Settings page.
Delete	Removes a notification list from the list on the Notification List page. To remove multiple notification lists from within the list, on the Notification List page, in each of the rows of the notification lists you want removed, select the check box and then select *Delete*. To remove all notification lists from the list, on the Notification List page, select the check box in the check box column and then select *Delete*.
Name	The name of the MMS content checksum list that you created.
# Entries	The number of checksums that are included in that content checksum list.
MMS Profiles	The MMS profile or profiles that are associated with
Comments	A description given to the MMS notification list.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*Security Profiles* > *Antivirus* > *Profiles*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
Notification List Settings page Provides settings for configuring a notification list, which is a list of viruses and is used for scanning viruses in MMS messages. This list is called the Antivirus Notification List in an MMS profile.	
Name	If editing the name of a notification list, enter the new name in this field. You must select *OK* to save the change.
Comments	If you want to enter a comment, enter the comment in the field. You must select *OK* to save the change.
Create New	Creates a notification entry in the list. When you select *Create New*, you are automatically redirected to the New Entry page.
Edit	Modifies settings within a notification list. When you select *Edit*, you are automatically redirected to the Edit Entry page.
Delete	Removes a notification entry from the list on the page. To remove multiple notification entries from within the list, on the Notification List Settings page, in each of the rows of the entries you want removed, select the check box and then select *Delete*. To remove all notification entries from the list, on the Notification List Settings page, select the check box in the check box column and then select *Delete*.
Enable	Enables a notification entry that is disabled.
Disable	Disables a notification entry so that it is not active and available for use, but it is not deleted.

Remove All Entries	Removes all notification entries that are listed on the Notification List Settings page.
Enable	Displays whether or not the checksum is enabled.
Virus Name/Profile	The name of the virus that was added to the list.
Entry Type	The type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
New Entry page	
Virus Name/Profile	Enter the virus name.
Entry Type	Select the type of match that will be used to match the virus stated in the notification list to the actual virus that is found.
Enable	Select to enable the virus in the list.

Message Flood

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse. A message flood occurs when a single subscriber sends a volume of messages that exceed the flood threshold that you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected. For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all outgoing messages blocked for 30 minutes.

Action		Description
Log		Add a log entry indicating that a message flood has occurred. You must also enable logging for *MMS Scanning* > *Bulk Messages* in the *Logging* section of the MMS protection profile.
DLP Archive		Save the first message to exceed the flood threshold, or all the messages that exceed the flood threshold, in the DLP archive. DLP archiving flood messages may not always produce useful results. Since different messages can be causing the flood, reviewing the archived messages may not be a good indication of what is causing the problem since the messages could be completely random.
	All messages	All the messages that exceed the flood threshold will be saved in the DLP archive.
	First message only	Save only the first message to exceed the flood threshold in the DLP archive. Other messages in the flood are not saved. For message floods this may not produce much useful information since a legitimate message could trigger the flood threshold.

Action	Description
Intercept	Messages that exceed the flood threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message will also quarantined for later examination. If the quarantine of intercepted messages is disabled, the *Intercept* action has no effect.
Block	Messages that exceed the flood threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each message will quarantined for later examination.
Alert Notification	If the flood threshold is exceeded, the Carrier-enabled FortiGate unit will send an MMS flood notification message. In the web-based manager when *Alert Notification* is selected it displays the fields to configure the notification.

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many messages from the same subscriber to your MMSC.

Message flood configuration settings

The following are message flood configuration settings in *Security Profiles* > *Carrier* > *Message Flood*.

Message Flood page **Lists the large amount of messages that are being sent to you, from outside sources.**	
Delete	Removes messages from the list. To remove multiple messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select *Delete*. To remove all messages from the list, on the Message Flood page, select the check box in the check box column and then select *Delete*.
Remove All Entries	Removes all messages from the list.
Protocol	The protocol used.
MMS Profile	The MMS profile that is used.
Sender	The sender's email address.
Level	The level of severity of the message.
Count	The count column can be up or down and these settings can be turned off by selecting beside the column's name.
Window Size (minutes)	The time in minutes.

Timer (minutes:seconds)	The time in seconds and in minutes. The timer column can be up or down and these settings turned off by selecting beside the column's name.
Page Controls	Use to navigate through the list.

Duplicate Message

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC.

The unit keeps track of the sent messages. If the same message appears more often than the threshold value that you have configured, action is taken. Possible actions are logging the duplicate messages, blocking or intercepting them, archiving, and sending an alert to inform an administrator that duplicate messages are occurring.

Duplicate message configuration settings

View duplicate messages in *Security Profiles* > *Carrier* > *Duplicate Message*.

Duplicate Message page **Lists duplicates of messages that were sent to you.**	
Delete	Removes a message from the list. To remove multiple duplicate messages from within the list, on the Message Flood page, in each row of the messages you want removed, select the check box and then select *Delete*. To remove all duplicate messages from the list, on the Message Flood page, select the check box in the check box column and then select *Delete*.
Page Controls	Use to navigate through the list.
Remove All Entries	Removes all duplicate messages from the list.
Protocol	Either MM1 or MM4
Profile	The MMS profile that logs the detection.
Checksum	The checksum of the MMS message.
Status	Either flagged or blank. Flagged means that the actions defined in the MMS profile are taken. For more information, see "MMS bulk email filtering options" on page 665.
Count	Displays the number of messages in the last window of time.

Window Size (minutes)	The period of time during which a message flood will be detected if the Message Flood Limit is exceeded.
Timer (minutes:seconds)	Either the time left in the window if the message is unflagged, or the time until the message will be unflagged if it is already flagged.

Carrier Endpoint Filter Lists

A carrier endpoint filter list contains carrier endpoint patterns. A pattern can match one carrier endpoint or can use wildcards or regular expressions to match multiple carrier endpoints. For each pattern, you select the action that the unit takes on a message when the pattern matches a carrier endpoint in the message. Actions include blocking the message, exempting the message from MMS scanning, and exempting the message from all scanning. You can also configure the pattern to intercept the message and content archive the message to a FortiAnalyzer unit.

Carrier endpoint filter lists configuration settings

The following are Carrier endpoint filter list configuration settings in *Security Profiles* > *Carrier* > *Carrier Endpoint Filter Lists*.

Carrier Endpoint Filter Lists page Lists all the endpoint filters that you created. On this page, you can edit, delete or create a new endpoint filter list.	
Create New	Creates a new endpoint filter list. When you select *Create New*, you are automatically redirected to the New List page. You must enter a name to go to the Carrier Endpoint Filter Lists Settings page.
Edit	Modifies settings within an endpoint filter list in the list.
Delete	Removes an endpoint filter in the list. To remove multiple endpoint filter lists from within the list, on the Carrier Endpoint Filter List page, in each of the rows of the endpoint filter lists you want removed, select the check box and then select *Delete*. To remove all endpoint filter lists from the list, on the Carrier Endpoint Filter List page, select the check box in the check box column and then select *Delete*.
Name	The name of the endpoint filter.
# Entries	The number of carrier endpoint patterns in each carrier endpoint filter list.
MMS Profiles	The MMS profile that the carrier endpoint filter list is added to.
Comments	A description about the endpoint filter.

Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*Security Profiles* > *Antivirus* > *Profiles*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: • **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. • **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. • **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
Carrier Endpoint Filter LIsts Settings page Provides settings for configuring an endpoint filter.	
Name	The name you entered on the New List page, after selecting *Create New* on the Carrier Endpoint Filter page.
Comments	A description about the endpoint filter. You can add one here if you did not enter one on the New List page.
Create New	Creates a new endpoint filter list. When you select *Create New*, you are automatically redirected to the New Entry page.
Edit	Select to modify the settings of a pattern in the list.
Delete	Select to remove a pattern in the list.
Enable	Enables a disabled pattern in the list.
Disable	Disables a pattern in the list.
Remove All Entries	Removes all patterns in the list on the Carrier Endpoint Filter Lists Settings page.
Enable	Indicates whether or not the pattern is enabled.

Pattern		Enter or change the pattern that FortiOS Carrier uses to match with carrier endpoints. The pattern can be a single carrier endpoint or consist of wildcards or Perl regular expressions that will match more than one carrier endpoint. Set *Pattern Type* to correspond to the pattern that you want to use.
Action		Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the carrier endpoint pattern:
Pattern Type		The type of pattern chosen.
New Entry page		
Pattern		Enter or change the pattern that FortiOS Carrier uses to match with carrier endpoints. The pattern can be a single carrier endpoint or consist of wildcards or Perl regular expressions that will match more than one carrier endpoint. Set *Pattern Type* to correspond to the pattern that you want to use.
Action(s)		Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the carrier endpoint pattern:
	Content Archive	MMS messages from the carrier endpoint are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
	Intercept	MMS messages from the carrier endpoint are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.
Pattern Type		Select a pattern type as one of Single Carrier Endpoint, Wildcard or Regular Expression. Wildcard and Regular Expression will match multiple patterns where Signle Carrier Endpoint matches only one.
Enable		Select to enable this carrier endpoint filter pattern.

GTP Profile

You can configure multiple GTP profiles within the GTP menu. GTP profiles concern GTP activity flowing through the unit. These GTP profiles are then applied to a security policy.

GTP profile configuration settings

The following are GTP profile configuration settings in *Security Profiles* > *Carrier* > *GTP Profile*.

GTP Profile page Lists each GTP profile that you have created. On this page, you can edit, delete or create a new GTP profile.	
Create New	Creates a new GTP profile. When you select *Create New*, you are automatically redirected to the New page.
Edit	Modifies settings within a GTP profile in the list. When you select *Edit*, you are automatically redirected to Edit page.
Delete	Removes a GTP profile from the list. To remove multiple GTP profiles from within the list, on the GTP Profile page, in each of the rows of the profiles you want removed, select the check box and then select *Delete*. To remove all GTP profiles from within the list, on the GTP Profile page, select the check box in the check box column and then select *Delete*.
Name	The name of the GTP profile.
Ref.	Displays the number of times the object is referenced to other objects. For example, av_1 profile is applied to a security policy; on the Profile page (*Security Profiles* > *Antivirus* > *Profiles*), 1 appears in *Ref.* . To view the location of the referenced object, select the number in *Ref.*, and the Object Usage window appears displaying the various locations of the referenced object. To view more information about how the object is being used, use one of the following icons that is avialable within the Object Usage window: **View the list page for these objects** – automatically redirects you to the list page where the object is referenced at. **Edit this object** – modifies settings within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy and so, when this icon is selected, the user is redirected to the Edit Policy page. **View the details for this object** – table, similar to the log viewer table, contains information about what settings are configured within that particular setting that the object is referenced with. For example, av_1 profile is referenced with a security policy, and that security policy's settings appear within the table.
New GTP Profile page **Provides settings for configuring a GTP profile.**	
Name	Enter a name for the GTP profile.
General Settings	Configure general options for the GTP profile. See "General settings options" on page 685.
Message Type Filtering	Configure filtering for messages. See "Message type filtering options" on page 687.

APN Filtering	Configure filtering options for APN. See “APN filtering options” on page 687.
IMSI Filtering	Configure filtering options for IMSI. See “Basic filtering options” on page 689.
Advanced Filtering	Configure advanced filtering options. See “Advanced filtering options” on page 690.
IE removal policy	Configure IE removal policy options. See “Information Element (IE) removal policy options” on page 694.
Encapsulated IP Traffic Filtering	Configure filtering options for encapsulated IP traffic. See “Encapsulated IP traffic filtering options” on page 694.
Encapsulated Non-IP End User Address Filtering	Configure filtering options for encapsulated non-IP end user addresses. See “Encapsulated non-IP end user traffic filtering options” on page 695.
Protocol Anomaly	Configure protocol anomaly options. See “Protocol Anomaly prevention options” on page 696.
Anti-Overbilling	Configure anti-overbilling options. See “Anti-Overbilling options” on page 697.
Log	Configure log options. See “Log options” on page 697.

General settings options

The following are mostly house keeping options that appear in the General Settings area of the GTP configuration page.

General Settings section of the New GTP Profile page	
Sequence Number Validation	Enable to check that packets are not duplicated or out of order. GTP packets contain a Sequence Number field. This number tells the receiving GGSN the order of the packets it is receiving. Normally the GGSN compares this sequence number in the packets with its own sequence counter — if the two do not match, the packet is dropped. This sequence number validation can be off-loaded to the FortiOS Carrier freeing up resources on the GGSN.
GTP-in-GTP	Select *Allow* to enable GTP packets to be allowed to contain GTP packets, or a GTP tunnel inside another GTP tunnel. To block all GTP-in-GTP packets, select *Deny*.
Minimum Message Length	Enter the shortest possible message length in bytes. Normally this is controlled by the protocol, and will vary for different message types. If a packet is smaller than this limit, it is discarded as it is likely malformed and a potential security risk. The default minimum message length is 0 bytes.

Maximum Message Length	Enter the maximum allowed length of a GTP packet in bytes. A GTP packet contains three headers and corresponding parts GTP, UDP, and IP. If a packet is larger than the maximum transmission unit (MTU) size, it is fragmented to be delivered in multiple packets. This is inefficient, resource intensive, and may cause problems with some applications. By default the maximum message length is 1452 bytes.
Tunnel Limit	Enter the maximum number of tunnels allowed open at one time. For additional GTP tunnels to be opened, existing tunnels must first be closed. This feature can help prevent a form of denial of service attack on your network. This attack involves opening more tunnels than the network can handle and consuming all the network resources doing so. By limiting the number of tunnels at any one time, this form of attack will be avoided. The tunnel limiting applies to the Handover Group, and Authorized SGSNs and GGSNs.
Tunnel Timeout	Enter the maximum number of seconds that a GTP tunnel is allowed to remain active. After the timeout the unit deletes GTP tunnels that have stopped processing data. A GTP tunnel may hang for various reasons. For example, during the GTP tunnel tear-down stage, the "delete pdap context response" message may get lost. By setting a timeout value, you can configure the FortiOS Carrier firewall to remove the hanging tunnels. The default is 86400 seconds, or 24 hours.
Control plane message rate limit	Enter the number of packets per second to limit the traffic rate to protect the GSNs from possible Denial of Service (DoS) attacks. The default limit of *0* does not limit the message rate. GTP DoS attacks can include: • **Border gateway bandwidth saturation**: A malicious operator can connect to your GRX and generate high traffic towards your Border Gateway to consume all the bandwidth. • **GTP flood**: A GSN can be flooded by illegitimate traffic
Handover Group	Select the allowed list of IP addresses allowed to take over a GTP session when the mobile device moves locations. Handover is a fundamental feature of GPRS/UMTS, which enables subscribers to seamlessly move from one area of coverage to another with no interruption of active sessions. Session hijacking can come from the SGSN or the GGSN, where a fraudulent GSN can intercept another GSN and redirect traffic to it. This can be exploited to hijack GTP tunnels or cause a denial of service. When the handover group is defined it acts like a whitelist with an implicit default deny at the end — the GTP address must be in the group or the GTP message will be blocked. This stops handover requests from untrusted GSNs.

Authorized SGSNs	Use *Authorized SGSNs* to only allow authorized SGSNs to send packets through the unit and to block unauthorized SGSNs. Go to *Firewall Objects* > *Address* > *Addresses* and add the IP addresses of the authorized SGSNs to a firewall address or address group. Then set *Authorized SGSNs* to this firewall address or address group. You can use *Authorized SGSNs* to allow packets from SGSNs that have a roaming agreement with your organization.
Authorized GGSNs	Use *Authorized GGSNs* to only allow authorized GGSNs to send packets through the unit and to block unauthorized GGSNs. Go to *Firewall Objects* > *Address* > *Addresses* and add the IP addresses of the authorized GGSNs to a firewall address or address group. Then set *Authorized GGSNs* to this firewall address or address group. You can use Authorized GGSNs to allow packets from SGSNs that have a roaming agreement with your organization.

Message type filtering options

On the *New GTP Profile* page, you can select to allow or deny the different types of GTP messages, which is referred to as message type filtering. You must expand the Message Type Filtering section to access the settings.

The messages types include Path Management, Tunnel Management, Location Management, Mobility Management, MBMS, and GTP-U and Charging Management messages.

For enhanced security, Fortinet best practices dictate that you set Unknown Message Action to deny. This will block all unknown GTP message types, some of which may be malicious.

To configure message type filter options, expand *Message Type Filtering* in the GTP profile.

APN filtering options

An Access Point Name (APN) is an Information Element (IE) included in the header of a GTP packet. It provides information on how to reach a network.

An APN has the following format:

```
<network_id>[.mnc<mnc_int>.mcc<mcc_int>.gprs]
```

Where:

- `<network_id>` is a network identifier or name that identifies the name of a network, for example, `example.com` or `internet`.
- `[.mnc<mnc_int>.mcc<mcc_int>.gprs]` is the optional operator identifier that uniquely identifies the operator's PLMN, for example `mnc123.mcc456.gprs`.

Combining these two examples results in a complete APN of `internet.mnc123.mcc456.gprs`.

By default, the unit permits all APNs. However, you can configure APN filtering to restrict roaming subscribers' access to external networks.

APN filtering applies only to the GTP *create pdp request* messages. The unit inspects GTP packets for both APN and selected modes. If both parameters match and APN filter entry, the unit applies the filter to the traffic.

Additionally, the unit can filter GTP packets based on the combination of an IMSI prefix and an APN. For more information, see “Basic filtering options” on page 689.

You cannot add an APN when creating a new profile.

APN Filtering section on the New GTP Profile page		
Enable APN Filter		Select to enable APN filtering.
Default APN Action		Select the default action for APN filtering. If you select *Allow*, all sessions are allowed except those blocked by individual APN filters. If you select *Deny*, all sessions are blocked except those allowed by individual APN filters.
Value		The APN to be filtered.
Mode		The type of mode chosen that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription:
Action		The type of action that will be taken.
Edit		Modifies the settings within the filter. When you select *Edit*, the Edit window appears, which allows you to modify the settings of the APN.
Delete		Removes the APN from the list within the table, in the APN Filtering section.
Add APN		Adds a new APN filter to the list. When you select *Add APN*, the New window appears, which allows you to configure the APN settings.
New APN page		
Value		Enter an APN to be filtered. You can include wild cards to match multiple APNs. For example, the value *internet** would match all APNs that being with *internet*.
Mode		Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
	Mobile Station provided	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
	Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.

	Subscription Verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network
Action		Select *Allow* or *Deny*.

Basic filtering options

The International Mobile Station Identity (IMSI) is used by a GPRS Support Node (GSN) to identify a mobile station. Three elements make up every IMSI:

- the mobile country code (MCC)
- the mobile network code (MNC)
- the mobile subscriber identification number (MSIN).

The subscriber's home network—the public land mobile network (PLMN)—is identified by the IMSI prefix, formed by combining the MCC and MNC.

By default, the unit allows all IMSIs. You can add IMSI prefixes to deny GTP traffic coming from non-roaming partners. Any GTP packets with IMSI prefixes not matching the prefixes you set will be dropped. GTP *Create pdp* request messages are filtered and only IMSI prefixes matching the ones you set are permitted. Each GTP profile can have up to 1000 IMSI prefixes set.

An IMSI prefix and an APN can be used together to filter GTP packets if you set an IMSI filter entry with a non-empty APN.

You cannot add an IMSI when creating a new profile. You must add it after the profile has been created and you are editing the profile.

IMSI Filtering section of the New GTP Profile page	
Enable IMSI Filter	Select to enable IMSI filtering.
Default IMSI Action	Select the default action for IMSI filtering. If you select *Allow*, all sessions are allowed except those blocked by individual IMSI filters. If you select *Deny*, all sessions are blocked except those allowed by individual IMSI filters.
APN	The APN that is part of the IMSI that will be filtered.
MCC-MNC	The MCC-MNC part of the IMSI that will be filtered.
Mode	The type of mode that indicates where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
Action	The type of action that will be taken.
Edit	Modifies settings to an IMSI filter. When you select *Edit*, the Edit window appears, which allows you to modify the IMSI filter's settings.
Delete	Removes an IMSI filter from within the table, in the IMSI Filtering section.

Add IMSI		Adds a new IMSI filter to the list. When you select *Add IMSI*, the New window appears, which allows you to configure IMSI filter settings.
New IMSI page		
APN		Enter the APN part of the IMSI to be filtered.
MCC-MNC		Enter the MCC-MCC part of the IMSI to be filtered.
Mode		Select one or more of the available modes to indicate where the APN originated and whether the Home Location Register (HLR) has verified the user subscription.
	Mobile Station provided	MS-provided APN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
	Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did not verify the user's subscription to the network.
	Subscription Verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network
Action		Select *Allow* or *Deny*.

Advanced filtering options

The FortiOS Carrier firewall supports advanced filtering against the attributes RAT, RAI, ULI, APN restriction, and IMEI-SV in GTP to block specific harmful GPRS traffic and GPRS roaming traffic. The following table shows some of the GTP context requests and responses that the firewall supports.

Table 37: Attributes supported by FortiCarrier firewalls

	GTP Create PDP Context Request	GTP Create PDP Context Response	GTP Update PDP Context Request	GTP Update PDP Context Response
APN	yes	yes	-	
APN Restriction	yes	-	-	yes
IMEI-SV	yes	-	-	-
IMSI	yes	-	yes	-
RAI	yes	-	yes	-

Table 37: Attributes supported by FortiCarrier firewalls

	GTP Create PDP Context Request	GTP Create PDP Context Response	GTP Update PDP Context Request	GTP Update PDP Context Response
APN	yes	yes	-	
RAT	yes	-	yes	-
ULI	yes	-	yes	-

When editing a GTP profile, select *Advanced Filtering* > *Add* to create and add a rule. When the rule matches traffic it will either allow or deny that traffic as selected in the rule.

Advanced Filtering section on New GTP Profile page	
Enable	Select to enable advanced filtering.
Default Action	Select the default action for advanced filtering. If you select *Allow*, all sessions are allowed except those blocked by individual advanced filters. If you select *Deny*, all sessions are blocked except those allowed by individual advanced filters.
Messages	The messages, for example, Create PDP Context Request.
APN Restriction	The APN restriction.
RAT Type	The RAT types associated with that filter.
ULI	The ULI pattern.
RAI	The RAI pattern.
IMEI	The IMEI pattern.
Action	The action that will be taken.
Edit	Modifies the filter's settings. When you select *Edit*, the Edit window appears, which allows you to modify the filter's settings.
Delete	Removes a filter from the list.
Add	Adds a filter to the list. When you select *Add*, the New window appears, which allows you to configure settings for messages, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI patterns as well as the type of action.
New Filtering page	
Messages	The PDP content messages this profile will match.
Create PDP Context Request	Select to allow create PDP context requests.

	Create PDP Context Response	Select to allow create PDP context responses.
	Update PDP Context Request	Select to allow update PDP context requests.
	Update PDP Context Response	Select to allow update PDP context responses.
APN		Enter the APN.
APN Mode		Select an APN mode as one or more of • Mobile Station provied • Network provided • Subscription provied This field is only available when an APN has been entered.
	Mobile Station provided	MS-provided PAN, subscription not verified, indicates that the mobile station (MS) provided the APN and that the HLR did not verify the user's subscription to the network.
	Network provided	Network-provided APN, subscription not verified, indicates that the network provided a default APN because the MS did not specify one, and that the HLR did no verify the user's subscription to the network.
	Subscription verified	MS or Network-provided APN, subscription verified, indicates that the MS or the network provided the APN and that the HLR verified the user's subscription to the network.
APN Restriction		Select the type of restriction that you want. You can choose all of the types, or one of the types. You cannot choose multiple types. Types include: • all • Public-1 • Public-2 • Private-1 • Private-2
IMSI		Enter the IMSI.
MSISDN		Enter the MSISDN.

RAT Type	Optionally select the RAT type as any combination of the following: • Any • UTRAN • GERAN • Wifi • GAN • HSPA Some RAT types are GTPv1 specific.
ULI pattern	Enter the ULI pattern.
RAI pattern	Enter the RAI pattern.
IMEI pattern	Enter the IMEI pattern.
Action	Select either *Allow* or *Deny*.

Adding an advanced filtering rule

When adding a rule, use the following formats:

- Prefix, for example, range 31* for MCC matches MCC from 310 to 319.
- Range, for example, range 310-319 for MCC matches MCC from 310 to 319.
- Mobile Country Code (MCC) consists of three digits. The MCC identifies the country of domicile of the mobile subscriber.
- Mobile Network Code (MNC) consists of two or three digits for GSM/UMTS applications. The MNC identifies the home PLMN of the mobile subscriber. The length of the MNC (two or three digits) depends on the value of the MCC. Best practices dictate not to mix two and three digit MNC codes within a single MCC area.
- Location Area Code (LAC) is a fixed length code (of 2 octets) identifying a location area within a PLMN. This part of the location area identification can be coded using a full hexadecimal representation except for the following reserved hexadecimal values: 0000 and FFFE. These reserved values are used in some special cases when no valid LAI exists in the MS (see 3GPP TS 24.008, 3GPP TS 31.102 and 3GPP TS 51.011).
- Routing Area Code (RAC) of a fixed length code (of 1 octet) identifies a routing area within a location.
- CI or SAC of a fixed length of 2 octets can be coded using a full hexadecimal expression.
- Type Allocation Code (TAC) has a length of 8 digits.
- Serial Number (SNR) is an individual serial number identifying each equipment within each TAC. SNR has a length of 6 digits.
- Software Version Number (SVN) identifies the software version number of the mobile equipment. SVN has a length of 2 digits.

You cannot add an advanced filtering rule when creating a new profile. You must add it after the profile has been created and you are editing the profile.

Information Element (IE) removal policy options

In some roaming scenarios, the unit is installed on the border of the PLMN and the GRX. In this configuration, the unit supports information element (IE) removal policies to remove any combination of R6 IEs (RAT, RAI, ULI, IMEI-SV and APN restrictions) from the types of messages described in "Advanced filtering options" on page 690, prior to forwarding the messages to the HGGSN (proxy mode).

IE removal policy section of the New GTP Profile page	
Enable	Select to enable this option.
SGSN address of message IE	The firewall address or address group that contains the SGSN addresses.
IEs to be removed	The IE types that will be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.
Add	Adds an IE removal policy. When you select *Add*, the New window appears, which allows you to configure the IE policy.
Edit	Modifies settings from within the IE removal policy. When you select *Edit*, the Edit window appears, which allows you to modify the settings within the policy.
Delete	Removes the IE removal policy from the list.
New IE policy page	
SGSN address	Select a firewall address or address group that contains SGSN addresses.
IEs to be removed	Select one or more IE types to be removed. These include APN Restriction, RAT, RAI, ULI, and IMEI.

Encapsulated IP traffic filtering options

You can use encapsulated IP traffic filtering to filter GTP sessions based on information contained in the data stream. to control data flows within your infrastructure. You can configure IP filtering rules to filter encapsulated IP traffic from mobile stations by identifying the source and destination policies. For more information, see "When to use encapsulated IP traffic filtering" on page 740.

Expand *Encapsulated IP Traffic Filtering* in the GTP profile to reveal the options.

Encapsulated IP Traffic Filtering section of the New GTP Profile page	
Enable IP Filter	Select to enable encapsulated IP traffic filtering options.
Default IP Action	Select the default action for encapsulated IP traffic filtering. If you select *Allow*, all sessions are allowed except those blocked by individual encapsulated IP traffic filters. If you select *Deny*, all sessions are blocked except those allowed by individual encapsulated IP traffic filters.

Source	Select a source IP address from the configured firewall IP address or address group lists. Any encapsulated traffic originating from this IP address will be a match if the destination also matches.
Destination	Select a destination IP address from the configured firewall IP address or address group lists. Any encapsulated traffic being sent to this IP address will be a match if the destination also matches.
Action	The type of action that will be taken. Select to Allow or Deny encapsulated traffic between this source and Destination.
Edit	Modifies the source, destination or action settings.
Add IP Policy	Adds a new encapsulated IP traffic filter. When you select *Add IP Policy*, the New window appears which allows you to configure IP policy settings.
New (window)	
Source	Select the source firewall address or address group.
Destination	Select the destination firewall address or address group.
Action	Select *Allow* or *Deny*.

Encapsulated non-IP end user traffic filtering options

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications list only PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the “Assigned PPP DLL Protocol Numbers” sections of RFC1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

Encapsulated Non-IP End User Address Filtering section of the New GTP Profile page	
Enable Non-IP Filter	Select to enable encapsulated non-IP traffic filtering.
Default Non-IP Action	Select the default action for encapsulated non-IP traffic filtering. If you select *Allow*, all sessions are allowed except those blocked by individual encapsulated non-IP traffic filters. If you select *Deny*, all sessions are blocked except those allowed by individual encapsulated non-IP traffic filters.
Type	The type chosen, *AESTI* or *IETF.*
Start Protocol	The beginning protocol port number range.

End Protocol	The end of the protocol port number range.
Action	The type of action that will be taken.
Edit	Modify a non-IP filter's settings in the list. When you select *Edit*, the Edit window appears, which allows you to modify the Non-IP policy settings.
Delete	Remove a non-IP policy from the list.
Add Non-IP Policy	Add a new encapsulated non-IP traffic filter. When you select *Add Non-IP Policy*, you are automatically redirected to the New page.
New (window)	
Type	Select *AESTI* or *IETF*.
Start Protocol **End Protocol**	Select a start and end protocol from the list of protocols in RFC 1700. Allowed range includes 0 to 255 (0x00 to 0xff). Some common protocols include: • 33 (0x0021) Internet Protocol • 35 (0x0023) OSI Network Layer • 63 (0x003f) NETBIOS Framing • 65 (0x0041) Cisco Systems • 79 (0x004f) IP6 Header Compression • 83 (0x0053) Encryption
Action	Select *Allow* or *Deny*.

Protocol Anomaly prevention options

Use protocol anomaly detection options to detect or deny protocol anomalies according to GTP standards and tunnel state. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of the protocol specifications. Packets cannot pass through if they fail the sanity check.

Protocol Anomaly section of the New GTP Profile page	
Invalid Reserved Field	GTP version 0 (GSM 09.60) headers specify a number of fields that are marked as ''Spare” and contain all ones (1). GTP packets that have different values in these fields are flagged as anomalies. GTP version 1 (GSM 29.060) makes better use of the header space and only has one, 1-bit, reserved field. In the first octet of the GTP version1 header, bit 4 is set to zero.
Reserved IE	Both versions of GTP allow up to 255 different Information Elements (IE). However, a number of Information Elements values are undefined or reserved. Packets with reserved or undefined values will be filtered.
Miss Mandatory IE	GTP packets with missing mandatory Information Elements (IE) will not be passed to the GGSN.

Out of State Message	The GTP protocol requires a certain level of state to be kept by both the GGSN and SGSN. Some message types can only be sent when in a specific GTP state. Packets that do not make sense in the current state are filtered or rejected Both versions of GTP allow up to 255 different message types. However, a number of message type values are undefined or reserved. Best practices dictate that packets with reserved or undefined values will be filtered.
Out of State IE	GTP Packets with out of order Information Elements are discarded.
Spoofed Source Address	The End User Address Information Element in the PDP Context Create & Response messages contain the address that the mobile station (MS) will use on the remote network. If the MS does not have an address, the SGSN will set the End User Address field to zero when sending the initial PDP Context Create message. The PDP Context Response packet from the GGSN will then contain an address to be assigned to the MS. In environments where static addresses are allowed, the MS will relay its address to the SGSN, which will include the address in the PDP Context Create Message. As the MS address is negotiated within the PDP Context creation handshake, any packets originating from the MS that contain a different source address are detected and dropped.

Anti-Overbilling options

You can configure the FortiOS Carrier firewall to prevent overbilling subscribers for traffic over the. To enable anti-overbilling, you must configure both the Gn/Gp firewall and the Gi firewall.

Expand *Anti-Overbilling* in the GTP profile to reveal these settings.

Anti-Overbilling section of the New GTP Profile page	
Gi Firewall IP Address	The IP address of the unit's interface configured as a Gi gateway.
Port	The SG security port number. The default port number is port 21123. Change this number if your system uses a different SG port.
Interface	Select the unit interface configured as a Gi gateway.
Security Context ID	Enter the security context ID. This ID must match the ID entered on the server Gi firewall. The default security context ID is 696.

Log options

All the GTP logs are treated as a subtype of the event logs. To enable GTP logging, you must:

- configure the GTP log settings in a GTP profile
- enable GTP logging when you configure log and report settings.

To enable GTP logging after a GTP profile has been configured

1. Go to *Log & Report* > *Log Config* > *Log Settings*.
2. Select *Event Logging*, and select *GTP service event*.
3. Select *Apply*.

Log section of the New GTP Profile page	
Log Frequency	Enter the number of messages to drop between logged messages. An overflow of log messages can sometimes occur when logging rate-limited GTP packets exceed their defined threshold. To conserve resources on the syslog server and the Carrier-enabled FortiGate unit, you can specify that some log messages are dropped. For example, if you want only every twentieth message to be logged, set a logging frequency of 20. This way, 20 messages are skipped and the next logged. Acceptable frequency values range from 0 to 2147483674. When set to '0', no messages are skipped.
Forwarded Log	Select to log forwarded GTP packets.
Denied Log	Select to log GTP packets denied or blocked by this GTP profile.
Rate Limited Log	Select to log rate-limited GTP packets.
State Invalid Log	Select to log GTP packets that have failed stateful inspection.
Tunnel Limit Log	Select to log packets dropped because the maximum limit of GTP tunnels for the destination GSN is reached.

Extension Log	Select to log extended information about GTP packets. When enabled, this additional information will be included in log entries: • IMSI • MSISDN • APN • Selection Mode • SGSN address for signaling • SGSN address for user data • GGSN address for signaling • GGSN address for user data
Traffic count Log	Select to log the total number of control and user data messages received from and forwarded to the GGSNs and SGSNs that the unit protects. The unit can report the total number of user data and control messages received from and forwarded to the GGSNs and SGSNs it protects. Alternately, the total size of the user data and control messages can be reported in bytes. The unit differentiates between traffic carried by each GTP tunnel, and also between GTP-User and GTP-Control messages. The number of messages or the number of bytes of data received from and forwarded to the SGSN or GGSN are totaled and logged if a tunnel is deleted. When a tunnel is deleted, the log entry contains: • Timestamp • Interface name (if applicable) • SGSN IP address • GGSN IP address • TID • Tunnel duration time in seconds • Number of messages sent to the SGSN • Number of messages sent to the GGSN

Specifying logging types

You can configure the unit to log GTP packets based on their status with GTP traffic logging.

The status of a GTP packet can be any of the following 5 states:

- **Forwarded** - a packet that the unit transmits because the GTP policy allows it
- **Prohibited** - a packet that the unit drops because the GTP policy denies it
- **Rate-limited** - a packet that the unit drops because it exceeds the maximum rate limit of the destination GSN
- **State-invalid** - a packet that the unit drops because it failed stateful inspection
- **Tunnel-limited** - a packet that the unit drops because the maximum limit of GTP tunnels for the destination GSN is reached.

The following information is contained in each log entry:

- Timestamp
- Source IP address
- Destination IP address
- Tunnel Identifier (TID) or Tunnel Endpoint Identifier (TEID)
- Message type
- Packet status: forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited
- Virtual domain ID or name
- Reason to be denied if applicable.

MMS Security features

FortiOS Carrier includes all the Security features of FortiOS with extra features specific to MMS carrier networks.

This section includes:

Why scan MMS messages for viruses and malware?

The requirement for scanning MM1 content comes from the fact that MMS is an increasingly popular technique for propagating malware between mobile devices. See “MMS virus scanning” on page 702.

Example: COMMWARRIOR

This is a virus for Series 60 type cell phones, such as Nokia, operating Symbian OS version 6 [or higher]. The object of the virus is to spread to other phones using Bluetooth and MMS as transport avenues. The targets are selected from the contact list of the infected phone and also sought via Bluetooth searching for other Bluetooth-enabled devices (phones, printers, gaming devices etc.) in the proximity of the infected phone.

This virus is more than a proof of concept - it has proven successfully its ability to migrate from a zoo collection to being in-the-wild. Currently, this virus is being reported in over 18 different countries around Europe, Asia and North America.

When the virus first infects a cell phone, a prompt is displayed asking the recipient if they want to install “Caribe”. Symptoms of an infected phone may include rapid battery power loss due to constant efforts by the virus to spread to other phones via a Bluetooth seek-and-connect outreach.

The following variants among others are currently scanned by the FortiOS Carrier devices, in addition to more signatures that cover all known threats.

- **SymbOS/COMWAR.V10B!WORM**
- Aliases: SymbOS.Commwarrior.B, SymbOS/Commwar.B, SymbOS/Commwar.B!wm, SymbOS/Commwar.B-net, SymbOS/Commwarrior.b!sis, SymbOS/Comwar.B,

SymbOS/Comwar.B!wm, SymbOS/Comwar.B-wm, SYMBOS_COMWAR.B, SymbOS/Comwar.1.0.B!wormSYMBOS/COMWAR.V10B.SP!WORM [spanish version]

- First Discovered In The Wild: July 04, 2007
- Impact Level: 1
- Virus Class: Worm
- Virus Name Size: 23,320
- **SymbOS/Commwar.A!worm**
- Aliases: Commwarrior-A, SymbOS.Commwarrior.A [NAV], SymbOS/Commwar.A-net, SymbOS/Commwar_ezboot.A-ne, SymbOS/Comwar.A, SymbOS/Comwar.A-wm, SYMBOS_COMWAR.A [Trend]
- First Discovered In The Wild: May 16 2005
- Impact Level: 1
- Virus Class: Worm
- Virus Name Size: 27,936
- SymbOS/Commwarriie.C-wm
- Aliases: None
- First Discovered In The Wild: Oct 17 2005
- Impact Level: 1
- Virus Class: File Virus
- Virus Name Size: None

For the latest list of threats Fortinet devices detect, go to the FortiGuard Center Resource Library's Mobile index.

MMS virus scanning

You can use MMS virus scanning to scan content contained within MMS messages for viruses. FortiOS Carrier virus scanning can be applied to the MM1, MM3, MM4, and MM7 interfaces to detect and remove content containing viruses at many points in an MMS network. Perhaps the most useful interface to apply virus scanning would be the MM1 interface to block viruses sent by mobile users before they get into the service provider network.

To go to MMS virus scanning, go to *Security Profiles* > *Carrier* > *MMS Profile*, select an existing or create a new profile, and expand *MMS Scanning*. See "MMS scanning options" on page 663.

This section includes:

MMS virus monitoring

To enable MMS virus monitoring, expand *MMS Scanning* and enable *Monitor only* for the selected MMS types.

This feature causes the FortiOS Carrier unit to record log messages when MMS scanning options find a virus, match a file name, or match content using any of the other MMS scanning options. Selecting this option enables reporting on viruses and other problems in MMS traffic without affecting users.

MMS virus scanning blocks messages (not just attachments)

To enable MMS virus scanning, expand *MMS Scanning* and enable *Virus Scan* for the selected MMS types.

Because MM1 and MM7 use HTTP, the oversize limits for HTTP and the HTTP antivirus port configurations also apply to MM1 and MM7 scanning. See

MM3 and MM4 use SMTP and the oversize limits for SMTP and the SMTP antivirus port configurations also apply to MM3 and MM4 scanning.

The message contents will be scanned for viruses, matched against the file extension blocking lists and scanned for banned words. All these items will be configured via the standard GUI interfaces available for the other protocols and will be controlled at the protection profile level with new options specifically for the MM1 messages.

The FortiOS Carrier unit extracts the sender's Mobile Subscriber Integrated Services Digital Network Number (MSISDN) from the HTTP headers if available. The `POST` payload will be sent to the scanunits which will parse the MMS content and scan each message data section. If any part of the data is to be blocked, the proxy will be informed, the connection to the MMSC will be reset and the Carrier-enabled FortiGate unit will return an `HTTP 200 OK` message with an `m-send-conf` payload to the client to prevent a retry. Finally the appropriate logging, alert, and replacement message events will be triggered.

For client notification, the `x-mms-response-status` and `x-mms-response-text` fields can also be customized as required.

Scanning MM1 retrieval messages

To scan MM1 retrieval messages, expand *MMS Scanning* and select *Scan MM1 message retrieval*.

Select to scan message retrievals that use MM1. If you enable *Virus Scan* for all MMS interfaces, messages are also scanned while being sent. In this case, you can disable MM1 message retrieval scanning to improve performance.

Configuring MMS virus scanning

To configure MMS virus scanning, expand *MMS Scanning* and enable *Virus Scan*.

Once applied to a security policy, the MMS protection profile will then perform virus scans on all traffic accepted by that policy.

Removing or replacing blocked messages

To remove blocked messages, expand *MMS Scanning* and select *Remove Blocked* for the selected MMS types.

Select *Remove Blocked* remove blocked content from each protocol and replace it with the replacement message. If FortiOS Carrier is to preserve the length of the message when

removing blocked content, as may occur when billing is affected by the length of the message, select *Constant*.

If you only want to monitor blocked content, select *Monitor Only*.

Carrier Endpoint Block

A carrier endpoint defines a specific client on the carrier network. Typically the client IP address is used to identify the client, however on a carrier network this may be impractical when the client is using a mobile device. Other identifying information such as the MSIDSN number is used instead.

This information can be used to block a specific endpoint on the network. Reasons for blocking may include clients whose accounts have expired, clients from another carrier, clients who have sent malicious content (phishing, exploits, viruses, etc), or other violations of terms of use.

Enabling carrier endpoint blocking

To enable carrier endpoint blocking you first need to create a carrier endpoint filter list, and then enable it.

To enable carrier endpoint blocking - web-based manager

1. Create a carrier endpoint filter list. See
2. Go to *Security Profiles* > *Carrier* > *MMS Profile*.
3. Select *Create New*, or select an existing profile to edit and select *Edit*.
4. Expand MMS Scanning.
5. Select one or more types of MMS messaging to enable endpoint blocking on.
6. Select the carrier endpoint filter list to use in matching the endpoints to be blocked.

In MMS Profile, endpoints can only be blocked.

Create a carrier endpoint filter list

A carrier endpoint filter list contains one or more carrier endpoints to match. When used in MMS scanning entries in the filter list that are matched are blocked.

You can configure multiple filter lists for different purposes and groups of clients, such as blocking clients, clients with different levels of service agreements, and clients from other carriers. See “Carrier endpoint filter lists configuration settings” on page 681.

To create a carrier endpoint filter list - web-based manager

1. Go to *Security Profiles* > *Carrier* > *Carrier Endpoint Filter Lists*.
2. Select *Create New*.
3. Enter a descriptive name for the filter list, such as `blocked_clients` or `CountryX_clients`, and select OK.
4. Select *Create New* to add one or more entries to the list.
5. Select OK to return to display the list of filter lists.

Configuring endpoint filter list entries

For each single endpoint or group of endpoints have part of their identifying information in common, you create an entry in the endpoint filter list.

For example a `blocked_clients` filter list may include entries for single endpoints added as each one needs to be blocked and a group of clients from a country that does not allow certain services.

To configure an endpoint filter list entry - web-based manager

1. Select *Create New*.
2. Enter the following information and select OK.

Name	Name of endpoint filter list. Select this name in an MMS protection profile.
Comments	Optional description of the endpoint filter list.
Check/Uncheck All	Select the check box to enable all endpoint patterns in the MMS filter list. Clear the check box to disable all entries on the MMS filter list. You can also select or clear individual check boxes to enable or disable individual endpoint patterns.
Pattern	The pattern that FortiOS Carrier uses to match with endpoints. The pattern can be a single endpoint or consist of wildcards or Perl regular expressions that will match more than one endpoint. For more on wildcard and regular expressions, see *Using wildcards and Perl regular expressions* in the *UTM* handbook chapter.
Action	Select the action taken by FortiOS Carrier for messages from a carrier endpoint that matches the endpoint pattern: None - No action is taken. Block - MMS messages from the endpoint are not delivered and FortiOS Carrier records a log message. **Exempt from mass MMS -** MMS messages from the endpoint are delivered and are exempt from mass MMS filtering. Mass MMS filtering is configured in MMS protection profiles and is also called MMS Bulk Email Filtering and includes MMS message flood protection and MMS duplicate message detection. A valid use of mass MMS would be when a service provider notifies customers of a system-wide event such as a shutdown. **Exempt from all scanning -** MMS messages from the endpoint are delivered and are exempt from all MMS protection profile scanning.
Content Archive	MMS messages from the endpoint are delivered, the message content is DLP archived according to MMS DLP archive settings. Content archiving is also called DLP archiving.
Intercept	MMS messages from the endpoint are delivered. Based on the quarantine configuration, attached files may be removed and quarantined.

Pattern Type	The pattern type: *Wildcard*, *Regular Expression*, or *Single Endpoint*.
Enable	Select to enable this endpoint filter pattern.

Blocking network access based on endpoints

You can use endpoint IP filtering to block traffic from source IP addresses associated with endpoints. You can also configure FortiOS Carrier to record log messages whenever endpoint IP filtering blocks traffic. Endpoint IP filtering blocks traffic at the IP level, before the traffic is accepted by a security policy.

To configure endpoint IP filtering, go to *Security Profiles* > *Carrier* > *IP Filter* and add endpoints to the IP filter list. For each endpoint you can enable or disable both blocking traffic and logging blocked traffic.

You cannot add endpoint patterns to the endpoint IP filter list. You must enter complete and specific endpoints that are valid for your network.

The only action available is block. You cannot use endpoint IP filtering to exempt endpoints from IP filtering or to content archive or quarantine communication sessions.

FortiOS Carrier looks in the current user context list for the endpoints in the IP filter list and extracts the source IP addresses for these endpoints. Then any communication session with a source IP address that matches one of these IP addresses is blocked at the IP level, before the communication session is accepted by a security policy.

FortiOS Carrier dynamically updates the list of IP addresses to block as the user context list changes. Only these updated IP addresses are blocked by endpoint IP filtering.

For information about the carrier endpoints and the user context list, including how entries are added to and removed from this list, see For more information on carrier endpoints, see the FortiOS Handbook User Authentication chapter.

MMS Content Checksum

The MMS content checksum feature attempts to match checksums of known malicious MMS messages, and on a successful match it will be blocked. The checksums are applied to each part of the message—attached files and message body have separate checksums. These checksums are created with CRC-32, the same method as FortiAnalyzer checksums.

For example, if an MMS message contains a browser exploit in the message body, you can add the checksum for that message body to the list, and future occurrences of that exact message will be blocked. Content will be replaced by the content checksum block notification replacement message for that type of MMS message, and if it is enabled the event will be logged.

One possible implementation would to configure all .sis files to be intercepted. When one is found to be infected or malicious it would be added to the MMS content checksum list.

To use this feature a list of one or more malicious checksums must be created and then the feature is enabled using that list. For a detailed list of options, see “MMS Content Checksum” on page 674.

To configure an MMS content checksum list

1. Go to *Security Profiles* > *Carrier* > *MMS Content Checksum*.
2. Select *Create New*.
3. Enter a name for the list of checksums, and select OK.

   You are taken to the edit screen for that new list.
4. Select *Create New* to add a checksum.
5. Enter the *Name* and *Checksum*, and select OK.

   The checksum is added to the list.

To add more checksums to the list, repeat steps 4 and 5.

To to remove a checksum from the list you can either delete the checksum or simply disable it and leave it in the list.

To enable MMS content checksums, expand *MMS Scanning* and select *MMS Content Checksum* for the selected MMS types. Select the checksum list to match.

Passing or blocking fragmented messages

Select to pass fragmented MM3 and MM4 messages. Fragmented MMS messages cannot be scanned for viruses. If you do not select these options, fragmented MM3 and MM4 message are blocked.

The Interval is the time in seconds before client comforting starts after the download has begun, and the time between sending subsequent data.

The *Amount* is the number of bytes sent by client or server comforting at each interval.

Client comforting

In general, client comforting is available for for MM1 and MM7 messaging and provides a visual display of progress for web page loading or HTTP or FTP file downloads. Client comforting does this by sending the first few packets of the file or web page being downloaded to the client at configured time intervals so that the client is not aware that the download has been delayed. The client is the web browser or FTP client. Without client comforting, clients and their users have no indication that the download has started until the Carrier-enabled FortiGate unit has completely buffered and scanned the download. During this delay users may cancel or repeatedly retry the transfer, thinking it has failed.

The appearance of a client comforting message (for example, a progress bar) is client-dependent. In some instances, there will be no visual client comforting cue.

During client comforting, if the file being downloaded is found to be infected, then the Carrier-enabled FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead the download stops, and the user is left with a partially downloaded file.

If the user tries to download the same file again within a short period of time, then the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting can send unscanned (and therefore potentially infected) content to the client. Only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

MM1 and MM7 client comforting steps

Since MM1 and MM7 messages use HTTP, MM1 and MM7 client comforting operates like HTTP client comforting.

The following steps show how client comforting works for a download of a 1 Mbyte file with the client comforting interval set to 20 seconds and the client comforting amount set to 512 bytes.

1. The client requests the file.
2. The Carrier-enabled FortiGate unit buffers the file from the server. The connection is slow, so after 20 seconds about one half of the file has been buffered.
3. The Carrier-enabled FortiGate unit continues buffering the file from the server, and also sends 512 bytes to the client.
4. After 20 more seconds, the FortiGate unit sends the next 512 bytes of the buffered file to the client.
5. When the file has been completely buffered, the client has received the following amount of data:

   `ca * (T/ci) bytes == 512 * (40/20) == 512 * 2 == 1024 bytes,`

   where `ca` is the client comforting amount, `T` is the buffering time and `ci` is the client comforting interval.
6. If the file does not contain a virus, the Carrier-enabled FortiGate unit sends the rest of the file to the client. If the file is infected, the FortiGate closes the data connection but cannot send a message to the client.

Server comforting

Server comforting can be selected for each protocol.

Similar to client comforting, you can use server comforting to prevent server connection timeouts that can occur while waiting for FortiOS Carrier to buffer and scan large `POST` requests from slow clients.

The *Interval* is the time in seconds before client and server comforting starts after the download has begun, and the time between sending subsequent data.

The *Amount* is the number of bytes sent by client or server comforting at each interval.

Handling oversized MMS messages

Select *Block* or *Pass* for files and email messages exceeding configured thresholds for each protocol.

The oversize threshold refers to the final size of the message, including attachments, after encoding by the client. Clients can use a variety of encoding types; some result in larger file sizes than the original attachment. As a result, a file may be blocked or logged as oversized even if the attachment is several megabytes smaller than the oversize threshold.

MMS file filtering

Use MMS file filtering to apply antivirus file filtering to MMS traffic. Select a file filter list to apply. To configure MMS file filtering, go to *Security Profiles* > *Carrier* > *MMS Profile*, select an existing or create a new profile, and expand *MMS Scanning*.

Configure the FortiGate file filter to block files by:

- ***File pattern***: Files can be blocked by name, extension, or any other pattern. File pattern blocking provides the flexibility to block potentially harmful content.
- File pattern entries are not case sensitive. For example, adding `*.exe` to the file pattern list also blocks any files ending in `.EXE`.
- In addition to the built-in patterns, you can specify more file patterns to block.
- **File type**: Files can be blocked by type, without relying on the file name to indicate what type of files they are. When blocking by file type, the FortiGate unit analyzes the file and determines the file type regardless of the file name.

For standard operation, you can choose to disable file filter in the protection profile, and enable it temporarily to block specific threats as they occur.

The FortiGate unit can take either of these actions toward files that match a configured file pattern or type:

- **Allow**: the file is allowed to pass.
- **Block**: the file is blocked and a replacement messages will be sent to the user. If both file filter and virus scan are enabled, the Carrier-enabled FortiGate unit blocks files that match the enabled file filter and does not scan these files for viruses.
- **Intercept**: the file will be archived to the local hard disk or the FortiAnalyzer unit.

The Carrier-enabled FortiGate unit also writes a message to the virus log and sends an alert email message if configured to do so.

Files are compared to the enabled file patterns and then the file types from top to bottom. If a file does not match any specified patterns or types, it is passed along to antivirus scanning (if enabled). In effect, files are passed if not explicitly blocked.

Using the allow action, this behavior can be reversed with all files being blocked unless explicitly passed. Simply enter all the file patterns or types to be passed with the allow attribute. At the end of the list, add an all-inclusive wildcard (*.*) with a block action. Allowed files continue to antivirus scanning (if enabled) while files not matching any allowed patterns are blocked by the wildcard at the end.

Built-in patterns and supported file types

The FortiGate unit is preconfigured with a default list of file patterns:

- executable files (*.bat, *.com, and *.exe)
- compressed or archive files (*.gz, *.rar, *.tar, *.tgz, and *.zip)
- dynamic link libraries (*.dll)
- HTML application (*.hta)
- Microsoft Office files (*.doc, *.ppt, *.xl?)
- Microsoft Works files (*.wps)
- Visual Basic files (*.vb?)
- screen saver files (*.scr)
- program information files (*.pif)
- control panel files (*.cpl)

The FortiGate unit can take actions against the following file types:

Table 38: Supported file types

arj	activemime	aspack	base64	bat	binhex	bzip	bzip2
cab	class	cod	elf	exe	fsg	gzip	hlp
hta	html	jad	javascript	lzh	mime	msc	msoffice
petite	prc	rar	sis	tar	upx	uue	zip
unknown	ignored						

The “unknown” type is any file type that is not listed in the table. The “ignored” type is the traffic the FortiGate unit typically does not scan. This includes primarily streaming audio and video.

Filtering based on file name

There are filenames that are known to be associated with malware such as viruses and trojans. There are filenames you may associate with other undesirable content in addition to malware. In these situations you want to select specific filenames to filter.

You do not have to match the entire filename. For example if you wanted to block all files with the word `trojan` in them you could use wildcards to accomplish this - `*trojan*` . This allows you to select the entire filename, part of the filename, or just the file type to match.

The following procedure creates a filter list called `filterExampleFiles` that filters two files called `exampleTrojanFile.abc` and `*trojan*.def` . When completed, this file filter list can be included in an MMS profile.

To create a file filter based on file name - web-based manager

1. Go to *Security Profiles* > *Data Leak Prevention* > *File Filter*.
2. Select *Create New*, to create a new file filtering list.
3. Name the list `filterExampleFiles`.

4. Select *Create New* to add a filter to the list.
5. Select File Name Pattern for Filter Type.
6. Enter `exampleTrojanFile.abc .`
7. Enter Block for the *Action*.
8. Select *Enable*, and *OK*.
9. Select *Create New* to add a filter to the list.
10. Select File Name Pattern for Filter Type.
11. Enter `*trojan*.def .`
12. Enter Block for the *Action*.
13. Select *Enable*, and *OK*.

Filtering based on file type

When filtering files, it is often useful to filter based on the file type. When malware finds a file type that allows them access to a system, the filename will change but the file type will remain the same. Even for preventing applications that are not malware but simply undesirable, filtering based on file type is often the easiest method.

Simply matching the file type, .zip for example, may not be as accurate a method as using the built-in patterns. If users see that .zip attachments are blocked, they may simply rename the file so the filters will allow it through. Checking against patterns can help prevent this bypassing.

There are two possible methods available to filter based on file type. If the file type is one of the built-in patterns, you can use them - for example blocking PalmOS files on your network since Palm devices are not supported. Otherwise, you can simply use wildcards to match the file type.

The following example will filter all batch files (`.bat`).

To filter files based on file type using file name pattern - web-based manager

1. Go to *Security Profiles* > *Data Leak Prevention* > *File Filter*.
2. Select *Create New* and name the list `blockedFileTypes`.
3. Select *Create New* to add files to the list.
4. Select `File name pattern` for *Filter Type*.
5. Enter `*.bat` for *Pattern.*
6. Select an *Action* of Block.
7. Select *Enable* and *OK*.
8. At the file filter list, select *OK*.

The file filter is now available to be used in an MMS profile, and will block all `.bat` files that MMS profile matches.

To filter files based on file type using file type - web-based manager

1. Go to *Security Profiles* > *Data Leak Prevention* > *File Filter*.
2. Select *Create New* and name the list `blockedFileTypes`.
3. Select *Create New* to add files to the list.
4. Select `File Type` for *Filter Type*.
5. Select `Batch File (bat)` for *File Type.*
6. Select an *Action* of Block.
7. Select *Enable* and *OK*.
8. At the file filter list, select *OK*.

The file filter is now available to be used in an MMS profile, and will block all batch files (that use `.bat` file extension) that the MMS profile matches.

MMS file filtering blocks messages (not just attachments)

When MMS file filtering finds a matching file in an MMS message, the entire message is blocked. This action is more secure, and can reduce the amount of processing required for that message. For example if one MMS message includes three files, and the first one is blocked then the other files won't be scanned or attempted to be matched because the whole message is already being blocked.

Configuring MMS file filtering

To apply MMS file filtering you must begin with a file filter list. You can create your own list or use the built-in patterns list. You then must create the file filter, then add the file filter list to an MMS profile, and then add the MMS profile to a security policy. The MMS profile, and the corresponding file filter then applies to the traffic accepted by the security policy.

The following procedure creates a file filtering list called `MMS_file_filter` that is used in the MMS profile called `filtering_profile`. The filter will be applied to all MMS message types.

To apply MMS file filtering

1. Go to *Security Profiles* > *Data Leak Prevention* > *File Filter* and create a file filter list called `MMS_file_filter`.
2. Select *Create New* to add entries to filter specific file types.
3. Select *OK*.
4. Go to *Security Profiles* > *Carrier* > *MMS Profile* and create a new profile called `filtering_profile`.
5. Expand MMS Scanning, and select all the MMS message types.
6. Select `MMS_file_filter` from the *Option* drop down menu.
7. Set other settings as required in the MMS profile.
8. Select *OK*.
9. Go to *Policy, and select Create New.*
10. *Within the new policy select Security Profiles* > *MMS Profile, and select* `filtering_profile`.
11. Configure the security policy as required.
12. Select *OK*.

Sender notifications and logging

In most cases you will notify the sender that they are causing problems on the network — either by sending malware content, flooding the network, or some other unwanted activity. The notification assumes the sender is unaware of their activity and will stop or correct it when notified.

However, senders who are notified may use this information to circumvent administration's precautions. For example if flood notification is set to 1000 messages per minute, a notified user may simply reduce their message to 990 messages per minute if this flood is intentional. For this reason, not all problems include sender notifications.

There are two methods of notifying senders:

- MMS notifications
- Replacement messages

And three details to consider for logging and notifying administrators:

- Logging and reporting
- MMS logging options
- SNMP

MMS notifications

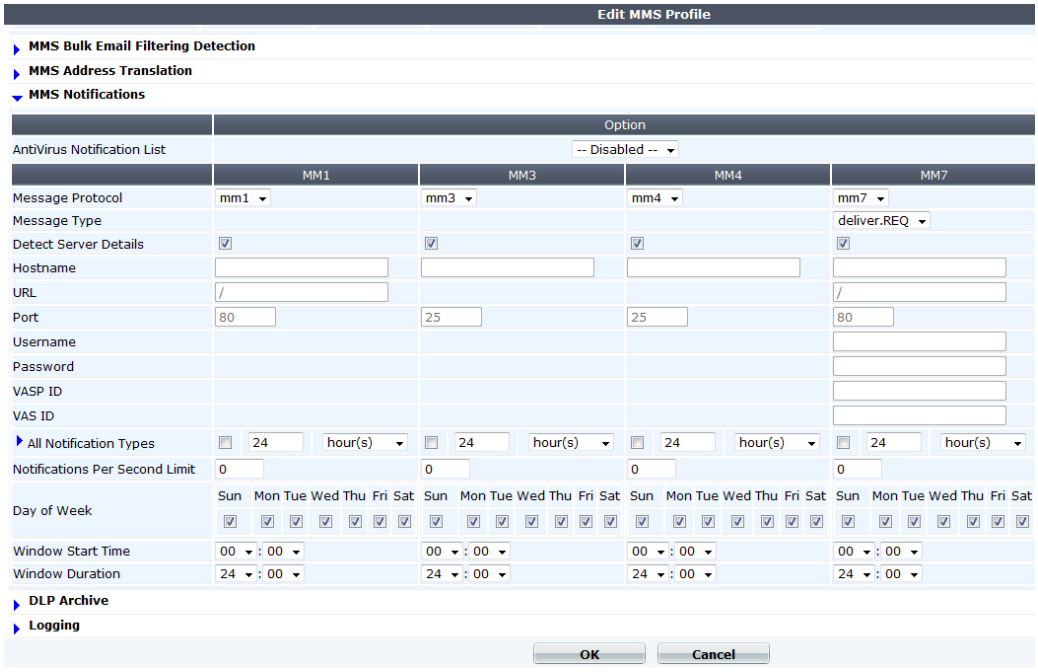
MMS notifications enable you to customize notifications for many different situations and differently for all the supported MMS message protocols — MM1, MM3, MM4, and MM7.

MMS notification types include:

- Content Filter
- File Block
- Carrier Endpoint Block
- Flood
- Duplicate
- MMS Content Checksum
- Virus Scan

Day of Week, *Window start time* and *Window Duration* define what days and what time of day alert notifications will be sent. This allows you to control what alerts are sent on weekends. It also lets you control when to start sending notifications each day. This can be useful if system maintenance is performed at the same time each night — you might want to start alert notifications after maintenance has completed. Another reason to limit the time alert messages are sent could be to limit message traffic to business hours.

Figure 149: Notifications screen for FortiOS Carrier MMS Profile



For MMS Notification options, see “MMS Notifications” on page 669.

Replacement messages

FortiGate units send replacement messages when messages or content is blocked, quarantined, or otherwise diverted from the receiver. In it's place a message is sent to notify the receiver what happened.

With FortiOS Carrier MMS replacement messages, send and receive message types are supported separately and receive their own custom replacement messages. This allows the network to potentially notify both the sender and reciever of the problem.

For example the replacement message *MM1 send-req file block message* is sent to the device that sent one or more files that were banned. The default message that is sent is `This device has sent %%NUM_MSG%% messages containing banned files in the last %%DURATION%% hours.` The two variables are replaced by the appropriate values.

Replacement messages are not as detailed or specific as MMS notifications, but they are also not as complicated to configure. They are also useful when content has been removed from an MMS message that was still delivered.

For more information on replacement messages, see "MMS Replacement messages" on page 115.

Logging and reporting

With each virus infection, or file block, a syslog message is generated. The format of this syslog message is similar to:

```
2005-09-22 19:15:47 deviceid=FGT5001ABCDEF1234 logid=0211060ABC
   type=virus subtype=infected level=warning src=10.1.2.3
   dst=10.2.3.4 srcintf=port1 dstintf=port2 service=mm1
   status=blocked from="<sending MSISDN>" to="<receiving MSISDN>"
   file="eicar.com.txt" virus="EICAR_TEST_FILE" msg="The file
   eicar.com.txt is infected with EICAR_TEST_FILE. ref
   http://www.fortinet.com/VirusEncyclopedia/search/encyclopediaSear
   ch.do?method=quickSearchDirectly&virusName=EICAR_TEST_FILE"
```

Note that the *from* and *to* fields are samples and not real values.

MMS logging options

You can enable logging in an MMS protection profile to write event log messages when the MMS protection profile options that you have enabled perform an action. For example, if you enable MMS antivirus protection, you could also use the MMS protection profile logging options to write an event log message every time a virus is detected.

To record these log messages you must first configure how the FortiOS Carrier unit stores log messages.

To configure MMS content archiving, go to *Security Profiles* > *Carrier* > *MMS Profile*. Select *Create New* or select the *Edit* icon beside an existing profile. Expand *MMS Bulk AntiSpam Detection* > *Logging*. Complete the fields as described in the following table and select *OK*. For more a detailed list of options, see "Logging" on page 673.

SNMP

A simple SNMP trap will be generated to inform the operators' alerting system that a virus has been detected. This SNMP trap could contain the sending and receiving MSISDN, however the initial solution would reflect the current behavior, i.e. only the fact that a virus has been detected will be communicated.

MMS content-based Antispam protection

Expand *MMS Scanning* and select *Content Filter* in an MMS protection profile to create content filter black/white lists that block or allow MMS messages based on the content of the message.

Overview

A school computer lab may block age-inappropriate content. A place of business may block unproductive content. A public access internet cafe may block offensive and graphic content. Each installation has its own requirements for what content needs to be blocked, and in what language.

FortiOS Carrier provides the ability to create custom local dictionaries, black lists, and white lists in multiple languages enables you to protect your customers from malicious content around the world.

Content-based protection includes:

- Configurable dictionary
- Black listing
- White listing

Configurable dictionary

You can create a dictionary of configurable terms and phrases using the CLI. The text of MMS messages will be searched for these terms and phrases. Add content filter lists that contain content that you want to match in MMS messages. For every match found, a score is added. If enough matches are found to set the total score above the configured threshold, the MMS message is blocked.

You can add words, phrases, wild cards and Perl regular expressions to create content patterns that match content in MMS messages. For more on wildcard and regular expressions, see *Using wildcards and Perl regular expressions* in the *UTM* handbook chapter.

For each pattern you can select *Block* or *Exempt*.

- Block adds an antispam black list pattern. A match with a block pattern blocks a message depending on the score of the pattern and the content filter threshold.
- Exempt adds an antispam white list pattern. A match with an exempt pattern allows the message to proceed through the FortiOS Carrier unit, even if other content patterns in the same content filter list would block it.

If a pattern contains a single word, the FortiOS Carrier unit searches for the word in MMS messages. If the pattern contains a phrase, the FortiOS Carrier unit searches for all of the words in the phrase. If the pattern contains a phrase in quotation marks, the FortiOS Carrier unit searches for the whole phrase.

You can create patterns with Simplified Chinese, Traditional Chinese, Cyrillic, French, Japanese, Korean, Spanish, Thai, or Western character sets.

Black listing

Black listing is the practice of banning entries on the list. For example if an IP address continuously sends viruses, it may be added to the black list. That means any computers that consult that list will not communicate with that IP address.

Sometimes computers or devices can be added to black lists for a temporary problem, such as a virus that is removed when notified. However, as a rule short of contacting the administrator in person to manually be removed form the black list, users have to wait and they generally will be removed after a period without problem.

White listing

White listing is the practice of adding all critical IP addresses to a list, such as company email and web servers. Then if those servers become infected and start sending spam or viruses, those servers are not blocked. This allows the critical traffic through, even if there might be some malicious traffic as well. Blocking all traffic from your company servers would halt company productivity.

Scores and thresholds

Each content pattern incudes a score. When a MMS message is matched with a pattern the score is recorded. If a message matches more than one pattern or matches the same pattern more than once, the score for the message increases. When the total score for a message equals or exceeds the threshold the message is blocked.

The default score for a content filter list entry is 10 and the default threshold is 10. This means that by default a message is blocked by a single match. You can change the scores and threshold so that messages can only be blocked if there are multiple matches. For example, you may only want to block messages that contain the phrase “example” if it appears twice. To do this, add the “example” pattern, set action to block and score to 5. Keep the threshold at 10. If “example” is found twice or more in a message the score adds up 10 (or more) and the message is blocked.

Configuring content-based antispam protection

To apply content-based antispam protection - CLI

```
config webfilter content
  edit <filter_table_number>
    set name <filter_table_name>
    config entries
      edit <phrase or regexp you want to block>
        set action {block | exempt}
        set lang <phrase language>
        set pattern-type {wildcard | regexp}
        set score <phrase score>
        set status {enable | disable}
      end
    end
```

Configuring sender notifications

When someone on the MMS network sends an MMS message that is blocked, in most cases you will notify the sender. Typically an administrator is notified in addition to the sender so action can be taken if required.

There are two types of sender notifications available in FortiOS Carrier:

- MMS notifications
- Replacement messages

MMS notifications

MMS notifications to senders are configured in *Security Profiles* > *Carrier* > *MMS Profile*, under MMS Notifications.

In this section you can configure up to four different notification recipients for any combination of MM1/3/4/7 protocol MMS messages. Also for MM7 messages the message type can be `submit.REQ` or `deliver.REQ`.

Useful settings include:

- delay in message based on notification type
- limit on notifications per second to prevent a flood
- schedules for notifications
- log in details for MM7 messages.

For more information on MMS notifications, see "Notifying message flood senders and receivers" on page 725 and "MMS Notifications" on page 669.

Replacement messages

Replacement messages are features common to both FortiOS and FortiOS Carrier, however FortiOS Carrier has additional messages for the MMS traffic.

While each MMS protocol has its own different rec placement messages, the one common to all MMS protocols is the *MMS blocked content replacement message*. This is the message that the receiver of the message sees when their content is blocked.

For more information on replacement messages, see "MMS Replacement messages" on page 115.

MMS DLP archiving

You can use DLP archiving to collect and view historical logs that have been archived to a FortiAnalyzer unit or the FortiGuard Analysis and Management service. DLP archiving is available for FortiAnalyzer when you add a FortiAnalyzer unit to the FortiOS Carrier configuration. The FortiGuard Analysis and Management server becomes available when you subscribe to the FortiGuard Analysis and Management Service.

You can configure full DLP archiving and summary DLP archiving. Full DLP archiving includes all content, for example, full email DLP archiving includes complete email messages and attachments. Summary DLP archiving includes just the meta data about the content, for example, email message summary records include only the email header.

You can archive MM1, MM3, MM4, and MM7 content:

Configuring MMS DLP archiving

Select DLP archive options to archive MM1, MM3, MM4, and MM7 sessions. For each protocol you can archive just session metadata (*Summary*), or metadata and a copy of the associated file or message (*Full*).

In addition to MMS protection profile DLP archive options you can:

- Archive MM1 and MM7 message floods
- Archive MM1 and MM7 duplicate messages
- Select *DLP archiving* for carrier endpoint patterns in a *Carrier Endpoint List* and select the *Carrier Endpoint Block* option in the *MMS Scanning* section of an MMS Protection Profile

FortiOS Carrier only allows one sixteenth of its memory for transferring content archive files. For example, for Carrier-enabled FortiGate units with 128MB RAM, only 8MB of memory is used when transferring content archive files. Best practices dictate to not enable full content archiving if antivirus scanning is also configured because of these memory constraints.

To configure MMS DLP archiving - web-based manager

1. Go to *Security Profiles* > *Carrier* > *MMS Profile*.
2. Select *Create New* or select the *Edit* icon beside an existing profile.
3. Expand *MMS Bulk AntiSpam Detection* > *Content Archive*.
4. Complete the fields as described in "DLP Archive options" on page 672.
5. Select *OK*.

Viewing DLP archives

You can view DLP archives from the Carrier-enabled FortiGate unit web-based manager. Archives are historical logs that are stored on a log device that supports archiving, such as a FortiAnalyzer unit.

These logs are accessed from either *Log & Report* > *DLP Archive* or if you subscribed to the FortiCloud service, you can view log archives from there.

The *DLP Archive* menu is only visible if one of the following is true.

- You have configured the FortiGate unit for remote logging and archiving to a FortiAnalyzer unit.
- You have subscribed to FortiCloud.

The following tabs are available when you are viewing DLP archives for one of these protocols.

- *E-mail* to view POP3, IMAP, SMTP, POP3S, IMAPS, SMTPS, and spam email archives.
- *Web* to view HTTP and HTTPS archives.
- *FTP* to view FTP archives.
- *IM* to view AIM, ICQ, MSN, and Yahoo! archives.
- *MMS* to view MMS archives.
- *VoIP* to view session control (SIP, SIMPLE and SCCP) archives.

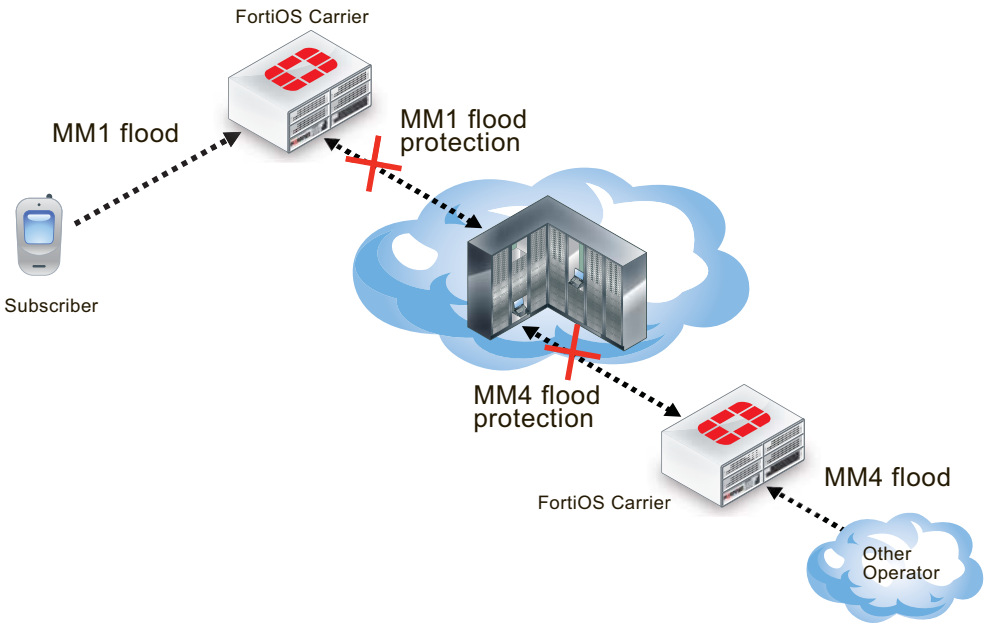
If you need to view log archives in Raw format, select *Raw* beside the *Column Settings* icon.

Message flood protection

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or attempting to overload the network with an excess of messages. MMS flood prevention can help prevent this type of abuse.

Flood protection for MM1 messages prevents your subscribers from sending too many messages to your MMSC. Configuring flood protection for MM4 messages prevents another service provider from sending too many messages from the same subscriber to your MMSC.

Figure 150:MM1 and MM4 flood protection



The FortiOS Carrier unit keeps track of the number of messages each subscriber sends for the length of time you specify. If the number of messages a subscriber sends exceeds the threshold, a configured action is taken. Possible actions are logging the flood, blocking or intercepting messages in the flood, archiving the flood messages, and sending an alert message to inform the administrator that the flood is occurring.

You can create three different thresholds to take different levels of action at different levels of activity.

With this highly configurable system, you can prevent subscribers from sending more messages than you determine is acceptable, or monitor anyone who exceeds the thresholds.

Setting message flood thresholds

A message flood occurs when a single subscriber sends a volume of messages that exceeds the flood threshold you set. The threshold defines the maximum number of messages allowed, the period during which the subscriber sent messages are considered, and the length of time the sender is restricted from sending messages after a flood is detected.

If a subscriber exceeds the message flood threshold and is blocked from sending more messages, any further attempts to send messages will re-start the block period. You must also

enable logging for *MMS Scanning* > *Bulk Messages* in the Logging section of the MMS protection profile.

A subscriber is still able to receive messages while they are blocked from sending messages.

Example

For example, for the first threshold you may determine that any subscriber who sends more than 100 MM1 messages in an hour (60 minutes) will have all messages blocked for half an hour (30 minutes).

Using this example, if the subscriber exceeds the flood threshold, they are blocked from sending message for 30 minutes. If the subscriber tries to send any message after 15 minutes, the message will be blocked and the block period will be reset again to 30 minutes. The block period must expire with no attempts to send a message. Only then will the subscriber be allowed to send more messages.

To configure MM1 message flood threshold - web-based manager

1. Go to *Security Profiles* > *Carrier* > *MMS Profile*.
2. Select *Create New*.
3. Enter `MM1 flood` for *Profile Name*.
4. Expand *MMS Bulk Email Filtering Detection*.
5. Enter the following information, and select *OK*.

MM1 (first column)	
Enable	Enable
Message Flood Window	60 minutes
Message Flood Limit	100
Message Flood Block Time	30 minutes
Message Flood Action	Block

To configure MM1 message flood threshold - CLI

```
config firewall mms-profile
  edit profile_name
    config flood mm1
      set status1 enable
      set window1 60
      set limit1 100
      set action1 block
      set block-time1 30
    end
end
```

The threshold values that you set for your network will depend on factors such as how busy your network is and the kinds of problems that your network and your subscribers encounter. For example, if your network is not too busy you may want to set message flood thresholds

relatively high so that only an exceptional situation will exceed a flood threshold. Then you can use log messages and archived MMS messages to determine what caused the flood.

If your subscribers are experiencing problems with viruses that send excessive amounts of messages, you may want to set thresholds lower and enable blocking to catch problems as quickly as possible and block access to keep the problem from spreading.

Flood actions

When the Carrier-enabled FortiGate unit detects a message flood, it can take any combination of the five actions that you can configure for the flood threshold. For detailed options, see "Message Flood" on page 678.

Notifying administrators of floods

You can configure alert notifications for message floods by selecting the Alert Notification message flood action.

The FortiOS Carrier unit sends alert notifications to administrators using the MM1, MM3, MM4, or MM7 content interface. To send an alert notification you must configure addresses and other settings required for the content interface.

For example, to send notifications using the MM1 content interface you must configure a source MSISDN, hostname, URL, and port to which to send the notification. You can also configure schedules for when to send the notifications.

Finally you can add multiple MSISDN numbers to the MMS protection profile and set which flood thresholds to send to each MSISDN.

Example — three flood threshold levels with different actions for each threshold

You can set up to three threshold levels to take different actions at different levels of activity.

The first example threshold records log messages when a subscriber's handset displays erratic behavior by sending multiple messages using MM1 at a relatively low threshold. The erratic behavior could indicate a problem with the subscriber's handset. For example, you may have determined for your network that if a subscriber sends more the 45 messages in 30 minutes that you want to record log messages as a possible indication or erratic behavior.

From the web-based manager in an MMS profile set message *Flood Threshold 1* to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	45
Message Flood Action	Log

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config flood mm1
```

```
        set status1 enable
        set window1 30
        set limit1 45
        set action1 log
      end
end
```

Set a second higher threshold to take additional actions when a subscriber sends more that 100 messages in 30 minutes. Set the actions for this threshold to log the flood, archive the message that triggered the second threshold, and block the sender for 15 minutes.

From the web-based manager in an MMS profile set message *Flood Threshold 2* to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	100
Message Block Time	15 minutes
Message Flood Action	Log, DLP archive First message only, Block

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config flood mm1
      set status2 enable
      set window2 30
      set limit2 100
      set action2 block log archive-first
      set block-time2 15
    end
end
```

Set the third and highest threshold to block the subscriber for an extended period and sand an administrator alert if the subscriber sends more than 200 messages in 30 minutes. Set the actions for this threshold to block the sender for four hours (240 minutes), log the flood, archive the message that triggered the third threshold, and send an alert to the administrator.

From the web-based manager in an MMS profile set message *Flood Threshold 3* to:

Enable	Selected
Message Flood Window	30 minutes
Message Flood Limit	200
Message Block Time	240 minutes
Message Flood Action	Log, Block, Alert Notification

Because you have selected the *Alert Notification* action you must also configure alert notification settings. For this example, the source MSISDN is 5551234—telephone number 555-1234. When administrators receive MMS messages from this MSIDSN they can assume a message flood has been detected.

In this example, alert notifications are sent by the FortiOS Carrier unit to the MMSC using MM1. The host name of the MMSC is `mmscexample`, the MMSC URL is `/`, and the port used by the MMSC is 80. In this example, the alert notification window starts at 8:00am and extends for eight hours on weekdays (Monday-Friday) and the minimum interval between message flood notifications is two hours.

Source MSISDN	5551234
Message Protocol	MM1
Hostname	mmscexample
URL	/
Port	80
Notifications Per Second Limit	0
Window Start Time	8:00
Window Duration	8:00
Day of Week	Mon, Tue, Wed, Thu, Fri, Sat
Interval	2 hours

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config notification alert-flood-1
      set alert-src-msisdn 5551234
      set set msg-protocol mm1
      set mmsc-hostname mmscexample
      set mmsc-url /
      set mmsc-port 80
      set rate-limit 0
      set tod-window-start 8:00
      set tod-window-duration 8:00
      set days-allowed monday tuesday wednesday thursday friday
      set alert-int 2
      set alert-int-mode hours
    end
end
```

You must also add the MSISDNs of the administrators to be notified of the message flood. In this example, the administrator flood threshold 3 alert notifications are sent to one administrator with MSISDN 5554321.

To add administrator's MSISDNs for flood threshold 3 from the web-based manager when configuring a protection profile, select *MMS Bulk Email Filtering Detection* > *Recipient MSISDN* > *Create New*.

MSISDN	5554321
Flood Level 3	Select

From the CLI:

```
config firewall mms-profile
  edit profile_name
    config notif-msisdn
      edit 5554321
        set threshold flood-thresh-3
    end
end
```

Notifying message flood senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver that cause a message flood. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around flood protection. For this reason, no notification is set to the sender or receiver.

However, FortiOS Carrier does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as message floods. For information about how FortiOS Carrier responds when message flood detection blocks a message, see “FortiOS Carrier and MMS duplicate messages and message floods” on page 642.

Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (`m-send.conf`) to the sender — otherwise the sender’s handset would keep retrying the message. The `m-send.conf` message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the MMSC and the MMSC sends the `m-send.conf` message.

You can customize the `m-send.conf` message by editing the *MM1 send-conf flood message* MM1 replacement message (from the CLI the `mm1-send-conf-flood` replacement message). You can customize the response status and message text for this message. The default response status is “Content not accepted”. To hide the fact that FortiOS Carrier is responding to a flood, you can change the response status to “Success”. The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to “Success” and changes the message text to “Message Sent OK”:

```
config system replacemsg mm1 mm1-send-conf-flood
  set rsp-status ok
  set rsp-text “Message Sent OK”
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a flood message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (m-retrieve.conf) to the sender (otherwise the sender’s handset would keep retrying the message). The m-retrieve.conf message is sent only when the MM1 message flood action is set to Block. For other message flood actions the message is actually delivered to the receiver, so the MMSC sends the m-retrieve.conf message.

You can customize the m-retrive.conf message by editing the *MM1 retrieve-conf flood message* MM1 replacement message (from the CLI the `mm1-retr-conf-flood` replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-flood
  set subject "Message blocked"
  set message "Message temporarily blocked by carrier"
end
```

Forward responses for MM4 message floods

When the FortiOS Carrier unit identifies an MM4 message as a flood message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4_forward.res message is sent only when the MM4 message flood action is set to Block and the MM4-forward.req message requested a response. For more information, see "FortiOS Carrier and MMS duplicate messages and message floods" on page 642.

You can customize the MM4_forward.res message by editing the *MM4 flood message* MM4 replacement message (from the CLI the `mm4-flood` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted" (`err-content-not-accept`). To hide the fact that the FortiOS Carrier unit is responding to a flood, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Sent OK" for the MM4 message forward response

```
config system replacemsg mm4 mm4-flood
  set rsp-status ok
  set rsp-text "Message Forwarded OK"
end
```

Viewing DLP archived messages

If *DLP Archive* is a selected message flood action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages, but you can configure the DLP archive setting to save only the first message that exceeds the threshold. This still provides a sample of the offending messages without requiring as requiring as much storage.

To select only the first message in a flood for DLP archiving - web-based manager

1. Go to *Security Profiles* > *Carrier* > *MMS Profile*.
2. Edit an existing MMS Profile.
3. Expand the *MMS Bulk Email Filtering Detection* section, the *Message Flood* subsection, and the desired *Flood Threshold* subsection.
4. Next to *DLP Archive*, select *First message only* from the dropdown menu.
5. Select *OK*.

Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totalling the number of

messages sent by each subscriber regardless of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The Carrier-enabled FortiGate unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a *Block* action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

Bypassing message flood protection based on user's carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from message flood protection. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns.

If you add a carrier endpoint pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier endpoints bypass message flood protection. This allows legitamite bulk messges, such as system outage notifications, to be delivered without triggering message flood protection.

For more information on carrier endpoints, see the FortiOS Handbook User Authentication chapter.

Configuring message flood detection

To have the Carrier-enabled FortiGate unit check for message floods, you must first configure the flood threshold in an MMS profile, select the MMS profile in a security policy. All the traffic examined by the security policy will be checked for message floods according to the threshold values you set in the MMS profile.

Configure the MMS profile - web-based manager

1. Go to *Firewall Objects* > *MMS Profile*.
2. If you are editing an MMS profile, select the *Edit* icon of the MMS profile.

   If you are create a new MMS profile, select *Create New* and enter a profile name.
3. Expand *MMS Bulk Email Filtering Detection*.
4. Expand *Message Flood*.
5. Expand *Flood Threshold 1*.
6. Select the *Enable* check box for MM1 messages, MM4 messages, or both.
7. In the *Message Flood Window* field, enter the length of time the Carrier-enabled FortiGate unit will keep track of the number of messages each subscriber sends.

   If the Carrier-enabled FortiGate unit detects the quantity of messages specified in the *Message Flood Limit* sent during the number of minutes specified in the *Message Flood Window*, a message flood is in progress.
8. In the *Message Flood Limit* field, enter the number of messages required to trigger the flood.
9. In the *Message Flood Block Time* field, enter the length of time a user will be blocked from sending messages after causing the message flood.
10. Select the message flood actions the Carrier-enabled FortiGate unit will take when the message flood is detected.

11. Select OK.

Configure the security policy - web-based manager

1. Go to *Policy*.
2. Select the *Edit* icon of the security policy that controls the traffic in which you want to detect message floods.
3. Select the *MMS Profile* check box to enable the use of a protection profile.
4. Select the MMS protection profile from the list.
5. Select OK.

Sending administrator alert notifications

When message floods are detected, the Carrier-enabled FortiGate unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the message flood action. Each message flood threshold can be configured separately.

This section includes:

Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 message floods. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually “/”)
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
- *submit.REQ* to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
- *deliver.REQ* to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually "/")
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

For more information, see "MMS notifications" on page 714.

To configure administrator alert notifications - web-based manager

1. Go to *Firewall Objects* > *MMS Profile* and edit or add a new MMS protection profile.
2. Expand *MMS Bulk Email Filtering Detection*.

   There are three message flood thresholds.
3. Expand the threshold that you want to configure alert notification for.
4. For *Message Flood Action*, select the *Alert Notification* check box. Alert notification options appear.
5. For the *Source MSISDN*, enter the MSISDN from which the alert notification message will be sent.
6. Select the Message Protocol the alert notification will use: *MM1*, *MM3*, *MM4*, or *MM7*.
7. Add the information required by FortiOS Carrier to send messages using the selected message protocol:
8. For *Notifications Per Second Limit*, enter the number of notifications to send per second.

   Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.
9. If required, change *Window Start Time* and *Window Duration* configure when the FortiOS Carrier unit sends alert notifications.

   By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.

   For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.

   You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.
10. For *Day of Week*, select the days of the week to send notifications.

    For example, you may only want to send alert notifications on weekends for higher thresholds.

11. In the *Interval field*, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.

    All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the message flood threshold that triggers sending notifications to this MSISDN.

To configure the alert notification recipients - web-based manager

1. Go to *Firewall Objects* > *MMS Profile*.
2. Select the *Edit* icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand *MMS Bulk Email Filtering Detection*.
4. Expand *Recipient MSISDN*.
5. Select *Create New*.
6. In the *New MSISDN* window, enter the MSISDN to use for flood threshold alert notification.
7. Select the duplicate thresholds at which to send alert notifications to the MSISDN.

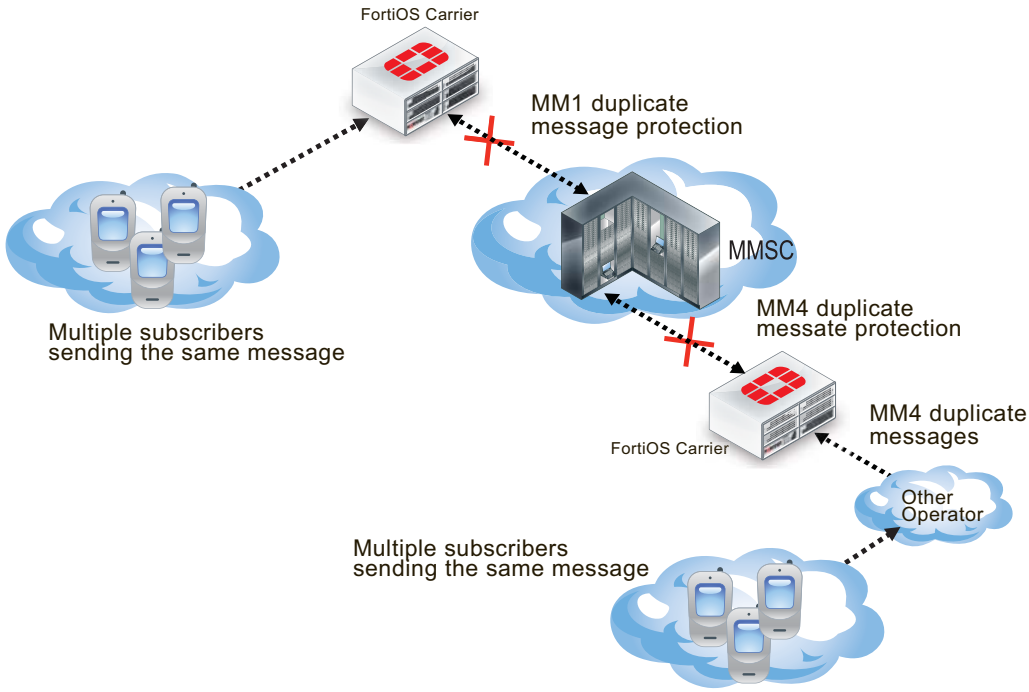
For the flood threshold to be able to send an alert notification to the MSISDN, the alert notification action must be enabled and configured within the flood threshold.

Duplicate message protection

The convenience offered by MM1 and MM4 messaging can be abused by users sending spam or other unwanted messages. Often, the same message will be sent by multiple subscribers. The message can be spam, viral marketing, or worm-generated messages. MMS duplicate prevention can help prevent this type of abuse by keeping track of the messages being sent.

Duplicate message protection for MM1 messages prevents multiple subscribers from sending duplicate messages to your MMSC. Duplicate message protection for MM4 messages prevents another service provider from sending duplicate messages from the same subscriber to your MMSC. This can help prevent a potential flood that would otherwise become widespread between carriers.

Figure 151:MM1 and MM4 duplicate message protection



The FortiOS Carrier unit keeps track of the sent messages. If the same message appears more often than the threshold value you configure, then action is taken. Possible actions are logging the duplicates, blocking or intercepting duplicate messages, archiving the duplicate messages, and sending an alert to inform an administrator that duplicates are occurring.

With this highly configurable system, you can prevent the transmission of duplicate messages when there are more than you determine is acceptable.

For detailed configuration options, see “Duplicate Message” on page 680.

Using message fingerprints to identify duplicate messages

The Carrier-enabled FortiGate unit detects duplicates by keeping a record of all the messages travelling on the network and comparing new messages to those that have already been sent.

Rather than save the messages, the FortiOS carrier creates a checksum using the message body and subject. This serves as a fingerprint to identify the message. If another message with the same message body and subject appears, the fingerprint will also be the same and the Carrier-enabled FortiGate unit will recognize it as a duplicate.

By creating and saving message fingerprints instead of saving the messages, the Carrier-enabled FortiGate unit can save resources and time.

Messages from any sender to any recipient

Duplicate message detection will detect duplicate messages regardless of the sender or recipient. To do this, message fingerprints are generated using only the message body and subject. The sender, recipient, and other header information is not included.

If multiple messages appear with the same subject and message body, the Carrier-enabled FortiGate unit will recognize them as being the same.

Setting duplicate message thresholds

The FortiOS Carrier recognizes all duplicate messages, but it will take action when it detects a volume of duplicate messages that exceed the duplicate threshold you set. The threshold defines the maximum number of duplicate messages allowed, the period during which the messages are considered, and the length of time the duplicate message can not be sent by anyone.

For example, you may determine that once a duplicate message is sent more than 300 times in an hour, any attempt to send the same duplicate message will be blocked for 30 minutes.

If a particular duplicate message exceeds the duplicate message threshold and is blocked, any further attempts to send the same message will re-start the block period.

Using the example above, if the duplicate message count exceeds the duplicate threshold, any attempt to send a copy of the duplicate message will be blocked for 30 minutes. If a subscriber tries to send a copy of the message after waiting 15 minutes, the message will be blocked and the block period will be reset to 30 minutes. The block period must expire with no attempts to send a duplicate message. Only then will a subscriber be allowed to send the message. Non-duplicate messages will not reset the block period.

Duplicate message actions

When the Carrier-enabled FortiGate unit detects that a duplicate message has exceeded duplicate threshold, it can take any combination of the five actions you configure for the duplicate threshold.

Action	Description
Log	Add a log entry indicating that a duplicate message event has occurred. You must also enable logging for *MMS Scanning* > *Bulk Messages* in the *Logging* section of the MMS protection profile.
DLP Archive	

	All messages	Save all the messages that exceed the duplicate threshold in the DLP archive.
	First message only	Save the first message to exceed the duplicate threshold in the DLP archive. Subsequent messages that exceed the duplicate threshold will not be saved.
Intercept		Messages that exceed the duplicate threshold are passed to the recipients, but if quarantine is enabled for intercepted messages, a copy of each message is also quarantined for later examination. If the quarantine of intercepted messages is disabled, the *Intercept* action has no effect.
Block		Messages that exceed the duplicate threshold are blocked and will not be delivered to the message recipients. If quarantine is enabled for blocked messages, a copy of each blocked message is quarantined for later examination.
Alert Notification		If the duplicate threshold is exceeded, the Carrier-enabled FortiGate unit will send an MMS duplicate message notification message.

Notifying duplicate message senders and receivers

The FortiOS Carrier unit does not send notifications to the sender or receiver of duplicate messages. If the sender or receiver is an attacker and is explicitly informed that they have exceeded a message threshold, the attacker may try to determine the exact threshold value by trial and error and then find a way around duplicate message protection. For this reason, no notification is set to the sender or receiver.

However, the FortiOS Carrier unit does have replacement messages for sending reply confirmations to MM1 senders and receivers and for MM4 senders for blocked messages identified as duplicate messages. For information about how FortiOS Carrier responds when message flood detection blocks a message, see “FortiOS Carrier and MMS duplicate messages and message floods” on page 642.

Responses to MM1 senders and receivers

When the FortiOS Carrier unit identifies an MM1 message sent by a sender to an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message submission confirmation (m-send.conf) to the sender (otherwise the sender’s handset would keep retrying the message). The m-send.conf message is sent only when the MM1 duplicate message action is set to Block. For other duplicate message actions the message is actually delivered to the MMSC and the MMSC sends the m-send.conf message.

You can customize the m-send.conf message by editing the *MM1 send-conf duplicate message* MM1 replacement message (from the CLI the `mm1-send-conf-dupe` replacement message). You can customize the response status and message text for this message. The default response status is “Content not accepted”. To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to “Success”. The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to “Success” and changes the message text to “Message Sent OK”:

```
config system replacemsg mm1 mm1-send-conf-dupe
```

```
  set rsp-status ok
  set rsp-text "Message Sent OK"
end
```

When the FortiOS Carrier unit identifies an MM1 message received by a receiver from an MMSC as a duplicate message and blocks it, the FortiOS Carrier unit returns a message retrieval confirmation (m-retrieve.conf) to the sender (otherwise the sender's handset would keep retrying). The m-retrieve.conf message is sent only when the `MM1duplicate` message action is set to Block. For other message flood actions the message is actually received by the receiver, so the MMSC sends the m-retrieve.conf message.

You can customize the m-retrive.conf message by editing the *MM1 retrieve-conf duplicate message* MM1 replacement message (from the CLI the `mm1-retr-conf-dupe` replacement message). You can customize the class, subject, and message text for this message.

For example, you could use the following command make the response more generic:

```
config system replacemsg mm1 mm1-retr-conf-dupe
  set subject "Message blocked"
  set message "Message temporarily blocked by carrier"
end
```

Forward responses for duplicate MM4 messages

When the FortiOS Carrier unit identifies an MM4 message as a duplicate message and blocks it, the FortiOS Carrier unit returns a message forward response (MM4_forward.res) to the forwarding MMSC (otherwise the forwarding MMSC would keep retrying the message). The MM4_forward.res message is sent only when the MM4 duplicate message action is set to Block and the MM4-forward.req message requested a response. For more information, see "FortiOS Carrier and MMS duplicate messages and message floods" on page 642.

You can customize the MM4_forward.res message by editing the *MM4 duplicate message* MM4 replacement message (from the CLI the `mm4-dupe` replacement message). You can customize the response status and message text for this message. The default response status is "Content not accepted" (`err-content-not-accept`). To hide the fact that the FortiOS Carrier unit is responding to a duplicate message, you can change the response status to "Success". The default message text informs the sender that the message was blocked. You could change this to something more generic.

For example, the following command sets the submission confirmation response status to "Success" and changes the message text to "Message Forwarded OK":

```
config system replacemsg mm4 mm4-dupe
  set rsp-status ok
  set rsp-text "Message Forwarded OK"
end
```

Viewing DLP archived messages

If *DLP Archive* is a selected duplicate message action, the messages that exceed the threshold are saved to the MMS DLP archive. The default behavior is to save all of the offending messages but you can configure the DLP archive setting to save only the first message that exceeds the threshold. See "Viewing DLP archived messages" on page 726.

Order of operations: flood checking before duplicate checking

Although duplicate checking involves only examination and comparison of message contents and not the sender or recipient, and flood checking involves only totalling the number of messages sent by each subscriber regardless of the message content, there are times when a selection of messages exceed both flood and duplicate thresholds.

The Carrier-enabled FortiGate unit checks for message floods before checking for duplicate messages. Flood checking is less resource-intensive and if the flood threshold invokes a *Block* action, the blocked messages are stopped before duplicate checking occurs. This saves both time and FortiOS Carrier system resources.

Bypassing duplicate message detection based on user's carrier endpoints

You can use carrier endpoint filtering to exempt MMS sessions from duplicate message detection. Carrier endpoint filtering matches carrier endpoints in MMS sessions with carrier endpoint patterns. If you add a carrier endpoint pattern to a filter list and set the action to exempt from mass MMS, all messages from matching carrier endpoints bypass duplicate message detection. For more information about endpoints, see *FortiOS Handbook User Authentication chapter*.

Configuring duplicate message detection

To have the Carrier-enabled FortiGate unit check for duplicate messages, configure the duplicate threshold in an MMS profile, and select the MMS profile in a security policy.

All traffic matching the security policy will be checked for duplicate messages according to the settings in the MMS profile.

The duplicate scanner will only scan content. It will not scan headers. Content must be exactly the same. If there is any difference at all in the content, it will not be considered a duplicate.

The modular nature of the profiles allows you great flexibility in how you configure the scanning options. MMS profiles can be used in any number of policies, with different GTP profiles.

In a complex configuration, there may be many security policies, each with a different MMS profile. For a simpler network, you may have many security policies all using the same MMS profile.

Sending administrator alert notifications

When duplicate messages are detected, the Carrier-enabled FortiGate unit can be configured to notify you immediately with an MMS message. Enable this feature by selecting Alert Notification in the duplicate message action. Each duplicate message threshold can be configured separately.

This section includes:

- Configuring how and when to send alert notifications
- Configuring who to send alert notifications to

Configuring how and when to send alert notifications

You can configure different alert notifications for MM1 and MM4 duplicate messages. You can configure the FortiOS Carrier unit to send these alert notifications using the MM1, MM3, MM4, or MM7 content interface. Each of these content interfaces requires alert notification settings that the FortiOS Carrier unit uses to communicate with a server using the selected content interface.

For the MM1 content interface you require:

- The hostname of the server
- The URL of the server (usually “/”)
- The server port (usually 80)

For the MM3 and MM4 content interfaces you require:

- The hostname of the server
- The server port (usually 80)
- The server user domain

For the MM7 content interface you require:

- The message type
- *submit.REQ* to send a notification message to the sender in the form of a submit request. The message goes from a VAS application to the MMSC.
- *deliver.REQ* to send a notification message to the sender in the form of a deliver request. The message goes from the MMSC to a VAS application.
- The hostname of the server
- The URL of the server (usually “/”)
- The server port (usually 80)
- A user name and password to connect to the server
- The value-added-service-provider (VASP) ID
- The value-added-service (VAS) ID

To configure administrator alert notifications - web-based manager

1. Go to *Security Profiles* > *Carrier* > *MMS Profile* and edit or add a new MMS protection profile.
2. Expand *MMS Bulk Email Filtering Detection*.

   There are three duplicate message thresholds.
3. Expand the threshold that you want to configure alert notification for.
4. For *Duplicate Message Action*, select the *Alert Notification* check box. Alert notification options appear.
5. For the *Source MSISDN*, enter the MSISDN from which the alert notification message will be sent.
6. Select the Message Protocol the alert notification will use: *MM1*, *MM3*, *MM4*, or *MM7*.
7. Add the information required by FortiOS Carrier to send messages using the selected message protocol:
8. For *Notifications Per Second Limit*, enter the number of notifications to send per second.

   Use this setting to reduce control the number of notifications sent by the FortiOS Carrier unit. If you enter zero (0), the notification rate is not limited.

9. If required, change *Window Start Time* and *Window Duration* configure when the FortiOS Carrier unit sends alert notifications.

   By default, notifications are sent at any time of the day. You can change the Window Start Time if you want to delay sending alert messages. You can also reduce the Window Duration if you want to stop sending alert notifications earlier.

   For example, you might not want FortiOS Carrier sending notifications except during business hours. In this case the Window Start Time could be 9:00 and the Window Duration could be 8:00 hours.

   You can set different alert notifications for each message threshold. For example, you could limit the message window for lower thresholds and set it to 24 hours for higher thresholds. This way administrators will only receive alert notifications outside of business hours for higher thresholds.

10. For *Day of Week*, select the days of the week to send notifications.

    For example, you may only want to send alert notifications on weekends for higher thresholds.

11. In the *Interval field*, enter the maximum frequency that alert notification messages will be sent, in minutes or hours.

    All alerts occurring during the interval will be included in a single alert notification message to reduce the number of alert messages that are sent.

Configuring who to send alert notifications to

In each MMS protection profile you add a list of recipient MSISDNs. For each of these MSISDNs you select the duplicate threshold that triggers sending notifications to this MSISDN.

To configure the alert notification recipients - web-based manager

1. Go to *Security Profiles* > *Carrier* > *MMS Profile*.
2. Select the *Edit* icon of the MMS profile in which you want to configure the alert notification recipients.
3. Expand *MMS Bulk Email Filtering Detection*.
4. Expand *Recipient MSISDN*.
5. Select *Create New*.
6. In the *New MSISDN* window, enter the MSISDN to use for duplicate threshold alert notification.

Select the duplicate thresholds at which to send alert notifications to the MSISDN.

For the duplicate threshold to be able to send an alert notification to the MSISDN, the duplicate message threshold alert notification action must be enabled and configured.

Configuring GTP on FortiOS Carrier

Configuring GTP support on FortiOS Carrier involves configuring a number of areas of features. Some features require longer explanations, and have their own chapters. The other features are addressed here.

This section includes:

- GTP support on the Carrier-enabled FortiGate unit
- Configuring General Settings on the Carrier-enabled FortiGate unit
- Configuring Encapsulated Filtering in FortiOS Carrier
- Configuring the Protocol Anomaly feature in FortiOS Carrier
- Configuring Anti-overbilling in FortiOS Carrier
- Logging events on the Carrier-enabled FortiGate unit

GTP support on the Carrier-enabled FortiGate unit

The FortiCarrier unit needs to have access to all traffic entering and exiting the carrier network for scanning, filtering, and logging purposes. This promotes one of two configurations — hub and spoke, or bookend.

A hub and spoke configuration with the Carrier-enabled FortiGate unit at the hub and the other GPRS devices on the spokes is possible for smaller networks where a lower bandwidth allows you to divide one unit into multiple virtual domains to fill multiple roles on the carrier network. It can be difficult with a single FortiOS Carrier as the hub to ensure all possible entry points to the carrier network are properly protected from potential attacks such as “Relayed network attacks” on page 741.

A bookend configuration uses two Carrier-enabled FortiGate units to protect the carrier network between them with high bandwidth traffic. One unit handles traffic from mobile stations, SGSNs, and foreign carriers. The other handles GGSN and data network traffic. Together they ensure the network is secure.

The Carrier-enabled FortiGate unit can access all traffic on the network. It can also verify traffic between devices, and verify that the proper GPRS interface is being used. For example there is no reason for a Gn interface to be used to communicate with a mobile station — the mobile station will not know what to do with the data — so that traffic is blocked.

When you are configuring your Carrier-enabled FortiGate unit’s GTP profile, you must first configure the APN. It is critical to GTP communications — no traffic will flow without the APN.

The Carrier-enabled FortiGate unit does more than just forward and route GTP packets over the network. It also performs:

- Packet sanity checking
- GTP stateful inspection
- Protocol anomaly detection and prevention
- HA
- Virtual domain support

Packet sanity checking

The FortiOS Carrier firewall checks the following items to determine if a packet confirms to the UDP and GTP standards:

- GTP release version number — must be 0, 1, or 2
- Settings of predefined bits
- Protocol type
- UDP packet length

If the packet in question does not confirm to the standards, the FortiOS Carrier firewall drops the packet, so that the malformed or forged traffic will not be processed.

GTP stateful inspection

Apart from the static inspection (checking the packet header), the FortiOS Carrier firewall performs stateful inspection.

Stateful inspection provides enhanced security by keeping track of communications sessions and packets over a period of time. Both incoming and outgoing packets are examined. Outgoing packets that request specific types of incoming packets are tracked; only those incoming packets constituting a proper response are allowed through the firewall.

The FortiOS Carrier firewall can also index the GTP tunnels to keep track of them.

Using the enhanced Carrier traffic policy, the FortiOS Carrier firewall can block unwanted encapsulated traffic in GTP tunnels, such as infrastructure attacks. Infrastructure attacks involve attempts by an attacker to connect to restricted machines, such as GSN devices, network management systems, or mobile stations. If these attmpts to connect are detected, they are to be flagged immediately by the firewall .

Protocol anomaly detection and prevention

The FortiOS Carrier firewall detects and optionally drops protocol anomalies according to GTP standards and specific tunnel states. Protocol anomaly attacks involve malformed or corrupt packets that typically fall outside of protocol specifications. These packets are not seen on a production network. Protocol anomaly attacks exploit poor programming practices when decoding packets, and are typically used to maliciously impair system performance or elevate privileges.

FortiOS Carrier also detects IP address spoofing inside GTP data channel.

See “Configuring the Protocol Anomaly feature in FortiOS Carrier” on page 742.

HA

FortiOS Carrier active-passive HA provides failover protection for the GTP tunnels. This means that an active-passive cluster can provide FortiOS Carrier firewall services even when one of the cluster units encounters a problem that would result in complete loss of connectivity for a stand-alone FortiOS Carrier firewall. This failover protection provides a backup mechanism that can be used to reduce the risk of unexpected downtime, especially for mission-critical environments.

FortiOS HA synchs TCP sessions by default, but UDP sessions are not synchronized by default. However synchronizing a session is only part of the solution if the goal is to continue GTP processing on a synchronized session after a HA switch. For that to be successful we also need to synch the GTP tunnel state. So, once the master completes tunnel setup then the GTP tunnel is synchronized to the slave.

GTP traffic will only flow without interruption on a HA switch if bidirectional GTP policies have been configured: an internal (GTP server) to external (all) UDP port GTP policy, and an external (all) to internal (GTP server) UDP port GTP policy. If either policy is missing then traffic may be interrupted until traffic flows in the opposite direction.

For more information on HA in FortiOS, see "High Availability for FortiOS 5.0" on page 1116.

Virtual domain support

FortiOS Carrier is suited to both large and smaller carriers. A single Carrier-enabled FortiGate unit can serve either one large carrier, or several smaller ones through virtual domains. As with any FortiGate unit, Carrier-enabled units have the ability to split their resources into multiple virtual units. This allows smaller carriers to use just the resources that they need without wasting the extra. For more information on virtual domains in FortiOS, see "Virtual Domains" on page 2332.

Configuring General Settings on the Carrier-enabled FortiGate unit

To configure the GTP General Settings, go to *Security Profiles* > *Carrier* > *GTP Profile*, and edit a GTP profile. Expand *General Settings* to configure settings. See "General settings options" on page 685.

Configuring Encapsulated Filtering in FortiOS Carrier

Encapsulated traffic on the GPRS network can come in a number of forms as it includes traffic that is "wrapped up" in another protocol. This detail is important for firewalls because it requires "unwrapping" to properly scan the data inside. If encapsulated packets are treated as regular packets, that inside layer will never be scanned and may allow malicious data into your network.

On Carrier-enabled FortiGate units, GTP related encapsulated filtering falls under encapsulated IP traffic filtering, and encapsulated non-IP end user address filtering.

Configuring Encapsulated IP Traffic Filtering

Generally there are a very limited number of IP addresses that are allowed to encapsulate GPRS traffic. For example GTP tunnels are a valid type of encapsulation when used properly. This is the GTP tunnel which uses the Gp or Gn interfaces between SGSNs and GGSNs. However, a GTP tunnel within a GTP tunnel is not accessible — FortiOS Carrier will either block or forward the traffic, but is not able to open it for inspection.

The ability to filter GTP sessions is based on information contained in the data stream and provides operators with a powerful mechanism to control data flows within their infrastructure. You can also configure IP filtering rules to filter encapsulated IP traffic from Mobile Stations.

To configure the Encapsulated IP Traffic Filtering, go to *Security Profiles* > *Carrier* > *GTP Profile*, and edit a GTP profile. Expand *Encapsulated IP Traffic Filtering* to configure settings. See "Encapsulated IP traffic filtering options" on page 694.

When to use encapsulated IP traffic filtering

The following are the typical cases that need encapsulated IP traffic filtering:

Mobile station IP pools

In a well-designed network, best practices dictate that the mobile station address pool is to be completely separate from the GPRS network infrastructure range of addresses. Encapsulated

IP packets originating from a mobile station will not contain source or destination addresses that fall within the address range of GPRS infrastructures. In addition, traffic originating from the users handset will not have destination/source IP addresses that fall within any Network Management System (NMS) or Charging Gateway (CG) networks.

Communication between mobile stations

Mobile stations on the same GPRS network are not able to communicate with other mobile stations. Best practices dictate that packets containing both source and destination addresses within the mobile station's range of addresses are to be dropped.

Direct mobile device or internet attacks

It may be possible for attackers to wrap attack traffic in GTP protocols and submit the resulting GTP traffic directly to a GPRS network element from their mobile stations or a node on the Internet. It is possible that the receiving SGSN or GGSN would then strip off the GTP header and attempt to route the underlying attack. This underlying attack could have any destination address and would probably have a source address spoofed as if it were valid from that PLMN.

You cannot add an IE removal policy when you are creating a new profile.

Relayed network attacks

Depending on the destination the attack could be directly routed, such as to another node of the PLMN, or rewrapped in GTP for transmission to any destination on the Internet outside the PLMN depending on the routing table of the GSN enlisted as the unwitting relay.

The relayed attack could have any source or destination addresses and could be any of numerous IP network attacks, such as an attack to hijack a PDP context, or a direct attack against a management interface of a GSN or other device within the PLMN. Best practices dictate that any IP traffic originating on the Internet or from an MS with a destination address within the PLMN is to be filtered.

Configuring Encapsulated Non-IP End User Address Filtering

Much of the traffic on the GPRS network is in the form of IP traffic. However some parts of the network do not used IP based addressing, so the Carrier-enabled FortiGate unit is unable to perform Encapsulated IP Traffic Filtering.

Depending on the installed environment, it may be beneficial to detect GTP packets that encapsulate non-IP based protocols. You can configure the FortiOS Carrier firewall to permit a list of acceptable protocols, with all other protocols denied.

The encoded protocol is determined in the PDP Type Organization and PDP Type Number fields within the End User Address Information Element. The PDP Type Organization is a 4-bit field that determines if the protocol is part of the ETSI or IETF organizations. Values are zero and one, respectively. The PDP Type field is one byte long. Both GTP specifications only list PPP, with a PDP Type value of one, as a valid ETSI protocol. PDP Types for the IETF values are determined in the "Assigned PPP DLL Protocol Numbers" sections of RFC 1700. The PDP types are compressed, meaning that the most significant byte is skipped, limiting the protocols listed from 0x00 to 0xFF.

To configure the Encapsulated Non-IP End User Address Filtering, go to *Security Profiles* > *Carrier* > *GTP Profile*, and edit a GTP profile. Expand *Encapsulated Non-IP End User Address Filtering* to configure settings. See “Encapsulated non-IP end user traffic filtering options” on page 695.

Configuring the Protocol Anomaly feature in FortiOS Carrier

When anomalies do happen, it is possible for the anomaly to interrupt network traffic or consume network resources — if precautions are not taken. Anomalies can be generated by accident or maliciously, but both methods can have the same results — degrading the performance of the carrier network, or worse.

To configure GTP protocol anomalies, go to *Security Profiles* > *Carrier* > *GTP Profile*, and edit a GTP profile. Expand the *Protocol Anomaly* option. See"Protocol Anomaly prevention options" on page 696.

The following are some examples:

- The GTP header specifies the length of the packet excluding the mandatory GTP header. In GTP version 0 (GSM 09.60), the mandatory GTP header size is 20 bytes, whereas GTP version 1 (GSM 29.060) specifies that the minimum length of the GTP header is 8 bytes. The GTP packet is composed of the header, followed by Information Elements typically presented in a Type-Length-Value format. It is possible for an attacker to create a GTP packet with a GTP header field length that is incompatible with the length of the necessary information elements.
- The same concepts are true for GTP version 2 headers even though there are different fields in them.
- It is similarly possible for an attacker to create a packet with an invalid IE length. Invalid lengths may cause protocol stacks to allocate incorrect amounts of memory, and thereby cause crashes or buffer overflows.

By default the FortiOS Carrier firewall detects these problems, as well as other protocol anomalies, and drops the packets. All protocol anomaly options are set to *Deny* by default. However, you can change the policy to allow them.

Configuring Anti-overbilling in FortiOS Carrier

This section includes:

Overbilling in GPRS networks

GPRS overbilling attacks can be prevented with a properly configured Carrier-enabled FortiGate unit.

Overbilling can occur when a subscriber returns his IP address to the IP pool. Before the billing server closes it, the subscriber's session is still open and vulnerable. If an attacker takes control of the subscriber's IP address, he can send or receive data and the subscriber will be billed for the traffic.

Overbilling can also occur when an available IP address is reassigned to a new mobile station (MS). Subsequent traffic by the previous MS may be forwarded to the new MS. The new MS would then be billed for traffic it did not initiate.

Anti-overbilling with FortiOS Carrier

The Carrier-enabled FortiGate unit can be configured to assist with anti-overbilling measures. These measures ensure that the customer is only billed for connection time and data transfer that they actually use.

Anti-overbilling on the Carrier-enabled FortiGate unit involves:

- the administrator configuring the overbilling settings in the GTP profile to notify the Gi firewall when a GTP tunnel is deleted
- the unit clearing the sessions when the Gi firewall receives a notification from the Gn/Gp firewall about a GTP tunnel being deleted This way, the Gi firewall prevents overbilling by blocking traffic initiated by other users.

The three locations to configure anti-overbilling options include:

- *System* > *Network* > *Interface* > *Gi Gatekeeper* — edit an interface, and enable to monitor Gi anti-overbilling traffic on this interface
- *System* > *Admin* > *Settings* > *Gi Gatekeeper Settings* — set the context ID and port that anti-overbilling will take place on.
- *Security Profiles* > *Carrier* > *GTP Profile* > *Anti-Overbilling* — the IP address, port, interface and context ID to use for anti-overbilling measures.

For detailed options, see "Anti-Overbilling options" on page 697.

Logging events on the Carrier-enabled FortiGate unit

Logging on the Carrier-enabled FortiGate unit is just like logging on any other FortiOS unit. The only difference with FortiOS Carrier is that there are a few additional events that you can log beyond the regular ones. These additional events are covered here. For more information on other logging issues, see the *Logging and Reporting Guide* and *FortiOS CLI Reference*.

To enable FortiOS Carrier logging, go to *Log&Report* > *Event Log*, and ensure *GTP service event* is enabled. Once this option is selected, the logging options under *Security Profiles* > *Carrier* > *GTP Profile* will be active.

To change FortiOS Carrier specific logging event settings, go to *Security Profiles* > *Carrier* > *GTP Profile* and edit a GTP profile. Expand the *Log* section to change the settings. For detailed options, see "Log options" on page 697.

The following information is contained in each log entry:

Timestamp	The time and date when the log entry was recorded
Source IP address	The sender's IP address.
Destination IP address	The reciever's IP address. The sender-receiver pair includes a mobile phone on the GPRS local network, and a device on a network external to the GPRS network, such as the Internet.
Tunnel Identifier (TID) **Tunnel Endpoint Identifier (TEID)**	An identifier for the start and endpoints of a GTP tunnel. This information uniquely defines all tunnels. It is important for billing information based on the length of time the tunnel was active and how much data passed over the tunnel.
Message type	For available message types, see "Common message types on carrier networks" on page 745.
Packet status	What action was performed on the packet. This field matches the logging options while you are configuring GTP logging. See "Anti-overbilling with FortiOS Carrier" on page 742. The status can be one of forwarded, prohibited, state-invalid, rate-limited, or tunnel-limited

Virtual domain ID or name	A Carrier-enabled FortiGate unit can be divided into multiple virtual units, each being a complete and self-contained virtual FortiCarrier unit. This field indicates which virtual domain (VDOM) was responsible for the log entry. If VDOMs are not enabled on your unit, this field will be `root`.
Reason to be denied if applicable	If the packet that generated this log entry was denied or blocked, this field will include what part of FortiOS denied or blocked that packet. Such as firewall, antivirus, webfilter, or spamfilter.

An example of the above log message format is for a Tunnel deleted log entry. When a tunnel is deleted, the log entry contains the following information:

- Timestamp
- Interface name (if applicable)
- SGSN IP address (source IP)
- GGSN IP address (destination IP)
- Tunnel ID
- Tunnel duration time in seconds
- Number of messages sent to the SGSN
- Number of messages sent to the GGSN

GTP message type filtering

FortiOS Carrier supports message filtering in GTP by the type of message.

This section includes:

Common message types on carrier networks

Carrier networks include many types of messages — some concern the network itself, others are content moving across the network, and still others deal with handshaking, billing, or other administration based issues.

GTP contains two major parts GTP for the control plane (GTP-C) and GTP for user data tunnelling (GTP-U). Outside of those areas there are only unknown message types.

GTP-C messages

GTP-C contains the networking layer messages. These address routing, versioning, and other similar low level issues.

When a subscriber requests a Packet Data Protocol (PDP) context, the SGSN will send a create PDP context request GTP-C message to the GGSN giving details of the subscriber's request. The GGSN will then respond with a create PDP context response GTP-C message which will either give details of the PDP context actually activated or will indicate a failure and give a reason for that failure. This is a UDP message on port 212.

GTP-C message types include Path Management Messages, Location Management Messages, and Mobility Management Messages.

Path Management Messages

Path management is used by one GSN to detect if another GSN is alive, or if it has restarted after a failure.

The path management procedure checks if a given GSN is alive or has been restarted after a failure. In case of SGSN restart, all MM and PDP contexts are deleted in the SGSN, since the associated data is stored in a volatile memory. In the case of GGSN restart, all PDP contexts are deleted in the GGSN.

Tunnel Management Messages

The tunnel management procedures are used to create, update, and delete GTP tunnels in order to route IP PDUs between an MS and an external PDN via the GSNs.

The PDP context contains the subscriber's session information when the subscriber has an active session. When a mobile wants to use GPRS, it must first attach and then activate a PDP context. This allocates a PDP context data structure in the SGSN that the subscriber is currently visiting and the GGSN serving the subscriber's access point.

Tunnel management procedures are defined to create, update, and delete tunnels within the GPRS backbone network. A GTP tunnel is used to deliver packets between an SGSN and a

GGSN. A GTP tunnel is identified in each GSN node by a TEID, an IP address, and a UDP port number.

Location Management Messages

The location-management procedure is performed during the network-requested PDP context activation procedure if the GGSN does not have an SS7 MAP interface (i.e., Gc interface). It is used to transfer location messages between the GGSN and a GTP-MAP protocol-converting GSN in the GPRS backbone network.

Location management subprocedures are used between a GGSN that does not support an SS7 MAP interface (i.e., Gc interface) and a GTP-MAP protocol-conversing GSN. This GSN supports both Gn and Gc interfaces and is able to perform a protocol conversing between GTP and MAP.

Mobility Management Messages

The MM procedures are used by a new SGSN in order to retrieve the IMSI and the authentication information or MM and PDP context information in an old SGSN. They are performed during the GPRS attach and the inter-SGSN routing update procedures.

The MM procedures are used between SGSNs at the GPRS-attach and inter-SGSN routing update procedures. An identity procedure has been defined to retrieve the IMSI and the authentication information in an old SGSN. This procedure may be performed at the GPRS attach. A recovery procedure enables information related to MM and PDP contexts in an old SGSN to be retrieved. This procedure is started by a new SGSN during an inter-SGSN RA update procedure.

GTP-U messages

GTP-U is focused on user related issues including tunneling, and billing. GTP-U message types include MBMS messages, and GTP-U and Charging Management Messages

MBMS messages

Multimedia Broadcast and Multicast Services (MBMS) have recently begun to be offered over GSM and UMTS networks on UTRAN and GERAN radio access technologies. MBMS is mainly used for mobile TV, using up to four GSM timeslots for one MBMS connection. One MBMS packet flow is replicated by GGSN, SGSN and RNCs.

MBMS is split into the MBMS Bearer Service and the MBMS User Service. The MBMS User Service is basically the MBMS Service Layer and offers a Streaming- and a Download Delivery Method. The Streaming Delivery method can be used for continuous transmissions like Mobile TV services. The Download Method is intended for "Download and Play" services.

GTP-U and Charging Management Messages

SGSNs and GGSNs listen for GTP-U messages on UDP port 2152.

GTP‘ (GTP prime) is used for billing messages. It uses the common GTP messages (GTP Version Not Supported, Echo Request and Echo Response) and adds additional messages related to billing procedures.

Unknown Action messages

If the system doesn't know what type of message it is, it falls into this category. This is an important category of message because malformed messages may appear and need to be handled with security in mind.

Fortinet best practices dictate that you set *Unknown Action messages* to deny for security reasons.

Configuring message type filtering in FortiOS Carrier

GPRS Tunnelling Protocol (GTP) is a group of IP-based communications protocols used to carry General Packet Radio Service (GPRS) traffic within Global System for Mobile Communications (GSM) and Universal Mobile Telecommunications System (UMTS) networks. It allows carriers to transport actual cellular packets over their network via tunneling.

In the CLI, there is a keyword for each type of GTP message for both message filtering, and for message rate limiting.

GTP message rate limiting is only accessible from the CLI using the command `configure firewall gtp`.

To configure GTP message type filtering - web-based manager

1. Go to *Security Profiles* > *Carrier* > *GTP Profile*.
2. Select *Create New*.
3. Enter a name for this profile such as `msg_type_filtering`.
4. Select *Message Type Filtering* to expand it.
5. For each type of message in the list, select Allow or Deny. All messages are set to Allow by default.

Fortinet best practices dictate that the unknown message action should be set to Deny for security reasons as this will block malformed messages.

6. Optionally select and configure any other GTP features for this profile, such as logging.
7. Select OK to save the profile.
8. Apply the `msg_type_filtering` profile a security policy configured for GTP tunnel traffic.

To configure GTP message filtering and block Unknown Message Action messages- CLI

```
config firewall gtp
  edit msg_type_filtering
    config message-filter
      set unknown-message-action deny
    next
  end
end
```

Message Type Fields

Each of the following message types can be allowed or denied by your Carrier-enabled FortiGate unit depending on your carrier network and GTP traffic.

The message types include:

- Unknown Message Action
- Path Management Messages
- Tunnel Management Messages
- Location Management Messages
- Mobility Management Messages
- MBMS messages
- GTP-U and Charging Management Messages

Unknown Message Action

Set this message type to deny.

Many attempts to hack into a carrier network will result in this unknown message type and therefore it is denied for security reasons.

Path Management Messages

Message Type	Used by	Description
Echo Request/Response	GTP-C, GTP-U, GTP'	Echo Request is sent on a path to another GSN to determine if the other node is alive. Echo Response is the reply.
Version not Supported	GTP-C, GTP-U, GTP'	There are multiple versions of GTP. Both devices communicating must use the same version of GTP, or this message will be the response.
Support Extension Headers Notification		Extensions are optional parts that a device can choose to support or not. If a device includes these extensions, it must include headers for the extensions to sure ensure proper formatting.

Tunnel Management Messages

Message Type	Used by	Description
Create PDP Context Request/ Response	GTP-C	Sent from an SGSN to a GGSN node as part of a GPRS PDP Context Activation procedure or the Network-Requested PDP Context Activation procedure. A valid request initiates the creation of a tunnel.
Update PDP Context Request/ Response	GTP-C	Used when PDP Context information changes, such as when a mobile device changes location.
Delete PDP Context Request/ Response	GTP-C	Used to terminate a PDP Context, and confirm the context has been deleted.

Create AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS Anonymous Access PDP Context Activation. It is used to create a tunnel between a context in the SGSN and a context in the GGSN.
Delete AA PDP Context Request/ Response	GTP-C	Sent as part of the GPRS PDP Anonymous Access Context Deactivation procedure to deactivate an activated PDP Context. It contains Cause and Private Extension Information Elements
Error Indication	GTP-U	Sent to the GGSN when a tunnel PDU is received for the following conditions: — No PDP context exists — PDP context is inactive — No MM context exists — GGSN deletes its PDP context when the message is received.
PDU Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	When receiving a Tunneled PDU (T-PDU), the GGSN checks if a PDP context is established for the given PDP address. If no PDP context has been established, the GGSN may initiate the Network-requested PDP Context Activation procedure by sending a PDU Notification Request to the SGSN. **Reject Request -** Sent when the PDP context requested by the GGSN cannot be established.

Location Management Messages

Message Type	Used By	Description
Send Routing Information for GPRS Request/ Response	GTP-C	Sent by the GGSN to obtain location information for the MS. This message type contains the IMSI of the MS and Private Extension.
Failure Report Request/ Response	GTP-C	Sent by the GGSN to the HLR when a PDU reject message is received. The GGSN requests the HLR to set the flag and add the GGSN to the list of nodes to report to when activity from the subscriber that owns the PDP address is detected. The message contains the subscriber IMSI and Private Extension
Note MS GPRS Present Request/ Response	GTP-C	When the HLR receives a message from a mobile with MDFG set, it clears the MDFG and sends the Note MS Present message to all GGSN's in the subscriber's list. This message type contains subscriber IMSI, GSN Address and Private Extension

Mobility Management Messages

Message Type	Used By	Description
Identification Request/Response	GTP-C	Sent by the new SGSN to the old SGSN to request the IMSI for a MS when a GPRS Attach is done with a P-TMSI and the MS has changed SGSNs since the GPRS Detach was done.
SGSN context Request/ Response/ Acknowledge	GTP-C	Sent by the new SGSN to the old SGSN to request the MM and PDP Contexts for the MS.
Forward Relocation Request/ Response/ Complete/ Complete Acknowledge	GTP-C	Indicates mobile activation/deactivation within a Routing Area. This prevents paging of a mobile that is not active (visited VLR rejects calls from the HLR or applies Call Forwarding). Note that the mobile station does not maintain an attach/detach state. SRNS contexts contain for each concerned RAB the sequence numbers of the GTP-PDUs next to be transmitted in uplink and downlink directions.
Relocation Cancel Request/ Response	GTP-C	Send to cancel the relocation of a connection.
Forward SRNS Context/ Context Acknowledge	GTP-C	This procedure may be used to trigger the transfer of SRNS contexts from RNC to CN (PS domain) in case of inter system forward handover.
RAN Information Relay	GTP-C	Forward the Routing Area Network (RAN) information. A Routing Area (RA) is a subset of a GSM Location Area (LA). A RA is served by only one SGSN. Ensures that regular radio contact is maintained by the mobile

MBMS messages

Message Type	Used By	Description
MBMS Notification Request/ Response/ Reject Request/ Reject Response	GTP-C	Notification of the radio access devices.
Create MBMS Context Request/ Response	GTP-C	Request to create an active MBMS context. The context will be pending until the response is received. Once active, the MBMS context allows the MS to receive data from a specific MBMS source

Update MBMS Context Request/ Response	GTP-C	
Delete MBMS Context Request/ Response	GTP-C	Request to deactivate the MBMS context. When the response is received, the MBMS context will be inactive.

GTP-U and Charging Management Messages

Message Type	Used By	Description
G-PDU	GTP-C, GTP-U	GPRS Packet data unit delivery message.
Node Alive Request/Response	GTP-C, GTP-U	Used to inform rest of network when a node starts service.
Redirection Request/Response	GTP-C, GTP-U	Used to divert the flow of CDRs from the CDFs to another CGF when the sender is being removed, or they are used when the CGF has lost its connection to a downstream system.
Data Record Transfer Request/Response	GTP-C, GTP-U	Used to reliably transport CDRs from the point of generation (SGSN/GGSN) to non-volatile storage in the CGF

GTP identity filtering

FortiOS Carrier supports a number of filtering methods based on subscriber identity such as APN filtering, IMSI filtering, and advanced filtering.

This section includes:

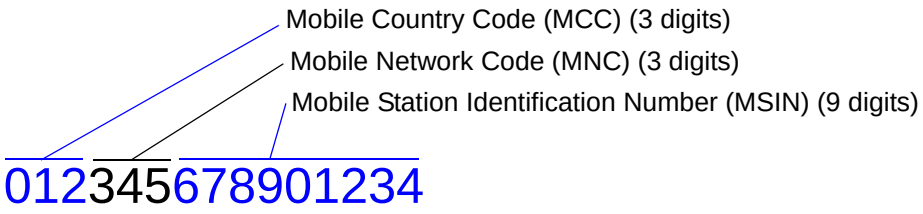
IMSI on carrier networks

The International Mobile Subscriber Identity (IMSI) number is central to identifying users on a carrier network. It is a unique number that is assigned to a cell phone or mobile device to identify it on the GMS or UTMS network.

Typical the IMSI number is stored on the SIM card of the mobile device and is sent to the network as required.

An IMSI number is 15 digits long, and includes the Mobile Country Code (MCC), Mobile Network Code (MNC), and Mobile Station Identification Number (MSIN).

Figure 152:IMSI codes



The Home Network Identity (HNI) is made up of the MCC and MNC. The HNI is used to fully identify a user's home network. This is important because some large countries have more than one country code for a single carrier. For example a customer with a mobile carrier on the East Coast of the United States would have a different MCC than a customer on the West Coast with the same carrier because even through the MNC would be the same the MCC would be different — the United States uses MCCs 310 to 316 due to its size.

If an IMSI number is not from the local carrier's network, IMSI analysis is performed to resolve the number into a Global Title which is used to access the user's information remotely on their home carrier's network for things like billing and international roaming.

See "Configuring IMSI filtering in FortiOS Carrier" on page 756.

Other identity and location based information elements

IMSI focuses on the user, their location, and carrier network. There are other numbers used to identify different user related Information Elements (IE).

These identity and location based elements include:

- Access Point Number (APN)
- Mobile Subscriber Integrated Services Digital Network (MSISDN)
- Radio Access Technology (RAT) type
- User Location Information (ULI)
- Routing Area Identifier (RAI)
- International Mobile Equipment Identity (IMEI)

Access Point Number (APN)

The Access Point Number (APN) is used in GPRS networks to identify an IP packet data network that a user wants to communicate with. The Network Identifier describes the network and optionally the service on that network that the GGSN is connected to. The APN also includes the MCC and MCN, which together locate the network the GGSN belongs to. An example of an APN in the Barbados using Digicel as the carrier that is connecting to the Internet is `internet.mcc342.mnc750.gprs`.

When you are configuring your Carrier-enabled FortiGate unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

The access point can then be used in a DNS query to a private DNS network. This process (called APN resolution) gives the IP address of the GGSN which serves the access point. At this point a PDP context can be activated. See "Configuring APN filtering in FortiOS Carrier" on page 755.

Mobile Subscriber Integrated Services Digital Network (MSISDN)

This is a 15-digit number that, along with the IMSI, uniquely identifies a mobile user. Normally this number includes a 2-digit country code, a 3-digit national destination code, and a 10-digit subscriber number or the phone number of the mobile device, and because of that may change over time if the user changes their phone number. The MSISDN number follows the ITU-T E.164 numbering plan.

Radio Access Technology (RAT) type

The RAT type represents the radio technology used by the mobile device. This can be useful in determining what services or content can be sent to a specific mobile device. FortiOS Carrier supports:

- **UMTS Terrestrial Radio Access Network (UTRAN)**, commonly referred to as 3G, routes many types of traffic including IP traffic. This is one of the faster types.
- **GSM EDGE Radio Access Network (GERAN)** is a key part of the GSM network which routes both phone calls and data.
- **Wireless LAN (WLAN)** is used but not as widely as the other types. It is possible for the mobile device to move from one WLAN to another such as from an internal WLAN to a commercial hot spot.
- **Generic Access Network (GAN)** can also be called unlicensed mobile access (UMA). It routes voice, data, and SIP over IP networks. GAN is commonly used for mobile devices that have a dual-mode and can hand-off between GSM and WLANs.
- **High Speed Packet Access (HSPA)** includes two other protocols High Speed Downlink and Uplink Packet Access protocols (HSDPA and HSUPA respectively). It improves on the older WCDMA protocols by better using the radio bandwidth between the mobile device and the radio tower. This results in an increased data transfer rate for the user.

RAT type is part of advanced filtering configuration. See "Configuring advanced filtering in FortiOS Carrier" on page 757.

User Location Information (ULI)

Gives Cell Global Identity/Service Area Identity (CGI/SAI) of where the mobile station is currently located. The ULI and the RAI are commonly used together to identify the location of the mobile device.

ULI is part of advanced filtering configuration. See “Configuring advanced filtering in FortiOS Carrier” on page 757.

Routing Area Identifier (RAI)

Routing Areas (RAs) divide the carrier network and each has its own identifier (RAI). When a mobile device moves from one routing area to another, the connection is handled by a different part of the network. There are normally multiple cells in a routing area. There is only one SSGN per routing area. The RAI and ULI are commonly used to determine a user’s location.

RAI is part of advanced filtering configuration. See “Configuring advanced filtering in FortiOS Carrier” on page 757.

International Mobile Equipment Identity (IMEI)

IMEI is a unique 15-digit number used to identify mobile devices on mobile networks. It is very much like the MAC address of a TCP/IP network card for a computer. It can be used to prevent network access by a stolen phone — the carrier knows the mobile phone’s IMEI, and when it is reported stolen that IMEI is blocked from accessing the carrier network no matter if it has the same SIM card as before or not. It is important to note that the IMEI stays with the mobile phone or device where the other information is either location based or stored on the removable SIM card.

IMEI type is part of advanced filtering configuration. See “Configuring advanced filtering in FortiOS Carrier” on page 757.

When to use APN, IMSI, or advanced filtering

At first glance APN, IMSI, and advanced filtering have parts in common. For example two can filter on APN, and another two can filter on IMSI. The difficulty is knowing when to use which type of filtering.

Figure 153: Identity filtering comparison

Filtering type	Filter on the following data:	When to use this type of filtering
APN	APN	Filter based on GTP tunnel start or destination
IMSI	IMSI, MCC-MNC	Filter based on subscriber information
Advanced	PDP context, APN, IMSI, MSISDN, RAT type, ULI, RAI, IMEI	When you want to filter based on: user phone number (MSISDN) what wireless technology the user employed to get on the network (RAT type) user location (ULI and RAI) handset ID, such as for stolen phones (IMEI)

APN filtering is very specific — the only identifying information that is used to filter is the APN itself. This will always be present in GTP tunnel traffic, so all GTP traffic can be filtered using this value. See "Configuring APN filtering in FortiOS Carrier" on page 755.

IMSI filtering can use a combination of the APN and MCC-MNC numbers. The MCC and MNC are part of the APN, however filtering on MCC-MNC separately allows you to filter based on country and carrier instead of just the destination of the GTP Tunnel. See "Configuring IMSI filtering in FortiOS Carrier" on page 756.

Advanced filtering can go into much deeper detail covering PDP contexts, MSISDN, IMEI, and more not to mention APN, and IMSI as well. If you can't find the information in APN or IMSI that you need to filter on, then use Advanced filtering. See "Configuring advanced filtering in FortiOS Carrier" on page 757.

Configuring APN filtering in FortiOS Carrier

To configure APN filtering go to *Security Profiles* > *Carrier* > *GTP Profile. Select a profile or create a new one,* and expand *APN filtering*.

When you are configuring your Carrier-enabled FortiGate unit's GTP profiles, you must first configure the APN. It is critical to GTP communications and without it no traffic will flow.

For more information on APN, see "Access Point Number (APN)" on page 753.

Enable APN Filter	Select to enable filtering based on APN value.
Default APN Action	Select either Allow or Deny for all APNs that are not found in the list. The default is Allow.
Value	Displays the APN value for this entry. Partial matches are allowed using wildcard. For example `*.mcc333.mcn111.gprs` would match all APNs from country `333` and carrier `111` on the gprs network.

Mode	Select one or more of the methods used to obtain APN values. Mobile Station provided - The APN comes from the mobile station where the mobile device connected. This is the point of entry into the carrier network for the user's connection. Network provided - The APN comes from the carrier network. Subscription Verified - The user's subscription has been verified for this APN. This is the most secure option.
Action	One of allow or deny to allow or block traffic associated with this APN.
Delete icon	Select to remove this APN entry from the list.
Edit icon	Select to change the information for this APN entry.
Add APN	Select to add an APN to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding APNs. A warning to this effect will be displayed when you select the *Add APN* button.

The Add APN button is not activated until you save the new GTP profile. When you edit that GTP profile, you will be able to add new APNs.

Configuring IMSI filtering in FortiOS Carrier

In many ways the IMSI on a GPRS network is similar to an IP address on a TCP/IP network. Different parts of the number provide different pieces of information. This concept is used in IMSI filtering on FortiOS Carrier.

To configure IMSI filtering go to *Security Profiles* > *Carrier* > *GTP Profile* and expand *IMSI filtering*.

While both the APN and MCC-MCN fields are optional, without using one of these fields the IMSI entry will not be useful as there is no information for the filter to match.

Enable IMSI Filter	Select to turn on IMSI filtering.
Default IMSI Action	Select Allow or Deny. This action will be applied to all IMSI numbers except as indicated in the IMSI list that is displayed. The default value is Allow.
APN	The Access Point Number (APN) to filter on. This field is optional.
MCC-MNC	The Mobile Country Code (MCC) and Mobile Network Code (MNC) to filter on. Together these numbers uniquely identify the carrier and network of the GGSN being used. This field is optional.

Mode	Select the source of the IMSI information as one or more of the following: **Mobile Station provided -** the IMSI number comes from the mobile station the mobile device is connecting to. **Network provided -** the IMSI number comes from the GPRS network which could be a number of sources such as the SGSN, or HLR. **Subscription Verified -** the IMSI number comes from the user's home network which has verified the information. While Subscription Verified is the most secure option, it may not always be available. Selecting all three options will ensure the most complete coverage.
Action	Select the action to take when this IMSI information is encountered. Select one of Allow or Deny.
Delete Icon	Select the delete icon to remove this IMSI entry.
Edit Icon	Select the edit icon to change information for this IMSI entry.
Add IMSI	Select to add an IMSI to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding IMSIs. A warning to this effect will be displayed when you select the *Add IMSI* button.

Also see "Basic filtering options" on page 689.

Configuring advanced filtering in FortiOS Carrier

Compared to ADN or IMSI filtering, advanced filtering is well named. Advanced filtering can be viewed as a catch-all filtering option — if ADN or IMSI filtering doesn't do what you want, then advanced filtering will. The advanced filtering can use more information elements to provide considerably more granularity for your filtering.

Enable	Select to turn on advanced filtering.
Default Action	Select Allow or Deny as the default action to take when traffic does not match an entry in the advanced filter list .

Messages	Optionally select one or more types of messages this filter applies to: Create PDP Context Request, Create PDP Context Response, Update PDP Context Request, or Update PDP Context Response. Selecting *Create PDP Context Response* or *Update PDP Context Response limits RAT type to only GAN and HSPA, and disables the APN, APN Mode, IMSI, MSISDN, ULI, RAI,* and *IMEI fields.* To select *Update PDP Context Request*, *APN Restriction* must be set to *all*. Selecting *Update PDP Context Request disables the APN, MSISDN,* and *IMEI fields.* if all message types are selected, only the RAT Types of GAN and HSPA are available to select.
APN Restriction	APN Restriction either allows all APNs or restricts the APNs to one of four categories — Public-1, Public-2, Private-1, or Private-2. This can also be combined with a specific APN or partial APN as well as specifying the APN mode. See "Access Point Number (APN)" on page 753.
RAT Type	Select one or more of the Radio Access Technology Types listed. These fields control how a user accesses the carrier's network. You can select one or more of UTRAN, GERAN, WLAN, GAN, HSPA, or any. See "Radio Access Technology (RAT) type" on page 753.
ULI	The user location identifier. Often the ULI is used with the RAI to locate a user geographically on the carrier's network. The ULI is disabled when *Create PDP Context Response* or *Update PDP Context Response* messages are selected. See "User Location Information (ULI)" on page 754.
RAI	The router area identifier. There is only one SGSN per routing area on a carrier network. This is often used with ULI to locate a user geographically on a carrier network. The RAI is disabled when *Create PDP Context Response* or *Update PDP Context Response* messages are selected. See "Routing Area Identifier (RAI)" on page 754.
IMEI	The International Mobile Equipment Identity. The IMEI uniquely identifies mobile hardware, and can be used to block stolen equipment. The IMEI is only available when *Create PDP Context Request* or no messages are selected. See "International Mobile Equipment Identity (IMEI)" on page 754
Action	Select Allow or Deny as the action when this filter matches traffic. The default is Allow.
Delete Icon	Select to delete this entry from the list.

Edit Icon	Select to edit this entry.
Add	Select to add an advanced filter to the list. Not active while creating GTP profile, only when editing an existing GTP profile. Save all changes before adding advanced filters. A warning to this effect will be displayed when you select the *Add* button.

Also see “Advanced filtering options” on page 690.

Troubleshooting

This section offers troubleshooting options for Carrier-related issues.

This section includes:

FortiOS Carrier diagnose commands

This section includes diagnose commands specific to FortiOS Carrier features such as GTP.

GTP related diagnose commands

This CLI command allows you to gain information on GTP packets, logs, statistics, and other information.

diag firewall gtp <command>

apn list <gtp_profile>	The APN list entries in the specified GTP profile
auth-ggsns show <gtp_profile>	The authorized GGSNs entries for the specified GTP profile. Any GGSNs not on this list will not be recognized.
auth-sgsns show <gtp_profile>	The authorized SGSNs list entries for the specified GTP profile. Any SGSNs not on this list will not be recognized.
handover-grp show <gtp_profile>	The handover group showing the range of allowed handover group IP addresses. The handover group acts like a whitelist of allowed GTP addresses with a default deny at the end — if the GTP address is not on the list, it is denied.
ie-remove-policy list <gtp_profile>	List of IE policies in the IE removal policy for this GTP profile. The information displayed includes the message count for this policy, the length of the SGSN, the list of IEs, and list of SGSN IP addresses.
imsi list <gtp_profile>	IMSI filter entries for this GTP profile. The information displayed includes the message count for this filter, length of the IMSI, the length of the APN and IMSI, and of course the IMSI and APN values.
invalid-sgsns-to-long list <gtp_profile>	List of SGSNs that do not match the filter criteria. These SGSNs will be logged.
ip-policy list <gtp_profile>	List the IP policies including message count for each policy, the action to take, the source and destination IP addresses or ranges, and masks.
noip-policy <gtp_profile>	List the non-IP policies including the message count, which mode, the action to take, and the start and end protocols to be used by decimal number.

path {list | flush}	Select list or flush. List the GTP related paths in FortiOS Carrier memory. Flush the GTP related paths from memory.
policy list <gtp_policy>	The GTP advanced filter policy information for this GTP profile. The information displayed for each entry includes a count for messages matching this filter, a hexidecimal mask of which message types to match, the associated flags, action to take on a match, APN selection mode, MSISDN, RAT types, RAI, ULI, and IMEI.
profile list	Displays information about the configured GTP profiles. You will not be able to see the bulk of the information if you do not log the output to a file.
runtime-stat flush	Select to flush the GTP runtime statistics from memory.
stat	Display the GTP runtime statistics — details on current GTP activity. This information includes how many tunnels are active, how many GTP profiles exist, how many IMSI filter entries, how many APN filter entries, advanced policy filter entries, IE remove policy filter entries, IP policy filter entries, clashes, and dropped packets.
tunnel {list | flush}	Select one of list or flush. List lists all the GTP tunnels currently active. Flush clears the list of active GTP tunnels.

Applying IPS signatures to IP packets within GTP-U tunnels

GTP-U (GTP user data tunnelling) tunnels carry user data packets, signalling messages and error information. GTP-U uses UDP port 2152. Carrier-enabled FortiGate units can apply IPS intrusion protection and detection to GTP-U user data sessions.

To apply IPS to GTP-U user data sessions, add an IPS Sensor to a profile and add the profile to a security policy that accepts GTP-U tunnels. The security policy Service field must be set to GTP or ANY to accept GTP-U packets.

The Carrier-enabled FortiGate unit intercepts packets with destination port 2152, removes the GTP header and handles the packets as regular IP packets. Applying an IPS sensor to the IP packets, the Carrier-enabled FortiGate unit can log attacks and pass or drop packets depending on the configuration of the sensor.

If the packet is GTP-in-GTP, or a nested tunnel, the packets are passed or blocked without being inspected.

To apply an IPS sensor to GTP-U tunnels

1. Go to *Security Profiles* > *Intrusion Protection* > *IPS Sensors* and select *Create New* to add an IPS Sensor.
2. Configure the IPS Sensor to detect attacks and log, drop, or pass attack packets.

   See the Intrusion Protection section of the *FortiOS UTM Guide*.
3. Go to *Policy* > *Policy* and apply the IPS sensor to the security policy.
4. Go to *Policy* > *Policy* and select Create New to add a security policy or select a security policy.

5. Configure the security policy to accept GTP traffic.

   In the security policy configure the source and destination settings to match the GTP traffic. Service to GTP or ANY so that the security policy accepts GTP traffic.
6. Select the GTP profile within the security policy.
7. Configure any other required security policy settings.
8. Select *OK* to save the security policy.

GTP packets are not moving along your network

When GTP packets are not getting to their destination, this could be caused by any one of a number of issues. General troubleshooting principals apply here.

The following sections provide some suggestions on how to troubleshoot this issue:

- Attempt to identify the section of your network with the problem
- Ensure you have an APN configured
- Check the logs and adjust their settings if required
- Check the routing table
- Perform a sniffer trace
- Generate specific packets to test the network

Attempt to identify the section of your network with the problem

The first step is to determine how widespread this problem is. Does it affect the whole GPRS network, or just one or two devices?

If the entire network is has this problem, the solution is likely a more general one such as ensuring the security policies allow GTP traffic to pass, the GTP profile specifies SSGNs and GSGNs, or ensuring the GTP general settings are not overly limiting.

If one part of the network is affected, the problem is more likely centered around configurations with those network devices specified such as the handover group, or authorized SGSNs/GGSNs. It is also possible that small portions of the network may have hardware related issues such as cabling or faulty hardware. This section does not address those issues, and assumes hardware is not the problem.

The handover group is a whitelist of GTP addresses allowed to handle GTP messages. If a device's address is not on this list, it will be denied.

Ensure you have an APN configured

When you configure your GTP profile, ensure you first configure the APN. Without it, there will be no flow of traffic. The APN is used in nearly all GTP communications and without it, the Carrier-enabled FortiGate unit doesn't have the information it needs.

Check the logs and adjust their settings if required

During normal operation, the log settings will show any problems on the network but may not provide the level of details required to fully troubleshoot the problem. The reason for this is that the level of detail required for troubleshooting would quickly overwhelm the daily logs without any real benefit.

GTP related events in the event log will have message IDs in the range 41216 to 41222. For more information on GTP log messages, see the *Log Message Reference*. For more information on logging in general, see the *Logging and Reporting* handbook chapter.

Once there is a problem to troubleshoot, check the logs to trace the traffic patterns and narrow down the possible sources of the problem. There may be enough detail for you to locate and fix the problem without changing the log settings.

Remember to set any changes you made to the log settings back to their original values when you are done troubleshooting. Otherwise, the amount of detail will overwhelm your logging.

However, if more detail is required you can change settings such as:

- Lower the Log Frequency number in GTP Profiles so fewer or no log messages are dropped. This will allow a more accurate picture of everything happening on the network, where you may have had only a partial picture before.
- Ensure all the GTP log events are enabled to provide you with a complete picture.
- Ensure that all relevant event types are enabled under *Log & Report* > *Log Config* > *Event Log.*

For more information on GTP related logging, see "Logging events on the Carrier-enabled FortiGate unit" on page 743. See the log and report chapters of Logging and Reporting Guide and FortiOS CLI Reference.

General information to look for in the logs includes:

- Are all packets having problems or just certain types?
- Are all devices on the network having problem, or just certain devices?
- Is it just GTP traffic that is having problems or are all types of traffic having the same problem?

Check the routing table

On any network, the routing table determines how packets reach their destination. This is also true on a carrier network.

If the Carrier-enabled FortiGate unit is running in NAT mode, verify that all desired routes are in the routing table — local subnets, default routes, specific static routes, and dynamic routing protocols. For complete information, it is best to check the routing table in the CLI. This method provides more complete information.

If VDOMs are enabled on your Carrier-enabled FortiGate unit, all routing related CLI commands must be performed within a VDOM and not in the global context.

To check the routing table using the CLI

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter
   area
* - candidate default
```

```
S*      0.0.0.0/0 [10/0] via 192.168.183.254, port2
S       1.0.0.0/8 [10/0] via 192.168.183.254, port2
S       2.0.0.0/8 [10/0] via 192.168.183.254, port2
C       10.142.0.0/23 is directly connected, port3
B       10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
C       192.168.182.0/23 is directly connected, port2
```

Examining an entry from the routing table above:

```
B       10.160.0.0/23 [20/0] via 10.142.0.74, port3, 2d18h02m
```

B	BGP. The routing protocol used.
10.160.0.0/23	The destination of this route including netmask.
[20/0]	20 indicates and administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF
10.142.0.74	The gateway, or next hop.
port3	The interface used by this route.
2d18h02m	How old this route is, in this case almost three days old.

Perform a sniffer trace

When troubleshooting network traffic, it helps to look inside the headers of packets to determine if they are traveling along the route you expect. Packet sniffing can also be called a network tap, packet capture, or logic analyzing.

If your Carrier-enabled FortiGate unit has NP interfaces that are offloading traffic, this will change the sniffer trace. Before performing a trace on any NP interfaces, disable offloading on those interfaces.

What can sniffing packets tell you

If you are running a constant traffic application such as ping, packet sniffing can tell you if the traffic is reaching the destination, what the port of entry is on the Carrier-enabled FortiGate unit, if the ARP resolution is correct, and if the traffic is being sent back to the source as expected.

Sniffing packets can also tell you if the Carrier-enabled FortiGate unit is silently dropping packets for reasons such as RPF (Reverse Path Forwarding), also called Anti Spoofing. This prevents an IP packet from being forwarded if its source IP address either does not belong to a locally attached subnet (local interface), or be a hop on the routing between the FortiOS Carrier and another source (static route, RIP, OSPF, BGP). Note that RPF can be disabled by turning on asymmetric routing in the CLI (`config system setting, set asymmetric enable`),

however this will disable stateful inspection on the Carrier-enabled FortiGate unit and consequently cause many features to be turned off.

If you configure virtual IP addresses on your Carrier-enabled FortiGate unit, the unit will use those addresses in preference to the physical IP addresses. If not configured properly, secondary IP addresses can cause a broadcast storm. You will notice the secondary address being preferred when you are sniffing packets because all the traffic will be using the virtual IP addresses. This is due to the ARP update that is sent out when the VIP address is configured.

How to sniff packets

The general form of the internal FortiOS packet sniffer command is:

```
diag sniffer packet <interface_name> <'filter'> <verbose> <count>
```

To stop the sniffer, type `CTRL+C`.

<interface_name>	The name of the interface to sniff, such as `port1` or `internal`. This can also be `any` to sniff all interfaces.
<'filter'>	What to look for in the information the sniffer reads. `none` indicates no filtering, and all packets will be displayed as the other arguments indicate. The filter must be inside single quotes (‘).
<verbose>	The level of verbosity as one of: **1 -** print header of packets **2 -** print header and data from IP of packets **3 -** print header and data from Ethernet of packets
<count>	The number of packets the sniffer reads before stopping. If you don't put a number here, the sniffer will run forever unit you stop it with `<CTRL C>`.

For a simple sniffing example, enter the CLI command `diag sniffer packet port1 none 1 3`. This will display the next 3 packets on the port1 interface using no filtering, and using verbose level 1. At this verbosity level you can see the source IP and port, the destination IP and port, action (such as ack), and sequence numbers.

In the output below, port 443 indicates these are HTTPS packets, and 172.20.120.17 is both sending and receiving traffic.

```
Head_Office_620b # diag sniffer packet port1 none 1 3
interfaces=[port1]
filters=[none]
0.545306 172.20.120.17.52989 -> 172.20.120.141.443: psh 3177924955
   ack 1854307757

0.545963 172.20.120.141.443 -> 172.20.120.17.52989: psh 1854307757
   ack 3177925808

0.562409 172.20.120.17.52988 -> 172.20.120.141.443: psh 4225311614
   ack 3314279933
```

Generate specific packets to test the network

If some packets are being delivered as expected while others are not, or after you believe you have fixed the problem, it is a good idea to generate specific traffic to test your network.

For example if you discover through log messages and packet sniffing that Create PDP Context Request messages are not being delivered between two SGSNs, you can generate those specific messages on your network to confirm they are the problem, and later that you have solved the problem and they are now being delivered as expected.

This step requires a third party traffic generation tool, either hardware or software. This is not be supported by Fortinet.

Chapter 5 Compliance

This handbook chapter contains the following sections:

Configuring FortiGate units for PCI DSS compliance explains the Payment Card Industry Data Security Standard (PCI DSS). It provides information about configuring your network and FortiGate unit to help you comply with PCI DSS requirements.

Configuring FortiGate units for PCI DSS compliance

This chapter provides information about configuring your network and FortiGate unit to help you comply with PCI DSS requirements. The following topics are included in this section:

Introduction to PCI DSS

The primary source of information for your PCI DSS compliance program is the *Payment Card Industry (PCI) Data Security Standard* itself. Version 3.0 of the standard was released in November 2013 and is active from January 1, 2014 to December 31, 2017. The following is only a brief summary of PCI DSS.

What is PCI DSS?

The Payment Card Industry Data Security Standard (PCI DSS) sets data handling requirements for organizations that hold, process, or exchange cardholder information.

What is the Customer Data Environment

Throughout the PCI DSS requirements, there are references to the Customer Data Environment (CDE). The CDE is the computer environment wherein cardholder data is transferred, processed, or stored, and any networks or devices directly connected to that environment.

PCI DSS objectives and requirements

PCI DSS consists of 6 control objectives and 12 requirements.

Table 39: PCI DSS Control Objectives and Requirements

Control Objective	Requirement	Fortinet Solution
Build and Maintain a Secure Network	1) Install and maintain a firewall configuration to protect cardholder data	FortiGate firewall functionality. See "Security policies for the CDE network" on page 773.
	2) Do not use vendor-supplied defaults for system passwords and other security parameters	FortiDB vulnerability assessment and auditing FortiScan OS vulnerability management FortiWeb web application password checking See "Password complexity and change requirements" on page 779.
Protect Cardholder Data	3) Protect stored cardholder data	FortiDB vulnerability assessment and monitoring FortiWeb web application firewall See "Protecting stored cardholder data" on page 776.
	4) Encrypt transmission of cardholder data across open, public networks	FortiGate IPsec VPN. See "Protecting communicated cardholder data" on page 776.

Table 39: PCI DSS Control Objectives and Requirements (Continued)

Control Objective	Requirement	Fortinet Solution
Maintain a Vulnerability Management Program	5) Protect all systems against malware and regularly update anti-virus software or programs	FortiGate integrated AV FortiClient integrated AV FortiMobile integrated AV FortiMail integrated AV FortiGuard automated AV updates See "Protecting the CDE network from viruses" on page 777.
	6) Develop and maintain secure systems and applications	FortiDB vulnerability assessment, auditing and monitoring FortiWeb web application security FortiScan OS vulnerability management See "Monitoring the network for vulnerabilities" on page 778.
Implement Strong Access Control Measures	7) Restrict access to cardholder data by business need to know	FortiDB vulnerability assessment, auditing and monitoring. See "Restricting access to cardholder data" on page 779.
	8) Identify and authenticate access to system components	FortiGate integrated database or hooks to Active Directory. See "Controlling access to the CDE network" on page 779.
	9) Restrict physical access to cardholder data	Fortinet professional services in partnership with partner solutions

Table 39: PCI DSS Control Objectives and Requirements (Continued)

Control Objective	Requirement	Fortinet Solution
Regularly Monitor and Test Networks	10) Track and monitor all access to network resources and cardholder data	FortiDB auditing and monitoring FortiAnalyzer event reporting See "Monitoring the network for vulnerabilities" on page 778.
	11) Regularly test security systems and processes	FortiDB vulnerability assessment FortiScan OS vulnerability management. See "Monitoring the network for vulnerabilities" on page 778.
Maintain an Information Security Policy	12) Maintain a policy that addresses information security for all personnel	FortiManager security policy management appliance

This chapter describes how the FortiGate unit's features can help your organization to be compliant with PCI DSS. Requirements that the FortiGate cannot enforce need to be met through organization policies with some means determined for auditing compliance.

Be sure to read the section, "Wireless guidelines", below. Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that wireless networking has not been introduced into the CDE.

Wireless guidelines

While wired networks usually connect fixed known workstations, wireless networks are more dynamic, introducing a different set of security concerns.

Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that unauthorized wireless networking has not been introduced into the CDE. Wireless networking could be introduced quite casually by adding a wireless device to a PC on the CDE network.

For all PCI DSS networks, whether they use wireless technology or not, the following requirement applies:

- Test for the presence of wireless access points (802.11), and detect and identify all authorized and unauthorized wireless access points on a quarterly basis (11.1)

If your organization uses wireless networking outside the CDE network and the firewall prevents communication with the CDE network, the wireless network is outside the PCI DSS scope, but the firewall configuration must meet PCI DSS requirements.

If your organization uses wireless networking inside the CDE network, the wireless network is within the PCI DSS scope. For information about wireless network requirements, see "Wireless network security" on page 774.

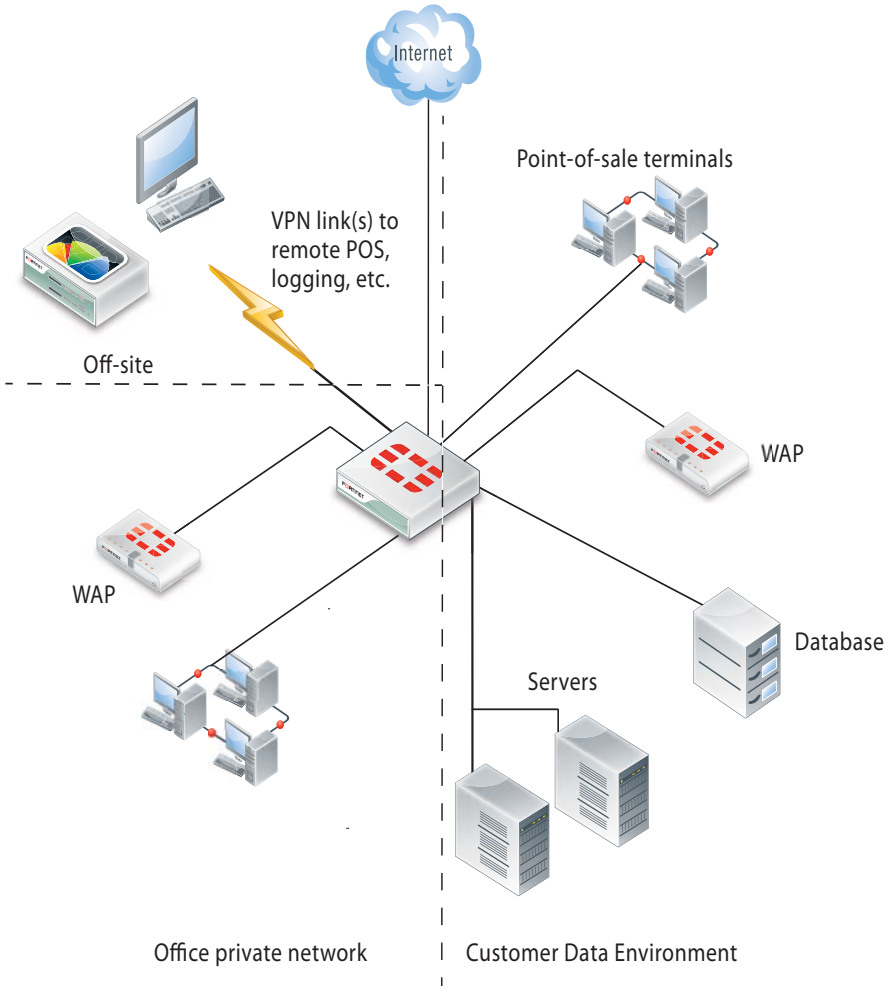
Network topology

The cardholder data environment must be protected against unauthorized access from the Internet and from other networks in your organization. FortiGate unit firewall functionality provides tight control over the traffic that can pass between the following network interfaces:

- Internet
- CDE wired LAN
- CDE wireless LAN
- Other internal networks

Figure 154 shows how the Customer Data Environment can be delineated in a typical network.

Figure 154: Enterprise network with a customer data environment



Internet

The FortiGate unit has at least one network interface connected to the Internet. If your organization uses more than one Internet service provider, there could be additional network interfaces that function as a route to the Internet.

The CDE wired LAN

The CDE network typically contains point-of-sale (POS) terminals, databases, and servers. The only security policies between the CDE network and the Internet should be for encrypted connections. For remote point-of-sale terminals or off-site databases, VPN connections are required and they should use strong encryption. For a web server that handles online purchases, only HTTPS (SSL or TLS) connections can be permitted. The security policies that enable these connections should have the narrowest possible definitions for source address, destination address and service.

PCI DSS does not require the CDE network to be isolated from the rest of your corporate LAN. But isolating the CDE network reduces the scope of required data protection measures and may reduce the scope of PCI DSS assessments that are periodically required.

The CDE wireless LAN

Wireless networking is a special issue. Even if you do not use wireless technology you must monitor to ensure that unauthorized wireless access has not been added to the CDE network. For this purpose, Figure 154 shows a FortiAP device in the CDE. The FortiAP device can provide dedicated wireless monitoring, an access point, or both.

A small retail outlet could reduce costs by using a FortiWiFi unit, a FortiGate unit with integrated wireless networking. The FortiWiFi unit would have to be located where it could provide sufficient wireless monitoring (or access point) coverage for the entire premises.

Other internal networks

Other internal networks such as your office LAN, unless they provide connection to the CDE, are not subject to PCI DSS requirements.

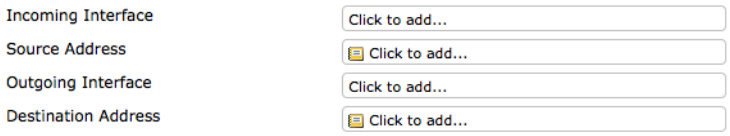
Security policies for the CDE network

The FortiGate unit's firewall functionality is ideally suited to PCI DSS requirement 3.0, "Restrict inbound and outbound traffic to that which is necessary for the cardholder data environment." Security policies control the source, destination, and type of traffic passing between networks.

The PCI DSS standard includes requirements to document your network topology and configuration. As part of that requirement, and to assist the auditing of your network, make use of the *Comment* field available in FortiGate security policies. Describe the purpose of each policy.

Controlling the source and destination of traffic

The source and destination are the first parameters you specify in a security policy. (Go to *Policy* > *Policy* > *Policy* and select *Create New*.)



The *Interface* settings depend on network topology. The *Address* settings define the IP addresses to which the policy applies. These should be as narrow as possible, so that only the appropriate hosts are included. For example, if the destination is a server with a single IP address, the named Destination Address should be defined as that single address, not the entire subnet on which the server resides.

Addresses are defined in *Firewall Objects* > *Address* > *Addresses*. You can also define a new address by selecting *Create* from either the *Source Address* or *Destination Address* drop-down lists in a security policy. Some addresses will be used in several security policies, so it is best to plan ahead and define the addresses first.

Controlling the types of traffic in the CDE

The *Service* setting in each security policy determines which types of traffic can pass based on protocol.

You can select a single protocol from the *Service* drop-down list. To add another protocol, select the green "+" button to access the *Service* drop-down list again. If several security policies will need the same list of services, consider creating a named service group. (Go to *Firewall Objects* > *Service* > *Groups*.) In the security policy, service groups are available at the bottom of the *Service* drop-down list.

The default deny policy

All traffic not specifically allowed by a security policy that you create is blocked by the Implicit policy listed at the bottom of the *Policy* > *Policy* > *Policy* page.

You cannot delete this policy and you can edit the policy only to enable or disable logging of the traffic that it handles.

Wireless network security

Scanning for rogue access points is the minimum requirement for wireless security. Even if your organization does not use wireless networking, PCI DSS requires you to verify periodically that wireless networking has not been introduced into the CDE.

If you use wireless networking, the wireless network is only within the PCI DSS scope if it can connect to the CDE.

On-wire detection of rogue APs

FortiGate units include an "on-wire" detection technique that correlates the SSID MAC addresses of the unknown access points with MAC addresses detected on your wired networks. This helps to differentiate unrelated neighboring APs from security-compromising unauthorized APs connected to your network.

Setting up rogue access point scanning

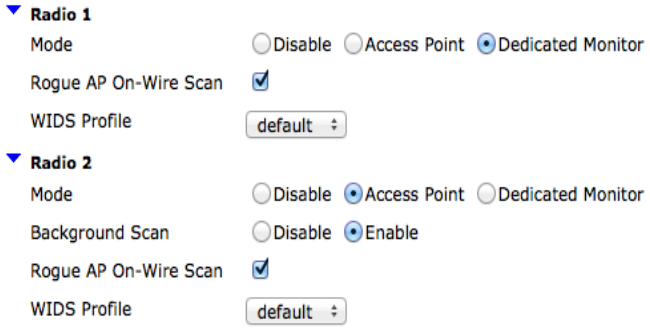
A FortiGate unit with a connected FortiAP unit can perform wireless scanning. Each of the FortiAP radios can act as a dedicated monitor or can perform scanning in the background while acting as a wireless access point.

Radio 1 operates in the 2.4GHz band and Radio 2 operates in the 5GHz band. Both bands should be monitored. The FortiAP unit(s) used for scanning must be located within the coverage area that would result if an access point were added to the CDE.

To configure rogue AP scanning in a custom AP profile

1. Go to *WiFi Controller* > *WiFi Network* > *Custom AP Profiles*.

   On some models, the menu is *WiFi & Switch Controller*.
2. Select an existing AP profile and edit it, or select *Create New*.
3. For each radio, select either *Access Point* or *Dedicated Monitor*, as required.



4. If you selected *Access Point*, enable *Background Scan*.
5. Select *Rogue AP On-Wire Scan.*
6. If needed, modify other settings.
7. Select *OK*.

To enable rogue AP scanning for the automatic AP profile

1. Go to *WiFi Controller* > *WiFi Network* > *Rogue AP Settings*.
2. Select *Enable Rogue AP Detection*.
3. Select *Enable On-wire Rogue AP Detection Technique* if you want to use that method of distinguishing rogues from neighbors.
4. Select *Apply*.

Viewing the results of rogue AP scanning

Go to *WiFi Controller* > *Monitor* > *Rogue AP* to view information about detected wireless access points.

Logging the results of rogue AP scanning

To ensure that detection of rogue access points is logged, go to *Log&Report* > *Log Config* > *Log* Setting and enable logging for *WiFi activity event*.

In the logs, the *Type* is event and the *Sub Type* is wireless.

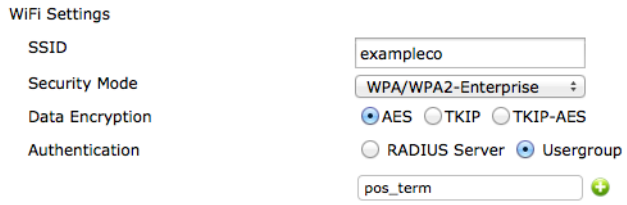
Securing a CDE network WAP

If your wireless network is within PCI DSS scope, it must meet the following requirements:

- Default settings such as SSID and passphrases must be changed.
- Use WPA security, not WEP.
- Log wireless activity.

Setting wireless security

On FortiGate units, go to *WiFi Controller* > *WiFi Network* > *SSID* to configure wireless security settings for either a new or existing virtual access point.



The default SSID for the FortiAP is “fortinet”. You must change this.

The *Security Mode* ***must*** be set to one of the WPA/WPA2 modes. Both WPA or WPA2 clients can be served. In the CLI, you can optionally select exclusively WPA or WPA2 operation.

AES is stronger *Data Encryption* than TKIP.

WPA/WPA2-Enterprise *Authentication* uses separate logon credentials for each user. Either FortiGate user group security or an external RADIUS server performs the authentication. Optionally, certificate-based security can also be applied. WPA/WPA2-Personal authentication requires a single pre-shared key that is used by all clients and is thus less secure.

For detailed information about wireless access points, see the *Deploying Wireless Networks* chapter of this FortiOS Handbook.

Logging wireless network activity

To ensure that wireless network activity is logged, go to *Log&Report* > *Log Config* > *Log Settings* and enable logging for *WiFi activity event*. In the logs, the *Type* is event and the *Sub Type* is wireless.

Protecting stored cardholder data

The Fortinet FortiDB and FortiWeb products can provide security for your sensitive cardholder data.

The Fortinet Database Security (FortiDB) device provides vulnerability assessment, database activity monitoring, auditing and monitoring. For more information about this product, see the Fortinet web site, www.fortinet.com.

The Fortinet FortiWeb Web Application Firewall deployed in front of public-facing web applications protects Web applications, databases, and the information exchanged between them. In particular, it addresses the PCI DSS requirements 6.5 and 6.6 regarding web application vulnerabilities such as cross-site scripting, SQL injection, and information leakage. For more information about this product, see the Fortinet web site, www.fortinet.com.

Protecting communicated cardholder data

If cardholder data must be communicated over an untrusted network, such as the Internet, use the FortiGate unit’s IPsec VPN capability to exchange the data securely. If you support customer on-line transactions, use HTTPS (SSL or TLS encryption) for security. The relevant PCI DSS requirement is:

- Use strong cryptography and security protocols (for example, SSL/TLS, IPSEC, SSH, etc.) to safeguard sensitive cardholder data during transmission over open, public networks. (4.1)

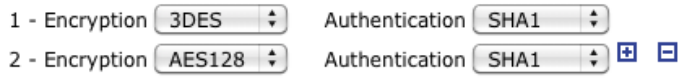
This does not prescribe particular cryptography, but it can be interpreted as a requirement to follow industry best practices.

Configuring IPsec VPN security

The security considerations for IPsec VPNs are encryption and authentication.

Encryption

Go to *VPN* > *IPsec* > *Auto Key (IKE)* to configure an IPsec VPN. In both Phase 1 and Phase 2 parts of the configuration, you select the encryption to use.



These are advanced settings, overriding defaults that are not necessarily the strongest algorithms. VPNs negotiate over standards, so you can list multiple proposed algorithms. The VPN will use the strongest encryption that both ends support.

Choose strong encryption. The available encryption algorithms in descending order of strength are AES256, AES192, AES128, 3DES, DES. DES encryption is the weakest with only a 64-bit key and does not meet the 80-bit key length minimum that PCI DSS requires. NULL means no encryption and must not be used.

The message digest (authentication) algorithms in descending order of strength are SHA512, SHA384, SHA256, SHA1 and MD5. MD5 is particularly weak and should be avoided. NULL means no message digest and must not be used.

Authentication

VPN peers authenticate each other before establishing a tunnel. FortiGate units support two different authentication methods: pre-shared key and RSA signature (certificate). Certificates provide the best security. PCI DSS does not prohibit pre-shared keys, but you should limit access to the keys to the personnel who are responsible for the FortiGate units or other equipment at either end of the VPN.

Configuring SSL VPN security

The SSL VPN configuration includes a choice of encryption algorithm. Go to *VPN* > *SSL* > *Config*. The *Default* selection, *RC4 (128 bits)* is acceptable, but the *High* option, *AES (128/256 bits) and 3DES* is more secure. The *Low* option, *RC4 (64 bits), DES and higher* does not meet PCI DSS requirements.

Protecting the CDE network from viruses

PCI DSS requires the use of regularly updated antivirus protection. The antivirus functionality of the FortiGate unit protects both the FortiGate unit and the networks it manages. Workstations on these networks can be protected using FortiClient Endpoint Security. Both FortiGate and FortiClient antivirus protection can receive updates from Fortinet's FortiGuard service. Workstations can also use third-party antivirus applications with update services.

The FortiGate unit can enforce the use of antivirus software, denying unprotected workstations access to the network.

Enabling FortiGate antivirus protection

The antivirus profile must apply AV scanning to all protocols. You also need to enable SSL inspection to include secure protocols in antivirus scanning. The extended AV database contains the largest number of virus signatures.

To create the antivirus profile

1. Go to *Security Profiles* > *Antivirus* > *Profiles*.
2. Edit the *default* predefined profile or select *Create New*.
3. Set *Inspection Mode* to *Proxy*.
4. Ensure that all *Virus Scan and Removal* check boxes are selected.
5. Select *Apply*.

To enable SSL inspection

1. Go to *Policy* > *Policy* > *SSL Inspection*.
2. Check that the *Enable* check box is selected for every protocol and then select *Apply*.

To select the extended antivirus database

The antivirus database is selectable using the CLI:

```
config antivirus settings
  set default-db extended
end
```

For detailed information about the Antivirus feature, see the *Security Profiles* chapter of this FortiOS Handbook.

Configuring antivirus updates

On the system dashboard, check the *License Information* widget. The *Support Contract* section should show Valid Contract and the contract expiry date. If your FortiGate unit is not registered, you need to visit the Fortinet Support web page (http://support.fortinet.com/) to register. Go to Product Registration and follow the instructions.

In the *FortiGuard Services* section, check the *Antivirus* field. If the service is unreachable, see the online Help for information about troubleshooting your connectivity to FortiGuard Services.

Enforcing firewall use on endpoint PCs

PCI DSS requires you to “Install personal firewall software on any mobile and/or employee-owned devices that connect to the Internet when outside the network (for example, laptops used by employees), and which are also used to access the network. (1.4)” Consider using the Endpoint Control feature of the FortiGate unit to enforce use of this software.

Monitoring the network for vulnerabilities

There are several tools that can assist you in monitoring your network for vulnerabilities and provide evidence to the PCI DSS auditor of such monitoring.

FortiGate logs

FortiGate units can be configured to send logs to FortiAnalyzer unit. In a larger network, this enables you to collect log information in a central location from several FortiGate units.

Using the FortiOS Network Vulnerability Scan feature

As part of its security features, FortiGate units provide a Network Vulnerability Scan. You define assets to monitor, such as servers, workstations, or point-of-sale terminals. Then, the FortiGate unit scans those devices on a regular schedule. The scan checks TCP and UDP ports against a

list of known vulnerabilities provided by FortiGuard Services. Scan settings determine how many of the ports are checked. Optionally, all ports are scanned.

To set up vulnerability scanning, go to *User & Device* > *Vulnerability Scan* > *Scan Definition*. To view scan logs, go to *User & Device* > *Vulnerability Scan* > *Vulnerability Result*. For more information, see Vulnerability Scan in this FortiOS Handbook.

Monitoring with other Fortinet products

In addition to your FortiGate unit and its FortiOS firmware, there are several other Fortinet products that can assist your organization to comply with PCI DSS requirements.

Fortinet Database Security (FortiDB)

A FortiDB appliance or FortiDB software can provide vulnerability scanning and activity monitoring for your databases. For more information, see the *FortiDB User Guide*.

FortiScan Vulnerability and Compliance Management platform

The FortiScan Vulnerability and Compliance Management (VCM) platform combines a FortiScan appliance with FortiScan agent software to monitor your network assets such as servers, workstations, or point-of-sale terminals. This system can perform vulnerability scans and apply software patches provided by the software vendors. The scan profiles include a predefined one for PCI DSS. The FortiScan appliance produces compliance reports detailing the results of the vulnerability scan. For more information, see the *FortiScan Administration Guide*.

FortiWeb Web Application Security

If your organization engages in e-Commerce, you can use FortiWeb Application Security to protect your web servers against attack. The FortiWeb application protects against HTTP and XML-based attacks, guards against attempts to deface your web sites, and scans web servers for vulnerabilities. For more information, see the *FortiWeb Web Application Security Administration Guide*.

Restricting access to cardholder data

In addition to security policies and authentication governing access to the CDE, you can deploy the Fortinet Database Security (FortiDB) device, which provides vulnerability assessment, database activity monitoring, auditing and monitoring. For more information about this product, see the Fortinet web site, www.fortinet.com.

Controlling access to the CDE network

PCI DSS requires each user to be uniquely identified and authenticated. On the FortiGate unit, this applies to administrators and to users of SSL VPN and IPsec VPNs.

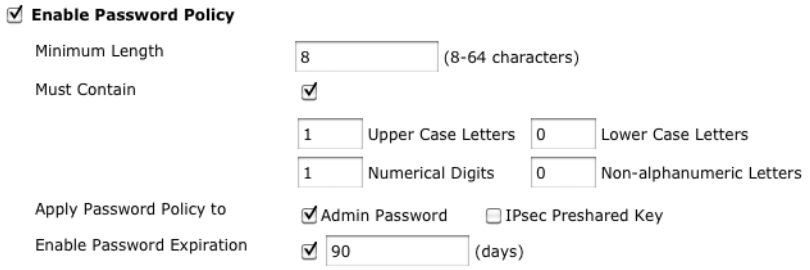
Password complexity and change requirements

By default, the FortiGate unit admin account has no password. Be sure to define a password.

PCI DSS password requirements are

- Require a minimum password length of at least seven characters. (8.2.3)
- Use passwords containing both numeric and alphabetic characters. (8.2.3)
- Change user passwords at least every 90 days. (8.2.4)

To facilitate creation of compliant administrator passwords, you can set a password policy. Go to *System* > *Admin* > *Settings*. In the *Password Policy* section, enter the following and then select OK at the bottom of the page.



Enable	Select the check box.
Minimum Length	8 or more. (Field does not accept a value less than 8.)
Must Contain	At minimum, set a required number of *Numerical Digits* and either *Upper Case Letters* or *Lower Case Letters*. Also setting a required number of *Non-alphabetic Letters* is acceptable.
Apply Password Policy to	Select *Admin Password*.
Enable Password Expiration	Set to 90 days or less. The default is 90 days.

Note that the FortiGate password policy does not apply to user passwords. Both password complexity and password expiry for users would need to addressed by making them a policy in your organization.

Password non-reuse requirement

PCI DSS requires that passwords are not re-used to satisfy the change requirement:

“Do not allow an individual to submit a new password that is the same as any of the last four passwords he or she has used.” (8.2.5)

FortiGate users don’t set their own passwords. The super_admin administrators can and so can admins with appropriate access. There is, however, no FortiGate-based mechanism to enforce non re-use of passwords.

Administrator lockout requirement

PCI DSS requires a user account lockout for administrators to guard against unauthorized access attempts:

- Limit repeated access attempts by locking out the user ID after not more than six attempts. (8.1.6),
- Set the lockout duration to a minimum of 30 minutes or until administrator enables the user ID. (8.1.7)

You can meet these requirements with the following CLI commands:

```
config system global
   set admin-lockout-threshold 6
   set admin-lockout-duration 1800
end
```

The threshold can be less than 6 and the lockout duration can be more than 1800.

Administrator timeout requirement

PCI DSS requires:

- If a session has been idle for more than 15 minutes, require the user to re-enter the password to reactivate the terminal. (8.1.8)

By default, the idle timeout is five minutes. You can go to *System* > *Admin* > *Settings* and change the *Idle Timeout* timeout to any value up to the permitted value of 15 minutes.

Administrator access security

To accommodate the requirement for unique identification of each user, the generic admin account should either be assigned to only one administrator or not used at all. You can create an administrator account for each administrator in *System* > *Admin* > *Administrators*.

If an administrator always works from the same workstation, consider using the Trusted Host feature. The administrator will be able to log in only from a trusted IP address. You can define up to three trusted IP addresses per administrator.

Administrative access must also be enabled per network interface. Go to *System* > *Network* > *Interface* to edit the interface settings. Enable administrative access only on interfaces where you would expect the administrator to connect. Allow only secure connection protocols, HTTPS for web-based access, SSH for CLI access.

Remote access security

For remote access, PCI DSS requires two-factor authentication: a password and some other authentication, such as a smart token or certificate. This applies to employees, administrators, and third parties.

SSL VPN users

For SSL VPN users, implement two-factor authentication by requiring users to have a certificate in addition to the correct password. Go to *VPN* > *SSL* > *Config*, enable *Require Client Certificate*, and then select *Apply*. For more information, see the SSL VPN chapter of this FortiOS Handbook.

IPsec VPN users

If users access your network using an IPsec VPN, you can implement two-factor authentication by enabling extended authentication (XAUTH). This requires the user to enter a password in addition to the VPN authentication provided by the certificate or pre-shared key. As PCI DSS requires each user to have a unique identifier, you should already have user accounts and user groups defined.

To configure XAUTH on your VPN

1. Go to *VPN* > *IPsec* > *Auto Key (IKE)* and edit your Phase 1 configuration.
2. Select *Advanced*.
3. In *XAUTH*, select *Enable as Server*.

   Enable as Server is available only if *Remote Gateway* is *Dialup User*.
4. Set *Server Type* to *PAP*, *CHAP*, or *AUTO* as appropriate.
5. Select the *User Group* to which the VPN users belong.
6. Select *OK*.

Chapter 6 Deploying Wireless Networks for FortiOS 5.0

This FortiOS Handbook chapter contains the following sections:

Introduction to wireless networking explains the basic concepts of wireless networking and how to plan your wireless network.

Configuring a WiFi LAN explains how to set up a basic wireless network, prior to deploying access point hardware.

Access point deployment explains how to deploy access point hardware and add it to your wireless network configuration.

Wireless Mesh explains how to configure a WiFi network where access points are connected to the WiFi controller wirelessly instead of by Ethernet.

WiFi-Ethernet Bridge Operation shows how to use the FortiAP WiFi-Ethernet bridge feature.

Protecting the WiFi Network explains the Wireless Intrusion Detection System (WIDS).

Wireless network monitoring explains how to monitor your wireless clients and how to monitor other wireless access points, potentially rogues, in your coverage area.

Configuring wireless network clients explains how to configure typical wireless clients to work with a WPA-Enterprise protected network.

Wireless network examples provides two examples. The first is a simple WiFi network using automatic configuration. The second is a more complex example of a business with two WiFi networks, one for employees and another for guests or customers.

Using a FortiWiFi unit as a client explains how to use a FortiWiFi unit as a wireless client to connect to other WiFi networks. This connection can take the place of an Ethernet connection where wired access to a network or to the Internet is not available.

Reference provides information about WiFi radio channels.

Introduction to wireless networking

This chapter introduces some concepts you should understand before working with wireless networks, describes Fortinet's wireless equipment, and then describes the factors you need to consider in planning deployment of a wireless network.

The following topics are included in this section:

Wireless concepts

Wireless networking is radio technology, subject to the same characteristics and limitations as the familiar audio and video radio communications. Various techniques are used to modulate the radio signal with a data stream.

Bands and channels

Depending on the wireless protocol selected, you have specific channels available to you, depending on what region of the world you are in.

- IEEE 802.11b and g protocols provide up to 14 channels in the 2.400-2.500 GHz Industrial, Scientific and Medical (ISM) band.
- IEEE 802.11a,n (5.150-5.250, 5.250-5.350, 5.725–5.875 GHz, up to 16 channels) in portions of Unlicensed National Information Infrastructure (U-NII) band

Note that the width of these channels exceeds the spacing between the channels. This means that there is some overlap, creating the possibility of interference from adjacent channels, although less severe than interference on the same channel. Truly non-overlapping operation requires the use of every fourth or fifth channel, for example ISM channels 1, 6 and 11.

The capabilities of your wireless clients is the deciding factor in your choice of wireless protocol. If your clients support it, 5GHz protocols have some advantages. The 5GHz band is less used than 2.4GHz and its shorter wavelengths have a shorter range and penetrate obstacles less. All of these factors mean less interference from other access points, including your own.

When configuring your WAP, be sure to correctly select the Geography setting to ensure that you have access only to the channels permitted for WiFi use in your part of the world.

For detailed information about the channel assignments for wireless networks for each supported wireless protocol, see "Wireless radio channels" on page 883.

Power

Wireless LANs operate on frequencies that require no license but are limited by regulations to low power. As with other unlicensed radio operations, the regulations provide no protection against interference from other users who are in compliance with the regulations.

Power is often quoted in dBm. This is the power level in decibels compared to one milliwatt. 0dBm is one milliwatt, 10dBm is 10 milliwatts, 27dBm, the maximum power on Fortinet FortiAP equipment, is 500 milliwatts. The FortiGate unit limits the actual power available to the maximum permitted in your region as selected by the WiFi controller country setting.

Received signal strength is almost always quoted in dBm because the received power is very small. The numbers are negative because they are less than the one milliwatt reference. A received signal strength of -60dBm is one millionth of a milliwatt or one nanowatt.

Antennas

Transmitted signal strength is a function of transmitter power and antenna gain. Directional antennas concentrate the signal in one direction, providing a stronger signal in that direction than would an omnidirectional antenna.

FortiWiFi units have detachable antennas. However, these units receive regulatory approvals based on the supplied antenna. Changing the antenna might cause your unit to violate radio regulations.

Security

There are several security issues to consider when setting up a wireless network.

Whether to broadcast SSID

Users who want to use a wireless network must configure their computers with the wireless service set identifier (SSID) or network name. Broadcasting the SSID makes connection to a wireless network easier because most wireless client applications present the user with a list of network SSIDs currently being received. This is desirable for a public network.

To obscure the presence of a wireless network, do not broadcast the SSID. This does not prevent attempts at unauthorized access, however, because the network is still detectable with wireless network “sniffer” software.

Encryption

Wireless networking supports the following security modes for protecting wireless communication, listed in order of increasing security.

None — Open system. Any wireless user can connect to the wireless network.

WEP64 — 64-bit Web Equivalent Privacy (WEP). This encryption requires a key containing 10 hexadecimal digits.

WEP128 — 128-bit WEP. This encryption requires a key containing 26 hexadecimal digits.

WPA — 256-bit Wi-Fi Protected Access (WPA) security. This encryption can use either the TKIP or AES encryption algorithm and requires a key of either 64 hexadecimal digits or a text phrase of 8 to 63 characters. It is also possible to use a RADIUS server to store a separate key for each user.

WPA2 — WPA with security improvements fully meeting the requirements of the IEEE 802.11i standard. Configuration requirements are the same as for WPA.

For best security use the WPA2 with AES encryption and a RADIUS server to verify individual credentials for each user. WEP, while better than no security at all, is an older algorithm that is easily compromised. With either WEP or WAP, changing encryption passphrases on a regular basis further enhances security.

Separate access for employees and guests

Wireless access for guests or customers should be separate from wireless access for your employees. This does not require additional hardware. Both FortiWiFi units and FortiAP units support multiple wireless LANs on the same access point. Each of the two networks can have its own SSID, security settings, firewall policies, and user authentication.

A good practice is to broadcast the SSID for the guest network to make it easily visible to users, but not to broadcast the SSID for the employee network.

Two separate wireless networks are possible because multiple virtual APs can be associated with an AP profile. The same physical APs can provide two or more virtual WLANs.

Captive portal

As part of authenticating your users, you might want them to view a web page containing your acceptable use policy or other information. This is called a captive portal. No matter what URL the user initially requested, the portal page is returned. Only after authenticating and agreeing to usage terms can the user access other web resources.

For information about setting up a captive portal, see “Captive Portal security” on page 803.

Power

Reducing power reduces unwanted coverage and potential interference to other WLANs. Areas of unwanted coverage are a potential security risk. There are people who look for wireless networks and attempt to access them. If your office WLAN is receivable out on the public street, you have created an opportunity for this sort of activity.

Monitoring for rogue APs

It is likely that there are APs available in your location that are not part of your network. Most of these APs belong to neighboring businesses or homes. They may cause some interference, but they are not a security threat. There is a risk that people in your organization could connect unsecured WiFi-equipped devices to your wired network, inadvertently providing access to unauthorized parties. The optional On-Wire Rogue AP Detection Technique compares MAC addresses in the traffic of suspected rogues with the MAC addresses on your network. If wireless traffic to non-Fortinet APs is also seen on the wired network, the AP is a rogue, not an unrelated AP.

Decisions about which APs are rogues are made manually on the Rogue AP monitor page. For detailed information about monitoring rogue APs, see “Monitoring rogue APs” on page 847.

Suppressing rogue APs

When you have declared an AP to be a rogue, you have the option of suppressing it. To suppress and AP, the FortiGate WiFi controller sends reset packets to the rogue AP. Also, the MAC address of the rogue AP is blocked in the firewall policy. You select the suppression action on the Rogue AP monitor page. For more information, see “Suppressing rogue APs” on page 851.

Rogue suppression is available only when there is a radio dedicated to scanning. It will not function during background scanning.

Wireless Intrusion Detection (WIDS)

You can create a WIDS profile to enable several types of intrusion detection:

- Unauthorized Device Detection
- Rogue/Interfering AP Detection
- Ad-hoc Network Detection and Containment
- Wireless Bridge Detection
- Misconfigured AP Detection
- Weak WEP Detection
- Multi Tenancy Protection
- MAC OUI Checking

Authentication

Wireless networks usually require authenticated access. FortiOS authentication methods apply to wireless networks the same as they do to wired networks because authentication is applied in the firewall policy.

The types of authentication that you might consider include:

- user accounts stored on the FortiGate unit
- user accounts managed and verified on an external RADIUS, LDAP or TACACS+ server
- Windows Active Directory authentication, in which users logged on to a Windows network are transparently authenticated to use the wireless network.

This Wireless chapter of the FortiOS Handbook will provide some information about each type of authentication, but more detailed information is available in the Authentication chapter.

What all of these types of authentication have in common is the use of user groups to specify who is authorized. For each wireless LAN, you will create a user group and add to it the users who can use the WLAN. In the identity-based firewall policies that you create for your wireless LAN, you will specify this user group.

Some access points, including FortiWiFi units, support MAC address filtering. You should not rely on this alone for authentication. MAC addresses can be “sniffed” from wireless traffic and used to impersonate legitimate clients.

Wireless networking equipment

Fortinet produces two types of wireless networking equipment:

- FortiWiFi units, which are FortiGate units with a built-in wireless access point/client
- FortiAP units, which are wireless access points that you can control from any FortiGate unit that supports the WiFi Controller feature.

FortiWiFi units

A FortiWiFi unit can:

- Provide an access point for clients with wireless network cards. This is called Access Point mode, which is the default mode.

or

- Connect the FortiWiFi unit to another wireless network. This is called Client mode. A FortiWiFi unit operating in client mode can only have one wireless interface.

or

- Monitor access points within radio range. This is called Monitoring mode. You can designate the detected access points as Accepted or Rogue for tracking purposes. No access point or client operation is possible in this mode. But, you can enable monitoring as a background activity while the unit is in Access Point mode.

FortiWiFi unit capabilities differ by model as follows:

Table 40: FortiWiFi model capabilities

Model	Radio	Simultaneous SSIDs
20C	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	7 for AP, 1 for monitoring
30B	802.11 b/g 2.4GHz	7 for AP, 1 for monitoring
40C	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	7 for AP, 1 for monitoring
50B	802.11 b/g 2.4GHz	7 for AP, 1 for monitoring
60B	802.11 b/g 2.4GHz 802.11 a 5GHz	7 for AP, 1 for monitoring
60C	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	7 for AP, 1 for monitoring
80/81CM	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	7 for AP, 1 for monitoring

FortiAP units

FortiAP series wireless access points are controlled by a FortiGate unit over Ethernet. Capabilities differ by model as follows:

Table 41: FortiAP model capabilities

Model	Radio 1	Radio 2	Simultaneous SSIDs
210B (indoor)	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	N/A	7 for AP, 1 for monitoring
220A (indoor)	802.11 b/g/n 2.4GHz	802.11 a/n 5GHz	14 for AP, 2 for monitoring

Table 41: FortiAP model capabilities

220B (indoor)	802.11 b/g/n 2.4GHz 802.11 a/n 5GHz	802.11 b/g/n 2.4GHz	14 for AP, 2 for monitoring
222B (outdoor)	802.11 b/g/n 2.4GHz	802.11 a/n 5GHz	14 for AP, 2 for monitoring

Dual-band radios can function as an AP on either band or as a dual-band monitor. The monitoring function is also available during AP operation if Background Scan is enabled in the custom AP profile for the device.

Deployment considerations

Several factors need to be considered when planning a wireless deployment.

Types of wireless deployment

This Handbook chapter describes two main types of wireless deployment: single WAP and multiple WAP. You will know which type of deployment you need after you have evaluated the coverage area environment.

Deployment methodology

1. Evaluate the coverage area environment.
2. Position access point(s).
3. Select access point hardware.
4. Install and configure the equipment.
5. Test and tune the network.

Evaluating the coverage area environment

Consider the following factors:

- **Size of coverage area** — Even under ideal conditions, reliable wireless service is unlikely beyond 100 metres outdoors or 30 metres indoors. Indoor range can be further diminished by the presence of large metal objects that absorb or reflect radio frequency energy. If wireless users are located on more than one floor of a building, a minimum of one WAP for each floor will be needed.
- **Bandwidth required** — Wireless interface data rates are between 11 and 150 Mb/s, depending on the 802.11 protocol that is used. This bandwidth is shared amongst all users of the wireless data stream. If wireless clients run network-intensive applications, fewer of them can be served satisfactorily by a single WAP.
- Note that on some FortiWiFi units you can define up to four wireless interfaces, increasing the available total bandwidth.
- **Client wireless capabilities** — The 802.11n protocol provides the highest data rates and has channels in the less interference-prone 5GHz band, but it is supported only on the latest consumer devices. The 802.11g protocol is more common but offers lower bandwidth. Some older wireless client equipment supports only 802.11b with a maximum data rate of 11Mb/s. WAP radios support the protocol that you select with backward compatibility to older modes. For example, if you select 802.11n, clients can also connect using 802.11g or 802.11b.

The most important conclusion from these considerations is whether more than one WAP is required.

Positioning access points

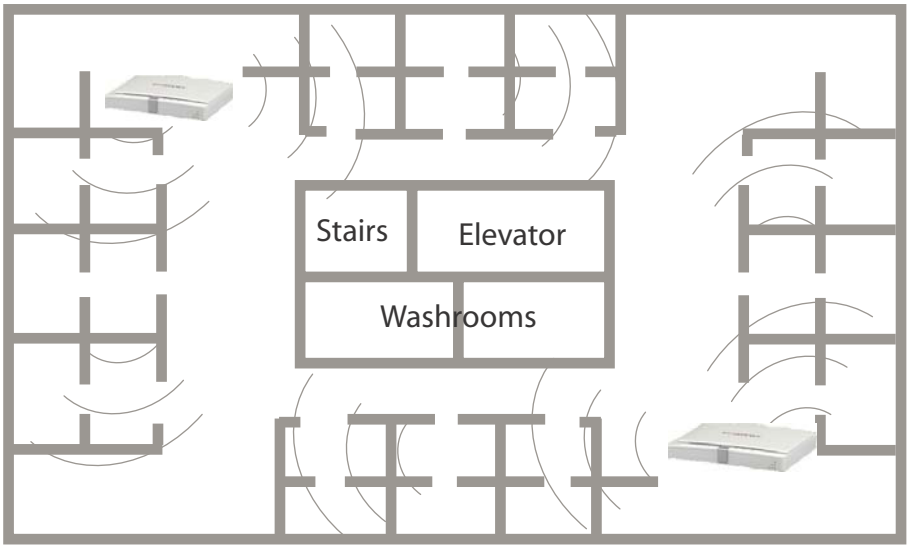
When placing the access point, your main concern is providing a strong signal to all users. A strong signal ensures a fast connection and efficient data transfer. A weaker signal means a greater chance of data transmission errors and the need to re-send information, slowing down data transfer.

Consider the following guidelines when placing access points:

- Physical barriers can impede the radio signals. Solid objects such as walls, furniture and people absorb radio waves, weakening the signal. Be aware of the physical barriers in your office space that may reduce a signal. If there is enough physical interference, you may encounter dead spots that receive no signal.
- Ensure the access point is located in a prominent location within a room for maximum coverage, rather than in a corner.
- Construction materials used in a building can also weaken radio signals. Rooms with walls of concrete or metal can affect the signal strength.

If you cannot avoid some of these impediments due to the shape of the office or building materials used, you may need to use multiple access points to help distribute the radio signal around the room. Figure 155 shows how positioning two FortiAP-220A units within a uniquely shaped office space helps to distribute signals around the area.

Figure 155: Using multiple APs to provide a constant strong signal.



This sample office has washrooms, a stairwell and an elevator shaft in the center of the building, making it impossible to use a single access point effectively. The elevator shaft and multiple metal stalls in the washrooms can cause signal degradation. However, placing access points in diagonally opposite areas of the office provides maximum coverage.

When using multiple access points, set each access point to a different channel to avoid interference in areas where signals from both access points can be received.

Selecting access point hardware

For a single WAP installation, you could deploy a single FortiWiFi unit. If the site already has a FortiGate unit that supports the WiFi controller feature, adding a FortiAP unit is the most economical solution.

For a multiple WAP deployment you need a FortiGate unit as a WiFi controller and multiple FortiAP units. A FortiWiFi unit can be used as a managed WAP, but it is more expensive.

The FortiAP unit offers more flexible placement. FortiWiFi units either sit on a shelf or are rack mounted. FortiAP units can be attached to any wall or ceiling, enabling you to locate them where they will provide the best coverage.

Single access point networks

A single access point is appropriate for a limited number of users in a small area. For example, you might want to provide wireless access for a group of employees in one area on one floor of an office building.

A good rule of thumb is that one access point for can serve 3000 to 4000 square feet of space, with no user more than 60 feet from the access point. Walls and floors reduce the coverage further, depending on the materials from which they are made.

Multiple access point networks

To cover a larger area, such as multiple floors of a building, or multiple buildings, multiple access points are required.

In the WiFi controller, you configure a single virtual access point, but the controller manages multiple physical access points that share the same configuration. A feature known as “fast roaming” enables users to move from one physical access point coverage area to another while retaining their authentication.

Fast Roaming

Users in a multi-AP network, especially with mobile devices, can move from one AP coverage area to another. But, the process of re-authentication can often take seconds to complete and this can impair wireless voice traffic and time sensitive applications. The FortiAP fast roaming feature solves this problem and is available only when moving between FortiAP units managed by the same FortiGate unit.

Fast roaming uses two standards-based techniques:

- Pairwise Master Key (PMK) Caching enables a RADIUS-authenticated user to roam away from an AP and then roam back without having to re-authenticate. To accomplish this, the FortiGate unit stores in a cache a master key negotiated with the first AP. This enables the 802.11i-specified method of “fast roam-back.”
- Pre-authentication or “fast-associate in advance” enables an 802.11 AP associated to a client to bridge to other APs over the wired network and pre-authenticate the client to the “next” AP to which the client might roam. This enables the PMK to be derived in advance of a roam and cached. When the client does roam, it will already have negotiated authentication in advance and will use its cached PMK to quickly associate to the next AP. This capability will ensure that wireless clients that support Pre-authentication to continue the data transfer without noticeable connection issues.

WiFi Mesh Network

FortiAP units can be connected to the WiFi controller by Ethernet or by WiFi. In the latter case, you configure a special backhaul network, the mesh, that carries traffic and control signals between FortiAP units and the WiFi controller. Regular WiFi clients cannot connect to the mesh network, they can connect only to non-mesh SSIDs. The mesh network is useful when running Ethernet cables is not practical. For best results, the mesh network should use a dedicated radio at both the WiFi controller and FortiAP unit. Otherwise, the client SSIDs compete for bandwidth with the mesh backhaul.

Automatic Radio Resource Provisioning

To prevent interference between APs, the FortiOS WiFi Controller includes the Automatic Radio Resource Provisioning (ARRP) feature. When enabled in an access point profile, *Radio Resource Provision* measures utilization and interference on the available channels and selects the clearest channel at each access point. The measurement can be repeated periodically to respond to changing conditions.

Configuring a WiFi LAN

When working with a FortiGate WiFi controller, you can configure your wireless network before you install any access points. If you are working with a standalone FortiWiFi unit, the access point hardware is already present but the configuration is quite similar. Both are covered in this section.

The following topics are included in this section:

On FortiGate model 30D, web-based manager configuration of the WiFi controller is disabled by default. To enable it, enter the following CLI commands:

```
config system global
  set gui-wireless-controller enable
end
```

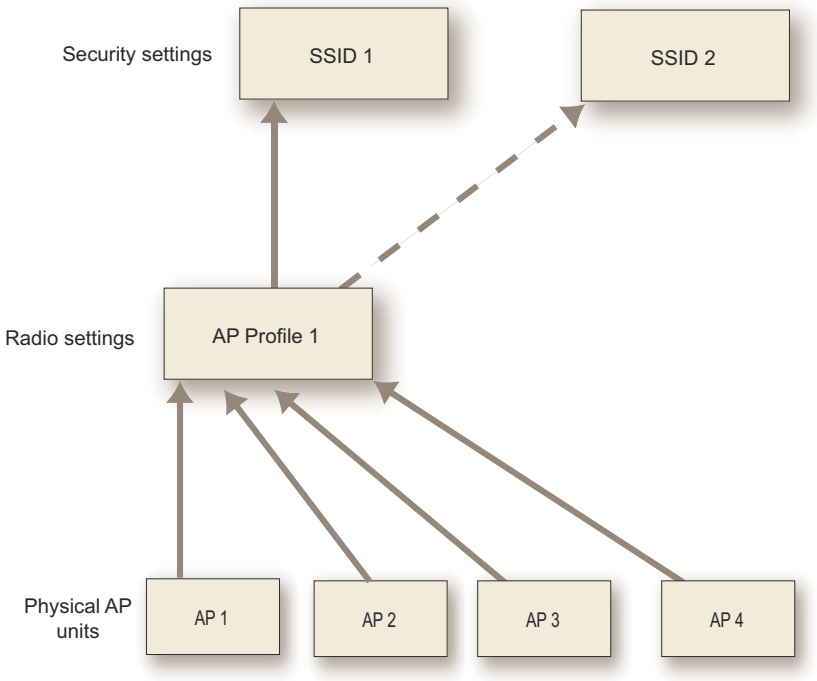
Overview of WiFi controller configuration

The FortiGate WiFi controller configuration is composed of three types of object, the SSID, the AP Profile and the physical Access Point.

- An **SSID** defines a virtual wireless network interface, including security settings. One SSID is sufficient for a wireless network, regardless how many physical access points are provided. You might, however, want to create multiple SSIDs to provide different services or privileges to different groups of users. Each SSID has separate firewall policies and authentication. Each radio in an access point can support up to 8 SSIDs.

  A more common use of the term SSID is for the identifier that clients must use to connect to the wireless network. Each SSID (wireless interface) that you configure will have an SSID field for this identifier. In Managed Access Point configurations you choose wireless networks by SSID values. In firewall policies you choose wireless interfaces by their SSID name.
- An **AP Profile** defines the radio settings, such as band (802.11g for example) and channel selection. The AP Profile names the SSIDs to which it applies. Managed APs can use automatic profile settings or you can create custom AP profiles.
- **Managed Access Points** represent local wireless APs on FortiWiFi units and FortiAP units that the FortiGate unit has discovered. There is one managed access point definition for each AP device. An access point definition can use automatic AP profile settings or select a custom AP Profile. When automatic profile settings are used, the managed AP definition also selects the SSIDs to be carried on the AP.

Figure 156: Conceptual view of FortiGate WiFi controller configuration



About SSIDs on FortiWiFi units

FortiWiFi units have a default SSID (wireless interface) named *wlan.* You can modify or delete this SSID as needed. As with external APs, the built-in wireless AP can be configured to carry any SSID.

The AP settings for the built-in wireless access point are located at *WiFi Controller* > *Managed Access Points* > *Local WiFi Radio*. The available operational settings are the same as those for external access points which are configured at *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.

About automatic AP profile settings

FortiOS simplifies wireless network configuration by providing an automatic setting for the access point profile. You can enable wireless AP operation and Rogue AP scanning with the radios in the AP automatically allocated as follows:

Table 42: Radio functions in automatic profile

No. of Radios	Wireless Access enabled	Rogue AP Scan enabled	Wireless Access and Rogue AP Scan enabled
1	Radio 1 - AP	Radio 1 - scan	Radio 1 - AP + background scan
2	Radio 1 - AP Radio 2 - disabled	Radio 1 - disabled Radio 2 - scan	Radio 1 - AP Radio 2 - scan

You can select which SSIDs (wireless networks) will be available through the access point and adjust the wireless power level of the AP. Also, you can configure the unit's LAN ports, if you are using a FortiAP model that has them (see "LAN port options" on page 823).

Process to create a wireless network

To set up your wireless network, you will need to perform the following steps.

- Make sure the FortiGate wireless controller is configured for your geographic location. This ensures that the available radio channels and radio power are in compliance with the regulations in your region.
- Optionally, if you don't want to use automatic AP profile settings, configure a custom Access Point (AP) profile, specifying the radio settings and the SSIDs to which they apply.
- Configure one or more SSIDs for your wireless network. The SSID configuration includes DHCP and DNS settings.
- Configure the user group and users for authentication on the WLAN.
- Configure the firewall policy for the WLAN.
- Optionally, customize the captive portal.
- Configure access points.

  Configuration of the built-in AP on FortiWiFi units is described in this chapter. Connection and configuration of FortiAP units is described in the next chapter, "Access point deployment".

Setting your geographic location

The maximum allowed transmitter power and permitted radio channels for Wi-Fi networks depend on the region in which the network is located. By default, the WiFi controller is configured for the United States. If you are located in any other region, you need to set your location before you begin configuring wireless networks.

To change the location setting - CLI

To change the country to France, for example, enter

```
config wireless-controller setting
  set country FR
end
```

To see the list of country codes, enter a question mark ('?') instead of a country code.

Before changing the country setting, you must remove all Custom AP profiles. To do this, go to *WiFi Controller* > *WiFi Network* > *Custom AP Profile*.

Creating a custom AP Profile

If the automatic AP profile settings don't meet your needs, you can define a custom AP Profile. For information about the automatic profile settings, see "About automatic AP profile settings" on page 794.

On FortiGate model 30D web-based manager configuration of custom AP profiles is disabled by default. To enable AP profiles, enter the following CLI commands:

```
config system global
  set gui-ap-profile enable
end
```

An AP Profile configures radio settings and selects the Virtual APs to which the settings apply. FortiAP units contain two radio transceivers, making it possible, for example, to provide both 2.4GHz 802.11b/g/n and 5GHz 802.11a/n service from the same access point.

FortiAP units also provide a monitoring function for the Rogue AP feature.

To configure an AP Profile - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *Custom AP Profile* and select *Create New*.
2. Enter a *Name* for the AP Profile.
3. In *Platform*, select the FortiWiFi or FortiAP model to which this profile applies.
4. For each radio, enter:

Mode	Select the type of mode. • *Disable* – radio disabled • *Access Point* – allows for the platform to be an access point • *Dedicated Monitor* – allows for the platform to be a dedicated monitor. See "Wireless network monitoring" on page 846.
Background Scan	Select to enable a background scan, which monitors other APs. This is needed for the Rogue AP feature. By default, background scan is disabled. See "Wireless network monitoring" on page 846.
Rogue AP On-Wire Scan	If Mode is either *Dedicated Monitor* or *Access Point* with *Background Scan* enabled, you can enable on-wire scan to distinguish rogue APs from neighbors. For more information, see "On-wire rogue AP detection technique" on page 847.
WIDS Profile	Optionally, select a Wireless Intrusion Detection (WIDS) profile. See "Wireless IDS" on page 843.
Radio Resource Provision	Select to enable the radio resource provision feature. This feature measures utilization and interference on the available channels and selects the clearest channel at each access point. The measurement can be repeated periodically to respond to changing conditions.
Client Load Balancing	Select Frequency Handoff or AP Handoff as needed. See "Wireless client load balancing for high-density deployments" on page 822.

Band	Select the wireless protocols that you want to support. The available choices depend on the radio's capabilities. Where multiple protocols are supported, the letter suffixes are combined: "802.11bg" means 802.11b ***and*** 802.11g. For 802.11n, 802.11n_2.4G indicates 2.4GHz, 802.11n_5G indicates 5GHz. Note that on two-radio units such as the FortiAP-220B it is not possible to put both radios on the same band.
20/40 Mhz Channel Width	Select to enable 20/40 MHz channel width for 802.11n-5G.
Short Guard Interval	Select to enable the short guard interval for 802.11n_5G with 20/40 MHz channel width.
Channel	Select the channel or channels to include. The available channels depend on which IEEE wireless protocol you selected in *Band*. By default, all available channels are enabled.
Auto Tx Power Control	Optionally, enable automatic adjustment of transmit power, specifying minimum and maximum power levels.
TX Power	By default, the TX power is set to 100% of the maximum power permitted in your region. To change the level, drag the slider.
SSID	Choose the SSIDs (WiFi networks) that APs using this profile will carry. Select the required SSIDs in the *Available* list and use the -> arrow to move them to the *Selected* list. To remove an SSID from the *Selected* list, select the SSID and then use the <- arrow to move it back to the *Available* list.

Radio 1 settings are the same as Radio 2 settings except for the options for *Channel*. Radio 2 settings are available only for FortiAP models with dual radios.

5. Select *OK*.

To configure an AP Profile - CLI

This example configures a FortiAP-220B to use only Radio 2 for 802.11g operation applied to SSID example_wlan.

```
config wireless-controller wtp-profile
  edit guest_prof
    config platform
      set type 220B
    end
    config radio-2
      set mode ap
      set band 802.11g
      set vaps example_wlan
    end
  end
```

Defining a wireless network interface (SSID)

You begin configuring your wireless network by defining one or more SSIDs to which your users will connect. When you create an SSID, a virtual network interface is also created with the *Name* you specified in the SSID configuration. You can configure the settings of an existing SSID in either *WiFi Controller* > *WiFi Network* > *SSID* or *System* > *Network* > *Interface*.

To create a new SSID

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.
2. Fill in the SSID fields as described below.

To configure the settings of an existing SSID

1. Either
   - Go to *WiFi Controller* > *WiFi Network* > *SSID*.

   or
   - Go to *System* > *Network* > *Interfaces*.

     WiFi interfaces list the SSID beside the interface *Name*.
2. Edit a WiFi interface, modifying the SSID fields as needed.

SSID fields

Name	Enter a name for the SSID interface.
Type	WiFi SSID.
Traffic Mode	**Tunnel to Wireless Controller** — Data for WLAN passes through WiFi Controller. This is the default. **Local bridge with FortiAP's Interface** — FortiAP unit Ethernet and WiFi interfaces are bridged. **Mesh Downlink** — Radio receives data for WLAN from mesh backhaul SSID.
IP/Netmask	Enter the IP address and netmask for the SSID.
IPv6 Address	Enter the IPv6 address. This is available only when IPv6 has been enabled on the unit.
Administrative Access	Select which types of administrative access are permitted on this SSID.
IPv6 Administrative Access	If you have IPv6 addresses, select the permitted IPv6 administrative access types for this SSID.
DHCP Server	Select to enable a DHCP server and define IP address ranges to assign to clients or to relay DHCP requests to another server. If the unit is in transparent mode, the DHCP server settings will be unavailable. For more information, see "Configuring DHCP for WiFi clients" on page 801.

WiFi Settings	
SSID	Enter the SSID. By default, this field contains `fortinet`.
Security Mode	Select the security mode for the wireless interface. Wireless users must use the same security mode to be able to connect to this wireless interface. Additional security mode options are available in the CLI. For more information, see "Configuring security" on page 801.
	WPA/WPA2-Personal – WPA or WPA2 security. WPA is WiFi protected access. WPA2 is WPA with additional security features. There is one shared key (password) that all users use.
	WPA/WPA2-Enterprise – similar to WPA/WPA2-Personal, but is best used for enterprise networks. Each user is separately authenticated by user name and password.
	Captive Portal – authenticates users through a customizable web page.
Pre-shared Key	Available only when *Security Mode* is *WPA/WPA2-Personal*. Enter the encryption key that the clients must use.
Data Encryption	Available only when *Security Mode* is *WPA/WPA2-Personal* or *WPA/WPA2-Enterprise*. Select *TKIP* or *AES* encryption as appropriate for the capabilities of your wireless clients. This is available for WPA/WPA2 security modes.
Authentication	Available only when *Security Mode* is *WPA/WPA2-Enterprise*. Select one of the following: *RADIUS Server* — Select the RADIUS server that will authenticate the clients. *Usergroup* – Select the user group(s) that can authenticate.
Customize Portal Messages	Available only when *Security Mode* is *Captive Portal*. Select to customize the endpoint replacement messages. When you select *Edit*, the Edit Message window appears. Within the window, you can modify each one of the endpoint replacement messages.
User Groups	Available only when *Security Mode* is *Captive Portal*. Select the user groups that can authenticate. To select a user group, select the group in *Available* and then use the -> arrow to move that group to *Selected*. To remove a user group from *Selected*, select the group and then use the <- arrow to move the group back to *Available*.
Block Intra-SSID Traffic	Select to enable the unit to block intra-SSID traffic.
Allow New WiFi Client Connections When Controller Is Down	This option is available for local bridge SSIDs with WPA-Personal security. See "Continued FortiAP operation when WiFi controller connection is down" on page 841.

Maximum Clients	Select to limit the number of clients permitted to connect simultaneously. Enter the limit value.
Device Management	Select *Detect and Identify Devices* if you want to monitor the device types using this interface or create device identity policies involving this interface. See “Managing “bring your own device”” on page 1996. Optionally, enable *Add New Devices to Vulnerability Scan List*.
Enable Explicit Web Proxy	Select to enable explicit web proxy for the SSID.
Listen for RADIUS Accounting Messages	This is required to permit RADIUS SSO authentication on this WiFi inteface. See “SSO using RADIUS accounting records” on page 602.
Secondary IP Address	Optioanally, enable and define secondary IP addresses. Administrative access can be enabled on secondary interfaces.
Comments	Enter a description or comment for the SSID.

By default, the AP will broadcast its SSID. Optionally, you can disable SSID Broadcast in the CLI:

```
config wireless controller vap
  edit vap_name
    set broadcast-ssid disable
  end
```

For more information, see “Whether to broadcast SSID” on page 785.

Each Virtual AP that you create is a wireless interface that establishes a wireless LAN. Go to *System* > *Network* > *Interfaces* to configure its IP address.

To configure a virtual access point (SSID) - CLI

This example creates an access point with SSID “example” and WPA2-Personal security. The wireless interface is named example_wlan.

```
config wireless-controller vap
  edit example_wlan
    set ssid "example"
    set broadcast-ssid enable
    set security wpa2-only-personal
    set passphrase "hardtoguess”
    set vdom root
  end
config system interface
  edit example_wlan
    set ip 10.10.120.1 255.255.255.0
  end
```

Configuring DHCP for WiFi clients

Wireless clients need to have IP addresses. If you use RADIUS authentication, each user's IP address can be stored in the Framed-IP-Address attribute. Otherwise, you need to configure a DHCP server on the WLAN interface to assign IP addresses to wireless clients.

To configure a DHCP server for WiFi clients - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID entry.
2. In the *WiFi Settings* section, enable *DHCP Server*.
3. In *Address Range*, select *Create New*.
4. In the *Starting IP* and *End IP* fields, enter the IP address range to assign.

   The address range needs to be in the same subnet as the wireless interface IP address, but not include that address.
5. Set the *Netmask* to an appropriate value, such as 255.255.255.0.
6. Set the *Default Gateway* to *Same as Interface IP*.
7. Set the *DNS Server* to *Same as System DNS*.
8. If you want to restrict access to the wireless network by MAC address, see "Adding a MAC filter" on page 804.
9. Select *OK*.

To configure a DHCP server for WiFi clients - CLI

In this example, WiFi clients on the example_wlan interface are assigned addresses in the 10.10.120.2-9 range to connect with the WiFi access point on 10.10.120.1.

```
config system dhcp server
  edit 0
    set default-gateway 10.10.120.1
    set dns-service default
    set interface example_wlan
    set netmask 255.255.255.0
    config ip-range
      edit 1
        set end-ip 10.10.120.9
        set start-ip 10.10.120.2
      end
    end
```

You cannot delete an SSID (wireless interface) that has DHCP enabled on it.

Configuring security

Using the web-based manager, you can configure Open Portal security or Wi-Fi Protected Access (WPA) security modes WPA-Personal and WPA-Enterprise. The WPA options support both WPA and WPA2, which has additional security improvements. Using the CLI, you can also choose WPA-only and WPA2-only modes.

Using the CLI, you can also choose Wireless Equivalent Privacy (WEP) modes. WEP modes are much less secure and are provided for legacy support only. Wherever possible, use WPA security.

WPA security with a preshared key for authentication is called WPA-Personal. This can work well for one person a small group of trusted people. But, as the number of users increases, it is difficult to distribute new keys securely and there is increased risk that the key could fall into the wrong hands.

A more secure form of WPA security is WPA-Enterprise. Users each have their own authentication credentials, verified through an authentication server, usually RADIUS. FortiOS can also authenticate WPA-Enterprise users through its built-in user group functionality. FortiGate user groups can include RADIUS servers and can select users by RADIUS user group. This makes possible Role-Based Access Control (RBAC).

WPA security can encrypt communication with either Temporal Key Integrity Protocol (TKIP) or Advanced Encryption Standard (AES). AES is the preferred encryption, but some older wireless clients do not support it. You can select the encryption during setup.

Captive Portal security connects users to an open web portal defined in replacement messages. To navigate to any location beyond the web portal, the user must pass FortiGate user authentication.

WPA-Personal security

WPA-Personal security setup requires only the preshared key that you will provide to your clients.

To configure WPA-Personal security - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID entry.
2. In *Security Mode*, select *WPA/WPA2-Personal*.
3. In *Data Encryption*, select *AES*.

   If some of your wireless clients do not support AES, select TKIP.
4. In *Pre-shared Key*, enter a key between 8 and 63 characters long.
5. Select *OK*.

To configure WPA-Personal security - CLI

```
config wireless-controller vap
  edit example_wlan
    set security wpa-personal
    set passphrase "hardtoguess"
    set encrypt AES
  end
```

WPA-Enterprise security

If you will use FortiOS user groups for authentication, go to *User & Device* > *User* > *User Group* and create those groups first. The groups should be Firewall groups.

If you will use a RADIUS server to authenticate wireless clients, you must first configure the FortiGate unit to access the RADIUS server.

To configure FortiGate unit access to the RADIUS server - web-based manager

1. Go to *User & Device* > *Authentication* > *RADIUS Server* and select *Create New*.
2. Enter a *Name* for the server.
3. In *Primary Server Name/IP*, enter the network name or IP address for the server.

4. In *Primary Server Secret*, enter the shared secret used to access the server.
5. Optionally, enter the information for a secondary or backup RADIUS server.
6. Select *OK*.

To configure the FortiGate unit to access the RADIUS server - CLI

```
config user radius
  edit exampleRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret aoewmntiasf
  end
```

To configure WPA-Enterprise security - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID entry.
2. In *Security Mode*, select *WPA/WPA2-Enterprise*.
3. In *Data Encryption*, select *AES*.

   If some of your wireless clients do not support AES, select TKIP.
4. In *Authentication*, do one of the following:
   - If you will use a RADIUS server for authentication, select *RADIUS* Server and then select the RADIUS server.
   - If you will use a local user group for authentication, select *Usergroup* and then select the user group that is permitted to use the wireless network.
5. Select *OK*.

To configure WPA-Enterprise security - CLI

```
config wireless-controller vap
  edit example_wlan
    set security wpa-enterprise
    set encrypt AES
    set auth radius
    set radius-server exampleRADIUS
  end
```

Captive Portal security

Captive Portal security provides an access point that initially appears open. The wireless client can connect to the AP with no security credentials. The AP responds to the client's first HTTP request with a web page requesting user name and password. Until the user enters valid credentials, no communication beyond the AP is permitted.

The wireless controller authenticates users through the FortiGate user accounts. In the SSID configuration, you select the user groups that are permitted access through the captive portal.

The captive portal contains the following web pages:

- **Login page**—requests user credentials
- **Login failed page**—reports that the entered credentials were incorrect and enables the user to try again.
- **Disclaimer page**—is a statement of the legal responsibilities of the user and the host organization to which the user must agree before proceeding.
- **Declined disclaimer page**—is displayed if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

These pages are defined in replacement messages. Defaults are provided. In the web-based manager, you can modify the default messages in the SSID configuration by selecting *Customize Portal Messages*. Each SSID can have its own unique portal content.

To configure Captive Portal security - web-based manager

1. Configure user groups as needed in *User & Device* > *User* > *User Groups*.
2. Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID entry.
3. In *Security Mode*, select *Captive Portal*.
4. Optionally, select *Customize Portal Messages* and modify the portal pages that users of this SSID will see.
5. In *User Groups*, select the group(s) that are allowed to use the wireless network and move them to the *Selected* list.
6. Select *OK*.

Adding a MAC filter

On each SSID, you can create a MAC address filter list to either permit or exclude a list of clients identified by their MAC addresses.

This is actually not as secure as it appears. Someone seeking unauthorized access to your network can obtain MAC addresses from wireless traffic and use them to impersonate legitimate users. A MAC filter list should only be used in conjunction with other security measures such as encryption.

To configure a MAC filter - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID entry.
2. In the *DHCP Server* section, expand Advanced.
3. In *MAC Address Access Control List*, select *Create New*.
4. Enter a MAC address In the *MAC* field.
5. Double-click in *IP or Action*, and do one of:
   - Select *Reserve IP* and enter the IP address to assign to this MAC address.
   - Select *Assign IP*. This MAC address will be assigned an IP address automatically.
   - Select *Block*. This MAC address will not be assigned an IP address.
6. Double-click in the Unknown MAC Addresses line and select Assign IP or Block, as needed.

   By default, unlisted MAC addresses are assigned an IP address automatically.
7. Repeat steps 3 through 6 for each additional MAC address that you want to add.
8. Select OK.

To configure a MAC filter - CLI

1. Enter

```
config system dhcp server
show
```

2. Find the entry where `interface` is your WiFi interface. Edit that entry and configure the MAC filter. In this example, the MAC address 11:11:11:11:11:11will be excluded. Unlisted MAC addresses will be assigned an IP address automatically.

```
edit 3
  config reserved-address
    edit 1
      set action block
      set mac 11:11:11:11:11:11
    end
  set mac-acl-default-action assign
end
```

Multicast enhancement

FortiOS can translate multicast traffic into unicast traffic to send to clients, maintaining its own multicast client through IGMP snooping. You can configure this in the CLI:

```
config wireless-controller vap
  edit example_wlan
    set multicast-enhance enable
    set me-disable-thresh 32
  end
```

If the number of clients on the SSID is larger than `me-disable-thresh`, multicast enhancement is disabled.

Dynamic VLAN assignment

You can assign each individual user to a VLAN based on information stored in the RADIUS authentication server. If the user's RADIUS record does not specify a VLAN ID, the user is assigned to the default VLAN for the SSID.

The RADIUS user attributes used for the VLAN ID assignment are:

IETF 64 (Tunnel Type)—Set this to VLAN.

IETF 65 (Tunnel Medium Type)—Set this to 802

IETF 81 (Tunnel Private Group ID)—Set this to the VLAN ID.

To configure dynamic VLAN assignment, you need to:

1. Configure access to the RADIUS server.
2. Create the SSID and enable dynamic VLAN assignment.
3. Create a custom AP profile and add the local bridge mode SSID to it.
4. Create the VLAN interfaces and their DHCP servers.
5. Create security policies to allow communication from the VLAN interfaces to the Internet.
6. Authorize the FortiAP unit and assign the custom profile to it.

To configure access to the RADIUS server

1. Go to *User & Device* > *Authentication* > *RADIUS Server* and select *Create New*.
2. Enter a Name, the name or IP address in Primary Server Name/IP, and the server secret in Primary Server Secret.

To create the dynamic VLAN SSID

1. Go to WiFi Controller > WiFi Network > SSID, select Create New and enter:

Name	An identifier, such as dynamic_vlan_ssid.
Traffic Mode	Local bridge or Tunnel, as needed.
SSID	An identifier, such as DYNSSID.
Security Mode	WPA/WPA2-Enterprise
Authentication	RADIUS Server. Select the RADIUS server that you configured.

2. Select OK.
3. Enable dynamic VLAN in the CLI. Optionally, you can also assign a VLAN ID to set the default VLAN for users without a VLAN assignment.

```
config wireless-controller vap
  edit dynamic_vlan_ssid
    set dynamic-vlan enable
    set vlanid 10
  end
```

To create the custom AP profile for the dynamic VLAN SSID

1. Go to *WiFi Controller* > *WiFi Network* > *Custom AP Profile*, select Create New and enter:

Name	A name for the profile, such as dyn_vlan_profile.
Platform	The FortiAP model you are using. If you use more than one model of FortiAP, you will need a custom AP profile for each model.
Radio 1 and Radio 2	
SSID	In the *Available* column, select the SSID you created (example dynamic_vlan_ssid) and move it to the *Selected* column. There should be no other SSIDs in the *Selected* column.

2. Adjust other radio settings as needed.
3. Select OK.

To create the VLAN interfaces

1. Go to *System* > *Network* > *Interfaces* and select *Create New*.
2. Enter:

Name	A name for the VLAN interface, such as VLAN100.
Interface	The physical interface associated with the VLAN interface.
VLAN ID	The numeric VLAN ID, for example 100.
Addressing mode	Select Manual and enter the IP address / Network Mask for the virtual interface.
DHCP Server	Enable and then select Create New to create an address range.

3. Select OK.
4. Repeat the preceding steps to create other VLANs as needed.

Security policies determine which VLANs can communicate with which other interfaces. These are the simple Firewall Address policy without authentication. Users are assigned to the appropriate VLAN when they authenticate.

To connect and authorize the FortiAP unit

1. Connect the FortiAP unit to the FortiGate unit.
2. Go to *WiFi Controller* > *Managed Access Points* > *Managed AP*.
3. When the FortiAP unit is listed, double-click the entry to edit it.
4. In *AP Profile*, select *Change*, then select the custom profile that you created. Select *Apply*.
5. Select Authorize.
6. Select OK.

Configuring user authentication

You can perform user authentication when the wireless client joins the wireless network and when the wireless user communicates with another network through a firewall policy. WEP and WPA-Personal security rely on legitimate users knowing the correct key or passphrase for the wireless network. The more users you have, the more likely it is that the key or passphrase will become known to unauthorized people. WPA-Enterprise and captive portal security provide separate credentials for each user. User accounts can be managed through FortiGate user groups or an external RADIUS authentication server.

WPA-Enterprise authentication

If your WiFi network uses WPA-Enterprise authentication verified by a RADIUS server, you need to configure the FortiGate unit to connect to that RADIUS server.

Configuring connection to a RADIUS server - web-based manager

1. Go to *User & Device* > *Authentication* > *RADIUS Server* and select *Create New*.
2. Enter a *Name* for the server.

   This name is used in FortiGate configurations. It is not the actual name of the server.
3. In *Primary Server Name/IP*, enter the network name or IP address for the server.
4. In *Primary Server Secret*, enter the shared secret used to access the server.
5. Optionally, enter the information for a secondary or backup RADIUS server.
6. Select *OK*.

To configure the FortiGate unit to access the RADIUS server - CLI

```
config user radius
  edit exampleRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret aoewmntiasf
  end
```

To implement WPA-Enterprise security, you select this server in the SSID security settings. See “Configuring security” on page 801.

To use the RADIUS server for authentication, you can create individual FortiGate user accounts that specify the authentication server instead of a password, and you then add those accounts to a user group. Or, you can add the authentication server to a FortiGate user group, making all accounts on that server members of the user group.

Creating a wireless user group

Most wireless networks require authenticated access. To enable creation of identity-based firewall policies, you should create at least one user group for your wireless users. You can add or remove users later. There are two types of user group to consider:

- A Firewall user group can contain user accounts stored on the FortiGate unit or external authentication servers such as RADIUS that contain and verify user credentials.
- A Directory Services user group is used for integration with Windows Active Directory or Novell eDirectory. The group can contain Windows or Novell user groups who will be permitted access to the wireless LAN. Fortinet Single Sign On (FSSO) agent must be installed on the network.

MAC-based authentication

Wireless clients can also be supplementally authenticated by MAC address. A RADIUS server stores the allowed MAC address for each client and the wireless controller checks the MAC address independently of other authentication methods.

MAC-based authentication must be configured in the CLI. In the following example, MAC-based authentication is added to an existing access point “vap1” to use a RADIUS server at 192.168.1.95:

```
config wireless-controller vap
  edit vap1
    set radius-mac-auth enable
    set radius-mac-auth-server 192.168.1.95
  end
```

Authenticating guest WiFi users

The FortiOS Guest Management feature enables you to easily add guest accounts to your FortiGate unit. These accounts are authenticate guest WiFi users for temporary access to a WiFi network managed by a FortiGate unit.

To implement guest access, you need to

1. Go to *User & Device* > *User* > *User Group* and create one or more guest user groups.
2. Go to *User & Device* > *User* > *Guest Management* to create guest accounts. You can print the guest account credentials or send them to the user as an email or SMS message.
3. Go to *WiFi Controller* > *WiFi Network* > *SSID* and configure your WiFi SSID to use captive portal authentication. Select the guest user group(s) that you created.

Guest users can log into the WiFi captive portal with their guest account credentials until the account expires. For more detailed information about creating guest accounts, see “Managing Guest Access” in the Authentication chapter of the this FortiOS Handbook.

Configuring firewall policies for the SSID

For users on the WiFi LAN to communicate with other networks, firewall policies are required. Before you create firewall policies, you need to define any firewall addresses you will need. This section describes creating a WiFi network to Internet policy.

To create a firewall address for WiFi users - web-based manager

1. Go to *Firewall Objects* > *Address* > *Addresses*.
2. Select *Create New*, enter the following information and select *OK*.

Name	Enter a name for the address, wifi_net for example.
Type	Select *Subnet.*
Subnet / IP Range	Enter the subnet address, 10.10.110.0/24 for example.
Interface	Select the interface where this address is used, e.g., example_wifi

To create a firewall address for WiFi users - CLI

```
config firewall address
  edit "wifi_net"
    set associated-interface "example_wifi"
    set subnet 10.10.110.0 255.255.255.0
  end
```

To create a firewall policy - web-based manager

1. Go to *Policy* > *Policy* > *Policy* and select *Create New*.
2. In *Incoming Interface*, select the wireless interface.
3. In *Source Address*, select the address of your WiFi network, wifi_net for example.
4. In *Outgoing Interface*, select the Internet interface, for example, *port1*.
5. In *Destination Address*, select *All*.
6. In *Service*, select ALL, or select the particular services that you want to allow, and then select the right arrow button to move the service to the *Selected Services* list.
7. In *Schedule*, select *always*, unless you want to define a schedule for limited hours.
8. In *Action*, select ACCEPT.
9. Select *Enable NAT.*
10. Optionally, set up UTM features for wireless users.
11. Select *OK*.

To create a firewall policy - CLI

```
config firewall policy
  edit 0
    set srcintf "example_wifi"
    set dstintf "port1"
    set srcaddr "wifi_net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
  end
```

Customizing captive portal pages

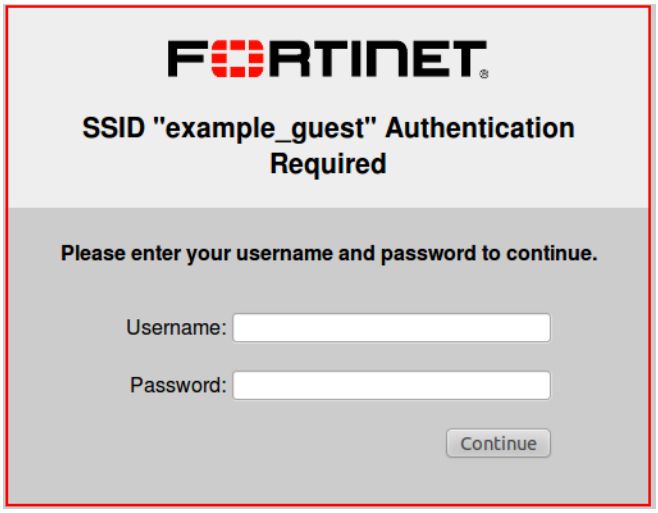
If you select Captive Portal authentication in the SSID, the wireless controller presents the user pages defined in Captive Portal Default replacement pages.

The captive portal contains the following web pages:

- **Captive Portal Login page**—requests user credentials
- **Captive Portal Login Failed page**—reports that the entered credentials were incorrect and enables the user to try again.
- **Captive Portal Disclaimer page**—is statement of the legal responsibilities of the user and the host organization to which the user must agree before proceeding.
- **Captive Portal Rejected page**—is displayed if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

These pages are defined in replacement messages. Defaults are provided. In the web-based manager, you can modify the default messages in the SSID configuration by selecting *Customize Portal Messages*. Each SSID can have its own unique portal content.

Figure 157: Default captive portal login page



Modifying the login page

The login page requests the user's credentials. Typical modifications for this page would be to change the logo and modify some of the text.

Changing the logo

You can replace the default Fortinet logo with your organization's logo. First, import the logo file into the FortiGate unit and then modify the Login page code to reference your file.

To import a logo file

1. Go to *System* > *Config* > *Replacement Messages* and select *Manage Images*.
2. Select *Create New*.
3. Enter a *Name* for the logo and select the appropriate *Content Type*.

   The file must not exceed 6000 bytes.
4. Select *Browse*, find your logo file and then select *Open*.
5. Select *OK*.

To specify the new logo in the replacement message

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID.

   The SSID *Security Mode* must be *Captive Portal*.
2. Make sure that *Customize Portal Messages* is selected and then select the adjacent Edit icon.
3. In the *Edit Message* window, select the *Login page* message.
4. In the Message HTML, find the %%IMAGE tag.

   By default it specifies the Fortinet logo:%%IMAGE:logo_fw_auth%%
5. Change the image name to the one you provided for your logo.

   The tag should now read, for example, %%IMAGE:mylogo%%
6. Select *OK*.

Modifying text

You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters. There are two exceptions to this rule:

- The line “Please enter your username and password to continue” is provided by the %%QUESTION%% tag. You can replace this tag with text of your choice.
- The line “SSID ... Authentication Required” includes the name of the SSID, provided by the %%CPAUTH_SSID%% tag. You can remove or change the position of this tag.

Except for these items, you should not remove any tags because they may carry information that the FortiGate unit needs.

To modify login page text

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and edit your SSID.

   The SSID *Security Mode* must be *Captive Portal*.
2. Make sure that *Customize Portal Messages* is selected and then select the adjacent Edit icon.
3. In the *Edit Message* window, select the *Login page* message.
4. In the *Message HTML* box, edit the text, then select *OK*.
5. Select *OK*.

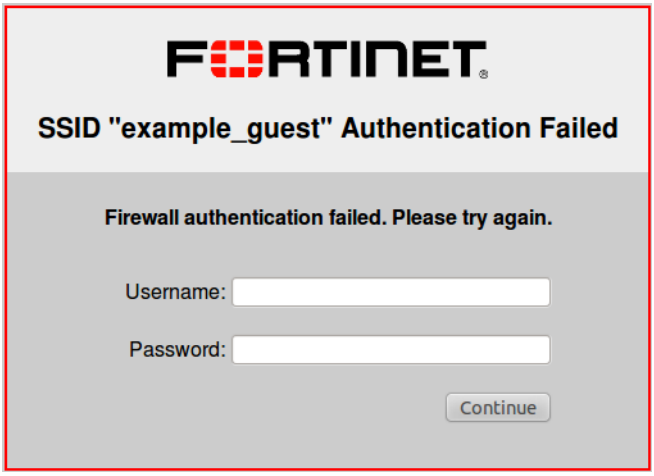
Modifying the login failed page

The Login failed page is similar to the Login page. It even contains the same login form. You can change any text that is not part of the HTML code nor a special tag enclosed in double percent (%) characters. There are two exceptions to this rule:

- The line “Firewall authentication failed. Please try again.” is provided by the %%FAILED_MESSAGE%% tag. You can replace this tag with text of your choice.
- The line “SSID ... Authentication Required” includes the name of the SSID, provided by the %%CPAUTH_SSID%% tag. You can remove or change the position of this tag.

Except for these items, you should not remove any tags because they may carry information that the FortiGate unit needs.

Figure 158: Default login failed page



Configuring the built-in access point on a FortiWiFi unit

Both FortiGate and FortiWiFi units have the WiFi controller feature. If you configure a WiFi network on a FortiWiFi unit, you can also use the built-in wireless capabilities in your WiFi network as one of the access points.

If Virtual Domains are enabled, you must select the VDOM to which the built-in access point belongs. You do this in the CLI. For example:

```
config wireless-controller global
  set local-radio-vdom vdom1
end
```

To configure the FortiWiFi unit's built-in WiFi access point

1. Go to *WiFi Controller* > *Managed Access Points* > *Local WiFi Radio*.
2. Make sure that *AP Profile* is *Automatic*.
3. Make sure that *Enable WiFi Radio* is selected.
4. In *SSID*, if you do not want this AP to carry all SSIDs, select *Select SSIDs* and then select the required SSIDs.
5. Optionally, adjust the *TX Power* slider.

   If you have selected your location correctly (see "Setting your geographic location" on page 795), the 100% setting corresponds to the maximum power allowed in your region.
6. If you do not want the built-in WiFi radio to be used for rogue scanning, select *Do not participate in Rogue AP scanning*.
7. Select *OK*.

If you want to connect external APs, such as FortiAP units, see the next chapter, "Access point deployment".

Access point deployment

This chapter describes how to configure access points for your wireless network. The following topics are included in this section:

Overview

FortiAP units discover WiFi controllers. The administrator of the WiFi controller authorizes the FortiAP units that the controller will manage.

In most cases, FortiAP units can find WiFi controllers through the wired Ethernet without any special configuration. Review the following section, "Network topology for managed APs", to make sure that your method of connecting the FortiAP unit to the WiFi controller is valid. Then, you are ready to follow the procedures in "Discovering and authorizing APs" on page 815.

If your FortiAP units are unable to find the WiFi controller, refer to "Advanced WiFi controller discovery" on page 820 for detailed information about the FortiAP unit's controller discovery methods and how you can configure them.

Network topology for managed APs

The FortiAP unit can be connected to the FortiGate unit in any of the following ways:

Direct connection: The FortiAP unit is directly connected to the FortiGate unit with no switches between them. This configuration is common for locations where the number of FortiAP's matches up with the number of 'internal' ports available on the FortiGate. In this configuration the FortiAP unit requests an IP address from the FortiGate unit, enters discovery mode and should quickly find the FortiGate WiFi controller. This is also known as a wirecloset deployment. See Figure 159, below.

Switched Connection: The FortiAP unit is connected to the FortiGate WiFi controller by an Ethernet switch operating in L2 switching mode or L3 routing mode. There must be a routable path between the FortiAP unit and the FortiGate unit and ports 5246 and 5247 must be open. This is also known as a gateway deployment. See Figure 159, below

Connection over WAN: The FortiGate WiFi controller is off-premises and connected by a VPN tunnel to a local FortiGate. In this method of connectivity its best to configure each FortiAP with the static IP address of the WiFi controller. Each FortiAP can be configured with three WiFi controller IP addresses for redundant failover. This is also known as a datacenter remote management deployment. See Figure 160, below.

Figure 159: Wirecloset and Gateway deployments

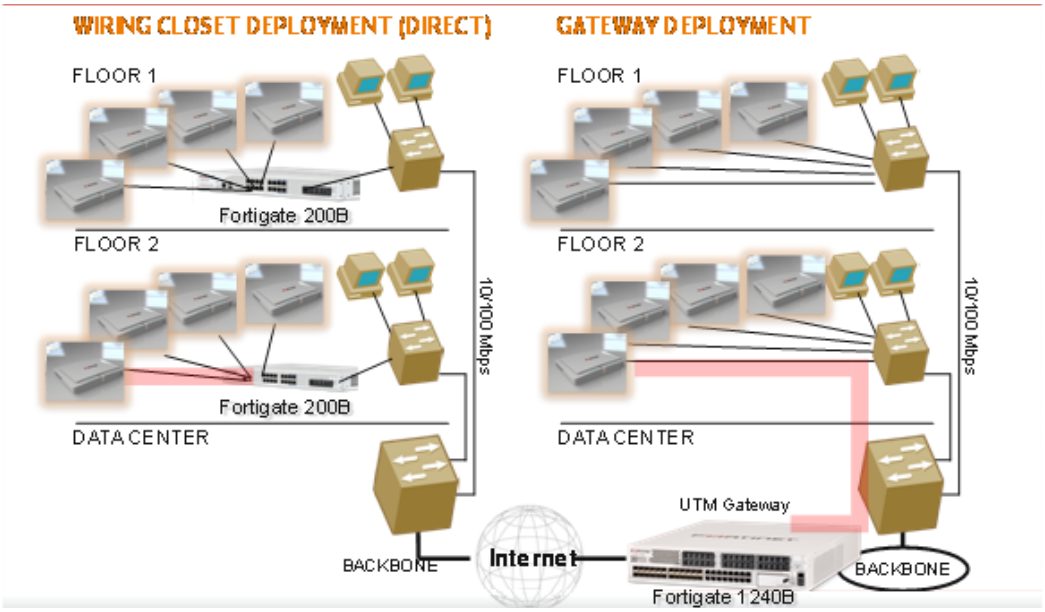


Figure 160: Remote deployment

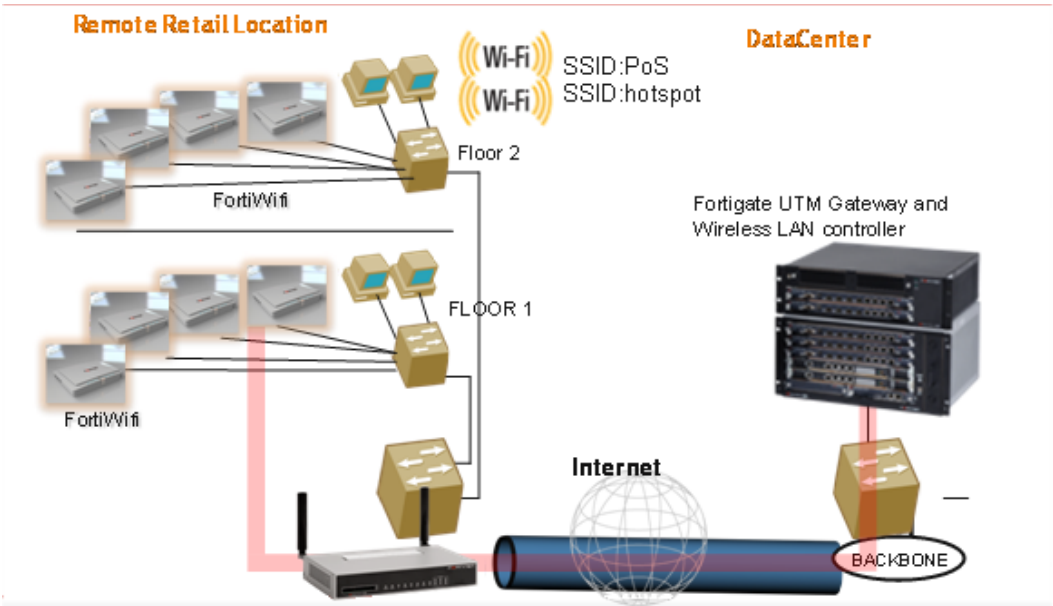


Discovering and authorizing APs

After you prepare your FortiGate unit, you can connect your APs to discover them using the discovery methods described earlier. To prepare the FortiGate unit, you need to

- Configure the network interface to which the AP will connect.
- Configure DHCP service on the interface to which the AP will connect.
- Optionally, preauthorize FortiAP units. They will begin to function when connected.
- Connect the AP units and let the FortiGate unit discover them.
- Enable each discovered AP and configure it or assign it to an AP profile.

Configuring the network interface for the AP unit

The interface to which you connect your wireless access point needs an IP address. No administrative access, DNS Query service or authentication should be enabled.

To configure the interface for the AP unit - web-based manager

1. Go to *System* > *Network* > *Interfaces* and edit the interface to which the AP unit connects.
2. Set *Addressing Mode* to *Dedicate to FortiAP.*
3. Enter the IP address and netmask to use.

   This FortiGate unit automatically configures a DHCP server on the interface that will assign the remaining higher addresses up to .254 to FortiAP units. For example, if the IP address is 10.10.1.100, the FortiAP units will be assigned 10.10.1.101 to 10.10.1.254. To maximize the available addresses, use the .1 address for the interface: 10.10.1.1, for example.
4. Select OK.

To configure the interface for the AP unit - CLI

In the CLI, you must configure the interface IP address and DHCP server separately.

```
config system interface
  edit port3
    set mode static
    set ip 10.10.70.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set interface "dmz"
    config ip-range
      edit 1
        set end-ip 10.10.70.254
        set start-ip 10.10.70.2
      end
    set netmask 255.255.255.0
    set vci-match enable
    set vci-string "FortiAP"
  end
```

The optional `vci-match` and `vci-string` fields ensure that the DHCP server will provide IP addresses only to FortiAP units.

Pre-authorizing a FortiAP unit

If you enter the FortiAP unit information in advance, it is authorized and will begin to function when it is connected.

To pre-authorize a FortiAP unit

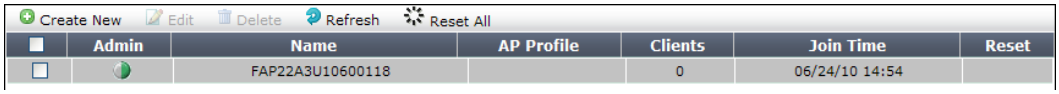
1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAPs* and select *Create New*.

   On some models the *WiFi Controller* menu is called *WiFi & Switch Controller*.
2. Enter the *Serial Number* of the FortiAP unit.
3. Configure the *Wireless Settings* as required.
4. Select *OK*.

Enabling and configuring a discovered AP

Within two minutes of connecting the AP unit to the FortiGate unit, the discovered unit should be listed on *WiFi Controller* > *Managed Access Points* > *Managed FortiAP* page.

Figure 161: Discovered access point unit



When you authorize (enable) a FortiAP unit, it is configured by default to

- use the Automatic profile
- operate at the maximum radio power permitted in your region
- carry all SSIDs

You can change the radio power and selection of SSIDs or assign the unit to a custom AP profile which defines the entire configuration for the AP.

To add and configure the discovered AP unit - web-based manager

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.

   This configuration also applies to local WiFi radio on FortiWiFi models.
2. Select the FortiAP unit from the list and edit it.
3. Optionally, enter a *Name*. Otherwise, the unit will be identified by serial number.
4. Select *Authorize*.
5. If you want to use the Automatic profile, adjust its settings if needed:

Enable WiFi Radio	This must be selected to enable operation of this AP.
SSID	**Automatically Inherit all SSIDs** — AP will carry all WiFi networks. **Select SSIDs** — select individual SSIDs for this AP to carry.
Auto TX Power Control	If you enable automatic transmitter power control, adjust TX Power Low and TX Power High to set the power range.
Tx Power	If you are not using automatic power control, adjust AP transmitter power. The 100% setting is the maximum permitted in your country. See "Setting your geographic location" on page 795

6. If you want to use a custom AP profile, in *AP Profile* select *Change*, choose the AP Profile. Select *Apply*.
7. Optionally, select *Do not participate in Rogue AP scanning* if scanning adversely affects traffic.
8. Select *OK*.

The physical access point is now added to the system. If the rest of the configuration is complete, it should be possible to connect to the wireless network through the AP.

To add the discovered AP unit - CLI

First get a list of the discovered access point unit serial numbers:

```
get wireless-controller wtp
```

Add a discovered unit and associate it with AP-profile1, for example:

```
config wireless-controller wtp
  edit FAP22A3U10600118
    set admin enable
    set wtp-profile AP-profile1
  end
```

To use the automatic profile, leave the `wtp-profile` field unset.

To modify settings within the Automatic profile - CLI

When `wtp-profile` is unset (null value), the Automatic profile is in use and some of its settings can be adjusted. This example sets the AP to carry only the employee and guest SSIDs and operate at 80% of maximum power.

```
config wireless-controller wtp
  edit FAP22A3U10600118
    set radio-enable enable
    set vap-all disable
    set vaps employee guest
    set power-level 80
  end
```

To select a custom AP profile - CLI

```
config wireless-controller wtp
  edit FAP22A3U10600118
    set wtp-profile AP-profile1
  end
```

To select automatic AP profile - CLI

```
config wireless-controller wtp
  edit FAP22A3U10600118
    unset wtp-profile
  end
```

To view the status of the added AP unit

```
config wireless-controller wtp
  edit FAP22A3U10600118
  get
```

The `join-time` field should show a time, not “N/A”. See the preceding web-based manager procedure for more information.

Assigning the same profile to multiple FortiAP units

The same profile can now be applied to multiple managed FortiAP units at the same time. To do this, do the following:

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAPs* to view the AP list.
2. Select all FortiAP units you wish to apply the profile to.
3. Right click on one of the selected FortiAPs and select *Assign Profile*.
4. Choose the profile you wish to apply.

Checking and updating FortiAP unit firmware

You can view and update the FortiAP unit's firmware from the FortiGate unit that acts as its WiFi controller.

Checking the FortiAP unit firmware version

Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP* to view the list of FortiAP units that the FortiGate unit can manage. The *OS Version* column shows the current firmware version running on each AP.

Updating FortiAP firmware from the FortiGate unit

You can update the FortiAP firmware using either the web-based manager or the CLI. Only the CLI method can update all FortiAP units at once.

To update FortiAP unit firmware - web-based manager

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.
2. Select the FortiAP unit from the list and edit it.
3. In *FortiAP OS Version*, select *[Upgrade]*.
4. Select *Browse* and locate the firmware upgrade file.
5. Select *OK*.
6. When the upgrade process completes, select *OK*.

   The FortiAP unit restarts.

To update FortiAP unit firmware - CLI

1. Upload the FortiAP image to the FortiGate unit.

   For example, the Firmware file is FAP_22A_v4.3.0_b0212_fortinet.out and the server IP address is 192.168.0.100.

   ```
   execute wireless-controller upload-wtp-image tftp
        FAP_22A_v4.3.0_b0212_fortinet.out 192.168.0.100
   ```

   If your server is FTP, change `tftp` to `ftp`, and if necessary add your user name and password at the end of the command.
2. Verify that the image is uploaded:

   ```
   execute wireless-controller list-wtp-image
   ```
3. Upgrade the FortiAP units:

   ```
   exec wireless-controller reset-wtp all
   ```

   If you want to upgrade only one FortiAP unit, enter its serial number instead of `all`.

Updating FortiAP firmware from the FortiAP unit

You can connect to a FortiAP unit's internal CLI to update its firmware from a TFTP server on the same network. This method does not require access to the wireless controller.

1. Place the FortiAP firmware image on a TFTP server on your computer.
2. Connect the FortiAP unit to a separate private switch or hub or directly connect to your computer via a cross-over cable.
3. Change your computer's IP address to 192.168.1.3.
4. Telnet to IP address 192.168.1.2.

   This IP address is overwritten if the FortiAP is connected to a DHCP environment. Ensure that the FortiAP unit is in a private network with no DHCP server.
5. Login with the username "admin" and no password.

6. Enter the following command.

   For example, the FortiAP image file name is FAP_22A_v4.3.0_b0212_fortinet.out.

   ```
   restore FAP_22A_v4.3.0_b0212_fortinet.out 192.168.1.3
   ```

Advanced WiFi controller discovery

A FortiAP unit can use any of four methods to locate a controller. By default, FortiAP units cycle through all four of the discovery methods. In most cases there is no need to make configuration changes on the FortiAP unit.

There are exceptions. The following section describes the WiFi controller discovery methods in more detail and provides information about configuration changes you might need to make so that discovery will work.

Controller discovery methods

There are four methods that a FortiAP unit can use to discover a WiFi controller.

Static IP configuration

If FortiAP and the controller are not in the same subnet, broadcast and multicast packets cannot reach the controller. The admin can specify the controller's static IP on the AP unit. The AP unit sends a discovery request message in unicast to the controller. Routing must be properly configured in both directions.

To specify the controller's IP address on a FortiAP unit

```
cfg -a AC_IPADDR_1="192.168.0.1"
```

By default, the FortiAP unit receives its IP address by DHCP. If you prefer, you can assign the AP unit a static IP address.

To assign a static IP address to the FortiAP unit

```
cfg -a ADDR_MODE=STATIC
cfg -a AP_IPADDR="192.168.0.100"
cfg -a AP_NETMASK="255.255.255.0"
```

For information about connecting to the FortiAP CLI, see "Connecting to the FortiAP CLI" on page 821.

Broadcast request

The AP unit broadcasts a discovery request message to the network and the controller replies. The AP and the controller must be in the same broadcast domain. No configuration adjustments are required.

Multicast request

The AP unit sends a multicast discovery request and the controller replies with a unicast discovery response message. The AP and the controller do not need to be in the same broadcast domain if multicast routing is properly configured.

The default multicast destination address is 224.0.1.140. It can be changed through the CLI. The address must be same on the controller and AP. For information about connecting to the FortiAP CLI, see "Connecting to the FortiAP CLI" on page 821.

To change the multicast address on the controller

```
config wireless-controller global
  set discovery-mc-addr 224.0.1.250
end
```

To change the multicast address on a FortiAP unit

```
cfg -a AC_DISCOVERY_MC_ADDR="224.0.1.250"
```

For information about connecting to the FortiAP CLI, see "Connecting to the FortiAP CLI" on page 821.

DHCP

If you use DHCP to assign an IP address to your FortiAP unit, you can also provide the WiFi controller IP address at the same time. This is useful if the AP is located remotely from the WiFi controller and other discovery techniques will not work.

When you configure the DHCP server, configure Option 138 to specify the WiFi controller IP address. You need to convert the address into hexadecimal. Convert each octet value separately from left to right and concatenate them. For example, 192.168.0.1 converts to C0A80001.

If Option 138 is used for some other purpose on your network, you can use a different option number if you configure the AP units to match.

To change the FortiAP DHCP option code

To use option code 139 for example, enter

```
cfg -a AC_DISCOVERY_DHCP_OPTION_CODE=139
```

For information about connecting to the FortiAP CLI, see "Connecting to the FortiAP CLI" below.

Connecting to the FortiAP CLI

The FortiAP unit has a CLI through which some configuration options can be set.

To access the FortiAP unit CLI

1. Connect your computer to the FortiAP directly with a cross-over cable or through a separate switch or hub.
2. Change your computer's IP address to 192.168.1.3
3. Telnet to IP address 192.168.1.2.

   Ensure that FortiAP is in a private network with no DHCP server for the static IP address to be accessible.
4. Login with user name admin and no password.
5. Enter commands as needed.
6. Optionally, use the `passwd` command to assign an administrative password for better security.
7. Save the configuration by entering the following command:

   ```
   cfg -c .
   ```

8. Unplug the FortiAP and then plug it back in, in order for the configuration to take effect.

When a WiFi controller has taken control of the FortiAP unit, Telnet access to the FortiAP unit's CLI is no longer available.

Wireless client load balancing for high-density deployments

Wireless load balancing allows your wireless network to distribute wireless traffic more efficiently among wireless access points and available frequency bands. FortiGate wireless controllers support the following types of client load balancing:

- Access Point Hand-off - the wireless controller signals a client to switch to another access point.
- Frequency Hand-off - the wireless controller monitors the usage of 2.4GHz and 5GHz bands, and signals clients to switch to the lesser-used frequency.

Load balancing is not applied to roaming clients.

Access point hand-off

Access point handoff wireless load balancing involves the following:

- If the load on an access point (ap1) exceeds a threshold (of for example, 30 clients) then the client with the weakest signal will be signaled by wireless controller to drop off and join another nearby access point (ap2).
- When one or more access points are overloaded (for example, more than 30 clients) and a new client attempts to join a wireless network, the wireless controller selects the least busy access point that is closest to the new client and this access point is the one that responds to the client and the one that the client joins.

Frequency hand-off or band-steering

Encouraging clients to use the 5GHz WiFi band if possible enables those clients to benefit from faster interference-free 5GHz communication. The remaining 2.4GHz clients benefit from reduced interference.

The WiFi controller probes clients to determine their WiFi band capability. It also records the RSSI (signal strength) for each client on each band.

If a new client attempts to join the network, the controller looks up that client's MAC address in its wireless device table and determines if it's a dual band device. If it is not a dual band device, then its allowed to join. If it is a dual band device, then its RSSI on 5GHz is used to determine whether the device is close enough to an access point to benefit from movement to 5GHz frequency.

If both conditions of 1) dual band device and 2) RSSI value is strong, then the wireless controller does not reply to the join request of the client. This forces the client to retry a few more times and then timeout and attempt to join the same SSID on 5GHz. Once the Controller see this new request on 5GHz, the RSSI is again measured and the client is allowed to join. If the RSSI is below threshold, then the device table is updated and the controller forces the client to timeout again. A client's second attempt to connect on 2.4GHz will be accepted.

Configuration

From the web-based manager edit a custom AP profile and select *Frequency Handoff* and *AP Handoff* as required for each radio on the AP.

From the CLI, you configure wireless client load balancing thresholds for each custom AP profile. Enable access point hand-off and frequency hand-off separately for each radio in the custom AP profile.

```
config wireless-controller wtp-profile
  edit new-ap-profile
    set handoff-rssi <rssi_int>
    set handoff-sta-thresh <clients_int>
    config radio-1
      set frequency-handoff {disable | enable}
      set ap-handoff {disable | enable}
    end
    config radio-2
      set frequency-handoff {disable | enable}
      set ap-handoff {disable | enable}
    end
  end
```

Where:

- `handoff-rssi` is the RSSI threshold. Clients with a 5 GHz RSSI threshold over this value are load balanced to the 5GHz frequency band. Default is 25. Range is 20 to 30.
- `handoff-sta-thresh` is the access point handoff threshold. If the access point has more clients than this threshold it is considered busy and clients are changed to another access point. Default is 30, range is 5 to 25.
- `frequency-handoff` enable or disable frequency handoff load balancing for this radio. Disabled by default.
- `ap-handoff` enable or disable access point handoff load balancing for this radio. Disabled by default.

Frequency handoff must be enabled on the 5GHz radio to learn client capability.

LAN port options

Some FortiAP models have one or more ethernet interfaces marked LAN. These ports can provide wired network access. LAN ports are bridged to either the wired WAN interface or to one of the WiFi SSIDs that the FortiAP unit carries.

Bridging a LAN port with a FortiAP SSID

Bridging a LAN port with a FortiAP SSID combines traffic from both sources to provide a single broadcast domain for wired and wireless users.

In this configuration

- The IP addresses for LAN clients come from the DHCP server that serves the wireless clients.
- Traffic from LAN clients is bridged to the SSID's VLAN. Dynamic VLAN assignment for hosts on the LAN port is not supported.
- Wireless and LAN clients are on the same network and can communicate locally, via the FortiAP.
- Any host connected to the LAN port will be taken as authenticated. RADIUS MAC authentication for hosts on the LAN port is not supported.

For configuration instructions, aee "Configuring FortiAP LAN ports", below.

Bridging a LAN port with the WAN port

Bridging a LAN port with the WAN port enables the FortiAP unit to be used as a hub which is also an access point.

In this configuration

- The IP addresses for LAN clients come from the WAN directly and will typically be in the same range as the AP itself.
- All LAN client traffic is bridged directly to the WAN interface.
- Communication between wireless and LAN clients can only occur if a policy on the FortiGate unit allows it.

For configuration instructions, aee "Configuring FortiAP LAN ports", below.

Configuring FortiAP LAN ports

How you configure FortiAP LAN ports depends on whether you use the automatic AP profile or create custom AP profiles. The Automatic AP profile enables APs to be individually configured. Custom AP profiles are useful if you have multiple APs that are the same model and share the same configuration.

Configuring LAN ports for an FortiAP unit - web-based manager

If your FortiAP units use the automatic AP profile, you configure each individual unit's LAN ports after you connect it to the FortiGate unit and the FortiAP discovers the WiFi controller. The AP is then listed in the Managed FortiAPs list.

To configure a FortiAP unit's LAN ports - web-based manager

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAPs.*

   On FortiGate models 100D, 600C, 800C, and 1000C, go to *WiFi & Switch Controller* > *Managed Devices* > *Managed FortiAPs.*
2. Select the FortiAP unit from the list and select *Edit*.
3. In the *LAN Port* section, set *Mode* to *Bridge to* and select an SSID or *WAN Port* as needed.

   On some models with multiple LAN ports, you can set *Mode* to *Custom* and configure the LAN ports individually. Enable each port that you want to use and select an SSID or *WAN Port* as needed.
4. Select *OK*.

To configure a FortiAP unit's LAN ports - CLI

In this example, a FortiAP unit's configuration is modified to bridge the LAN port to the office SSID.

```
config wireless-controller wtp
  edit FAP11C3X13000412
    config lan
      set port-mode bridge-to-ssid
      set port-ssid office
    end
  end
```

In this example, a FortiAP-28C unit's configuration is modified to bridge LAN port1 to the office SSID and to bridge the other LAN ports to the WAN port.

```
config wireless-controller wtp
  edit FAP28C3X13000412
    config lan
      set port1-mode bridge-to-ssid
      set port1-ssid office
      set port2-mode bridge-to-wan
      set port3-mode bridge-to-wan
      set port4-mode bridge-to-wan
      set port5-mode bridge-to-wan
      set port6-mode bridge-to-wan
      set port7-mode bridge-to-wan
      set port8-mode bridge-to-wan
    end
  end
```

Configuring LAN ports in a custom AP profile - web-based manager

When multiple FortiAP units will have the same LAN port configuration, you can create a custom AP profile or edit the default profile for that model.

To configure FortiAP LAN ports in a custom AP profile - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *Custom AP Profiles*.
2. Either
   - Edit the default profile for your model,

   or
   - Select *Create New* and then in *Platform*, select your FortiAP model.
3. In the *LAN Port* section, set mode to *Bridge to* and select an SSID or *WAN Port* as needed.

   On some models with multiple LAN ports, you can select *Custom* to configure the ports individually. Enable each port that you want to use and select an SSID or *WAN Port* as needed.
4. Optionally, adjust other settings. See "Creating a custom AP Profile" on page 796.
5. Select *OK*.

To configure FortiAP LAN ports in a custom AP profile - CLI

In this example, the default FortiAP-11C profile is configured to bridge the LAN port to the office SSID.

```
config wireless-controller wtp-profile
  edit FAP11C-default
    config lan
      set port-mode bridge-to-ssid
      set port-ssid office
    end
  end
end
```

In this example, the default FortiAP-28C profile is configured to bridge LAN port1 to the office SSID and to bridge the other LAN ports to the WAN port.

```
config wireless-controller wtp-profile
  edit FAP28C-default
    config lan
      set port1-mode bridge-to-ssid
      set port1-ssid office
      set port2-mode bridge-to-wan
      set port3-mode bridge-to-wan
      set port4-mode bridge-to-wan
      set port5-mode bridge-to-wan
      set port6-mode bridge-to-wan
      set port7-mode bridge-to-wan
      set port8-mode bridge-to-wan
    end
  end
```

Preventing IP fragmentation of packets in CAPWAP tunnels

A common problem with controller-based WiFi networks is reduced performance due to IP fragmentation of the packets in the CAPWAP tunnel.

Fragmentation can occur because of CAPWAP tunnel overhead increasing packet size. If the original wireless client packets are close to the maximum transmission unit (MTU) size for the network (usually 1500 bytes for Ethernet networks unless jumbo frames are used) the resulting CAPWAP packets may be larger than the MTU, causing the packets to fragmented. Fragmented packets can result in data loss, jitter, and decreased throughput.

The FortiOS/FortiAP solution to this problem is to cause wireless clients to send smaller packets to FortiAP devices, resulting in1500-byte CAPWAP packets and no fragmentation. The following options configure CAPWAP IP fragmentation control:

```
config wireless-controller wtp
  edit new-wtp
    set ip-fragment-preventing {tcp-mss-adjust | icmp-unreachable}
    set tun-mtu-uplink {0 | 576 | 1500}
    set tun-mtu-downlink {0 | 576 | 1500}
  end
end
```

By default, `tcp-mss-adjust` is enabled, `icmp-unreachable` is disabled, and `tun-mtu-uplink` and `tun-mtu-downlink` are set to 0.

To set `tun-mtu-uplink` and `tun-mtu-downlink`, use the default TCP MTU value of 1500. This default configuration prevents packet fragmentation because the FortiAP unit limits the size of TCP packets received from wireless clients so the packets don’t have to be ed before CAPWAP encapsulation.

The `tcp-mss-adjust` option causes the FortiAP unit to limit the maximum segment size (MSS) of TCP packets sent by wireless clients. The FortiAP does this by adding a reduced MSS value to the SYN packets sent by the FortiAP unit when negotiating with a wireless client to establish a session. This results in the wireless client sending packets that are smaller than the `tun-mtu-uplink` setting, so that when the CAPWAP headers are added, the CAPWAP packets have an MTU that matches the `tun-mtu-uplink` size.

The `icmp-unreachable` option affects all traffic (UDP and TCP) between wireless clients and the FortiAP unit. This option causes the FortiAP unit to drop packets that have the "Don't Fragment" bit set in their IP header and that are large enough to cause fragmentation and then send an ICMP packet -- type 3 "ICMP Destination unreachable" with code 4 "Fragmentation Needed and Don't Fragment was Set" back to the wireless controller. This should cause the wireless client to send smaller TCP and UDP packets.

Wireless Mesh

The access points of a WiFi network are usually connected to the WiFi controller through Ethernet wiring. A wireless mesh eliminates the need for Ethernet wiring by connecting WiFi access points to the controller by radio. This is useful where installation of Ethernet wiring is impractical.

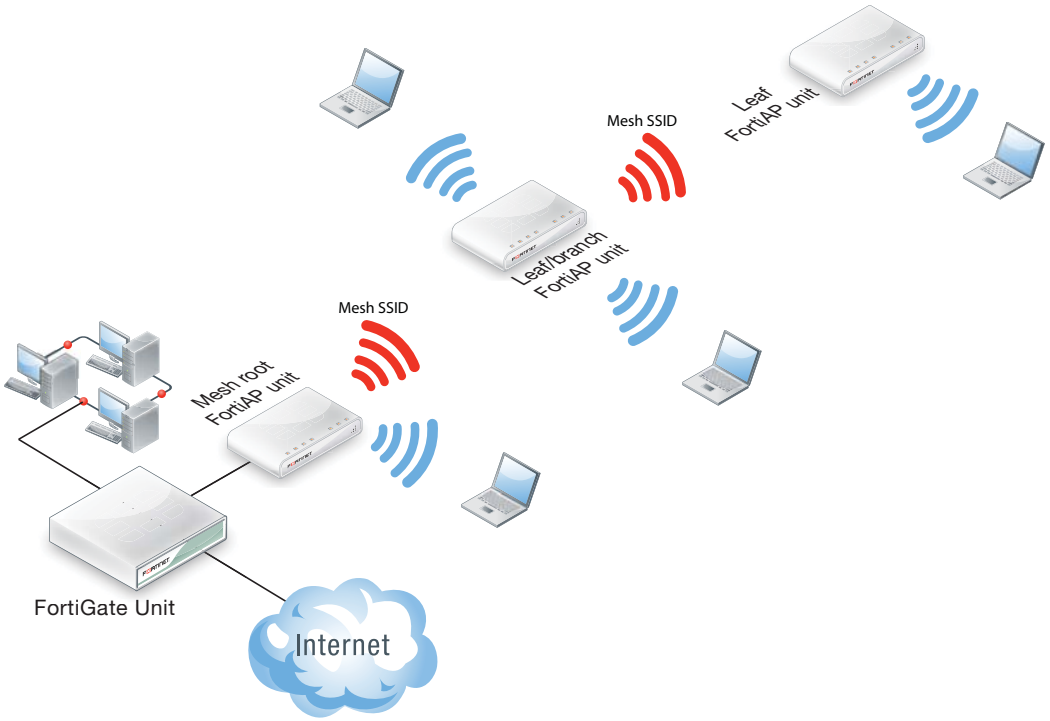
The following topics are included in this section:

- Overview of Wireless Mesh
- Configuring a meshed WiFi network
- Configuring a point-to-point bridge

Overview of Wireless Mesh

Figure 162 shows a wireless mesh topology.

Figure 162: Wireless mesh topology



The AP that is connected to the network by Ethernet is called the Mesh Root node. It is configured with an SSID (also called a virtual access point or VAP) dedicated to backhaul communication with the remote FortiAP units. The backhaul SSID carries CAPWAP discovery, configuration, and other communications that would usually be carried on an Ethernet connection. Regular WiFi clients cannot connect to the backhaul SSID. They connect to the regular SSIDs carried on the access points.

The root node can be a FortiAP unit or the built-in AP of a FortiWiFi unit. APs that serve only regular WiFi clients are called Leaf nodes. Leaf APs that also carry the mesh SSID for more distant Leaf nodes are called Leaf/branch nodes.

All access points in a wireless mesh configuration must have at least one of their radios configured to provide mesh backhaul communication. As with wired APs, when mesh APs start up they can be discovered by a FortiGate or FortiWiFi unit WiFi controller and authorized to join the network.

The backhaul SSID delivers the best performance when it is carried on a dedicated radio. On a two-radio FortiAP unit, for example, the 5GHz radio could carry only the backhaul SSID while the 2.4GHz radio carries one or more SSIDs that serve users. Background WiFi scanning is possible in this mode.

The backhaul SSID can also share the same radio with SSIDs that serve users. Performance is reduced because the backhaul and user traffic compete for the available bandwidth. Background WiFi scanning is not available in this mode. One advantage of this mode is that a two-radio AP can offer WiFi coverage on both bands.

The root mesh AP is the AP unit that has a wired Ethernet connection to the WiFi controller. The AP units that are wirelessly linked to the controller over the backhaul SSID are called branch or leaf APs.

Wireless mesh deployment modes

There are two common wireless mesh deployment modes:

Wireless Mesh	Access points are wirelessly connected to a FortiGate or FortiWiFi unit WiFi controller. WiFi users connect to wireless SSIDs in the same way as on non-mesh WiFi networks.
Wireless bridging	Two LAN segments are connected together over a wireless link (the backhaul SSID). On the leaf AP, the Ethernet connection can be used to provide a wired network. Both WiFi and wired users on the leaf AP are connected to the LAN segment to which the root AP is connected.

Firmware requirements

All FortiAP units that will be part of the wireless mesh network must be upgraded to FAP firmware version 5.0 build 003. FortiAP-222B units must have their BIOS upgraded to version 400012. The FortiWiFi or FortiGate unit used as the WiFi controller must be running FortiOS 5.0.

Types of wireless mesh

A WiFi mesh can provide access to widely-distributed clients. The root mesh AP which is directly connected to the WiFi controller can be either a FortiAP unit or the built-in AP of a FortiWiFi unit that is also the WiFi controller.

Figure 163: FortiAP units used as both mesh root AP and leaf AP

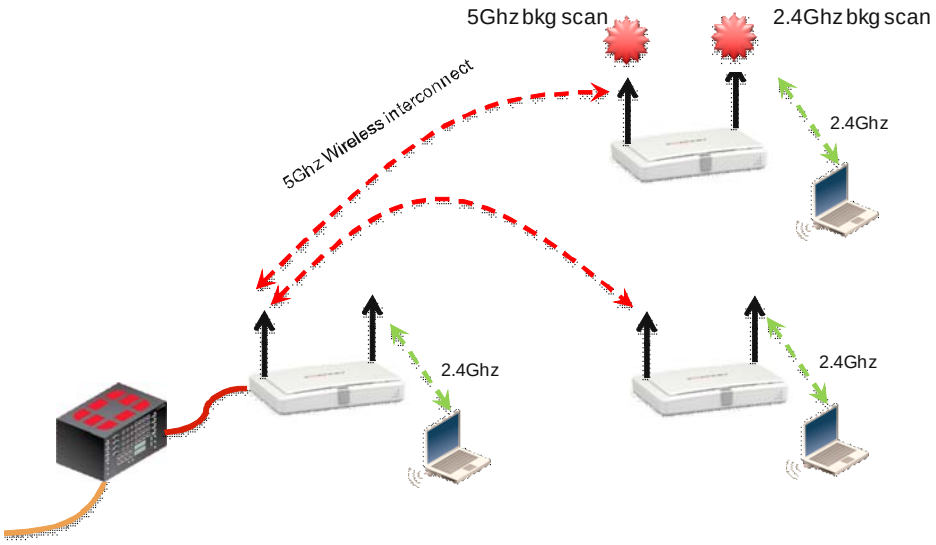


Figure 164: FortiWiFi unit as root mesh AP with FortiAP units as leaf APs

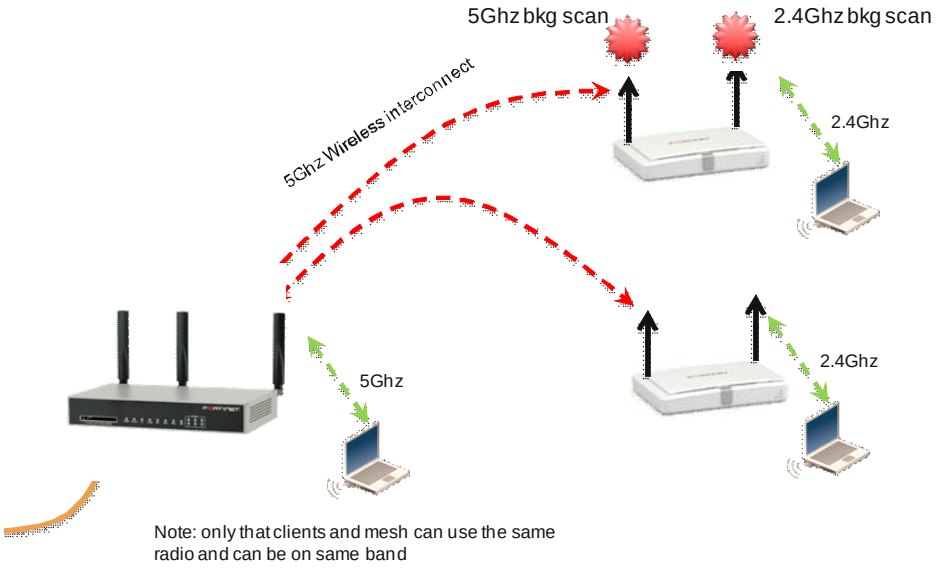
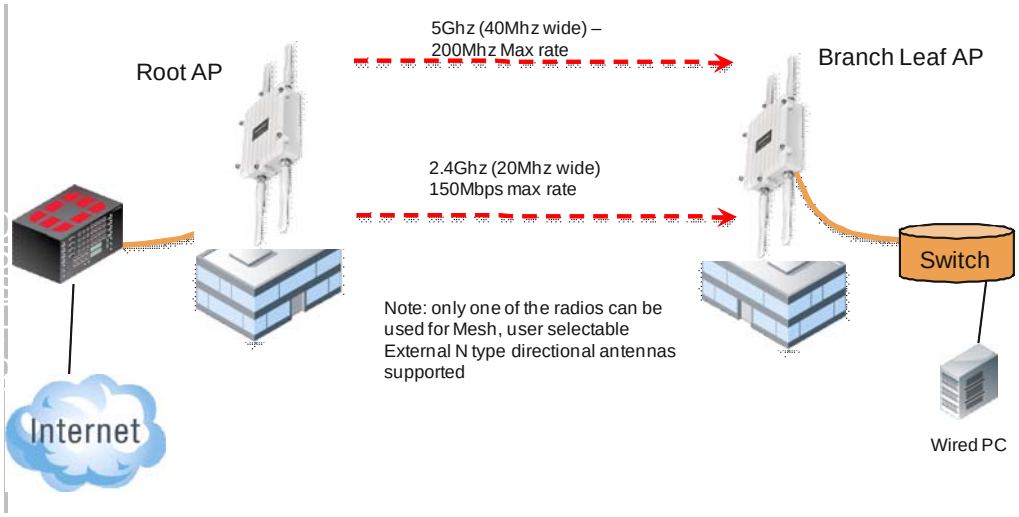


An alternate use of the wireless mesh functionality is as a point-to-point relay. Both wired and WiFi users on the leaf AP side are connected to the LAN segment on the root mesh side.

Figure 165: Point-to-point wireless mesh



Configuring a meshed WiFi network

Each VDOM on the FortiGate unit contains a predefined WiFi mesh interface named wl.mesh and a predefined SSID (which cannot be deleted) named fortinet.mesh.<vdom-name>. You can create additional mesh SSIDs. Create the SSID with *Traffic Mode* set to *Mesh Downlink*.

You need to:

- Create custom AP profiles, if you are not using the automatic AP profile.
- Configure the mesh root AP, either a FortiWiFi unit's Local Radio or a FortiAP unit.
- Configure mesh branch/leaf AP units.
- Authorize the mesh branch/leaf units when they connect to the WiFi Controller.

Creating custom AP profiles

You can apply the automatic AP profile or create one or more custom AP profiles for the mesh root and branch/leaf APs. A custom profile provides more control over which radio channels are used, intrustion protection, load balancing, background rogue AP scanning, and so on. Typically, the custom profiles are configured so that Radio 1 (5GHz) carries the mesh backhaul SSID while Radio 2 (2.4GHz) carries the SSIDs to which users connect.

For more information, see "Creating a custom AP Profile" on page 796.

Configuring the mesh root AP

The mesh root AP can be either a FortiWiFi unit's built-in AP or a FortiAP unit.

To enable a FortiWiFi unit's Local Radio as mesh root - web-based manager

1. Go to *WiFi Controller* > *Managed Access Points* > *Local WiFi Radio*.
2. Select *Enable WiFi Radio*.
3. In *SSID*, select *Select SSIDs*, then select *fortinet.mesh.root*.
4. Optionally, adjust *TX Power* or select *Auto Tx Power Control*.

5. Select *Apply*.

In a network with multiple wireless controllers, you need to change the mesh SSID so that each mesh root has a unique SSID. Other controllers using the same mesh root SSID might be detected as fake or rogue APs. Go to *WiFi Controller* > *WiFI Network* > *SSID* to change the SSID.

Fortinet also recommends that you create a new preshared key instead of using the default.

To configure a network interface for the FortiAP unit

1. On the FortiGate unit, go to *System* > *Network* > *Interfaces*.
2. Select the interface where you will connect the FortiAP unit and edit it.
3. In *Addressing mode*, select *Manual*.
4. In *IP/Network Mask*, enter an IP address and netmask for the interface.

   To maximize the number of addresses available for clients, the interface address should end with 1, for example 192.168.10.1.
5. In *DHCP Server* select *Enable*.

   An *Address Range* is entered automatically. It consists of the subnet address space above the interface address. For example, if the interface IP/mask is 192.168.10.100/24, the DHCP address range is 192.168.10.101 through 192.168.10.254.
6. Select *OK*.

To enable a FortiAP unit as mesh root - web-based manager

1. Connect the root FortiAP unit's Ethernet port to the FortiGate network interface that you configured for it. Connect the FortiAP unit to its power source.
2. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.

   If the root FortiAP unit is not listed, wait 15 seconds and select *Refresh*. Repeat if necessary. If the unit is still missing after a minute or two, power cycle the root FortiAP unit and try again.
3. Select the discovered FortiAP unit and edit its settings.
   - To use the Automatic profile enter:

AP Profile	Automatic
Enable WiFi Radio	Selected
SSID	Select SSID, then enable fortinet.root.mesh.
Tx Power	Optionally, adjust *TX Power* or select *Auto Tx Power Control*.

   or

   - In *AP Profile*, select *Change* and the select the custom AP profile you created for the mesh root AP.
4. In *State*, select *Authorize*.
5. Select *OK*.

You need to create firewall policies to permit traffic to flow from the network interface where the FortiAP unit is connected to the network interfaces for the Internet and other networks. Enable NAT.

Configuring the mesh branches or leaves

The FortiAP units that will serve as branch/leaf nodes must be preconfigured.

1. Connect to the FortiAP unit web-based manager on its default Ethernet interface IP address, 192.168.1.2.
2. In the *Connectivity* section enter:

Uplink	Mesh
Mesh AP SSID	fortinet.mesh.<vdom-name> For example, for the root domain, fortinet.mesh.root.
Mesh AP Password	Same as Mesh AP SSID.
Ethernet Bridge	Select

3. Select *Apply* and then select *Logout*.

Authorizing mesh branch/leaf APs

The pre-configured branch/leaf FortiAP units will connect themselves wirelessly to the WiFi Controller through the mesh network. You must authorize each unit

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*. Periodically select *Refresh* until the FortiAP unit is listed.

   The *State* of the FortiAP unit should be *Waiting for Authorization*.
2. Open the FortiAP entry for editing.
   - To use the Automatic profile enter:

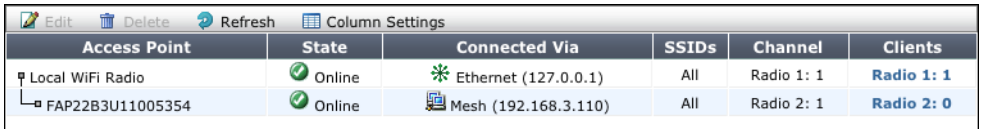
AP Profile	Automatic
Enable WiFi Radio	Selected
SSID	Optionally, select the SSIDs to make available to users.
Tx Power	Optionally, adjust *TX Power* or select *Auto Tx Power Control*.

   or

   - In *AP Profile*, select *Change* and the select the custom AP profile that you created for the branch/leaf APs and then select *[Apply]*.
3. Select *Authorize*.
4. Select *OK*.

   Initially, the *State* of the FortiAP unit is *Offline*. Periodically select *Refresh* to update the status. Within about two minutes, the state changes to *Online*.

Figure 166: FortiWiFi unit as root mesh with FortiAP unit as branch/leaf node



Viewing the status of the mesh network

Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP* to view the list of APs. The *Connected Via* field shows *Mesh* for mesh-connected units and lists the IP address to which they connect.

In the FortiAP CLI, you can check the `main ip` field in the output from the command

```
cw_diag -c mesh
```

Configuring a point-to-point bridge

You can create a point-to-point bridge to connect two wired network segments using a WiFi link. The effect is the same as connecting the two network segments to the same wired switch.

You need to:

- Configure a backhaul link and root mesh AP as described in "Configuring a meshed WiFi network" on page 831. **Note:** The root mesh AP for a point-to-point bridge must be a FortiAP unit, not the internal AP of a FortiWiFi unit.
- Configure bridging on the leaf AP unit.

To configure the leaf AP unit for bridged operation - FortiAP web-based manager

1. With your browser, connect to the FortiAP unit web-based manager.

   You can temporarily connect to the unit's Ethernet port and use its default address: 192.168.1.2.

2. Enter:

Operation Mode	Mesh
Mesh AP SSID	fortinet-ap
Mesh AP Password	fortinet
Ethernet Bridge	Select

3. Select *Apply*.
4. Connect the local wired network to the Ethernet port on the FortiAP unit.

   Users are assigned IP addresses from the DHCP server on the wired network connected to the root mesh AP unit.

To configure a FortiAP unit as a leaf AP - FortiAP CLI

```
cfg -a MESH_AP_SSID=fortinet-ap
cfg -a MESH_AP_PASSWD=fortinet
cfg -a MESH_ETH_BRIDGE=1
cfg -a MESH_AP_TYPE=1
cfg -c
```

WiFi-Ethernet Bridge Operation

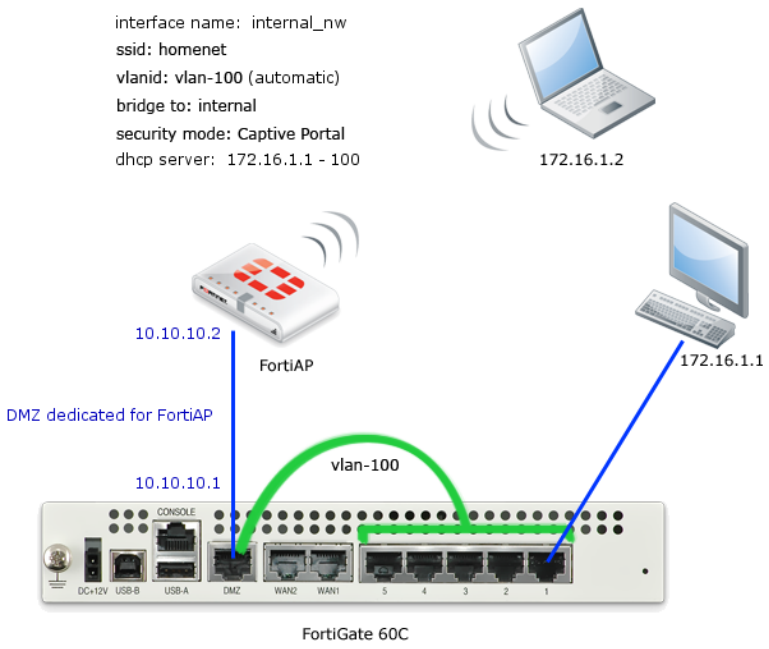
The following topics are included in this section:

- Bridge SSID to FortiGate wired network
- FortiAP local bridging (Private Cloud-Managed AP)
- Using bridged FortiAPs to increase scalability

Bridge SSID to FortiGate wired network

A WiFi network can be combined with a wired LAN so that WiFi and wired clients are on the same subnet. This is a convenient configuration for users.

Figure 167:A FortiAP unit bridged with the internal network



This configuration cannot be used in conjunction with Wireless Mesh features because it enables the FortiAP Local Bridge option.

To create the bridged WiFi and wired LAN configuration, you need to

- Configure the SSID with the Local Bridge option so that traffic is sent directly over the FortiAP unit's Ethernet interface to the FortiGate unit, instead of being tunneled to the WiFi controller.
- Configure a software switch interface on the FortiGate unit with the WiFi and Internal network interfaces as members.
- Configure Captive Portal security for the software switch interface.

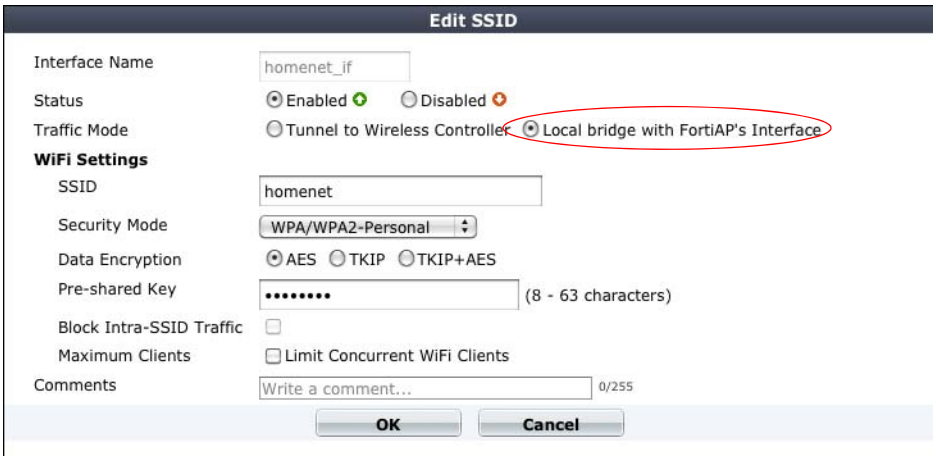
To configure the SSID - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.
2. Enter:

Interface name	A name for the new WiFi interface, `homenet_if` for example.
Traffic Mode	Local bridge with FortiAP's Interface
SSID	The SSID visible to users, `homenet` for example.
Security Mode **Data Encryption** **Preshared Key**	Configure security as you would for a regular WiFi network.

3. Select OK.
4. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP,* select the FortiAP unit for editing.
5. Authorize the FortiAP unit.
6. The FortiAP unit can carry regular SSIDs in addition to the Bridge SSID.

Figure 168:SSID configured with Local Bridge option



To configure the SSID - CLI

This example creates a WiFi interface “homenet_if” with SSID “homenet” using WPA-Personal security, passphrase “Fortinet1”.

```
config wireless-controller vap
  edit "homenet_if"
    set vdom "root"
    set ssid "homenet"
    set local-bridging enable
    set security wpa-personal
    set passphrase "Fortinet1"
  end
config wireless-controller wtp
  edit FAP22B3U11005354
    set admin enable
    set vaps "homenet_if"
  end
```

To configure the FortiGate unit - web-based manager

1. Go to *System* > *Network* > *Interfaces* and select *Create New*.
2. Enter:

Name	A name for the new interface, `homenet_nw` for example.
Type	Software Switch
Interface Members	Move internal and homenet_if into the *Selected Interfaces* list.
Addressing Mode	Select Manual and enter an address, for example `172.16.96.32/255.255.255.0`
Enable DHCP Server	Enable.
Security Mode	Select *Captive Portal*. Add the permitted *User Groups*.

3. Select OK.

To configure the FortiGate unit - CLI

```
config system interface
  edit homenet_nw
    set ip 172.16.96.32 255.255.255.0
    set type switch
    set security-mode captive-portal
    set security-groups "Guest-group"
  end
config system interface
  edit homenet_nw
    set member "homenet_if" "internal"
  end
```

VLAN configuration

If your environment uses VLAN tagging, you assign the SSID to a specific VLAN in the CLI. For example, to assign the homenet_if interface to VLAN 100, enter:

```
config wireless-controller vap
  edit "homenet_if"
    set vlanid 100
  end
```

Additional configuration

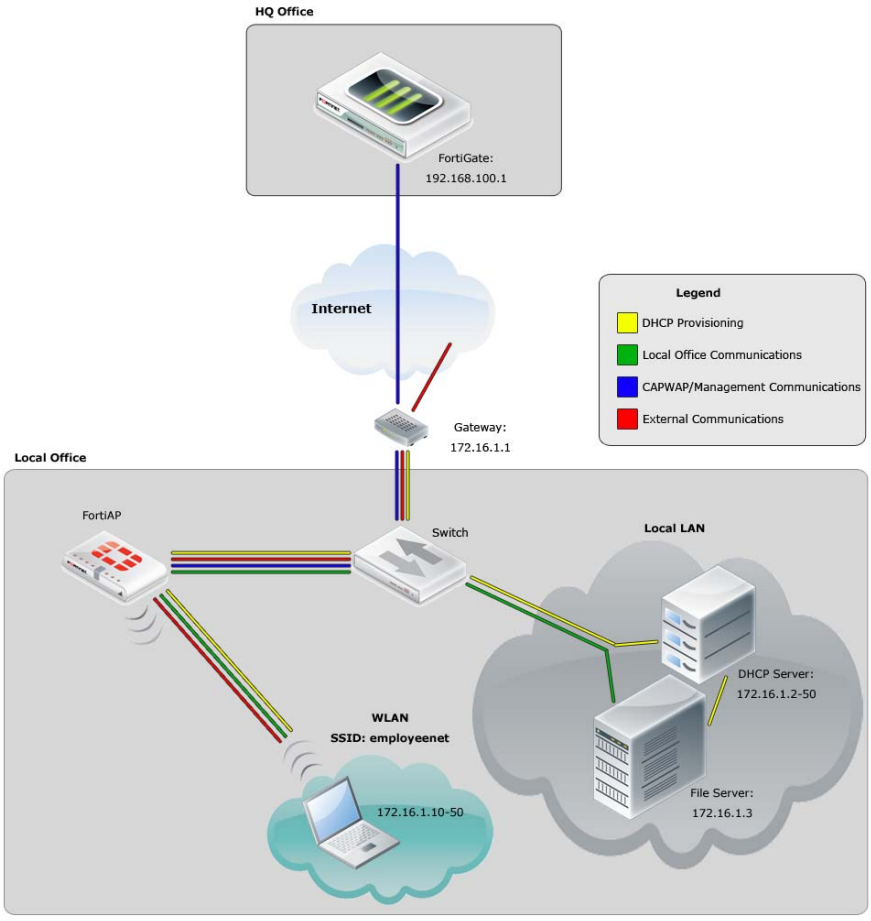
The configuration described above provides communication between WiFi and wired LAN users only. To provide access to other networks, create appropriate firewall policies between the software switch and other interfaces.

FortiAP local bridging (Private Cloud-Managed AP)

A FortiAP unit can provide WiFi access to a LAN, even when the wireless controller is located remotely. This configuration is useful for the following situations:

- Installations where the WiFI controller is remote and most of the traffic is local or uses the local Internet gateway
- Wireless-PCI compliance with remote WiFi controller
- Telecommuting, where the FortiAP unit has the WiFi controller IP address pre-configured and broadcasts the office SSID in the user's home or hotel room. In this case, data is sent in the wireless tunnel across the Internet to the office and you should enable encryption using DTLS.

Figure 169: Remotely-managed FortiAP providing WiFi access to local network



On the remote FortiGate wireless controller, the WiFi SSID is created with the *Bridge with FortiAP Interface* option selected. In this mode, no IP addresses are configured. The FortiAP unit's WiFi and Ethernet interfaces behave as a switch. WiFi client devices obtain IP addresses from the same DHCP server as wired devices on the LAN.

There can be only one Bridge mode SSID per FortiAP unit.

The Local Bridge feature cannot be used in conjunction with Wireless Mesh features.

Block-Intra-SSID Traffic is not available in Bridge mode.

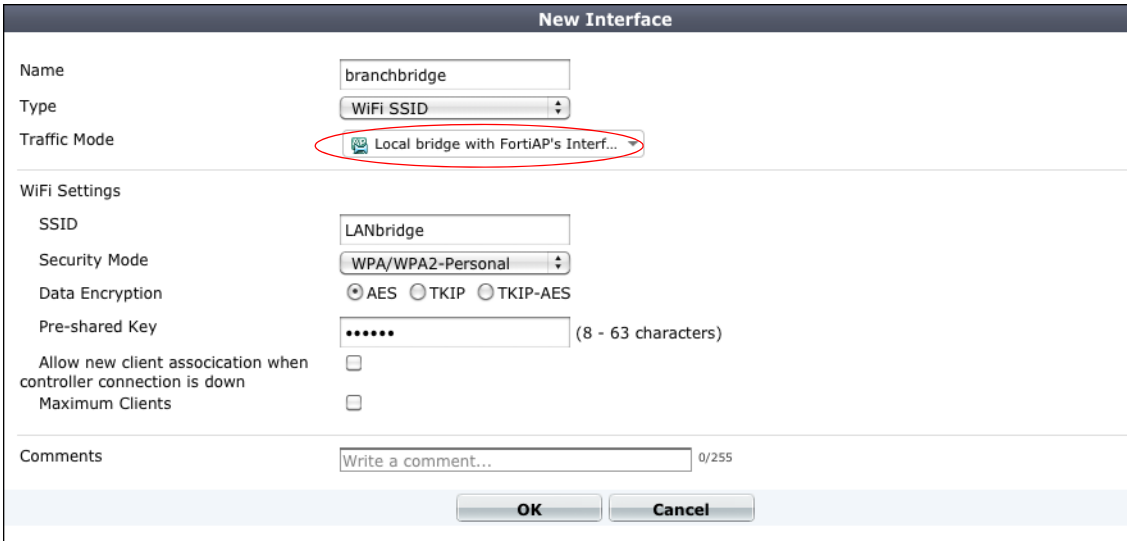
To configure a FortiAP local bridge - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.
2. Enter:

Interface name	A name for the new WiFi interface.
Traffic Mode	Local bridge with FortiAP's Interface
SSID	The SSID visible to users.
Security Mode **Data Encryption** **Preshared Key**	Configure security as you would for a regular WiFi network.

3. Select *OK*.
4. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP,* select the FortiAP unit for editing.
5. Authorize the FortiAP unit.
6. The FortiAP unit can carry regular SSIDs in addition to the Bridge SSID.

Figure 170:SSID configured for Local Bridge operation



To configure a FortiAP local bridge - CLI

This example creates a WiFi interface “branchbridge” with SSID “LANbridge” using WPA-Personal security, passphrase “Fortinet1”.

```
config wireless-controller vap
  edit "branchbridge"
    set vdom "root"
    set ssid "LANbridge"
    set local-bridging enable
    set security wpa-personal
    set passphrase "Fortinet1"
  end
config wireless-controller wtp
  edit FAP22B3U11005354
    set admin enable
    set vaps "branchbridge"
  end
```

Continued FortiAP operation when WiFi controller connection is down

The wireless controller, or the connection to it, might occasionally become unavailable. During such an outage, clients already associated with a bridge mode FortiAP unit continue to have access to the WiFi and wired networks. Optionally, the FortiAP unit can also continue to authenticate users if the SSID meets these conditions:

- *Traffic Mode* is *Local bridge with FortiAP’s Interface*.

  In this mode, the FortiAP unit does not send traffic back to the wireless controller.
- *Security Mode* is either *WPA/WPA2-Personal* or *Open*.

  These modes do not require the user database. In WPA/WPA2-Personal authentication, all clients use the same pre-shared key which is known to the FortiAP unit.
- *Allow new client assocication when controller connection is down* is enabled.

  This field is available only if the other conditions have been met.

The “LANbridge” SSID example would be configured like this in the CLI:

```
config wireless-controller vap
  edit "branchbridge"
    set vdom "root"
    set ssid "LANbridge"
    set local-bridging enable
    set security wpa-personal
    set passphrase "Fortinet1"
    set local-authentication enable
  end
```

Using bridged FortiAPs to increase scalability

The FortiGate wireless controller can support more FortiAP units in local bridge mode than in the normal mode. But this is only true if you configure some of your FortiAP units to operate in remote mode, which supports only local bridge mode SSIDs.

The Managed FortAP page (*WiFi Controller* > *Managed Devices* > *Managed FortiAP*) shows at the top right the current number of Managed FortiAPs and the maximum number that can be managed, “5/64” for example. The maximum number, however, is true only if all FortiAP units operate in remote mode. For more detailed information, consult the *Maximum Values Table.* For each FortiGate model, there are two maximum values for managed FortiAP units: the total number of FortiAPs and the number of FortiAPs that can operate in normal mode.

To configure FortiAP units for remote mode operation

1. Create at least one SSID with *Traffic Mode* set to *Local Bridge*.
2. Create a custom AP profile that includes only local bridge SSIDs.
3. Configure each managed FortiAP unit to use the custom AP profile. You also need to set the FortiAP unit’s `wtp-mode` to `remote`, which is possible only in the CLI. The following example uses the CLI both to set `wtp-mode` and select the custom AP profile:

```
config wireless-controller wtp
  edit FAP22B3U11005354
    set wtp-mode remote
    set wtp-profile 220B_bridge
  end
```

Protecting the WiFi Network

The FortiGate unit provides WiFi-specific network protection. The following topics are included in this section:

Wireless IDS

The FortiGate Wireless Intrusion Detection System (WIDS) monitors wireless traffic for a wide range of security threats by detecting and reporting on possible intrusion attempts. When an attack is detected the FortiGate unit records a log message.

You can create a WIDS profile to enable the types of intrusion detection:

- Asleap Attack—ASLEAP is a tool used to perform attacks against LEAP authentication.
- Association Frame Flooding—A Denial of Service attack using association requests. The default detection threshold is 30 requests in 10 seconds.
- Authentication Frame Flooding—A Denial of Service attack using association requests. The default detection threshold is 30 requests in 10 seconds.
- Broadcasting De-authentication—This is a type of Denial of Service attack. A flood of spoofed de-authentication frames forces wireless clients to de-athenticate, then re-authenticate with their AP.
- EAPOL Packet Flooding—Extensible Authentication Protocol over LAN (EAPOL) packets are used in WPA and WPA2 authentication. Flooding the AP with these packets can be a denial of service attack. Several types of EAPOL packets are detected: EAPOL-FAIL, EAPOL-LOGOFF, EAPOL-Start, EAPOL-SUCC.
- Invalid MAC OUI—Some attackers use randomly-generated MAC addresses. The first three bytes of the MAC address are the Organizationally Unique Identifier (OUI), administered by IEEE. Invalid OUIs are logged.
- Long Duration Attack—To share radio bandwidth, WiFi devices reserve channels for brief periods of time. Excessively long reservation periods can be used as a denial of service attack. You can set a threshold between 1000 and 32 767 microseconds. The default is 8200.
- Null SSID Probe Response—When a wireless client sends out a probe request, the attacker sends a response with a null SSID. This causes many wireless cards and devices to stop responding.
- Spoofed De-authentication—Spoofed de-authentication frames form the basis for most denial of service attacks.
- Weak WEP IV Detection—A primary means of cracking WEP keys is by capturing 802.11 frames over an extended period of time and searching for patterns of WEP initialization vectors (IVs) that are known to be weak. WIDS detects known weak WEP IVs in on-air traffic.
- Wireless Bridge—WiFi frames with both the fromDS and ToDS fields set indicate a wireless bridge. This will also detect a wireless bridge that you intentionally configured in your network.

You can enable wireless IDS by going to *WiFi Controller* > *WiFi Network* > *Custom AP Profile* and editing an access point profile. Inside the profile set *WIDS Profile* to the name of a wireless IDS profile to apply wireless IDS protection to the access points that uses the profile.

To create a WIDS Profile

1. Go to *WiFi Controller* > *WiFi Network* > *WIDS Profile*.
2. Select a profile to edit or select *Create New*.
3. Select the types of intrusion to protect against.

   By default, all types are selected.
4. Select *Apply*.

You can also configure a WIDS profile in the CLI using the `config wireless-controller wids-profile` command.

WiFi data channel encryption

Optionally, you can apply DTLS encryption to the data channel between the wireless controller and FortiAP units. This enhances security.

There are data channel encryption settings on both the FortiGate unit and the FortiAP units. At both ends, you can enable Clear Text, DTLS encryption, or both. The settings must agree or the FortiAP unit will not be able to join the WiFi network. By default, both Clear Text and DTLS-encrypted communication are enabled on the FortiAP unit, allowing the FortiGate setting to determine whether data channel encryption is used. If the FortiGate unit also enables both Clear Text and DTLS, Clear Text is used.

Data channel encryption settings are located in the Custom AP profile. If you use Automatic profile, only Clear Text is supported.

Data channel encryption is software-based and can affect performance. Verify that the system meets your performance requirements with encryption enabled.

Configuring encryption on the FortiGate unit

You can use the CLI to configure data channel encryption.

Enabling encryption

In the CLI, the `wireless wtp-profile` command contains a new field, `dtls-policy`, with options `clear-text` and `dtls-enabled`. To enable encryption in profile1 for example, enter:

```
config wireless-controller wtp-profile
  edit profile1
    set dtls-policy dtls-enabled
  end
```

Configuring encryption on the FortiAP unit

The FortiAP unit has its own settings for data channel encryption.

Enabling CAPWAP encryption - FortiAP web-based manager

1 On the *System Information* page, in *WTP Configuration* > *AC Data Channel Security*, select one of:

- Clear Text
- DTLS Enabled
- Clear Text or DTLS Enabled (default)

2 Select *Apply*.

Enabling encryption - FortiAP CLI

You can set the data channel encryption using the AC_DATA_CHAN_SEC variable: 0 is Clear Text, 1 is DTLS Enabled, 2 (the default) is Clear Text or DTLS Enabled.

For example, to set security to DTLS and then save the setting, enter

```
cfg -a AC_DATA_CHAN_SEC=1
cfg -c
```

Wireless network monitoring

You can monitor both your wireless clients and other wireless networks that are available in your coverage area.

The following topics are included in this section:

Monitoring wireless clients

To view connected clients on a FortiWiFi unit

- Go to *WiFi Controller* > *Monitor* > *Client Monitor.*

The following information is displayed:

SSID	The SSID that the client connected to.
FortiAP	The serial number of the FortiAP unit to which the client connected.
User	User name
IP	The IP address assigned to the wireless client.
Device	
Auth	The type of authentication used.
Channel	WiFi radio channel in use.
Bandwidth Tx/Rx	Client received and transmitted bandwidth, in Kbps.
Signal Strength / Noise	The signal-to-noise ratio in deciBels calculated from signal strength and noise level.
Signal Strength	
Association Time	How long the client has been connected to this access point.

Results can be filtered. Select the filter icon on the column you want to filter. Enter the values to include or select NOT if you want to exclude the specified values.

Monitoring rogue APs

The access point radio equipment can scan for other available access points, either as a dedicated monitor or as a background scan performed while the access point is idle.

Discovered access points are listed in the *Rogue AP Monitor* list. You can then mark them as either Accepted or Rogue access points. This designation helps you to track access points. It does not affect anyone's ability to use these access points.

Rogue AP Settings (*WiFi Controller* > *WiFi Network* > *Rogue AP Settings*) control rogue AP detection for APs that use the Automatic profile. For APs that use a custom AP profile, rogue AP detection settings are contained in the custom AP profile (*WiFi Controller* > *WiFi Network* > *Custom AP Profile*).

It is also possible to suppress rogue APs. See "Suppressing rogue APs" on page 851.

On-wire rogue AP detection technique

Other APs that are available in the same area as your own APs are not necessarily rogues. A neighboring AP that has no connection to your network might cause interference, but it is not a security threat. A rogue AP is an unauthorized AP connected to your wired network. This can enable unauthorized access. When rogue AP detection is enabled, the *On-wire* column in the *Rogue AP Monitor* list shows a green up-arrow on detected rogues.

Rogue AP monitoring of WiFi client traffic builds a table of WiFi clients and the Access Points that they are communicating through. The FortiGate unit also builds a table of MAC addresses that it sees on the LAN. The FortiGate unit's on-wire correlation engine constantly compares the MAC addresses seen on the LAN to the MAC addresses seen on the WiFi network.

There are two methods of Rogue AP on-wire detection operating simultaneously: Exact MAC address match and MAC adjacency.

Exact MAC address match

If the same MAC address is seen on the LAN and on the WiFi network, this means that the wireless client is connected to the LAN. If the AP that the client is using is not authorized in the FortiGate unit configuration, that AP is deemed an 'on-wire' rogue. This scheme works for non-NAT rogue APs.

MAC adjacency

If an access point is also a router, it applies NAT to WiFi packets. This can make rogue detection more difficult. However, an AP's WiFi interface MAC address is usually in the same range as its wired MAC address. So, the MAC adjacency rogue detection method matches LAN and WiFi network MAC addresses that are within a defined numerical distance of each other. By default, the MAC adjacency value is 7. If the AP for these matching MAC addresses is not authorized in the FortiGate unit configuration, that AP is deemed an 'on-wire' rogue.

Limitations

On-wire rogue detection has some limitations. There must be at least one WiFi client connected to the suspect AP and continuously sending traffic. If the suspect AP is a router, its WiFi MAC address must be very similar to its Ethernet port MAC address.

Logging

Information about detected rogue APs is logged and uploaded to your FortiAnalyzer unit, if you have one. By default, rogue APs generate an alert level log, unknown APs generate a warning level log. This log information can help you with PCI-DSS compliance requirements.

Rogue AP scanning as a background activity

Each WiFi radio can perform monitoring of radio channels in its operating band while acting as an AP. It does this by briefly switching from AP to monitoring mode. By default, a scan period starts every 300 seconds. Each second a different channel is monitored for 20ms until all channels have been checked.

During heavy AP traffic, it is possible for background scanning to cause lost packets when the radio switches to monitoring. To reduce the probability of lost packets, you can set the CLI `ap-bgscan-idle` field to delay the switch to monitoring until the AP has been idle for a specified period. This means that heavy AP traffic may slow background scanning.

The following CLI example configures default background rogue scanning operation except that it sets `ap-bgscan-idle` to require 100ms of AP inactivity before scanning the next channel.

```
config wireless-controller wtp-profile
  edit ourprofile
    config radio-1
      set ap-bgscan enable
      set rogue-scan enable
      set ap-bgscan-period 300
      set ap-bgscan-intv 1
      set ap-bgscan-duration 20
      set ap-bgscan-idle 100
    end
  end
```

Configuring rogue scanning

All APs using the Automatic profile share the same rogue scanning settings. APs using a custom AP profile follow the settings in the custom profile.

To enable rogue AP scanning for the automatic AP profile

1. Go to *WiFi Controller* > *WiFi Network* > *Rogue AP Settings*.
2. Select *Enable Rogue AP Detection*.
3. Select *Enable On-wire Rogue AP Detection Technique* if you want to use that method of distinguishing rogues from neighbors.
4. Select *Apply*.

To enable the rogue AP scanning feature for the automatic AP profile - CLI

```
config wireless-controller setting
  set ap-scan enable
  set on-wire-scan enable
end
```

To configure rogue AP scanning in a custom AP profile

1. Go to *WiFi Controller* > *WiFi Network* > *Custom AP Profiles*.

   On some models, the menu is *WiFi & Switch Controller*.
2. Select an existing AP profile and edit it, or select *Create New*.
3. For each radio, select either *Access Point* or *Dedicated Monitor*, as required.
4. If you selected *Access Point*, enable *Background Scan*.
5. Select *Rogue AP On-Wire Scan.*

6. If needed, modify other settings.
7. Select *OK*.

To enable the rogue AP scanning feature in a custom AP profile - CLI

```
config wireless-controller wtp-profile
  edit FAP220B-default
    config radio-1
      set mode ap
      set ap-bgscan enable
      set rogue-scan enable
```

Exempting an AP from rogue scanning

By default, if Rogue AP Detection is enabled, it is enabled on all managed FortiAP units. Optionally, you can exempt an AP from scanning. You should be careful about doing this if your organization must perform scanning to meet PCI-DSS requirements.

To exempt an AP from rogue scanning - web-based manager

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.
2. Select which AP to edit.
3. Select *Do not participate in Rogue AP Scanning* and then select *OK*.

To exempt an AP from rogue scanning - CLI

This example shows how to exempt access point AP1 from rogue scanning.

```
config wireless-controller wtp
  edit AP1
    set ap-scan disable
  end
```

MAC adjacency

You can adjust the maximum WiFi to Ethernet MAC difference used when determining whether an suspect AP is a rogue.

To adjust MAC adjacency

For example, to change the adjacency to 8, enter

```
config wireless-controller global
  set rogue-scan-mac-adjacency 8
end
```

Using the Rogue AP Monitor

Go to *WiFi Controller* > *Monitor* > *Rogue AP Monitor* to view the list of other wireless access points that are receivable at your location.

Information Columns Actual columns displayed depends on *Column Settings*.	
State	 Rogue AP — Use this status for unauthorized APs that *On-wire* status indicates are attached to your wired networks.  Accepted AP — Use this status for APs that are an authorized part of your network or are neighboring APs that are not a security threat. To see accepted APs in the list, select *Show Accepted*.  Unclassified — This is the initial status of a discovered AP. You can change an AP back to unclassified if you have mistakenly marked it as Rogue or Accepted.
Online Status	 Active AP  Inactive AP  Active ad-hoc WiFi device  Inactive ad-hoc WiFi device
SSID	The wireless service set identifier (SSID) or network name for the wireless interface.
Security Type	The type of security currently being used.
Channel	The wireless radio channel that the access point uses.
MAC Address	The MAC address of the Wireless interface.
Vendor Info	The name of the vendor.
Signal Strength	The relative signal strength of the AP. Mouse over the symbol to view the signal-to-noise ratio.
Detected By	The name or serial number of the AP unit that detected the signal.
On-wire	A green up-arrow indicates a suspected rogue, based on the on-wire detection technique. A red down-arrow indicates AP is not a suspected rogue.
First Seen	How long ago this AP was first detected.
Last Seen	How long ago this AP was last detected.
Rate	Data rate in bps.

To change the Online Status of an AP, right-click it and select Mark Accepted or Mark Rogue.

Suppressing rogue APs

In addition to monitoring rogue APs, you can actively prevent your users from connecting to them. When suppression is activated against an AP, the FortiGate WiFi controller sends deauthentication messages to the rogue AP's clients, posing as the rogue AP, and also sends deauthentication messages to the rogue AP, posing as its clients. This is done using the monitoring radio.

To enable rogue AP suppression, you must enable monitoring of rogue APs with the on-wire detection technique. See "Monitoring rogue APs" on page 847. The monitoring radio must be in the Dedicated Monitor mode.

To activate AP suppression against a rogue AP

1. Go to *WiFi Controller* > *Monitor* > *Rogue AP Monitor.*
2. When you see an AP listed that is a rogue detected "on-wire", select it and then select *Mark* > *Mark Rogue*.
3. To suppress an AP that is marked as a rogue, select it and then select *Suppress AP.*

To deactivate AP suppression

1. Go to *WiFi Controller* > *Monitor* > *Rogue AP Monitor.*
2. Select the suppressed rogue AP and then select *Suppress AP* > *Unsuppress AP.*

Monitoring wireless network health

The Wireless Health Dashboard provides a comprehensive view of the health of your network's wireless infrastructure. The dashboard includes widgets to display

- AP Status - Active, Down or missing, up for over 24 hours, rebooted in past 24 hours
- Client Count Over TIme - viewable for past hour, day, or 30 days
- Top Client Count Per-AP - separate widgets for 2.4GHz and 5GHz bands
- Top Wireless Interference - separate widgets for 2.4GHz and 5GHz bands
- Login Failures Information

To view the Wireless Health dashboard, go to *WiFi Controller* > *Monitor* > *Wireless Health*.

Configuring wireless network clients

This chapter shows how to configure typical wireless network clients to connect to a wireless network with WPA-Enterprise security. The following topics are included in this section:

Windows XP client

To configure the WPA-Enterprise network connection

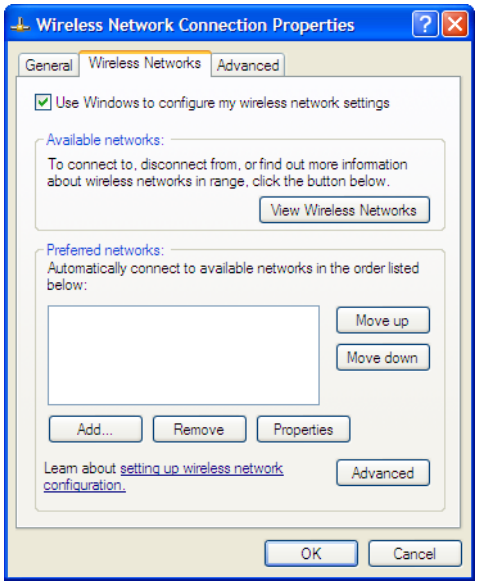
1. In the Windows Start menu, go to *Control Panel* > *Network Connections* > *Wireless Network Connection* or select the wireless network icon in the Notification area of the Taskbar. A list of available networks is displayed.

   If you are already connected to another wireless network, the Connection Status window displays. Select *View Wireless Networks* on the *General* tab to view the list.

   If the network broadcasts its SSID, it is listed. But do not try to connect until you have completed the configuration step below. Because the network doesn't use the Windows XP default security configuration, configure the client's network settings manually before trying to connect.

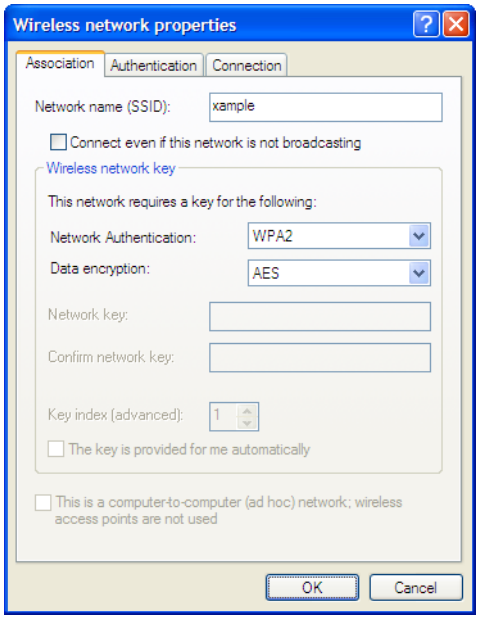
2. You can configure the WPA-Enterprise network to be accessible from the *View Wireless Networks* window even if it does not broadcast its SSID.

3. Select *Change Advanced Settings* and then select the *Wireless Networks* tab.



Any existing networks that you have already configured are listed in the *Preferred Networks* list.

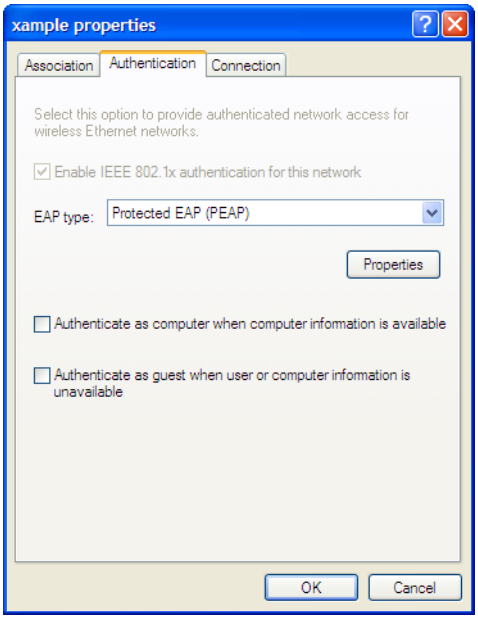
4. Select *Add* and enter the following information:



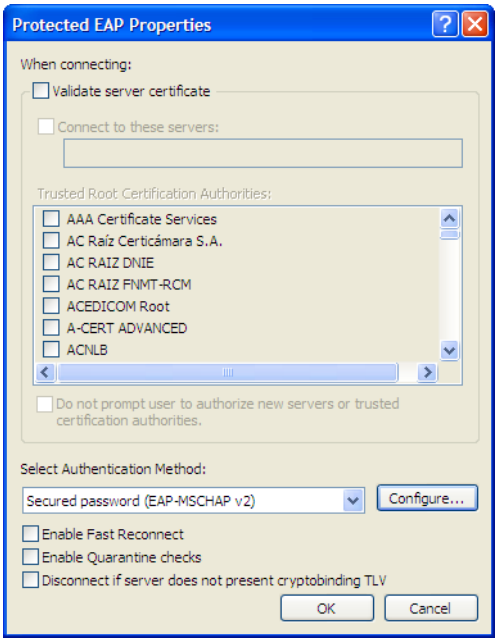
Network Name (SSID)	The SSID for your wireless network
Network Authentication	WPA2
Data Encryption	AES

5. If this wireless network does not broadcast its SSID, select *Connect even if this network is not broadcasting* so that the network will appear in the *View Wireless Networks* list.

6. Select the *Authentication* tab.

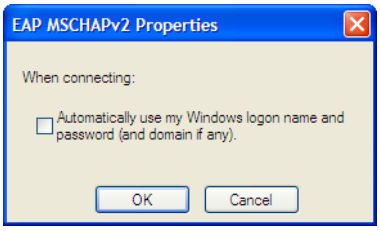


7. In *EAP Type*, select *Protected EAP (PEAP)*.
8. Make sure that the other two authentication options are not selected.
9. Select *Properties*.



10. Make sure that *Validate server_certificate* is selected.
11. Select the server certificate UTN-USERFirst-Hardware.
12. In *Select Authentication Method*, select *Secured Password (EAP-MSCHAPv2)*.
13. Ensure that the remaining options are not selected.

14. Select *Configure*.

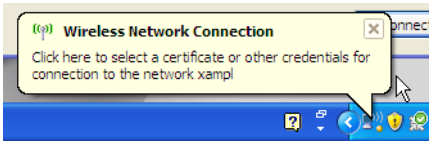


15. If your wireless network credentials are the same as your Windows logon credentials, select *Automatically use my Windows logon name and password*. Otherwise, make sure that this option is not selected.
16. Select OK. Repeat until you have closed all of the *Wireless Network Connection Properties* windows.

To connect to the WPA-Enterprise wireless network

1. Select the wireless network icon in the Notification area of the Taskbar.
2. In the *View Wireless Networks* list, select the network you just added and then select *Connect*.

   You might need to log off of your current wireless network and refresh the list.
3. When the following popup displays, click on it.

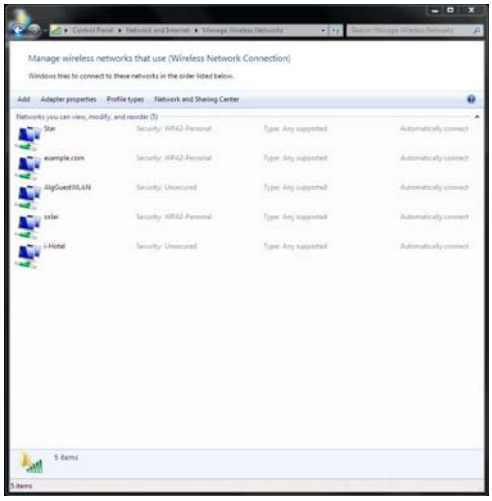


4. In the *Enter Credentials* window, enter your wireless network *User name*, *Password*, and *Logon domain* (if applicable). Then, select *OK*.

In future, Windows will automatically send your credentials when you log on to this network.

Windows 7 client

1. In the Windows Start menu, go to *Control Panel* > *Network and Internet* > *Network and Sharing Center* > *Manage Wireless Networks* or select the wireless network icon in the Notification area of the Taskbar. A list of available networks is displayed.



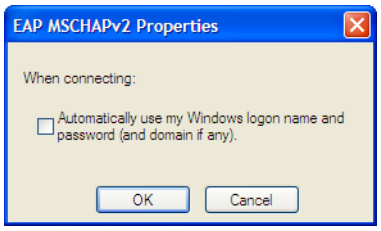
2. Do one of the following:
   - If the wireless network is listed (it broadcasts its SSID), select it from the list.
   - Select *Add* > *Manually create a network profile*.
3. Enter the following information and select *Next*.

Network name	Enter the SSID of the wireless network. (Required only if you selected *Add*.)
Security type	WPA2-Enterprise
Encryption type	AES
Start this connection automatically	Select
Connect even if the network is not broadcasting.	Select

The Wireless Network icon will display a popup requesting that you click to enter credentials for the network. Click on the popup notification.

4. In the *Enter Credentials* window, enter your wireless network *User name*, *Password*, and *Logon domain* (if applicable). Then, select *OK*.

5. Select *Change connection settings*.
6. On the *Connection* tab, select *Connect automatically when this network is in range*.
7. On the *Security* tab, select the Microsoft PEAP authentication method and then select *Settings*.
8. Make sure that *Validate server_certificate* is selected.
9. Select the server certificate UTN-USERFirst-Hardware.
10. In *Select Authentication Method*, select *Secured Password (EAP-MSCHAPv2)*.
11. Select *Configure*.

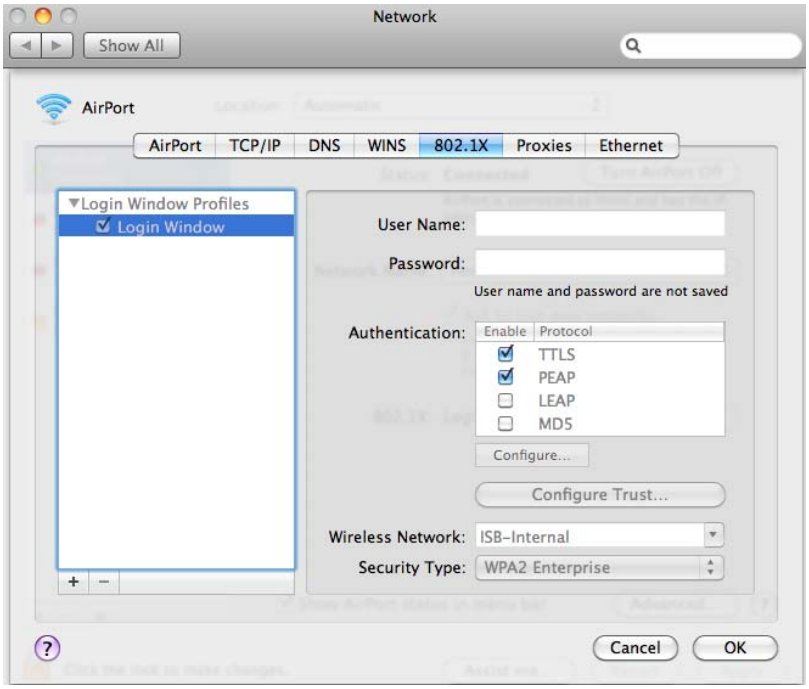


12. If your wireless network credentials are the same as your Windows logon credentials, select *Automatically use my Windows logon name and password*. Otherwise, make sure that this option is not selected.
13. Ensure that the remaining options are not selected.
14. Select OK. Repeat until you have closed all of the *Wireless Network Properties* windows.

Mac OS client

To configure network preferences

1. Right-click the *AirPort* icon in the toolbar and select *Open Network Preferences*.
2. Select *Advanced* and then select the *802.1X* tab.



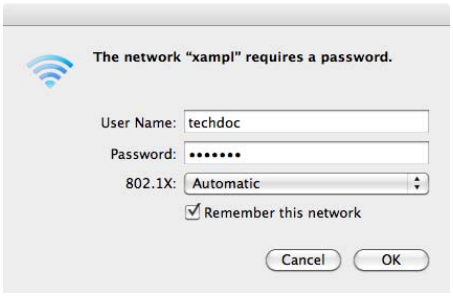
3. If there are no Login Window Profiles in the left column, select the + button and then select *Add Login Window Profile*.

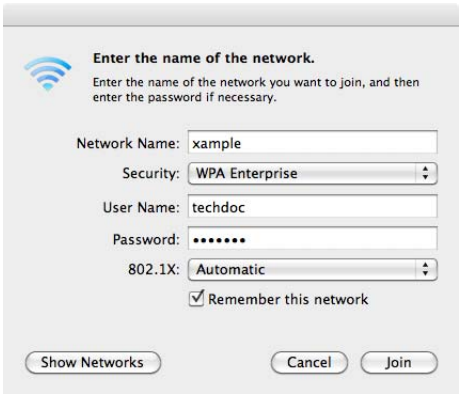
4. Select the Login Window Profile and then make sure that both TTLS and PEAP are selected in *Authentication*.

To configure the WPA-Enterprise network connection

1. Select the *AirPort* icon in the toolbar.
2. Do one of the following:
   - If the network is listed, select the network from the list.
   - Select *Connect to Other Network*.

   One of the following windows opens, depending on your selection.





3. Enter the following information and select *OK* or *Join*:

Network name	Enter the SSID of your wireless network. (Other network only)
Wireless Security	WPA Enterprise
802.1X	Automatic
Username **Password**	Enter your logon credentials for the wireless network.
Remember this network	Select.

You are connected to the wireless network.

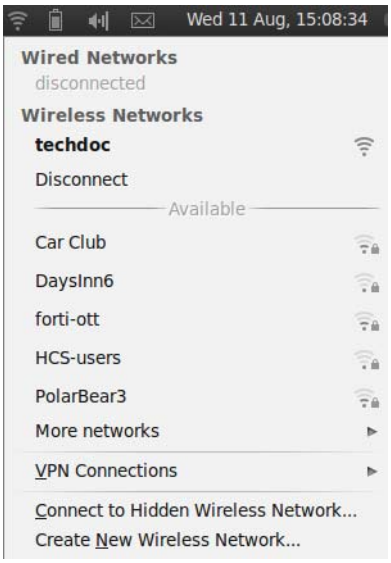
Mac OS supports only PEAP with MSCHAPv2 authentication and therefore can authenticate only to a RADIUS server, not an LDAP or TACACS+ server.

Linux client

This example is based on the Ubuntu 10.04 Linux wireless client.

To connect to a WPA-Enterprise network

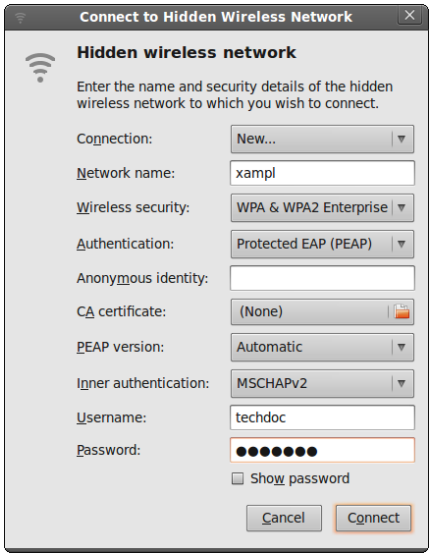
1. Select the Network Manager icon to view the Wireless Networks menu.



Wireless networks that broadcast their SSID are listed in the *Available* section of the menu. If the list is long, it is continued in the *More Networks* submenu.

2. Do one of the following:
   - Select the network from the list (also check *More Networks*).
   - Select *Connect to Hidden Wireless Network*.

   One of the following windows opens, depending on your selection.



3. Enter the following information:

Connection	Leave as *New*. (Hidden network only)
Network name	Enter the SSID of your wireless network. (Hidden network only)
Wireless Security	WPA & WPA2 Enterprise
Authentication	Protected EAP (PEAP) for RADIUS-based authentication Tunneled TLS for TACACS+ or LDAP-based authentication
Anonymous identity	This is not required.
CA Certificate	If you want to validate the AP's certificate, select the UTN-USERFirst-Hardware root certificate. The default location for the certificate is /usr/share/ca-certificates/mozilla/.
PEAP version	Automatic (applies only to PEAP)
Inner authentication	MSCHAPv2 for RADIUS-based authentication PAP or CHAP for TACACS+ or LDAP-based authentication
Username **Password**	Enter your logon credentials for the wireless network.

4. If you did not select a CA Certificate above, you are asked to do so. Select Ignore.

5. Select *Connect.* You are connected to the wireless network.

To connect to a WPA-Enterprise network

1. Select the Network Manager icon to view the Wireless Networks menu.
2. Select the network from the list (also check *More Networks*).

   If your network is not listed (but was configured), select *Connect to Hidden Wireless Network*, select your network from the Connection drop-down list, and then select *Connect*.

Troubleshooting

Using tools provided in your operating system, you can find the source of common wireless networking problems.

Checking that the client has received IP address and DNS server information

Windows XP

1. Double-click the network icon in the taskbar to display the *Wireless Network Connection Status* window. Check that the correct network is listed in the *Connection* section.
2. Select the *Support* tab.

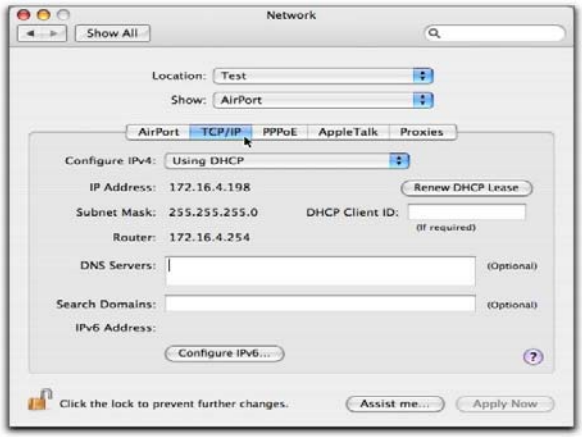
   Check that the *Address Type* is *Assigned by DHCP*. Check that the *IP Address*, *Subnet Mask*, and *Default Gateway* values are valid.
3. Select *Details* to view the DNS server addresses.

   The listed address should be the DNS serves that were assigned to the WAP. Usually a wireless network that provides access to the private LAN is assigned the same DNS servers as the wired private LAN. A wireless network that provides guest or customer users access to the Internet is usually assigned public DNS servers.
4. If any of the addresses are missing, select *Repair*.

   If the repair procedure doesn't correct the problem, check your network settings.

Mac OS

1. From the Apple menu, open *System Preferences* > *Network*.
2. Select *AirPort* and then select *Configure*.
3. On the *Network* page, select the *TCP/IP* tab.



4. If there is no IP address or the IP address starts with 169, select *Renew DHCP Lease*.
5. To check DNS server addresses, open a terminal window and enter the following command:

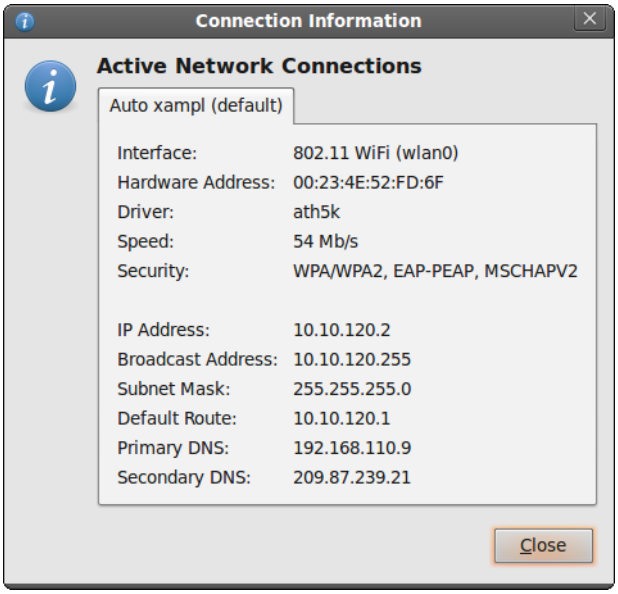
   `cat /etc/resolv.conf`

   Check the listed nameserver addresses. A network for employees should us the wired private LAN DNS server. A network for guests should specify a public DNS server.

Linux

This example is based on the Ubuntu 10.04 Linux wireless client.

1. Right-click the Network Manager icon and select *Connection Information*.



2. Check the IP address, and DNS settings. If they are incorrect, check your network settings.

Wireless network examples

This chapter provides an example wireless network configuration. The following topics are included in this section:

Basic wireless network

This example uses automatic configuration to set up a basic wireless network.

To configure this wireless network, you must:

- Configure authentication for wireless users
- Configure the SSID (WiFi network interface)
- Configure the firewall policy
- Configure and connect FortiAP units

Configuring authentication for wireless users

You need to configure user accounts and add the users to a user group. This example shows only one account, but multiple accounts can be added as user group members.

To configure a WiFi user - web-based manager

1. Go to *User & Device* > *User* > *User Definition* and select *Create New*.
2. Enter a *User Name* and *Password* and then select *OK*.

To configure the WiFi user group - web-based manager

1. Go to *User & Device* > *User* > *User Group* and select *Create New*.
2. Enter the following information and then select OK:

Name	wlan_users
Type	*Firewall*
Available Users/ Members	Move users to the *Members* list.

To configure a WiFi user and the WiFi user group - CLI

```
config user user
  edit "user01"
    set type password
    set passwd "asdf12ghjk"
  end
config user group
  edit "wlan_users"
    set member "user01"
  end
```

Configuring the SSID

First, establish the SSID (network interface) for the network. This is independent of the number of physical access points that will be deployed. The network assigns IP addresses using DHCP.

To configure the SSID - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.
2. Enter the following information and select OK:

Name	example_wifi
IP/Netmask	10.10.110.1/24
Administrative Access	Ping (to assist with testing)
SSID	example_wifi
Enable DHCP Server	Enable
Address Range	10.10.110.2 - 10.10.110.199
Netmask	255.255.255.0
Default Gateway	Same As Interface IP
DNS Server	Same as System DNS
Security Mode	WPA/WPA2-Enterprise
Data Encryption	AES
Authentication	Usergroup, select *wlan_users*.
Leave other settings at their default values.	

To configure the SSID - CLI

```
config wireless-controller vap
  edit example_wifi
    set ssid "example_wifi"
    set broadcast-ssid enable
    set security wpa-enterprise
    set auth usergroup
    set usergroup wlan_users
  end
config system interface
  edit example_wifi
    set ip 10.10.110.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set default-gateway 10.10.110.1
    set dns-service default
    set interface "example_wifi"
    config ip-range
      edit 1
        set end-ip 10.10.110.199
        set start-ip 10.10.110.2
      end
    set netmask 255.255.255.0
  end
```

Configuring firewall policies

A firewall policy is needed to enable WiFi users to access the Internet on port1. First you create firewall address for the WiFi network, then you create the example_wifi to port1 policy.

To create a firewall address for WiFi users - web-based manager

1. Go to *Firewall Objects* > *Address* > *Addresses*.
2. Select *Create New*, enter the following information and select *OK*.

Address Name	wlan_user_net
Type	Subnet / IP Range
Subnet / IP Range	10.10.110.0/24
Interface	example_wifi

To create a firewall address for WiFi users - CLI

```
config firewall address
  edit "wlan_user_net"
    set associated-interface "example_wifi"
    set subnet 10.10.110.0 255.255.255.0
  end
```

To create a firewall policy for WiFi users - web-based manager

1. Go to *Firewall Objects* > *Policy* and select *Create New*.
2. Enter the following information and select *OK*:

Incoming Interface	example_wifi
Source Address	wlan_user_net
Outgoing Interface	port1
Destination Address	All
Schedule	always
Service	ALL
Action	ACCEPT
Enable NAT	Selected. Select *Use Destination Interface Address* (default).
Leave other settings at their default values.	

To create a firewall policy for WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "example_wifi"
    set dstintf "port1"
    set srcaddr "wlan_user_net"
    set dstaddr "all"
    set schedule always
    set service ALL
    set action accept
    set nat enable
  end
```

Connecting the FortiAP units

You need to connect each FortiAP unit to the FortiGate unit, wait for it to be recognized, and then assign it to the AP Profile. But first, you must configure the interface to which the FortiAP units connect and the DHCP server that assigns their IP addresses.

In this example, the FortiAP units connect to port 3 and are controlled through IP addresses on the 192.168.8.0/24 network.

To configure the interface for the AP unit - web-based manager

1. Go to *System* > *Network* > *Interfaces* and edit the port3 interface.
2. Set the *Addressing mode* to *Dedicate to FortiAP* and set the *IP/Network Mask* to `192.168.8.1/255.255.255.0`.
3. Select *OK*.

This procedure automatically configures a DHCP server for the AP units. You can see this configuration in *System* > *Network* > *DHCP Server*.

To configure the interface for the AP unit - CLI

```
config system interface
  edit port3
    set mode static
    set ip 192.168.8.1 255.255.255.0
  end
```

To configure the DHCP server for AP units - CLI

```
config system dhcp server
  edit 0
    set interface port3
    config exclude-range
      edit 1
        set end-ip 192.168.8.1
        set start-ip 192.168.8.1
      end
    config ip-range
      edit 1
        set end-ip 192.168.8.254
        set start-ip 192.168.8.2
      end
      set netmask 255.255.255.0
      set vci-match enable
      set vci-string "FortiAP"
  end
```

To connect a FortiAP unit - web-based manager

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.
2. Connect the FortiAP unit to port 3.
3. Periodically select *Refresh* while waiting for the FortiAP unit to be listed.

   Recognition of the FortiAP unit can take up to two minutes.

   If FortiAP units are connected but cannot be recognized, try disabling VCI-Match in the DHCP server settings.
4. When the FortiAP unit is listed, select the entry to edit it.

   The *Edit Managed Access Point* window opens.
5. In *State*, select *Authorize.*
6. Make sure that AP Profile is set to *Automatic*.
7. In *SSID*, select *Automatically Inherit all SSIDs*.
8. Select *OK*.
9. Repeat Steps 2 through 8 for each FortiAP unit.

To connect a FortiAP unit - CLI

1. Connect the FortiAP unit to port 3.
2. Enter

   ```
   config wireless-controller wtp
   ```

3. Wait 30 seconds, then enter `get`.

   Retry the `get` command every 15 seconds or so until the unit is listed, like this:

   ```
   == [ FAP22A3U10600118 ]
   wtp-id: FAP22A3U10600118
   ```

4. Edit the discovered FortiAP unit like this:

   ```
   edit FAP22A3U10600118
     set admin enable
   end
   ```

5. Repeat Steps 2 through 4 for each FortiAP unit.

A more complex example

This example creates multiple networks and uses custom AP profiles.

Scenario

In this example, Example Co. provides two wireless networks, one for its employees and the other for customers or other guests of its business. Guest users have access only to the Internet, not to the company's private network. The equipment for these WiFi networks consists of FortiAP-220A units controlled by a FortiGate unit.

The employee network operates in 802.11n mode on both the 2.4GHz and 5GHz bands. Client IP addresses are in the 10.10.120.0/24 subnet, with 10.10.120.1 the IP address of the WAP. The guest network also operates in 802.11n mode, but only on the 2.4GHz band. Client IP addresses are on the 10.10.115.0/24 subnet, with 10.10.115.1 the IP address of the WAP.

On FortiAP-220A units, the 802.11n mode also supports 802.11g and 802.11b clients on the 2.4GHz band and 802.11a clients on the 5GHz band.

The guest network WAP broadcasts its SSID, the employee network WAP does not.

The employees network uses WPA-Enterprise authentication through a FortiGate user group. The guest network features a captive portal. When a guest first tries to connect to the Internet, a login page requests logon credentials. Guests use numbered guest accounts authenticated by RADIUS. The captive portal for the guests includes a disclaimer page.

In this example, the FortiAP units connect to port 3 and are assigned addresses on the 192.168.8.0/24 subnet.

Configuration

To configure these wireless networks, you must:

- Configure authentication for wireless users
- Configure the SSIDs (network interfaces)
- Configure the AP profile
- Configure the WiFi LAN interface and a DHCP server
- Configure firewall policies

Configuring authentication for employee wireless users

Employees have user accounts on the FortiGate unit. This example shows creation of one user account, but you can create multiple accounts and add them as members to the user group.

To configure the user group for employee access - web-based manager

1. Go to *User & Device* > *User* > *User Group* and select *Create New*.
2. Enter the following information and then select OK:

Name	employee-group
Type	*Firewall*
Available Users **Members**	Move appropriate user accounts to the *Members* list.

To configure the user group for employee access - CLI

```
config user group
  edit "employee-group"
    set member "user01"
  end
```

The user authentication setup will be complete when you select the employee-group in the SSID configuration.

Configuring authentication for guest wireless users

Guests are assigned temporary user accounts created on a RADIUS server. The RADIUS server stores each user's group name in the Fortinet-Group-Name attribute. Wireless users are in the group named "wireless".

The FortiGate unit must be configured to access the RADIUS server.

To configure the FortiGate unit to access the guest RADIUS server - web-based manager

1. Go to *User & Device* > *Authentication* > *RADIUS Server* and select *Create New*.
2. Enter the following information and select OK:

Name	guestRADIUS
Primary Server Name / IP	10.11.102.100
Primary Server Secret	grikfwpfdfg
Secondary Server Name / IP	Optional
Secondary Server Secret	Optional
Authentication Scheme	Use default, unless server requires otherwise.
Leave other settings at their default values.	

To configure the FortiGate unit to access the guest RADIUS server - CLI

```
config user radius
  edit guestRADIUS
    set auth-type auto
    set server 10.11.102.100
    set secret grikfwpfdfg
  end
```

To configure the user group for guest access - web-based manager

1. Go to *User & Device* > *User* > *User Group* and select *Create New*.
2. Enter the following information and then select OK:

Name	guest-group
Type	*Firewall*
Available Users / Members	Move *guestRADIUS* to the *Members* list.
Match one of these group names	Select Add and fill in the following fields:
Remote Server	Select *guestRADIUS*.
Group Name	Enter `wireless`

3. Select *Add*.
4. Enter

Remote Server	Select *guestRADIUS*.
Group Name	Select *Specify* and then enter `wireless`

To configure the user group for guest access - CLI

```
config user group
  edit "guest-group"
    set member "guestRADIUS"
    config match
      edit 0
        set server-name "guestRADIUS"
        set group-name "wireless"
      end
  end
```

The user authentication setup will be complete when you select the guest-group user group in the SSID configuration.

Configuring the SSIDs

First, establish the SSIDs (network interfaces) for the employee and guest networks. This is independent of the number of physical access points that will be deployed. Both networks assign IP addresses using DHCP.

To configure the employee SSID - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.
2. Enter the following information and select OK:

Interface Name	example_inc
IP/Netmask	10.10.120.1/24
Administrative Access	Ping (to assist with testing)
SSID	example_inc
Enable DHCP	Enable
Address Range	10.10.120.2 - 10.10.120.199
Netmask	255.255.255.0
Default Gateway	Same As Interface IP
DNS Server	Same as System DNS
Security Mode	WPA/WPA2-Enterprise
Data Encryption	AES
Authentication	Select *Usergroup*, then select *employee-group.*
Leave other settings at their default values.	

To configure the employee SSID - CLI

```
config wireless-controller vap
  edit example_inc
    set ssid "example_inc"
    set security wpa-enterprise
    set auth usergroup
    set usergroup employee-group
  end
config system interface
  edit example_inc
    set ip 10.10.120.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set default-gateway 10.10.120.1
    set dns-service default
    set interface example_inc
```

```
    config ip-range
      edit 1
        set end-ip 10.10.120.199
        set start-ip 10.10.120.2
      end
    set lease-time 7200
    set netmask 255.255.255.0
  end
```

To configure the example_guest SSID - web-based manager

1. Go to *WiFi Controller* > *WiFi Network* > *SSID* and select *Create New*.
2. Enter the following information and select OK:

Name	example_guest
IP/Netmask	10.10.115.1/24
Administrative Access	Ping (to assist with testing)
SSID	example_guest
Enable DHCP	Enable
Address Range	10.10.115.2 - 10.10.115.50
Netmask	255.255.255.0
Default Gateway	Same as Interface IP
DNS Server	Same as System DNS
Security Mode	Captive Portal
Customize Portal Messages	Select
User Groups	Select *guest-group*
Leave other settings at their default values.	

To configure the example_guest SSID - CLI

```
config wireless-controller vap
  edit example_guest
    set ssid "example_guest"
    set security captive-portal
    set selected-usergroups guest-group
  end
config system interface
  edit example_guest
    set ip 10.10.115.1 255.255.255.0
  end
config system dhcp server
  edit 0
    set default-gateway 10.10.115.1
    set dns-service default
```

```
    set interface "example_guest"
    config ip-range
      edit 1
        set end-ip 10.10.115.50
        set start-ip 10.10.115.2
      end
    set lease-time 7200
    set netmask 255.255.255.0
end
```

Configuring the custom AP profile

The custom AP Profile defines the radio settings for the networks. The profile provides access to both Radio 1 (2.4GHz) and Radio 2 (5GHz) for the employee virtual AP, but provides access only to Radio 1 for the guest virtual AP.

To configure the AP Profile - web-based manager

1. Go to *WiFi Controller* > *Managed Access Points* > *Custom AP Profile* and select *Create New*.
2. Enter the following information and select OK:

Name	example_AP
Platform	FAP220A
Radio 1	
Mode	Access Point
Background Scan	Enable
Rogue AP On-wire Scan	Enabled
Radio Resource Provision	Not enabled
Band	802.11n
Short Guard Interval	Not enabled
Channel	Select 1, 6, and 11.
Tx Power	100%
SSID	Select *example_inc* and *example_guest*.
Radio 2	
Mode	Access Point
Background Scan	Enable
Rogue AP On-wire Scan	Enabled
Radio Resource Provision	Enabled
Band	802.11n_5G

Short Guard Interval	Not enabled
20/40 MHz Channel Width	Not enabled
Channel	Select all.
Tx Power	100%
SSID	Select *example_inc*.

To configure the AP Profile - CLI

```
config wireless-controller wtp-profile
  edit "example_AP"
    config platform
      set type 220A
    end
    config radio-1
      set ap-bgscan enable
      set band 802.11n
      set channel "1" "6" "11"
      set rogue-scan enable
      set vaps "example_inc" "example_guest"
    end
    config radio-2
      set ap-bgscan enable
      set band 802.11n-5G
      set channel "36" "40" "44" "48" "149" "153" "157" "161" "165"
      set rogue-scan enable
      set vaps "example_inc"
    end
```

Configuring firewall policies

Identity-based firewall policies are needed to enable the WLAN users to access the Internet on Port1. First you create firewall addresses for employee and guest users, then you create the firewall policies.

To create firewall addresses for employee and guest WiFi users

1. Go to *Firewall Objects* > *Address* > *Addresses*.
2. Select *Create New*, enter the following information and select *OK*.

Address Name	employee-wifi-net
Type	Subnet / IP Range
Subnet / IP Range	10.10.120.0/24
Interface	example_inc

3. Select *Create New*, enter the following information and select *OK*.

Address Name	guest-wifi-net
Type	Subnet / IP Range
Subnet / IP Range	10.10.115.0/24
Interface	example_guest

To create firewall policies for employee WiFi users - web-based manager

1. Go to *Policy* > *Policy* and select *Create New*.
2. Enter the following information and select OK:

Source Interface/Zone	example_inc
Source Address	employee-wifi-net
Destination Interface/Zone	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enable NAT

3. Optionally, select *UTM* and set up UTM features for wireless users.
4. Select *OK*.
5. Repeat steps 1 through 4 but select Internal as the Destination Interface/Zone to provides access to the ExampleCo private network.

To create firewall policies for employee WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "employee_inc"
    set dstintf "port1"
    set srcaddr "employee-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
    set schedule "always"
    set service "ANY"
  next
  edit 0
    set srcintf "employee_inc"
    set dstintf "internal"
```

```
    set srcaddr "employee-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
    set schedule "always"
    set service "ANY"
  end
```

To create a firewall policy for guest WiFi users - web-based manager

1. Go to *Policy* > *Policy* and select *Create New*.
2. Enter the following information and select OK:

Source Interface/Zone	example_guest
Source Address	guest-wifi-net
Destination Interface/Zone	port1
Destination Address	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enable NAT

3. Optionally, select *UTM* and set up UTM features for wireless users.
4. Select *OK*.

To create a firewall policy for guest WiFi users - CLI

```
config firewall policy
  edit 0
    set srcintf "example_guest"
    set dstintf "port1"
    set srcaddr "guest-wifi-net"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ANY"
    set nat enable
  end
```

Connecting the FortiAP units

You need to connect each FortiAP-220A unit to the FortiGate unit, wait for it to be recognized, and then assign it to the AP Profile. But first, you must configure the interface to which the FortiAP units connect and the DHCP server that assigns their IP addresses.

In this example, the FortiAP units connect to port 3 and are controlled through IP addresses on the 192.168.8.0/24 network.

To configure the interface for the AP unit - web-based manager

1. Go to *System* > *Network* > *Interfaces* and edit the port3 interface.
2. Set the *Addressing mode* to *Manual* and set the *IP/Netmask* to `192.168.8.1`.
3. Enable *Connect FortiAP to this interface and* set *Reserve IP addresses for FortiAP* to `192.168.8.2 - 192.168.8.9`.

   This step automatically configures a DHCP server for the AP units.
4. Select *OK*.

To configure the interface for the AP unit - CLI

```
config system interface
  edit port3
    set mode static
    set ip 192.168.8.1 255.255.255.0
  end
```

To configure the DHCP server for AP units - CLI

```
config system dhcp server
  edit 0
    set interface port3
    config ip-range
      edit 1
        set end-ip 192.168.8.9
        set start-ip 192.168.8.2
      end
    set netmask 255.255.255.0
    set vci-match enable
    set vci-string "FortiAP"
  end
```

To connect a FortiAP-220A unit - web-based manager

1. Go to *WiFi Controller* > *Managed Access Points* > *Managed FortiAP*.
2. Connect the FortiAP unit to port 3.
3. Periodically select *Refresh* while waiting for the FortiAP unit to be listed.

   Recognition of the FortiAP unit can take up to two minutes.

   If there is persistent difficulty recognizing FortiAP units, try disabling VCI-Match in the DHCP server settings.
4. When the FortiAP unit is listed, select the entry to edit it.

   The *Edit Managed Access Point* window opens.
5. In *State*, select *Authorize.*
6. In the *AP Profile,* select *[Change]* and then select the *example_AP* profile.
7. Select *OK*.
8. Repeat Steps 2 through 8 for each FortiAP unit.

To connect a FortiAP-220A unit - CLI

1. Connect the FortiAP unit to port 3.
2. Enter

   ```
   config wireless-controller wtp
   ```

3. Wait 30 seconds, then enter `get`.

   Retry the `get` command every 15 seconds or so until the unit is listed, like this:

   ```
   == [ FAP22A3U10600118 ]
   wtp-id: FAP22A3U10600118
   ```

4. Edit the discovered FortiAP unit like this:

   ```
   edit FAP22A3U10600118
     set admin enable
     set wtp-profile example_AP
   end
   ```

5. Repeat Steps 2 through 4 for each FortiAP unit.

Using a FortiWiFi unit as a client

A FortiWiFi unit by default operates as a wireless access point. But a FortiWiFi unit can also operate as a wireless client, connecting the FortiGate unit to another wireless network.

This section includes the following topics:

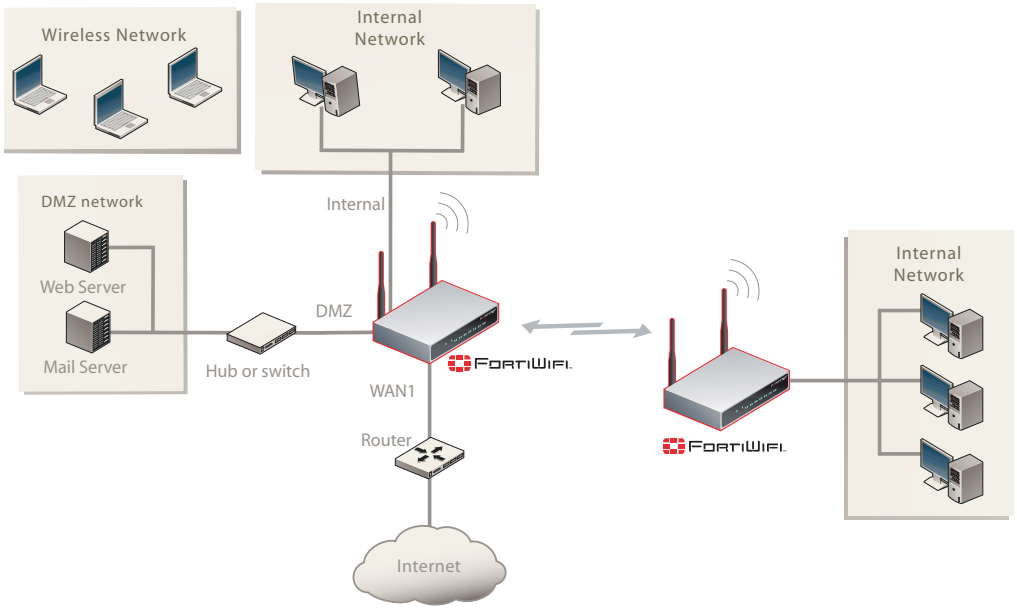
Use of client mode

In client mode, the FortiWiFi unit connects to a remote WiFi access point to access other networks or the Internet. This is most useful when the FortiWiFi unit is in a location that does not have a wired infrastructure.

For example, in a warehouse where shipping and receiving are on opposite sides of the building, running cables might not be an option due to the warehouse environment. The FortiWiFi unit can support wired users using its Ethernet ports and can connect to another access point wirelessly as a client. This connects the wired users to the network using the 802.11 WiFi standard as a backbone.

Note that in client mode the FortiWiFi unit cannot operate as an AP. WiFi clients cannot see or connect to the FortiWifi unit in Client mode.

Figure 171: Fortinet unit in Client mode



Configuring client mode

To set up the FortiAP unit as a WiFi client, you must use the CLI. Before you do this, be sure to remove any AP WiFi configurations such as SSIDs, DHCP servers, policies, and so on.

To configure wireless client mode

1. Change the WiFi mode to client.

   In the CLI, enter the following commands:

   ```
   config system global
     set wireless-mode client
   end
   ```

   Respond “y” when asked if you want to continue. The FortiWiFi unit will reboot.

2. Configure the WiFi interface settings.

   For example, to configure the client for WPA-Personal authentication on the *our_wifi* SSID with passphrase *justforus*, enter the following in the CLI:

   ```
   config system interface
     edit wifi
       set mode dhcp
       config wifi-networks
         edit 0
           set wifi-ssid our_wifi
           set wifi-security wpa-personal
           set wifi-passphrase "justforus"
         end
   end
   ```

   The WiFi interface client_wifi will receive an IP address using DHCP.

3. Configure a wifi to port1 policy.

   You can use either CLI or web-based manager to do this. The important settings are:

Incoming Interface (srcintf)	wifi
Source Address (srcaddr)	all
Outgoing Interface (dstintf)	port1
Destination Address (dstaddr)	all
Schedule	always
Service	ALL
Action	ACCEPT
Enable NAT	Selected

Support for location-based services

FortiOS supports location-based services by collecting information about WiFi devices near FortiGate-managed access points, even if the devices don't associate with the network.

The following topics are included in this section:

Overview

WiFi devices broadcast packets as they search for available networks. The FortiGate WiFi controller can collect information about the interval, duration, and signal strength of these packets. The Euclid Analytics service uses this information to track the movements of the device owner. A typical application of this technology is to analyze shopper behavior in a shopping center. Which stores do people walk past? Which window displays do they stop to look at? Which stores do they enter and how long do they spend there? The shoppers are not personally identified, each is known only by the MAC address of their WiFi device.

After enabling location tracking on the FortiGate unit, you can confirm that the feature is working by using a specialized diagnostic command to view the raw tracking data. The Euclid Analytics service obtains the same data in its proprietary format using a JSON inquiry through the FortiGate unit's web-based manager interface.

Configuring location tracking

You can enable location tracking in any custom AP profile, using the CLI. For each radio, set the `station-locate` field to `enable`. For example:

```
config wireless-controller wtp-profile
  edit "FAP220B-locate"
    set ap-country US
    config platform
      set type 220B
    end
    config radio-1
      set station-locate enable
    end
    config radio-2
      set station-locate enable
    end
  end
```

Viewing device location data on the FortiGate unit

You can use the FortiGate CLI to list located devices. This is mainly useful to confirm that the location data feature is working, You can also reset device location data.

To list located devices

```
diag wireless-controller wlac -c sta-locate
```

To reset device location data

```
diag wireless-controller wlac -c sta-locate-reset
```

Example output

The following output shows data for three WiFi devices.

```
FWF60C3G11004319 # diagnose wireless-controller wlac -c sta-locate
sta_mac               vfid  rid base_mac          freq_lst  frm_cnt
     frm_fst frm_last     intv_sum    intv2_sum    intv3_sum intv_min
     intv_max   signal_sum  signal2_sum  signal3_sum  sig_min  sig_max
     sig_fst sig_last   ap
00:0b:6b:22:82:61       0
 FAP22B3U11005354       0    0 00:09:0f:f1:bb:e4     5745      257
     708      56         651        1836        6441       0      12
     -21832     1855438   -157758796     -88     -81     -84     -88
     0
00:db:df:24:1a:67       0
 FAP22B3U11005354       0    0 00:09:0f:f1:bb:e4     5745       42
     1666      41        1625       97210     5831613       0      60
     -3608       310072    -26658680     -90      -83      -85      -89
     0
10:68:3f:50:22:29       0
 FAP22B3U11005354       0    0 00:09:0f:f1:bb:e4     5745      102
     1623      58        1565       94136     5664566       0      60
     -8025       631703    -49751433     -84      -75      -78      -79
     0
```

The output for each device appears on two lines. The first line contains only the device MAC address and the VLAN ID. The second line begins with the ID (serial number) of the FortiWiFi or FortiAP unit that detected the device, the AP's MAC address, and then the fields that the Euclid service uses. Because of its length, this line wraps around and displays as multiple lines.

Reference

This chapter provides some reference information pertaining to wireless networks. The following topics are included in this section:

- Wireless radio channels
- FortiAP CLI

Wireless radio channels

IEEE 802.11a/n channels

Table 43 lists the channels supported on FortiWiFi products that support the IEEE 802.11a and 802.11n wireless standards. 802.11a is available on FortiWiFi models 60B and higher. 802.11n is available on FortiWiFi models 80CM and higher.

All channels are restricted to indoor usage except in the Americas, where both indoor and outdoor use is permitted on channels 52 through 64 in the United States.

Table 43: IEEE 802.11a/n (5-GHz Band) channel numbers

Channel number	Frequency (MHz)	Regulatory Areas				
		Americas	Europe	Taiwan	Singapore	Japan
34	5170					•
36	5180	•	•		•	
38	5190					
40	5200	•	•		•	•
42	5210					
44	5220	•	•		•	•
46	5230					
48	5240	•	•		•	•

153	5765	•		•	•	
157	5785	•		•	•	
161	5805	•		•	•	
165	5825	•			•	

IEEE 802.11b/g/n channel numbers

Table 44 lists IEEE 802.11b/g/n channels. All FortiWiFi units support 802.11b and 802.11g. Newer models also support 802.11n.

Mexico is included in the Americas regulatory domain. Channels 1 through 8 are for indoor use only. Channels 9 through 11 can be used indoors and outdoors. You must make sure that the channel number complies with the regulatory standards of Mexico.

Table 44: IEEE 802.11b/g/n (2.4-GHz Band) channel numbers

Channel number	Frequency (MHz)	Regulatory Areas			
		Americas	EMEA	Israel	Japan

FortiAP CLI

The FortiAP CLI now includes more configuration commands and a complete set of diagnose commands.

Configuration commands include the following

`cfg -h`	Display help for all commands.
`cfg -r var`	Remove variables.
`cfg -e`	Export variables.
`cfg -s`	List variables.
`cfg -x`	Reset to factory defaults.
`cfg -c`	Commit the change to flash.
`cfg -a var=value`	Add or change variables.

Diagnose commands include:

`cw_diag help`	Display help for all diagnose commands.
`cw_diag uptime`	Show daemon uptime.
`cw_diag --tlog <on|off>`	Turn on/off telnet log message.
`cw_diag --clog <on|off>`	Turn on/off console log message.
`cw_diag baudrate [9600 | 19200 | 38400 | 57600 | 115200]`	Set the console baud rate.
`cw_diag plain-ctl [0|1]`	Show or change current plain control setting.
`cw_diag sniff-cfg ip port`	Set sniff server ip and port.
`cw_diag sniff [0|1|2]`	Enable/disable sniff packet.
`cw_diag stats wl_intf`	Show wl_intf status.
`cw_diag admin-timeout [30]`	Set shell idle timeout in minutes.
`cw_diag -c wtp-cfg`	Show current wtp config parameters in control plane.
`cw_diag -c radio-cfg`	Show current radio config parameters in control plane.
`cw_diag -c vap-cfg`	Show current vaps in control plane.
`cw_diag -c ap-rogue`	Show rogue APs pushed by AC for on-wire scan.
`cw_diag -c sta-rogue`	Show rogue STAs pushed by AC for on-wire scan.
`cw_diag -c arp-req`	Show scanned arp requests.
`cw_diag -c ap-scan`	Show scanned APs.

`cw_diag -c sta-scan`	Show scanned STAs.
`cw_diag -c sta-cap`	Show scanned STA capabilities.
`cw_diag -c wids`	Show scanned WIDS detections.
`cw_diag -c darrp`	Show darrp radio channel.
`cw_diag -c mesh`	Show mesh status.
`cw_diag -c mesh-veth-acinfo`	Show mesh veth ac info, and mesh ether type.
`cw_diag -c mesh-veth-vap`	Show mesh veth vap.
`cw_diag -c mesh-veth-host`	Show mesh veth host.
`cw_diag -c mesh-ap`	Show mesh ap candidates.
`cw_diag -c scan-clr-all`	Flush all scanned AP/STA/ARPs.
`cw_diag -c ap-suppress`	Show suppressed APs.
`cw_diag -c sta-deauth`	De-authenticate an STA.

FortiAP web-based manager

You can access the FortiAP unit's built-in web-based manager. This is useful to adjust settings that are not available through the FortiGate unit's WiFi Controller. Logging into the FortiAP web-based manager is similar to logging into the FortiGate web-based manager.

The advanced settings are in the WTP Configuration section on the System Information tab.

Uplink	The FortiAP unit can be connected to the controller by Ethernet, WiFi mesh, or Ethernet with mesh fallback.
AC Discovery Type	Static, DHCP, DNS, Broadcast, Multicast, Auto
AC Control Port	Default port is 5246.
AC IP Address 1 **AC IP Address 2** **AC IP Address 3**	You enter up to three WiFi controller IP addresses for static discovery. Routing must be properly configured in both directions.
AC Host Name 1 **AC Host Name 2** **AC Host Name 3**	As an alternetive to AC IP addresses, you can enter their fully qualified domain names (FQDNs).
AC Discovery Multicast Address	224.0.1.140
AC Discovery DHCP Option Code	When using DHCP discovery, you can configure the DHCP server to provide the controller address. By default the FortiAP unit expects this in option 138.
AC Data Channel Security	Select whether the FortiAP unit requires Clear Text data, DTLS encrypted data, or will accept either.

Chapter 7 Firewall for FortiOS 5.0

Firewall concepts explains the ideas behind the components, techniques and processes that are involved in setting up and running a firewall in general and the FortiGate firewall in particular. The premise here is that regardless of how experienced someone is with firewalls as they go through the process of configuring a firewall that is new to them they are likely to come across a term or setting that they may not be familiar with even if it is only in the context of the setting they are working in at the moment. FortiGate firewall are quite comprehensive and can be very granular in the functions that they perform, so it makes sense to have a consistent frame of reference for the ideas that we will be working with.

Some examples of the concepts that will be addressed here are:

- What is a Firewall?
- NAT
- IPv6

Firewall objects describes the following firewall objects:

- Addressing
- Services
- Firewall Policies

Network defense describes various methods of defending your Network using the abilities of the FortiGate Firewall.

GUI & CLI - What You May Not Know helps you navigate and find the components in the Web-based Manager that you will need to build the functions. This section is does not include any in-depth explanations of what each object does as that is covered in the concepts section. This section is for showing you where you need to input your information and let you know what format the interface expects to get that information

Building firewall objects and policies is similar to a cookbook in that it will refer to a number of common tasks that you will likely perform to get the full functionality out of your FortiGate firewall. Because of the way that firewall are designed, performing many of the tasks requires that firewall components be set up in a number of different sections of the interface and be configured to work together to achieve the desired result. This section will bring those components all together as a straight forward series of instructions.

Multicast forwarding is a reference guide including the concepts and examples that are involved in the use of multicast addressing and policy forwarding as it is used in the FortiGate firewall.

FortiGate Firewall Components

The FortiGate firewall is made up of a number of different components that are used to build an impressive list of features that have flexibility of scope and granularity of control that provide protection that is beyond that provided by the basic firewalls of the past.

Some of the components that FortiOS uses to build features are:

- Interfaces
- VLANs
- Soft Switches
- Zones
- Predefined Addresses
- IP address based
- FQDN based
- Geography based
- Access Schedules
- Authentication
- Local User based
- Authentication Server based (Active Directory, Radius, LDAP)
- Device Based
- Configureable Services
- IPv4 and IPv6 protocol support

The features of FortiOS include but are not limited to:

- Security profiles, sometimes referred to as Unified Threat Management (UTM) or Next Generation Firewall (NGFW)
- Predefined firewall addresses (this includes IPv4 and IPv6, IP pools,. wildcard addresses and netmasks, and geography-based addresses)
- Monitoring traffic
- Traffic shaping and per-IP traffic shaping (advanced)
- Firewall schedules
- Services (such as AOL, DHCP and FTP)
- Logging traffic
- Quality of Service (QoS)
- Identity-based policies
- Endpoint security

The Firewall concepts expands on what each of the features does and how they relate to the administration of the FortiGate firewall. The section will also try to explain some of the common firewall concepts that will be touched on in the implementing of these features.

Building firewall objects and policies shows how to perform specific tasks with the FortiGate firewall.

How does a FortiGate Protect Your Network

The FortiGate firewall protects your network by taking the various components and using them together to build a kind of wall or access control point so that anyone that is not supposed to be on your network is prevented from accessing your network in anyway other than those approved by you. It also protects your network from itself by keeping things that shouldn't happen from happening and optimizing the flow of traffic so that the network is protected from traffic congestion that would otherwise impede traffic flow.

Most people have at one time or another played with the children's toy system that is made up of interlocking blocks. The blocks come in different shapes and sizes so that you can build

structures to suit your needs and in your way. The components of the FortiGate firewall are similar. You are not forced to use all of the blocks all of the time. You mix and match them to get the results that you are looking for. You can build a very basic structure that's only function is to direct traffic in and out to the correct subnets or you can build a fortress that only allows specific traffic to specific hosts from specific hosts at specific times of day and that is only if they provide the credentials that have been pre-approved and all of the traffic is encrypted so that even when the traffic is out on the Internet it is private from the world. Just like the interlocking blocks, what you build is up to you, but chances are if you put them together the right way there isn't much that can't be built.

Here is one example of how the components could be put together to support the requirements of a network infrastructure design.

- Off the Internal interface you could have separate VLANs. One for each for the departments of Sales, Marketing and Engineering so that the traffic from the users on one VLAN does not intrude upon the hosts of the other VLANs and the department are isolated from one another for security reasons.
- To ease in the administration each of the VLAN sub-interfaces is made a member of a zone so that security policies that apply to all of the hosts on all of the VLANs can be applied to all of them at once.
- Using the addresses component each of the IP address ranges could be assigned a user friendly name so that they could be referred to individually and then for policies that would refer to them all as a whole the individual ranges to be made members of an address group.
- Firewall schedules could be created to address the differing needs of each of the groups so that Sales and Marketing could be allowed access to the Internet during regular business hours and the Engineering department could be allowed access during the lunch break.
- By setting up the outgoing policies to use FortiGuard Web-filtering the employees could be prevented from visiting inappropriate sites and thus enforcing the policies of the HR department.
- A couple of virtual IP addresses with port forwarding could be configured to allow users on the Internet to access a web server on the DMZ subnet using the company's only Public IP address without affecting the traffic that goes to the company's mail server that is hosted on a complete different computer.
- Even though the Web server on the same DMZ has an FTP service to allow for the uploading of web pages to the web server from the Marketing and Engineer teams, by placing a DENY policy on any FTP traffic from the Internet malicious users are prevented from abusing the FTP service.
- By monitoring the traffic as it goes through the policies you can verify that the policies are in working order.
- By using a combination of ALLOW and DENY policies and placing them in the correct order you could arrange for an outside contractor to be allowed to update the web site as well

These set of configurations is not extensive but it does give an idea of how different components can be mixed and matched to build a configuration that meets an organization's needs but at the same time protect it from security risks.

Firewall concepts

There are a number of concepts that are consistent throughout the firewall industry and having a solid grasp of these ideas and terms can give you a better idea of what your FortiGate firewall is capable of and how it will be able to fit within your networks architecture.

This chapter describes the following firewall concepts:

What is a Firewall?

The term firewall originally referred to a wall intended to confine a fire or potential fire within a building. Later uses refer to similar structures, such as the metal sheet separating the engine compartment of a vehicle or aircraft from the passenger compartment.

A firewall can either be software-based or hardware-based and is used to help keep a network secure. Its primary objective is to control the incoming and outgoing network traffic by analyzing the data packets and determining whether it should be allowed through or not, based on a predetermined rule set. A network's firewall builds a bridge between an internal network that is assumed to be secure and trusted, and another network, usually an external (inter)network, such as the Internet, that is not assumed to be secure and trusted.

Network Layer or Packet Filter Firewalls

Stateless Firewalls

Stateless firewalls are the oldest form of these firewalls. They are faster and simple in design requiring less memory because they process each packet individually and don't require the resources necessary to hold onto packets like stateful firewalls. Stateful firewalls inspect each packet individually and check to see if it matches a predetermined set of rules. According to the matching rule the packet is either be allowed, dropped or rejected. In the case of a rejection an error message is sent to the source of the traffic. Each packet is inspected in isolation and information is only gathered from the packet itself. Simply put, if the packets were not specifically allowed according to the list of rules held by the firewall they were not getting through.

Stateful Firewalls

Stateful firewalls retain packets in memory so that they can maintain context about active sessions and make judgements about the state of an incoming packet's connection. This enables Stateful firewalls to determine if a packet is the start of a new connection, a part of an existing connection, or not part of any connection. If a packet is part of an existing connection based on comparison with the firewall's state table, it will be allowed to pass without further processing. If a packet does not match an existing connection, it will be evaluated according to

the rules set for new connections. Predetermined rules are used in the same way as a stateless firewall but they can now work with the additional criteria of the state of the connection to the firewall.

Best Practices Tip for improving performance:

Blocking the packets in a denied session can take more cpu processing resources than passing the traffic through. By putting denied sessions in the session table, they can be kept track of in the same way that allowed session are so that the FortiGate unit does not have to redetermine whether or not to deny all of the packets of a session individually. If the session is denied all packets of that session are also denied.

In order to configure this you will need to use 2 CLI commands

```
config system setting
    set ses-denied-traffic enable
    set block-session-timer <integer 1 - 300> (this determines in seconds
        how long, in seconds, the session is kept in the table)
  end
```

Application Layer Firewalls

Application layer filtering is yet another approach and as the name implies it works primarily on the Application Layer of the OSI Model.

Application Layer Firewalls actually, for lack of a better term, understand certain applications and protocols. Examples would be FTP, DNS and HTTP. This form of filtration is able to check to see if the packets are actually behaving incorrectly or if the packets have been incorrectly formatted for the protocol that is indicated. This process also allows for the use of deep packet inspection and the sharing of functionality with Intrusion Prevention Systems (IPS).

Application-layer firewalls work on the application level of the TCP/IP stack (i.e., all browser traffic, or all telnet or ftp traffic), and may intercept all packets traveling to or from an application. They block other packets (usually dropping them without acknowledgment to the sender). Application firewalls work much like a packet filter but application filters apply filtering rules (allow/block) on a per process basis instead of filtering connections on a per port basis.

On inspecting all packets for improper content, firewalls can restrict or prevent outright the spread of networked computer worms and trojans. The additional inspection criteria can add extra latency to the forwarding of packets to their destination.

Proxy Servers

A proxy server is an appliance or application that acts as an intermediary for communicating between computers. A computer has a request for information. The packets are sent to the designated resource but before they can get there they are blocked by the proxy server saying that it will take the request and pass it on. The Proxy Server processes the request and if it is valid it passes onto the designated computer. The designated computer gets the packet and processes the request, sending the answer back to the proxy server. The proxy server sends the information back to the originating computer. It's all a little like a situation with two people who refuse to talk directly with each other using someone else to take messages back and forth.

From a security stand point a Proxy Server can serve a few purposes:

- Protects the anonymity of the originating computer
- The two computers never deal directly with each other
- Packets that are not configured to be forwarded are dropped before reaching the destination computer.
- If malicious code is sent it will affect the Proxy server with out affecting the originating or sending computer.

Proxies can perform a number of roles including:

- Content Filtering
- Caching
- DNS proxy
- Bypassing Filters and Censorship
- Logging and eavesdropping
- Gateways to private networks
- Accessing service anonymously

Security Profiles

Unified Threat Management and Next Generation Firewall are terms originally coined by market research firms and refer to the concept of a comprehensive security solution provided in a single package. It is basically combining of what used to be accomplished by a number of different security technologies all under a single umbrella or in this case, a single device. On the FortiGate firewall this is achieved by the use of Security Profiles and optimized hardware.

In effect it is going from a previous style of firewall that included among its features:

- Gateway Network Firewall
- Routing
- VPN

To a more complete system that includes:

- Gateway Network Firewall
- Routing
- VPN
- Traffic Optimization
- Proxy Services
- Content Filtering
- Application Control
- Intrusion Protection
- Denial of Service Attack Protection
- Anti-virus
- Anti-spam
- Data Leak Prevention
- Endpoint Control of Security Applications
- Load Balancing
- WiFi Access Management
- Authentication Integration into Gateway Security
- Logging
- Reporting

Advantages of using Security Profiles

- Avoidance of multiple installations.
- Hardware requirements are fewer.
- Fewer hardware maintenance requirements.
- Less space required.
- Compatibility - multiple installations of products increase the probability of incompatibility between systems.
- Easier support and management.
- There is only one product to learn therefore a reduced requirement of technical knowledge.
- Only a single vendor so there are fewer support contracts and Service Level Agreements.
- Easier to incorporated into existing security architecture.
- Plug and play architecture.
- Web based GUI for administration.

IPv6

What is IPv6?

Internet Protocol version 6 (IPv6) will succeed IPv4 as the standard networking protocol of the Internet. IPv6 provides a number of advances over IPv4 but the primary reason for its replacing IPv4 is its limitation in addresses. IPv4 uses 32 bit addresses which means there is a theoretical limit of 2 to the power of 32. The IPv6 address scheme is based on a 128 bit address or a theoretical limit of 2 to the power of 128.

Possible Addresses:

- IPv4 = 4,294,967,296 (over 4 billion)
- IPv6 = 340,282,366,920,938,463,463,374,607,431,768,211,456 (over 340 undecillion - We had to look that term up. We didn't know what a number followed by 36 digits was either)

Assuming a world population of approximately 8 billion people, IPv6 would allow for each individual to have approximately 42,535,295,865,117,200,000,000,000,000 devices with an IP address. That's 42 quintillion devices.

There is little likelihood that you will ever need to worry about these numbers as any kind of serious limitation in addressing but they do give an idea of the scope of the difference in the available addressing.

Aside from the difference of possible addresses there is also the different formatting of the addresses that will need to be addressed.

A computer would view an IPv4 address as a 32 bit string of binary digits made up of 1s and 0s, broken up into 4 octets of 8 digits separated by a period "."

Example:

10101100.00010000.11111110.00000001

To make number more user friendly for humans we translate this into decimal, again 4 octets separated by a period "."which works out to:

172.16.254.1

A computer would view an IPv6 address as a 128 bit string of binary digits made up of 1s and 0s, broken up into 8 octets of 16 digits separated by a colon ":"

1000000000000001:0000110110111000:101011000001000:1111111000000001:0000000000000000:0000000000000000:0000000000000000:0000000000000000

To make number a little more user friendly for humans we translate this into hexadecimal, again 8 octets separated by a colon ":" which works out to:

8001:0DB8:AC10:FE01:0000:0000:0000:0000:

Because any four-digit group of zeros within an IPv6 address may be reduced to a single zero or altogether omitted, this address can be shortened further to:

8001:0DB8:AC10:FE01:0:0:0:0

or

8001:0DB8:AC10:FE01::

Some of the other benefits of IPv6 include:

- More efficient routing
- Reduced management requirement
- Stateless auto-reconfiguration of hosts
- Improved methods to change Internet Service Providers
- Better mobility support
- Multi-homing
- Security
- Scoped address: link-local, site-local and global address space

IPv6 in FortiOS

From an administrative point of view IPv6 works almost the same as IPv4 in FortiOS. The primary difference is the use IPv6 format for addresses. There is also no need for NAT if the FortiGate firewall is the interface between IPv6 networks. If the subnets attached to the FortiGate firewall are IPv6 and IPv4 NAT can be configured between the 2 different formats. This will involve either configuring a dual stack routing or IPv4 tunnelling configuration. The reason for this is simple. NAT was developed primarily for the purpose of extending the number of usable IPv4 addresses. IPv6's addressing allows for enough available addresses so the NAT is no longer necessary.

When configuring IPv6 in FortiOS, you can create a dual stack route or IPv4-IPv6 tunnel. A dual stack routing configuration implements dual IP layers, supporting both IPv4 and IPv6, in both hosts and routers. An IPv4-IPv6 tunnel is essentially similar, creating a tunnel that encapsulates IPv6 packets within IPv4 headers that carry these IPv6 packets over IPv4 tunnels. The FortiGate unit can also be easily integrated into an IPv6 network. Connecting the FortiGate unit to an IPv6 network is exactly the same as connecting it to an IPv4 network, the only difference is that you are using IPv6 addresses.

By default the IPv6 settings are not displayed in the Web-based Manager. It is just a matter of enabling the display of these feature to use them through the web interface. To enable them just go to System > Admin > Settings and select IPv6 Support on GUI. Once enabled, you will be able to use IPv6 addresses as well as the IPv4 addressing for the following FortiGate firewall features:

- Static routing
- Policy Routing
- Packet and network sniffing
- Dynamic routing (RIPv6, BGP4+, and OSPFv3)
- IPSec VPN
- DNS
- DHCP
- SSL VPN
- Network interface addressing
- Security Profiles protection
- Routing access lists and prefix lists
- NAT/Route and Transparent mode
- NAT 64 and NAT 66
- IPv6 tunnel over IPv4 and IPv4 tunnel over IPv6
- Logging and reporting
- Security policies
- SNMP
- Authentication
- Virtual IPs and groups
- IPv6 over SCTP
- IPv6-specific troubleshooting, such as ping6

Dual Stack routing configuration

Dual stack routing implements dual IP layers in hosts and routers, supporting both IPv6 and IPv4. A dual stack architecture supports both IPv4 and IPv6 traffic and routes the appropriate

traffic as required to any device on the network. Administrators can update network components and applications to IPv6 on their own schedule, and even maintain some IPv4 support indefinitely if that is necessary. Devices that are on this type of network, and connect to the Internet, can query Internet DNS servers for both IPv4 and IPv6 addresses. If the Internet site supports IPv6, the device can easily connect using the IPv6 address. If the Internet site does not support IPv6, then the device can connect using the IPv4 addresses. In the FortiOS dual stack architecture it is not just the basic addressing functions that operate in both versions of IP. The other features of the appliance such as Security Profiles and routing can also use both IP stacks.

If an organization with a mixed network uses an Internet service provider that does not support IPv6, they can use an IPv6 tunnel broker to connect to IPv6 addresses that are on the Internet. FortiOS supports IPv6 tunnelling over IPv4 networks to tunnel brokers. The tunnel broker extracts the IPv6 packets from the tunnel and routes them to their destinations.

IPv6 Tunnelling

IPv6 Tunnelling is the act of tunnelling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. This is different than Network Address Translation (NAT) because once the packet reaches its final destination the true originating address of the sender will still be readable. The IPv6 packets are encapsulated within packets with IPv4 headers, which carry their IPv6 payload through the IPv4 network. This type of configuration is more appropriate for those who have completely transitional over to IPv6, but need an Internet connection, which is still mostly IPv4 addresses.

The key to IPv6 tunnelling is the ability of the 2 devices, whether they are a host or a network device, to be dual stack compatible. The have to be able to work with both IPv4 and IPv6 at the same time. In the process the entry node of the tunnel portion of the path will create an encapsulating IPv4 header and transmit the encapsulated packet. The exit node at the end of the tunnel receives the encapsulated packet. The IPv4 header is removed. The IPv6 header is updated and the IPv6 packet is processed.

There are two types of tunnels in IPv6:

Automatic tunnels	Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address – the IPv6 address of the destination host includes information about which IPv4 address the packet should be tunnelled to.
Configured tunnels	Configured tunnels must be configured manually. These tunnels are used when using IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the endpoints of the tunnel must be specified.

Tunnel Configurations

There are a few ways in which the tunnelling can be performed depending on which segment of the path between the end points of the session the encapsulation takes place.

Network Device to Network Device	Dual Stack capable devices connected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans one segment of the path taken by the IPv6 packets.
Host to Network Device	Dual Stack capable hosts can tunnel IPv6 packets to an intermediary IPv6 or IPv4 network device that is reachable through an IPv4 infrastructure. This type of tunnel spans the first segment of the path taken by the IPv6 packets.

Host to Host	Dual Stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. In this case, the tunnel spans the entire path taken by the IPv6 packets.
Network Device to Host	Dual Stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. This tunnel spans only the last segment of the path taken by the IPv6 packets.

Regardless of whether the tunnel starts at a host or a network device, the node that does the encapsulation needs to maintain soft state information, such as the maximum transmission unit (MTU), about each tunnel in order to process the IPv6 packets.

Tunnelling IPv6 through IPSec VPN

A variation on the tunnelling IPv6 through IPv4 is using an IPSec VPN tunnel between to FortiGate devices. FortiOS supports IPv6 over IPSec. In this sort of scenario, 2 networks using IPv6 behind FortiGate units are separated by the Internet, which uses IPv4. An IPSec VPN tunnel is created between the 2 FortiGate units and a tunnel is created over the IPv4 based Internet but the traffic in the tunnel is IPv6. This has the additional advantage of make the traffic secure as well.

NAT

What is NAT?

NAT or Network Address Translation is the process that enables a single device such as a router or firewall to act as an agent between the Internet or Public Network and a local or private network. This “agent”, in real time, translates the source IP address of a device on one network interface, usually the Internal, to a different IP address as it leaves another interface, usually the interface connected to the ISP and the Internet. This enables a single public address to represent a significantly larger number of private addresses.

The Origins of NAT

In order to understand NAT it helps to know why it was created. At one time, every computer that was part of a network had to have it’s own addresses so that the other computers could talk to it. There were a few protocols in use at the time, some of which were only for use on a single network, but of those that were routable, the one that had become the standard for the Internet was IP (Internet Protocol) version 4.

When IP version 4 addressing was created nobody had any idea how many addresses would be needed. The total address range was based on the concept of 2 to the 32nd power, which works out to be 4 294 967 296 potential addresses. Once you eliminate some of those for reserved addresses, broadcast addresses, network addresses, multicasting, etc., you end up with a workable scope of about 3.2 million addressees. This was thought to be more than enough at the time. The designers were not expecting the explosion of personal computing, the World Wide Web or smart phones. As of the beginning of 2012, some estimate the number of computers in the world in the neighborhood of 1 billion, and most of those computer users are going to want to be on the Internet or Search the World Wide Web. In short, we ran out of addresses.

This problem of an address shortage was realized before we actually ran out, and in the mid 1990s 2 technical papers called RFCs numbered 1631 (http://www.ietf.org/rfc/rfc1631.txt) and 1918 (http://tools.ietf.org/html/rfc1918), proposed components of a method that would be used

as a solution until a new addressing methodology could be implemented across the Internet infrastructure. For more information on this you can look up IP version 6.

RFC 1631 described a process that would allow networking devices to translate a single public address to multiple private IP addresses and RFC 1918 laid out the use of the private addresses. The addresses that were on the Internet (Public IP addresses) could not be duplicated for them to work as unique addresses, but behind a firewall, which most large institutions had, they could use their own Private IP addresses for internal use and the internal computers could share the external or Public IP address.

To give an idea on a small scale how this works, image that a company has a need for 200 computer addresses. Before Private IP addresses and NAT the company would have purchased a full Class C address range which would have been 254 usable IP addresses; wasting about 50 addresses. Now with NAT, that company only needs 1 IP address for its 200 computers and this leaves the rest of the IP addresses in that range available for other companies to do the same thing.

NAT gives better value than it would first appear because it is not 253 companies that can use 254 addresses but each of those 254 companies could set up their networking infrastructures to use up to thousands of Private IP addresses, more if they don't all have to talk to the Internet at the same time. This process enabled the Internet to keep growing even though we technically have many more computers networked than we have addresses.

Static NAT

In Static NAT one internal IP address is always mapped to the same public IP address.

In FortiGate firewall configurations this is most commonly done with the use of Virtual IP addressing.

An example would be if you had a small range of IP addresses assigned to you by your ISP and you wished to use one of those IP address exclusively for a particular server such as an email server.

Say the internal address of the Email server was 192.168.12.25 and the Public IP address from your assigned addresses range from 256.16.32.65 to 256.16.32.127. Many readers will notice that because one of the numbers is above 255 that this is not a real Public IP address. The Address that you have assigned to the interface connected to your ISP is 256.16.32.66, with 256.16.32.65 being the remote gateway. You wish to use the address of 256.16.32.70 exclusively for your email server.

When using a Virtual IP address you set the external IP address of 256.16.32.70 to map to 192.168.12.25. This means that any traffic being sent to the public address of 256.16.32.70 will be directed to the internal computer at the address of 192.168.12.25

When using a Virtual IP address, this will have the added function that when ever traffic goes from 192.168.12.25 to the Internet it will appear to the recipient of that traffic at the other end as coming from 256.16.32.70.

You should note that if you use Virtual IP addressing with the Port Forwarding enabled you do not get this reciprocal effect and must use IP pools to make sure that the outbound traffic uses the specified IP address.

Dynamic NAT

Dynamic NAT maps the private IP addresses to the first available Public Address from a pool of possible Addresses. In the FortiGate firewall this can be done by using IP Pools.

Overloading

This is a form of Dynamic NAT that maps multiple private IP address to a single Public IP address but differentiates them by using a different port assignment. This is probably the most widely used version of NAT. This is also referred to as PAT (Port Address Translation) or Masquerading.

An example would be if you had a single IP address assigned to you by your ISP but had 50 or 60 computers on your local network.

Say the internal address of the interface connected to the ISP was 256.16.32.65 (again an impossible address) with 256.16.32.64 being the remote gateway. If you are using this form of NAT any time one of your computers accesses the Internet it will be seen from the Internet as 256.16.32.65. If you wish to test this go to 2 different computers and verify that they each have a different private IP address then go to a site that tells you your IP address such as www.ipchicken.com. You will see that the site gives the same result of 256.16.32.65, if it existed, as the public address for both computers.

As mentioned before this is sometimes called Port Address Translation because network device uses TCP ports to determine which internal IP address is associated with each session through the network device. For example, if you have a network with internal addresses ranging from 192.168.1.1 to 192.168.1.255 and you have 5 computers all trying to connect to a web site which is normally listening on port 80 all of them will appear to the remote web site to have the IP address of 256.16.32.65 but they will each have a different sending TCP port, with the port numbers being somewhere between 1 and 65 535, although the port numbers between 1 to 1024 are usually reserved or already in use. So it could be something like the following:

```
192.168.1.10    256.16.32.65:   port 486
192.168.1.23    256.16.32.65:   port 2409
192.168.1.56    256.16.32.65:   port 53763
192.168.1.109   256.16.32.65:   port 5548
192.168.1.201   256.16.32.65:   port 4396
```

And the remote web server would send the responding traffic back based on those port numbers so the network device would be able to sort through the incoming traffic and pass it on to the correct computer.

Overlapping

Because everybody is using the relative same small selection of Private IP addresses it is inevitable that there will be two networks that share the same network range that will need to talk with each other. This happens most often over Virtual Private Networks or when one organization ends up merging with another. This is a case where a private IP address may be translated into a different private IP address so there are no issues with conflict of addresses or confusion in terms of routing.

An example of this would be when you have a Main office that is using an IP range of 172.16.0.1 to 172.20.255.255 connecting through a VPN to a recently acquired branch office that is already running with an IP range of 172.17.1.1 to 172.17.255.255. Both of these ranges are perfectly valid but because the Branch office range is included in the Main Office range any time the system from the Main office try to connect to an address in the Branch Office the routing the system will not send the packet to the default gateway because according to the routing table the address is in its own subnet.

The plan here would be to NAT in both directions so that traffic from neither side of the firewall would be in conflict and they would be able to route the traffic. Everything coming from the Branch Office could be assigned an address in the 192.168.1.1 to 192.168.1.255 range and everything from the Main office going to the Branch Office could be assigned to an address in the 192.168.10.1 to 192.168.10.255 range.

Benefits of NAT

More IP addresses Available while Conserving Public IP Addresses

As explained earlier, this was the original intent of the technology and does not need to be gone into further.

Financial Savings

Because an organization does not have to purchase IP addresses for every computer in use there is a significant cost savings due to using the process of Network Address Translation.

Security Enhancements

One of the side benefits of the process of NAT is an improvement in security. Individual computers are harder to target from the outside and if port forwarding is being used computers on the inside of a firewall are less likely to have unmonitored open ports accessible from the Internet.

Ease of Compartmentalization of Your Network

With a large available pool of IP addresses to use internally a network administrator can arrange things to be compartmentalized in a rational and easily remembered fashion and networks can be broken apart easily to isolate for reasons of network performance and security.

Example:

You have a large organization that for security reasons has certain departments that do not share network resources.

You can have the main section of the organization set up as follows;

Network Devices	192.168.1.1 to 192.168.1.25
Internal Servers	192.168.1.26 to 192.168.1.50
Printers	192.168.1.51 to 192.168.1.75
Administration Personnel	192.168.1.76 to 192.168.1.100
Sales People	192.168.1.101 to 192.168.1.200
Marketing	192.168.1.201 to 192.168.1.250

You could then have the following groups broken off into separate subnets:

Accounting	192.168.100.1 to 192.168.100.255
Research and Development	172.16.1.1 to 172.16.255.255
Executive Management	192.168.50.1 to 192.168.50.255
Web sites and Email Servers	10.0.50.1 to 10.0.50.255

These addresses do not have to be assigned right away but can be used as planned ranges.

NAT in Transparent Mode

Similar to operating in NAT mode, when operating a FortiGate unit in Transparent mode you can add security policies and:

- Enable NAT to translate the source addresses of packets as they pass through the FortiGate unit.
- Add virtual IPs to translate destination addresses of packets as they pass through the FortiGate unit.
- Add IP pools as required for source address translation

A FortiGate unit operating in Transparent mode normally has only one IP address - the management IP. To support NAT in Transparent mode, you can add a second management IP. These two management IPs must be on different subnets. When you add two management IP addresses, all FortiGate unit network interfaces will respond to connections to both of these IP addresses.

Use the following steps to configure NAT in Transparent mode

1. Add two management IPs
2. Add an IP pool to the WAN1 interface
3. Add an Internal to WAN1 security policy

You can add the security policy from the web-based manager and then use the CLI to enable NAT and add the IP pool.

The usual practice of NATing in transparent mode makes use of two management IP addresses that are on different subnets, but this is not an essential requirement in every case.

If there is a router between the client systems and the FortiGate unit you can use the router's capabilities of tracking sessions to assign NATed addresses from an IP pool to the clients even if the assigned address don't belong to a subnet on your network.

Example:

Client computer has an IP address of 1.1.1.33 on the subnet 1.1.1.0/24

Router "A" sits between the client computer and the FortiGate (in Transparent mode) with the IP address of 1.1.1.1 on the client's side of the router and the IP address of 192.168.1.211 on the FortiGate's side of the router.

Use NAT to assign addresses from an address pool of 9.9.9.1 to 9.9.9.99 to traffic coming from gateway of 192.168.1.211.

To enable the return traffic to get to the original computer, set up a static route than assigns any traffic with a destination of 9.9.9.0/24 to go through the 192.168.1.211 gateway. As long as the session for the outgoing traffic has been maintained, communication between the client computer and the external system on the other side of the FortiGate will work.

Central NAT Table

The central NAT table enables you to define, and control with more granularity, the address translation performed by the FortiGate unit. With the NAT table, you can define the rules which dictate the source address or address group and which IP pool the destination address uses.

While similar in functionality to IP pools, where a single address is translated to an alternate address from a range of IP addresses, with IP pools there is no control over the translated port. When using the IP pool for source NAT, you can define a fixed port to guarantee the source port number is unchanged. If no fix port is defined, the port translation is randomly chosen by the FortiGate unit. With the central NAT table, you have full control over both the IP address and port translation.

The FortiGate unit reads the NAT rules in a top-down methodology, until it hits a matching rule for the incoming address. This enables you to create multiple NAT policies that dictate which IP pool is used based on the source address. The NAT policies can be rearranged within the policy list as well. NAT policies are applied to network traffic after a security policy.

NAT 64 and NAT46

NAT64 and NAT46 are the terms used to refer to the mechanism that allows IPv6 addressed hosts to communicate with IPv4 addressed hosts and vice-versa. Without such a mechanism an IPv6 node on a network such as a corporate LAN would not be able to communicate with a web site that was still in a IPv4 only environment and IPv4 environments would not be able to connect to IPv6 networks.

One of these setups involves having at least 2 interfaces, 1 on an IPv4 network and 1 on an IPv6 network. The NAT64 server synthesizes AAAA records, used by IPv6 from A records used by IPv4. This way client-server and peer to peer communications will be able to work between an IPv6 only client and an IPv4 server without making changes to either of the end nodes in the communication transaction. The IPv6 network attached to the FortiGate unit should be a 32 bit segment, (for instance 64:ff9b::/96, see RFC 6052[Set up a link to http://tools.ietf.org/html/rfc6052], RFC 6146[set up a link http://tools.ietf.org/html/rfc6146]). IPv4 address will be embedded into the communications from the IPv6 client.

Because the IPv6 range of addresses is so much larger than the IPv4 range, a one to one mapping is not feasible. Therefore the NAT64 function is required to maintain any IPv6 to IPv4 mappings that it synthesizes. This can be done either statically by the administrator or automatically by the service as the packets from the IPv6 network go through the device. The first method would be a stateless translation and the second would be a stateful translation. NAT64 is designed for communication initiated from IPv6 hosts to IPv4 addresses. It is address mapping like this that allows the reverse to occur between established connections. The stateless or manual method is an appropriate solution when the NAT64 translation is taking place in front of legacy IPv4 servers to allow those specific servers to be accessed by remote IPv6-only clients. The stateful or automatic solution is best used closer to the client side when you have to allow some specific IPv6 clients to talk to any of the IPv4-only servers on the Internet.

There are currently issues with NAT64 not being able to make everything accessible. Examples would be SIP, Skype, MSN, Goggle talk, and sites with IPv4 literals. IPv4 literals being IPv4 addresses that are imbedded into content rather than a FQDN.

Policies that employ NAT64 or NAT46 can be configured from the web-based manager as long as the feature is enabled using the Features setting found at *System* > *Config* > *Features*.

- To create a NAT64 policy go to *Policy* > *Policy* > *NAT64 Policy* and select *Create New*.
- To create a NAT46 policy go to *Policy* > *Policy* > *NAT46 Policy* and select *Create New*.

The difference between these NAT policies and regular polices is that there is no option to use the security profiles and sensors.

NAT 66

NAT 66 is Network Address Translation between 2 IPv6 network. The basic idea behind NAT 66 is no different than the regular NAT between IPv4 networks that we are all used to. The difference are in the mechanics of how it is performed, mainly because of the complexity and size of the addresses that are being dealt with.

In an IPv4 world, the reason for the use of NAT was usually one or a combination of the following 3 reasons:

- Improved security - actual addresses behind NAT are virtually hidden
- Amplification of addresses - hundreds of computers can use as little as a single public IP address
- Internal address stability - there is control of internal addressing. The addresses can stay the same even if Internet Service Providers change.

In these days of security awareness the protective properties of NAT are not something that are not normally depended on by themselves to defend a network and with the vastly enlarged IPv6 address scope there is no longer a need to amplify the available addresses. However, the desire to have internal address control still exists. The most common reason for using NAT66 is likely to be the maintaining of the existing address scheme of the internal network despite changes outside of it. Imagine that you have an internal network of 2000 IP addresses and one day the company changes its ISP and thus the addresses assigned to it. Even if most of the addressing is handled by DHCP, changing the address scheme is going to have an impact on operations.

Addressing stability can be achieved by:

- Keeping the same provider - this would depend on the reason for the change. If the cost of this provider has become too expensive this is unlikely. If the ISP is out of business it becomes impossible.
- Transfer the addresses from the old provider to the new one - There is little motivation for an ISP to do you a favor for not doing business with them.
- Get your own autonomous system number - this can be too expensive for smaller organizations.
- NAT - this is the only one on the list that is in the control of IT.

There are differences between NAT66 and IPv4 NAT. Because there is no shortage of addresses most organizations will be given a /48 network that can be translated into another /48 network. This allows for a one to one translation, no need for port forwarding. This is a good thing because port forwarding is more complicated in IPv6. In fact, NAT66 will actually just be the rewriting of the prefix on the address.

Example:

If your current IPv6 address is

```
2001:db8:cafe::/48
```

you could change it to

```
2001:db8:fea7::/48
```

There is an exception to the one to one translation. NAT66 cannot translate internal networks that contain 0xffff in bits 49 through 63 - this is due to the way checksums are calculated in TCP/IP: they use the one's-complement representation of numbers which assigns the value zero to both 0x0000 and 0xffff.

How Packets are handled by FortiOS

To give you idea of what happens to a packet as it makes its way through the FortiGate unit here is a brief overview. This particular trip of the packet is starting on the Internet side of the FortiGate firewall and ends with the packet exiting to the Internal network. An outbound trip would be similar. At any point in the path if the packet is going through what would be considered a filtering process and if fails the filter check the packet is dropped and does not continue any further down the path.

This information is covered in more detail in other in the Troubleshooting chapter of the FortiOS Handbook in the Life of a Packet section.

The incoming packet arrives at the external interface. This process of entering the device is referred to as ***ingress***.

Step #1 - Ingress

1. Denial of Service Sensor
2. IP integrity header checking
3. IPSec connection check
4. Destination NAT
5. Routing

Step #2 - Stateful Inspection Engine

1. Session Helpers
2. Management Traffic
3. SSL VPN
4. User Authentication
5. Traffic Shaping
6. Session Tracking
7. Policy lookup

Step #3 - Security Profiles scanning process

1. Flow-based Inspection Engine
2. IPS
3. Application Control
4. Data Leak Prevention
5. Email Filter
6. Web Filter
7. Anti-virus
8. Proxy-based Inspection Engine
9. VoIP Inspection
10. Data Leak Prevention
11. Email Filter
12. Web Filter
13. Anti-virus
14. ICAP

Step #4 - Egress

1. IPSec
2. Source NAT
3. Routing

FortiGate Modes

The FortiGate unit has a choice of modes that it can be used in, either NAT/Route mode or Transparent mode. The FortiGate unit is able to operate as a firewall in both modes, but some of

its features are limited in Transparent mode. It is always best to choose which mode you are going to be using at the beginning of the set up. Once you start configuring the device, if you want to change the mode you are going to lose all configuration settings in the change process.

NAT/Route Mode

NAT/Route mode is the most commonly used mode by a significant margin and is thus the default setting on the device. As the name implies the function of NAT is commonly used in this mode and is easily configured but there is no requirement to use NAT. The FortiGate unit performs network address translation before IP packets are sent to the destination network.

These are some of the characteristics of NAT/Route mode:

- Typically used when the FortiGate unit is a gateway between private and public networks.
- Can act as a router between multiple networks within a network infrastructure.
- When used, the FortiGate unit is visible to the networks that is connected to.
- Each logical interface is on a distinct subnet.
- Each Interface needs to be assigned a valid IP address for the subnet that it is connected to it.

Transparent Mode

Transparent mode is so named because the device is effectively transparent in that it does not appear on the network in the way that other network devices show as a nodes in the path of network traffic. Transparent mode is typically used to apply the FortiOS features such as Security Profiles etc. on a private network where the FortiGate unit will be behind an existing firewall or router.

These are some of the characteristics of Transparent mode:

- The FortiGate unit is invisible to the network.
- All of its interfaces are on the same subnet and share the same IP address.
- The FortiGate unit uses a Management IP address for the purposes of Administration.
- Still able to use NAT to a degree, but the configuration is less straightforward

In Transparent mode, you can also perform NAT by creating a security policy or policies that translates the source addresses of packets passing through the FortiGate unit as well as virtual IP addresses and/or IP pools.

Quality of Service

The Quality of Service (QoS) feature allows the management of the level of service and preference given to the various types and sources of traffic going through the firewall so that the traffic that is important to the services and functions connecting through the firewall gets the treatment required to ensure the level of quality that is required. QoS can be helpful for organizations that are trying to manage their voice and streaming multi-media traffic, which can rapidly consume bandwidth. Both voice and streaming multi-media are sensitive to latency. FortiGate units support QoS using traffic policing, traffic shaping, and queuing.

Traffic policing

Packets are dropped that do not conform to bandwidth limitations

Traffic Shaping

Assigning minimum levels of bandwidth to be allocated to specific traffic flows to guarantee levels of service or assigning maximum levels of bandwidth to be allocated to specific traffic flows so that they do not impede other flows of traffic.

This helps to ensure that the traffic may consume bandwidth at least at the guaranteed rate by assigning a greater priority queue if the guarantee is not being met. Traffic shaping also ensures that the traffic cannot consume bandwidth greater than the maximum at any given instant in time. Flows that are greater than the maximum rate are subject to traffic policing.

Queuing

Assigning differing levels of priority to different traffic flows so that traffic flows that are adversely effected by latency are prevented from being effected by traffic flows that are not subject to the effects of latency. All traffic in a higher priority traffic queue must be completely transmitted before traffic in lower priority queues will be transmitted.

An example of where you would want to use something like this is if you had competing traffic flows of Voice over IP traffic and email traffic. The VoIP traffic is highly susceptible to latency issues. If you have a delay of a few seconds it is quickly noticeable when it is occurring. Email on the other hand can have a time delay of much longer and it is highly unlikely that it will be noticed at all.

By default, the priority given to any traffic is high, so if you want to give one type of traffic priority over all other traffic you will need to lower the priority of all of the other traffic.

For additional information about QoS, see the Traffic Shaping chapter of the FortiOS Handbook.

Interfaces and Zones

A Firewall is a gateway device that may be the nexus point for more than 2 networks. The interface that the traffic is coming in on and should be going out on is a fundamental concern for the purposes of routing as well as security. Routing, policies and addresses are all associated with interfaces. The interface is essentially the connection point of a subnet to the FortiGate unit and once connected can be connected to other subnets.

Physical interfaces or not the only ones that need to be considered. There are also virtual interfaces that can be applied to security policies. VLANs are one such virtual interface. Interfaces if certain VPN tunnels are another.

Polices are the foundation of the traffic control in a firewall and the Interfaces and addressing is the foundation that policies are based upon. Using the identity of the interface that the traffic connects to the FortiGate unit tells the firewall the initial direction of the traffic. The direction of the traffic is one of the determining factors in deciding how the traffic should be dealt with. You can tell that interfaces are a fundamental part of the policies because, by default, this is the criteria that the polices are sorted by.

Zones are a mechanism that was created to help in the administration of the firewalls. If you have a FortiGate unit with a large number of ports and a large number of nodes in you network the chances are high that there is going to be some duplication of policies. Zones provide the option of logically grouping multiple virtual and physical FortiGate firewall interfaces. The zones can then be used to apply security policies to control the incoming and outgoing traffic on those interfaces. This helps to keep the administration of the firewall simple and maintain consistency.

For example you may have several floors of people and each of the port interfaces could go to a separate floor where it connects to a switch controlling a different subnet. The people may be on different subnets but in terms of security they have the same requirements. If there were 4 floors and 4 interfaces a separate policy would have to be written for each floor to be allowed out on to the Internet off the WAN1 interface. This is not too bad if that is all that is being done, but now start adding the use of more complicated policy scenarios with Security Profiles, then throw in a number of Identity based issues and then add the complication that people in that organization tend to move around in that building between floors with their notebook computers. Each time a policy is created for each of those floors there is a chance of an inconsistency cropping up. Rather than make up an additional duplicate set of policies for each floor, a zone can be created that combines multiple interfaces. And then a single policy can created that uses that zone as one side of the traffic connection.

Firewall objects

As was mentioned earlier, the components of the FortiGate firewall go together like interlocking building blocks. The Firewall objects are a prime example of those building blocks. They are something that can be configured once and then used over and over again to build what you need. They can assist in making the administration of the FortiGate unit easier and more intuitive as well as easier to change. By configuring these objects with their future use in mind as well as building in accurate descriptions the firewall will become almost self documenting. That way, months later when a situation changes, you can take a look at a policy that needs to change and use a different firewall object to adapt to the new situation rather than build everything new from the ground up to accommodate the change.

This chapter includes information about the following Firewall objects:

Addresses

Firewall addresses define sources and destinations of network traffic and are used when creating policies. When properly set up these firewall objects can be used with great flexibility to make the configuration of firewall policies simpler and more intuitive. The FortiGate unit compares the IP addresses contained in packet headers with a security policy's source and destination addresses to determine if the security policy matches the traffic.

The addresses in the FortiGate unit can include:

- IPv4 addresses
- IPv6 addresses
- IPv4 Address Groups
- IPv6 Address Groups
- IP Pools
- Virtual IP Addresses
- Geography based addresses
- Wildcard addresses and netmasks
- Fully Qualified Domain Name addresses

When setting up an address one of the parameters that is asked for is the interface. This means that the system will expect to see that address only on the interface that you select. You can only select one interface. If you expect that the address may be seen at more than one interface you can choose the "any" interface option. Whenever, possible it is best to choose a more specific interface than the "any" option because in the GUI configuration of firewall policies there is a drop down field that will show the possible addresses that can be used. The drop down will only show those addresses that can be on the interface assigned for that interface in the policy.

Example:

- You have an address called “XYZ”
- “XYZ” is set to the WAN1 interface because that is the only interface that will be able to access that address.
- When you are selecting a Source Address in the Web-based Manager for a policy that is using the DMZ the address “XYZ” will not be in the drop-down menu.

When there are only 10 or 20 addresses this is not a concern, but if there are a few hundred addresses configured it can make your life easier.

Addresses, address groups, and virtual IPs must have unique names to avoid confusion in firewall policies. If an address is selected in a policy, the address cannot be deleted until it is deselected from the policy.

Addressing Best Practices Tip

The other reason to assign a specific interface to addresses is that it will prevent you from accidentally assigning an address where it will not work properly. Using the example from earlier, if the “XYZ” address was assigned to the “Any” interface instead of WAN1 and you configure the “XYZ” address.

IPv4 Address and Net Mask

When representing hosts by an IP address with a netmask, the IP address can represent one or more hosts. For example, a firewall address can be:

- A single host such as a single computer with the address 192.45.46.45
- A range of hosts such as all of the hosts on the subnet 192.45.46.1 to 192.45.46.255
- All hosts, represented by 0.0.0.0 which matches any IP address

The netmask corresponds to the subnet class of the address being added, and can be represented in either dotted decimal or CIDR format. The FortiGate unit automatically converts CIDR formatted netmasks to dotted decimal format. Example formats:

- Netmask for a class A subnet of 16,777,214 usable addresses: 255.0.0.0, or /8
- Netmask for a class B subnet of 65,534 usable addresses: 255.255.0.0, or /16
- Netmask for a class C subnet of 254 usable addresses: 255.255.255.0, or /24
- Netmask for subnetted class C of 126 usable addresses: 255.255.255.128, or /25
- Netmask for subnetted class C of 62 usable addresses: 255.255.255.128, or /26
- Netmask for subnetted class C of 30 usable addresses: 255.255.255.128, or /27
- Netmask for subnetted class C of 14 usable addresses: 255.255.255.128, or /28
- Netmask for subnetted class C of 6 usable addresses: 255.255.255.128, or /29
- Netmask for subnetted class C of 2 usable addresses: 255.255.255.128, or /30
- Netmask for a single computer: 255.255.255.255, or /32
- Netmask used with 0.0.0.0 to include all IP addresses: 0.0.0.0, or /0

So for a single host or subnet the valid format of IP address and netmask could be either:

x.x.x.x/x.x.x.x, such as 192.168.1.0/255.255.255.0

or

x.x.x.x/x, such as 192.168.1.0/24

It is also possible to describe a range of IP addresses with a subnet. This would be a continuous set of IP addresses within a subnet. It does not have to include the whole subnet. The formats would be (the * being used as a wildcard character):

x.x.x.x-x.x.x.x, such as 192.168.110.100-192.168.110.120

x.x.x.[x-x], such as 192.168.110.[100-120]

x.x.x.*, such as 192.168.110.*

FQDN Addressing

By using Fully Qualified Domain Name (FQDN) addressing you can take advantage of the dynamic ability of the service to keep up with address changes without having to manually change the addresses on the FortiGate. FQDN addresses are most often used with external web sites but they can be used for internal web sites as well if there is a trusted DNS server that can be accessed. FQDN addressing also comes in handy for large web sites that may use multiple addresses and load balancers for their web sites. The FortiGate firewall automatically maintains a cached record of all the addresses resolved by the DNS for the FQDN addresses used.

For example, if you were doing this manually and you wanted to have a security policy that involved Google you could track down all of the IP addresses that they use across multiple countries. Using the FQDN address is simpler and more convenient.

When representing hosts by an FQDN, the domain name can also be a subdomain, such as mail.example.com.

Valid FQDN formats include:

- <host_name>.<top_level_domain_name> such as example.com
- <host_name>.<second_level_domain_name>.<top_level_domain_name>, such as mail.example.com

When creating FQDN entries it is important to remember that:

- Wildcards are not supported in FQDN address objects
- While there is a level of convention that would imply it, “www.example.com” is not necessarily the same address of “example.com”. they will each have their own records on the DNS server.

The FortiGate firewall keeps track of the DNS TTLs so as the entries change on the DNS servers the IP address will effectively be updated for the FortiGate. As long as the FQDN address is used in a security policy, it stores the address in the DNS cache.

There is a possible security downside to using FQDN addresses. Using a fully qualified domain name in a security policy means that your policies are relying on the DNS server to be accurate and correct. DNS servers in the past were not seen as potential targets because the thinking was that there was little of value on them and therefore are often not as well protected as some other network resources. People are becoming more aware that the value of the DNS server is that in many ways it controls where users and computers go on the Internet. Should the DNS server be compromised, security policies requiring domain name resolution may no longer function properly.

Geography Based Addressing

Geography based addressing enables you to design policies based on addresses that are associated with a country.

This feature can be used to make either inclusive or exclusive policies. For instance, if you have a SSL VPN where the users will only be connecting from a single country, but you don’t know

from where in that country, you can filter out any connections coming in that are from outside that country.

On the other side of the equation, if you find that you are constantly being attacked by malicious intruders from a few countries that you have no dealings with you can block access to them before any traffic comes through.

The matching of geographical country designations to an IP address is achieved by collecting data from any IP addresses that connect to any of the FortiGuard Servers throughout the world. As a secondary task, when a FortiGuard server connects to an IP it also does a search on the Country of origin for the address and updates the database.

There is no single comprehensive list of IP addresses and their locations available because IP addresses can be transferred between ISPs or countries and some organization may not keep complete or up-to-date records regarding locations. FortiGuard Services are constantly updating their database of addresses matched to locations, but the database is dynamic and there may be addresses that have not been resolved to a location. While this means that there can be gaps in the completeness of the database it is possible to fill them in manually by means local to your FortiGate unit.

IPv6 does not support geography-based addressing. This feature is for IPv4 addresses only.

Best Practices Tip:

Based on the limitation of the IP address matched to country database, it is best to use this type of address in a group with other addresses to fill in the gaps. For instance, if you are a company in Country “A” and all of your employees that will be using the SSL-VPN connection are in that country, the best practice would be to create an address group that includes the geographical address of Country “A”. As valid addresses appear that are not allowed, you can add these other IPs to that group using IP addresses or IP range addresses without having to change the policy itself.

If you are trying to block addresses the principle works just the same. Your logs show that someone from IP address x.x.x.x has been trying to connect inappropriately to your network. You use a IP locator web site to determine that they have been attempting to connect from Country “X”. Up until now they have not been successful, but you don’t deal with the country they are connecting from so don’t mind blocking the whole country. Create an address group that is designed for Blocking Access to any addresses in it, then add the geographical address for Country “X”. Even if the policy does not block every single IP address from that country you have greatly increased your odds of blocking potential intrusion attempts. As your logs show other attempts you can look them up in an IP locator web site and if they are from the same country you can add the IP address for the subnet that they are connecting from.

Address Groups

Address groups are designed for ease of use in the administration of the device. If you have a number of addresses or address ranges that will commonly be treated the same or require the same security policies, you can put them into address groups, rather than entering multiple individual addresses in each policy refers to them.

The use of groups is not required. If you have a number of different addresses you could add them individually to a policy and the FortiGate firewall will process them just as quickly and efficiently as if they were in a group, but the chances are that if you have used a group once you could need to use it again and depending on the number of addresses involved entering them individually for each policy can become tedious and the likelihood of an address being missed becomes greater. If you have a number of policies using that combination of addresses it is much easier to add or subtract addresses from the group than to try and remember all of the firewall policies that combination of addresses was used in. With the group, you only have to make the one edit and it is used by any firewall policy using that address group.

Because security policies require addresses with homogenous network interfaces, address groups should contain only addresses bound to the same network interface, or to Any.

For example, if address 1.1.1.1 is associated with port1, and address 2.2.2.2 is associated with port2, they cannot be in the same group. However, if 1.1.1.1 and 2.2.2.2 are configured with an interface of Any, they can be grouped, even if the addresses involve different networks.

IPv4 address groups and IPv6 address groups are created and treated separately. You cannot mix IPv4 firewall addresses and IPv6 firewall addresses in the same address group. Because the Internet is currently based on IPv4 addresses IPv6 address groups cannot include FQDN or Geography based addresses.

Wildcard Addressing

Wildcard addresses are addresses that identify ranges of IP addresses, reducing the amount of firewall addresses and security policies required to match some of the traffic on your network. Wildcard addresses are an advanced feature, usually required only for complex networks with complex firewall filtering requirements. By using these wildcard addresses in the firewall configuration, administrators can eliminate creating multiple, separate IP based address objects and then grouping them to then apply to multiple security policies.

A wildcard address consists of an IP address and a wildcard netmask, for example, 192.168.0.56 255.255.0.255. In this example, the IP address is 192.168.0.56 and the wildcard netmask is 255.255.0.255. The IP address defines the networks to match and the wildcard netmask defines the specific addresses to match on these networks.

In a wildcard netmask, zero means ignore the value of the octet in the IP address, which means the wildcard firewall address matches any number in this address octet. This also means that the number included in this octet of IP address is ignored and can be any number. Usually, if the octet in the wildcard netmask is zero, the corresponding octet in the IP address is also zero.

In a wildcard netmask, a number means match addresses according to how the numbers translate into binary addresses. For example, the wildcard netmask is 255; the wildcard address will only match addresses with the value for this octet that is in the IP address part of the wildcard address. So, if the first octet of the IP address is 192 and the first octet of the wildcard netmask is 255, the wildcard address will only match addresses with 192 in the first octet.

In the above example, the wildcard address 192.168.0.56 255.255.0.255 would match the following IP addresses:

192.168.0.56, 192.168.1.56, 192.168.2.56,..., 192.168.255.56

The wildcard addresses 192.168.0.56 255.255.0.255 and 192.168.1.56 255.255.0.255 define the same thing since the 0 in the wildcard mask means to match any address in the third octet.

If we use the wildcard address 172.0.20.10 255.0.255.255, it would match the following IP addresses:

172.1.20.10, 172.2.20.10, 172.3.20.10,..., 172.255.20.10

In a wildcard netmask, a number other than 255 matches multiple addresses for this octet. You can perform a binary conversion to calculate the addresses that would be matched by a given

value. For example, to create the IP address and wildcard netmask to match the following network addresses:

192.168.32.0/24

192.168.33.0/24

192.168.34.0/24

192.168.35.0/24

192.168.36.0/24

192.168.37.0/24

192.168.38.0/24

192.168.39.0/24

Table 45 shows how to write the third octet for these networks according to the octet bit position and address value for each bit.

Table 45: Octet bit position and address value for each bit

Decimal	128	64	32	16	8	4	2	1
32	0	0	1	0	0	0	0	0
33	0	0	1	0	0	0	0	1
34	0	0	1	0	0	0	1	0
35	0	0	1	0	0	0	1	1
36	0	0	1	0	0	1	0	0
37	0	0	1	0	0	1	0	1
38	0	0	1	0	0	1	1	0
39	0	0	1	0	0	1	1	1
	M	M	M	M	M	D	D	D

Since the first five bits match, the networks can be summarized into one network (192.168.32.0/21 or 192.168.32.0 255.255.248.0). All eight possible combinations of the three low-order bits are relevant for the network ranges. The wildcard address that would match all of these subnet addresses can be written as 192.168.32.0 255.255.248.0.

Wildcard addresses are similar to routing access list wildcard masks. You add routing access lists containing wildcard masks using the `config router access list` command. However, router access list wildcard masks use the inverse of the masking system used for firewall wildcard addresses. For the router access list wildcard masks, zero (0)means match all IP addresses and one (1)means ignore all IP addresses. So to match IP addresses 192.168.0.56, 192.268.1.56, 192.168.2.56,... 192.168.255.56 you would use the following router access IP address prefix and wildcard mask: 192.168.0.56 0.0.255.0.

Wildcard firewall addresses are configured only in the CLI. The following is an example of how to configure a wildcard firewall address.

```
config firewall address
  edit example_wildcard_address
    set type wildcard
    set wildcard 192.168.0.56 255.255.0.255
  end
```

Virtual IP Addresses (VIPs)

The mapping of a specific IP address to another specific IP address is usually referred to as Destination NAT. FortiOS has a component that is a bit more specialized along this line called a Virtual IP Address, sometimes referred to as a VIP. FortiOS uses a Virtual IP address to map an External IP address to an IP address. This address does not have to be an individual host, it can also be an address range. This mapping can include all TCP/UDP ports or if Port Forwarding is enabled it will only refer to the specific ports configured.

Virtual IP addresses are typically used to NAT external or Public IP addresses to internal or Private IP addresses. Using a Virtual IP address between 2 internal Interfaces made up of Private IP addresses is possible but there is rarely a reason to do so as the 2 networks can just use the IP addresses of the networks without the need for any address translation. Using a Virtual IP address for traffic going from the inside to the Internet is even less likely to be a requirement, but it is supported.

Something that needs to be considered when there are multiple Public IP addresses on the external interface(s) is that when a Virtual IP address is used without Port Forwarding enabled there is a reciprocal effect as far as traffic flow is concerned. Normally, on a firewall policy where NAT is enabled, for outgoing traffic the internal address is translated to the Public address that is assigned to the FortiGate, but if there is a Virtual IP address with no port forwarding enabled, then the Internal IP address in the Mapped field would be translated to the IP address configured as the External Address in the VIP settings.

Best practice: Put any policies with a VIP right at the beginning of the policy list, with nothing before them. VIP traffic is processed first, before the regular rules of order in policies are applied. The sequence of the policies not containing VIPS will not effect those that do contain VIPS, regardless of the order they are in. Put VIP policies before any others to remind yourself of where they really are in the sequence.

For more on this topic, read the "Exception to policy order (VIPs)" on page 956.

Example:

- The assigned External address (WAN1) of the FortiGate unit is 172.12.96.3 with a subnet mask of 255.255.255.128
- There is a Virtual IP address set up to map the external address 172.12.96.127 on WAN1 to the internal IP address of 192.168.1.127
- Port Forwarding is not enabled because you want all allowed traffic going to the external IP address to go to this server.

In this case any outbound traffic from 192.168.1.127 will go out on WAN1 with the IP address of 172.12.96.127 as the source IP address.

In terms of actually using the Virtual IP address, they would be using in the security policies in the same places that other addresses would be used, usually as a Destination Address.

There is another type of address that the term "virtual IP address" commonly refers to which is used in load balancing and other similar configurations. In those cases, a number of devices share a separately created virtual IP address that can be sent to multiple possible devices. In FortiOS these are referred to as Virtual Servers and are configured in the "Load Balance" section.

Virtual IP Groups

Just like other address, Virtual IP addresses can be organized into groups for ease of administration. If you have multiple virtual IPs that are likely to be associated to common firewall policies rather than add them individually to each of the policies you can add the instead. That

way, if the members of the group change then any changes made to the group will propagate to all of the polices using that group.

When using a Virtual IP address group the firewall policy will take into account all of the configured parameters of the Virtual IPs: IP addresses, Ports and port types.

IP Pools

IP Pools are a mechanism that allow sessions leaving the FortiGate Firewall to use NAT. An IP pool defines a single IP address or a range of IP addresses to be used as the source address for the duration of the session. These assigned addresses will be used instead of the IP address assigned to that FortiGate interface.

When using IP pools for NATing, there is a limitation that must be taken into account when configuring the pool. If the IP address(es) within the pool are different from the IP address(es) that are assigned to the interface communications based on those IP addresses will fail. For example if the IP addresses assigned to an interface are 172.16.100.1 -172.16.100.14, you cannot choose 10.11.12.50 - 10.11.12.59 for the IP pool.

There are 4 types of IP Pools that can be configured on the FortiGate firewall:

- One-to-One - in this case the only internal address used by the external address is the internal address that it is mapped to.
- Overload - this is the default setting. Internal addresses other than the one designated in the policy can use this address for the purposes of NAT.
- Fixed Port Range - rather than a single address to be used, there is a range of addresses that can be used as the NAT address. These addresses are randomly assigned as the connections are made.
- Port Block Allocation - this setting is used to allocate a block of port numbers for IP pool users. Two variables will also have to be set. The block size can be set from 64 to 4096 and as the name implies describes the number of ports in one block of port numbers. The number of blocks per user determines how many of these blocks will be assigned. This number can range from 1 to 128.

Be careful when calculating the values of the variables. The maximum number of ports that are available on an address is 65,536. If you chose the maximum value for both variables you will get a number far in excess of the available port numbers.

4096 x 128 = 524,288

One of the more common examples is when you have an email server behind your FortiGate firewall and the range of IP addresses assigned to you by your ISP is more than one. If an organization is assigned multiple IP addresses it is normally considered a best practice to assign a specific address other than the one used for the Firewall to the mail server. However, when normal NAT is used the address assigned to the firewall is also assigned to any outbound sessions. Anti-spam services match the source IP address of mail traffic that they receive to the MX record on DNS servers as an indicator for spam. If there is a mismatch the mail may not get through so there is a need to make sure that the NATed address assigned matches the MX record.

You can also use the Central NAT table as a way to configure IP pools.

Source IP address and IP pool address matching when using a range

When the source addresses are translated to an IP pool that is a range of addresses, one of the following three cases may occur:

Scenario 1:

The number of source addresses equals that of IP pool addresses

In this case, the FortiGate unit always matches the IP addressed one to one.

If you enable fixed port in such a case, the FortiGate unit preserves the original source port. This may cause conflicts if more than one security policy uses the same IP pool, or the same IP addresses are used in more than one IP pool.

Scenario 2:

The number of source addresses is more than that of IP pool addresses

In this case, the FortiGate unit translates IP addresses using a wrap-around mechanism. If you enable fixed port in such a case, the FortiGate unit preserves the original source port. But conflicts may occur since users may have different sessions using the same TCP 5 tuples.

Scenario 3:

The number of source addresses is fewer than that of IP pool addresses

In this case, some of the IP pool addresses are used and the rest of them are not be used.

ARP Replies

If a FortiGate firewall interface IP address overlaps with one or more IP pool address ranges, the interface responds to ARP requests for all of the IP addresses in the overlapping IP pools. For example, consider a FortiGate unit with the following IP addresses for the port1 and port2 interfaces:

- port1 IP address: 1.1.1.1/255.255.255.0 (range is 1.1.1.0-1.1.1.255)
- port2 IP address: 2.2.2.2/255.255.255.0 (range is 2.2.2.0-2.2.2.255)

And the following IP pools:

- IP_pool_1: 1.1.1.10-1.1.1.20
- IP_pool_2: 2.2.2.10-2.2.2.20
- IP_pool_3: 2.2.2.30-2.2.2.40

The port1 interface overlap IP range with IP_pool_1 is:

(1.1.1.0-1.1.1.255) and (1.1.1.10-1.1.1.20) = 1.1.1.10-1.1.1.20

The port2 interface overlap IP range with IP_pool_2 is:

(2.2.2.0-2.2.2.255) & (2.2.2.10-2.2.2.20) = 2.2.2.10-2.2.2.20

The port2 interface overlap IP range with IP_pool_3 is:

(2.2.2.0-2.2.2.255) & (2.2.2.30-2.2.2.40) = 2.2.2.30-2.2.2.40

And the result is:

- The port1 interface answers ARP requests for 1.1.1.10-1.1.1.20
- The port2 interface answers ARP requests for 2.2.2.10-2.2.2.20 and for 2.2.2.30-2.2.2.40

Select Enable NAT in a security policy and then select Dynamic IP Pool. Select an IP pool to translate the source address of packets leaving the FortiGate unit to an address randomly selected from the IP pool. Whether or not the external address of an IP Pool will respond to an ARP request can be disabled. You might want to disable the ability to responded to ARP requests so that these address cannot be used as a way into your network or show up on a port scan.

IP pools and zones

Because IP pools are associated with individual interfaces

IP pools cannot be set up for a zone. IP pools are connected to individual interfaces.

Fixed Port

Some network configurations do not operate correctly if a NAT policy translates the source port of packets used by the connection. NAT translates source ports to keep track of connections for a particular service.

However, enabling the use of a fixed port means that only one connection can be supported through the firewall for this service. To be able to support multiple connections, add an IP pool, and then select Dynamic IP pool in the policy. The firewall randomly selects an IP address from the IP pool and assigns it to each connection. In this case, the number of connections that the firewall can support is limited by the number of IP addresses in the IP pool.

Match-VIP

The match-vip feature allows the FortiGate unit to log virtual IP traffic that gets implicitly dropped. This feature eliminates the need to create two policies for virtual IPs; one that allows the virtual IP, and the other to get proper log entry for DROP rules.

For example, you have a virtual IP security policy and enabled the match-vip feature; the virtual IP traffic that is not matched by the policy is now caught.

The match-vip feature is available only in the CLI. By default, the feature is disabled.

Services and TCP ports

There are a number of different services and protocols in use on the Internet. The most commonly known is HTTP which is used by web servers to transmit requests and responses for unencrypted web pages. These services are set up to listen for requests on a numbered port. These services and protocols can use any port from 1 to 65,535. To keep things simple for everyone a large number of the more commonly used services started using a standardized list of ports. For instance, though it is not required, by default, most web servers listen for HTTP requests on port 80 and by default, web browsers will send HTTP traffic to port 80. If you wish to use another port such as 8080 you would put ":8080" at the end of the URL to indicate that you want the browser to use 8080 instead of the default port.

Example:

Default URL for HTTP traffic when the web server is listening on the standard HTTP port:

http://fortinet.com

URL to the same address when the web server is listening for HTTP traffic on port 8080

http://fortinet.com:8080

Services represent typical traffic types and application packets that pass through the FortiGate unit. Firewall services define one or more protocols and port numbers associated with each service. Security policies use service definitions to match session types. You can organize related services into service groups to simplify your security policy list.

Many well-known traffic types have been predefined on the FortiGate unit. If there is a service that does not appear on the list you can create a service or edit an existing one. You need to

know the ports, IP addresses or protocols of that particular service or application uses, to create a service.

Best Practices

While you can edit a predefined service it is best to leave those ones alone and create a new service and name it something similar such as the same service name with a descriptive identifier appended.

Based on the previous example, instead of the name “HTTP” you could name the service “HTTP8080” or use the application that is using that port, “HTTP-Application”.

Categories

In order to make sorting through the services easier there is a field to categorize the services. The services can be sorted into the following groups:

- Uncategorized
- General
- Web Access
- File Access
- Email
- Network Services
- Authentication
- Remote Access
- Tunnelling
- VoIP, Messaging and Other Applications

Protocol Types

One of the fundamental aspects of a service is the type of protocol that use used to define it. When a service is defined one of the following categories of protocol needs to be determined:

- TCP/UDP/SCTP
- ICMP
- ICMP6
- IP

Depending on which of these protocol categories is choose another set of specifications will can also be defined.

TCP/UDP/SCTP

This is the most commonly used service protocol category. Once this category has been selected the other available options to choose are an address, either IP or FQDN, and the protocol and port number.

The protocol will be TCP, UDP or SCTP.

ICMP or ICMP6

When ICMP or ICMP6 is chosen the available options are the ICMP Type and its code.

IP

When IP is the chosen protocol type the addition option is the Protocol Number.

TCP

Transmission Control Protocol (TCP) is one of the core or fundamental protocols of the Internet. It is part of the Transport Layer of the OSI Model. It is designed to provide reliable delivery of data from a program on one device on the network or Internet to another program on another device on the network or Internet. TCP achieves its reliability because it is a connection based protocol. TCP is stream-oriented. It transports streams of data reliably and in order.

TCP establishes a prior connection link between the hosts before sending data. This is often referred to as the handshake. Once the link is established the protocol uses checks to verify that the data transmitted. If an error check fails the data is retransmitted. This makes sure that the data is getting to the destination error free and in the correct order so that it can be put back together into a form that is identical to the way they were sent.

TCP is configured more for reliability than for speed and because of this TCP will likely be slower than a connectionless protocol such as UDP. This is why TCP is generally not used for real time applications such as voice communication or online gaming.

Some of the applications that use TCP are:

- World Wide Web (HTTP and HTTPS)
- Email (SMTP, POP3, IMAP4)
- Remote administration (RDP)
- File transfer (FTP)

UDP

User Datagram Protocol (UDP) like TCP is one of the core protocols of the Internet and part of the Transport Layer of the OSI Model. UDP is designed more for speed than reliability and is generally used for different applications than TCP. UDP sends messages, referred to as datagrams across the network or Internet to other hosts without establishing a prior communication link. In other words, there is no handshake.

UDP is an unreliable service as the datagrams can arrive out of order, duplicated or go missing without any mechanism to verify them. UDP works on the assumption that any error checking is done by the application or is not necessary for the function of the application. This way it avoids the overhead that is required to verify the integrity of the data.

This lack of overhead improves the speed of the data transfer and is why UDP is often used by applications that are time sensitive in nature. UDP's stateless nature is also great for applications that answer a large number of small queries from a large number of clients.

Common uses for UDP are:

- Domain Name Resolution (DNS)
- Time (NTP)
- Streaming media (RTSP, RTP and RTCP)
- Telephone of the Internet (VoIP)
- File Transfer (TFTP)
- Logging (SNMP)
- Online games (GTP and OGP)

SCTP

Stream Control Transmission Protocol (SCTP) is part of the Transport Layer of the OSI Model just like TCP and UDP and provides some of the features of both of those protocols. It is message or datagram orientated like UDP but it also ensures reliable sequential transport of data with congestion control like TCP.

SCTP provides the following services:

- Acknowledged error-free non-duplicated transfer of user data
- Data fragmentation to conform to discovered path MTU size
- Sequenced delivery of user messages within multiple streams, with an option for order-of-arrival delivery of individual user messages
- Optional bundling of multiple user messages into a single SCTP packet
- Network-level fault tolerance through supporting of multi-homing at either or both ends of an association
- Congestion avoidance behavior and resistance to flooding and masquerade attacks

SCTP uses multi-streaming to transport its messages which means that there can be several independent streams of messages traveling in parallel between the points of the transmission. The data is sent out in larger chunks of data than is used by TCP just like UDP but the messages include a sequence number within each message in the same way that TCP does so that the data can be reassembled at the other end of the transmission in the correct sequence without the data having to arrive in the correct sequence.

SCTP is effective as the transport protocol for applications that require monitoring and session-loss detection. For such applications, the SCTP path and session failure detection mechanisms actively monitor the connectivity of the session. SCTP differs from TCP in having multi-homing capabilities at either or both ends and several streams within a connection, typically referred to as an association. A TCP stream represents a sequence of bytes; an SCTP stream represents a sequence of messages.

Some common applications of SCTP include supporting transmission of the following protocols over IP networks:

- SCTP is important in 3G and 4G/LTE networks (for example, HomeNodeB = FemtoCells)
- SS7 over IP (for example, for 3G mobile networks)
- SCTP is also defined and used for SIP over SCTP and H.248 over SCTP
- Transport of Public Switched Telephone Network (PSTN) signaling messages over IP networks.

SCTP is a much newer protocol. It was defined by the IETF Signaling Transport (SIGTRAN) working group in 2000. It was introduced by RFC 3286 and more fully define by RFC 4960.

The FortiGate firewall can apply security policies to SCTP sessions in the same way as TCP and UDP sessions. You can create security policies that accept or deny SCTP traffic by setting the service to “ALL”. FortiOS does not include pre-defined SCTP services. To configure security policies for traffic with specific SCTP source or destination ports you must create custom firewall services for SCTP.

FortiGate units route SCTP traffic in the same way as TCP and UDP traffic. You can configure policy routes specifically for routing SCTP traffic by setting the protocol number to 132. SCTP policy routes can route SCTP traffic according to the destination port of the traffic if you add a port range to the policy route.

You can configure a FortiGate unit to perform stateful inspection of different types of SCTP traffic by creating custom SCTP services and defining the port numbers or port ranges used by

those services. FortiGate units support SCTP over IPv4. The FortiGate unit performs the following checks on SCTP packets:

- Source and Destination Port and Verification Tag.
- Chunk Type, Chunk Flags and Chunk Length
- Verify that association exists
- Sequence of Chunk Types (INIT, INIT ACK, etc)
- Timer checking
- Four way handshake checking
- Heartbeat mechanism
- Protection against INIT/ACK flood DoS attacks, and long-INIT flooding
- Protection against association hijacking

FortiOS also supports SCTP sessions over IPSec VPN tunnels, as well as full traffic and event logging for SCTP sessions.

Specific Addresses in TCP/UDP/SCTP

In the TCP/UDP/SCTP services it is also possible to set the parameter for a specific IP or Fully Qualified Domain Name address. The IP/FQDN field refers to the destination address of the traffic, not the source. This means for example, that you can set up a custom service that will describe in a policy the TCP traffic over port 80 going to the web site example.com, but you cannot set up a service that describes the TCP traffic over port 80 that is coming from the computer with the address 192.168.29.59.

Protocol Port Values

The source and destination ports for TCP/UDP/SCTP services are important to get correct. If they are reversed the service will not work. The destination port(s) are the on ones that refer to the ports that the computer will be listening on. These are the port numbers that most people are familiar with when they associate a port number to a protocol. In most cases the source port will be one that is randomly assigned by the computer that is not being already used by another service.

Most people associate HTTP with port 80. This means that a web-server will be listening on port 80 for any http requests being sent to the computer. The computer that is sending the request can use any port that is not already assigned to another service or communication session. There are 65,535 ports that it can randomly assign, but because the ports from 1 to 1024 are normally used for listening for incoming communications it is usually not in that range. It is unless there is a specific instance when you know that a communication will be coming from a predefined source port it is best practice to set the source port range from 1 to 65,535.

ICMP

The Internet Control Message Protocol (ICMP) is a protocol layered onto the Internet Protocol Suite to provide error reporting flow control and first-hop gateway redirection. It is normally used by the operating systems of networked computers to send connectivity status query, response and error messages. It is assigned protocol number 1. There is a version of the protocol for both IPv4 and for IPv6. It is not designed to be absolutely reliable like TCP.

ICMP is not typically used for transporting data or for end-user network applications with the exception of some diagnostic utilities such as ping and traceroute.

ICMP messages are sent in several situations, for example:

- when a datagram cannot reach its destination,
- time exceeded messages
- redirect messages
- when the gateway does not have the buffering capacity to forward a datagram
- when the gateway can direct the host to send traffic on a shorter route.

Some of the specific ICMP message types are:

- ICMP_ECHO
- ICMP_TIMESTAMP
- ICMP_INFO_REQUEST
- ICMP_ADDRESS

For ICMP error messages, only those reporting an error for an existing session can pass through the firewall. The security policy will allow traffic to be routed, forwarded or denied. If allowed, the ICMP packets will start a new session. Only ICMP error messages of a corresponding security policy is available will be sent back to the source. Otherwise, the packet is dropped. That is, only ICMP packets for a corresponding security policy can traverse the FortiGate unit.

ICMP Types and Codes

ICMP has a number of messages that are identified by the “Type” field. Some of these types have assigned “Code” fields as well. The table below shows the different types of ICMP Types with their associated codes if there are any.

Table 46: ICMP Types and Codes

Type Number	Type Name	Code
0	Echo Reply	
1	Unassigned	
2	Unassigned	

Table 46: ICMP Types and Codes (continued)

Type Number	Type Name	Code
3	Destination Unreachable	0 Net Unreachable 1 Host Unreachable 2 Protocol Unreachable 3 Port Unreachable 4 Fragmentation Needed and Don't Fragment was Set 5 Source Route Failed 6 Destination Network Unknown 7 Destination Host Unknown 8 Source Host Isolated 9 Communication with Destination Network is Administratively Prohibited 10 Communication with Destination Host is Administratively Prohibited 11 Destination Network Unreachable for Type of Service 12 Destination Host Unreachable for Type of Service 13 Communication Administratively Prohibited 14 Host Precedence Violation 15 Precedence cutoff in effect
4	Source Quench	
5	Redirect	0 Redirect Datagram for the Network (or subnet) 1 Redirect Datagram for the Host 2 Redirect Datagram for the Type of Service and Network 3 Redirect Datagram for the Type of Service and Host
6	Alternate Host Address	
7	Unassigned	
8	Echo	
9	Router Advertisement	
10	Router Selection	
11	Time Exceeded	0 Time to Live exceeded in Transit 1 Fragment Reassembly Time Exceeded
12	Parameter Problem	0 Pointer indicates the error 1 Missing a Required Option 2 Bad Length

Table 46: ICMP Types and Codes (continued)

Type Number	Type Name	Code
13	Timestamp	
14	Timestand Reply	
15	Information Request	
16	Information Reply	
17	Address Mask Request	
18	Address Mask Reply	
19	REserved (for Security)	
20 - 29	Reserved (for Robustness Experiment)	
30	Traceroute	
31	Datagram Conversion Error	
32	Mobile Host Redirect	
33	IPv6 Where-Are-You	
34	IPv6 I-Am-Here	
35	Mobile Registration	
36	Mobile Registration Reply	
37	Domain Name Request	
38	Domain Name Reply	
39	SKIP	
40	Photuris	
41 - 255	Reserved	

ICMPv6

Internet Control Message Protocol version 6 (ICMPv6) is the new implementation of the Internet Control Message Protocol (ICMP) that is part of Internet Protocol version 6 (IPv6). The ICMPv6 protocol is defined in RFC 4443.

ICMPv6 is a multipurpose protocol. It performs such things as:

- error reporting in packet processing
- diagnostic functions
- Neighbor Discovery process
- IPv6 multicast membership reporting

It also designed as a framework to use extensions for use with future implementations and changes.

Examples of extensions that have already been written for ICMPv6:

- Neighbor Discovery Protocol (NDP) - a node discovery protocol in IPv6 which replaces and enhances functions of ARP.
- Secure Neighbor Discovery Protocol (SEND) - an extension of NDP with extra security.
- Multicast Router Discovery (MRD) - allows discovery of multicast routers.

ICMPv6 messages use IPv6 packets for transportation and can include IPv6 extension headers. ICMPv6 includes some of the functionality that in IPv4 was distributed among protocols such as ICMPv4, ARP (Address Resolution Protocol), and IGMP (Internet Group Membership Protocol version 3).

ICMPv6 has simplified the communication process by eliminating obsolete messages.

ICMPv6 messages are subdivided into two classes: error messages and information messages.

Error Messages are divided into four categories:

1. Destination Unreachable
2. Time Exceeded
3. Packet Too Big
4. Parameter Problems

Information messages are divided into three groups:

1. Diagnostic messages
2. Neighbor Discovery messages
3. Messages for the management of multicast groups.

ICMPv6 Types and Codes

ICMPv6 has a number of messages that are identified by the “Type” field. Some of these types have assigned “Code” fields as well. The table below shows the different types of ICMP Types with their associated codes if there are any.

Type codes 0 – 127 are error messages and type codes 128 – 255 are for information messages.

Table 47: ICMPv6 Types and Codes

Type Number	Type Name	Code
0	Reserved	0 - no route to destination 1 - communication with destination administratively prohibited 2 - beyond scope of source address 3 - address unreachable 4 - port unreachable 5 - source address failed ingress/egress policy 6 - reject route to destination 7 - Error in Source Routing Header
1	Destination Unreachable	
2	Packet Too Big	
3	Time Exceeded	0 - hop limit exceeded in transit 1 - fragment reassembly time exceeded
4	Parameter Problem	0 - erroneous header field encountered 1 - unrecognized Next Header type encountered 2 - unrecognized IPv6 option encountered
100	Private Experimentation	
101	Private Experimentation	
102 - 126	Unassigned	
127	Reserved for expansion if ICMPv6 error messages	
128	Echo Request	
129	Echo Replay	
130	Multicast Listener Query	
131	Multicast Listener Report	
132	Multicast Listener Done	
133	Router Solicitation	
134	Router Advertisement	

Table 47: ICMPv6 Types and Codes (continued)

Type Number	Type Name	Code
135	Neighbor Solicitation	
136	Neighbor Advertisement	
137	Redirect Message	
138	Router Renumbering	0 - Router Renumbering Command 1 - Router Renumbering Result 255 - Sequence Number Reset
139	ICMP Node Information Query	0 - The Data field contains an IPv6 address which is the Subject of this Query. 1 - The Data field contains a name which is the Subject of this Query, or is empty, as in the case of a NOOP. 2 - The Data field contains an IPv4 address which is the Subject of this Query.
140	ICMP Node Information Response	0 - A successful reply. The Reply Data field may or may not be empty. 1 - The Responder refuses to supply the answer. The Reply Data field will be empty. 2 - The Qtype of the Query is unknown to the Responder. The Reply Data field will be empty.
141	Inverse Neighbor Discovery Solicitation Message	
142	Inverse Neighbor Discovery Advertisement Message	
143	Version 2 Multicast Listener Report	
144	Home Agent Address Discovery Request Message	

Table 47: ICMPv6 Types and Codes (continued)

Type Number	Type Name	Code
145	Home Agent Address Discovery Reply Message	
146	Mobile Prefix Solicitation	
147	Mobile Prefix Advertisement	
148	Certification Path Solicitation Message	
149	Certification Path Advertisement Message	
150	ICMP messages utilized by experimental mobility protocols such as Seamoby	
151	Multicast Router Advertisement	
152	Multicast Router Solicitation	
153	Multicast Router Termination	
154	FMIPv6 Messages	
155	RPL Control Message	
156	ILNPv6 Locator Update Message	
157	Duplicate Address Request	
158	Duplicate Address Confirmation	
159 – 199	Unassigned	
200	Private experimentation	
201	Private experimentation	
255	Reserved for expansion of ICMPv6 informational messages	

IP

Internet Protocol (IP) is the primary part of the Network Layer of the OSI Model that is responsible for routing traffic across network boundaries. It is the protocol that is responsible for addressing. IPv4 is probable the version that most people are familiar with and it has been around since 1974. IPv6 is its current successor and due to a shortage of available IPv4 addresses compared to the explosive increase in the number of devices that use IP addresses, IPv6 is rapidly increasing in use.

When IP is chosen as the protocol type the available option to further specify the protocol is the protocol number. This is used to narrow down which protocol within the Internet Protocol Suite and provide a more granular control.

Protocol Number

IP is responsible for more than the address that it is most commonly associated with and there are a number of associated protocols that make up the Network Layer. While there are not 256 of them, the field that identifies them is a numeric value between 0 and 256.

In the Internet Protocol version 4 (IPv4) [RFC791] there is a field called “Protocol” to identify the next level protocol. This is an 8 bit field. In Internet Protocol version 6 (IPv6) [RFC2460], this field is called the “Next Header” field.

Table 48: Protocol Numbers

#	Protocol	Protocol's Full Name
0	HOPOPT	IPv6 Hop-by-Hop Option
1	ICMP	Internet Control Message Protocol
2	IGMP	Internet Group Management
3	GGP	Gateway-to-Gateway
4	IPv4	IPv4 encapsulation Protocol
5	ST	Stream
6	TCP	Transmission Control Protocol
7	CBT	CBT
8	EGP	Exterior Gateway Protocol
9	IGP	Any private interior gateway (used by Cisco for their IGRP)
10	BBN-RCC-MON	BBN RCC Monitoring
11	NVP-II	Network Voice Protocol
12	PUP	PUP
13	ARGUS	ARGUS
14	EMCON	EMCON
15	XNET	Cross Net Debugger
16	CHAOS	Chaos

Table 48: Protocol Numbers

#	Protocol	Protocol's Full Name
17	UDP	User Datagram Protocol
18	MUX	Multiplexing
19	DCN-MEAS	DCN Measurement Subsystems
20	HMP	Host Monitoring
21	PRM	Packet Radio Measurement
22	XNS-IDP	XEROX NS IDP
23	TRUNK-1	Trunk-1
24	TRUNK-2	Trunk-2
25	LEAF-1	Leaf-1
26	LEAF-2	Leaf-2
27	RDP	Reliable Data Protocol
28	IRTP	Internet Reliable Transaction
29	ISO-TP4	ISO Transport Protocol Class 4
30	NETBLT	Bulk Data Transfer Protocol
31	MFE-NSP	MFE Network Services Protocol
32	MERIT-INP	MERIT Internodal Protocol
33	DCCP	Datagram Congestion Control Protocol
34	3PC	Third Party Connect Protocol
35	IDPR	Inter-Domain Policy Routing Protocol
36	XTP	XTP
37	DDP	Datagram Delivery Protocol
38	IDPR-CMTP	IDPR Control Message Transport Proto
39	TP++	TP++ Transport Protocol
40	IL	IL Transport Protocol
41	IPv6	IPv6 encapsulation
42	IPv6	SDRPSource Demand Routing Protocol
43	IPv6-Route	Routing Header for IPv6
44	IPv6-Frag	Fragment Header for IPv6
45	IDRP	Inter-Domain Routing Protocol

Table 48: Protocol Numbers

#	Protocol	Protocol's Full Name
46	RSVP	Reservation Protocol
47	GRE	General Routing Encapsulation
48	DSR	Dynamic Source Routing Protocol
49	BNA	BNA
50	ESP	Encap Security Payload
51	AH	Authentication Header
52	I-NLSP	Integrated Net Layer Security TUBA
53	SWIPE	IP with Encryption
54	NARP	NBMA Address Resolution Protocol
55	MOBILE	IP Mobility
56	TLSP	Transport Layer Security Protocol using Kryptonet key management
57	SKIP	SKIP
58	IPv6-ICMP	ICMP for IPv6
59	IPv6-NoNxt	No Next Header for IPv6
60	IPv6-Opts	Destination Options for IPv6
61		any host internal protocol
62	CFTP	CFTP
63		any local network
64	SAT-EXPAK	SATNET and Backroom EXPAK
65	KRYPTOLAN	Kryptolan
66	RVD	MIT Remote Virtual Disk Protocol
67	IPPC	Internet Pluribus Packet Core
68		any distributed file system
69	SAT-MON	SATNET Monitoring
70	VISA	VISA Protocol
71	IPCV	Internet Packet Core Utility
72	CPNX	Computer Protocol Network Executive
73	CPHB	Computer Protocol Heart Beat

Table 48: Protocol Numbers

#	Protocol	Protocol's Full Name
74	WSN	Wang Span Network
75	PVP	Packet Video Protocol

127	CRUDP	Combat Radio User Datagram
128	SSCOPMCE	
129	IPLT	
130	SPS	Secure Packet Shield

Table 48: Protocol Numbers

#	Protocol	Protocol's Full Name
131	PIPE	Private IP Encapsulation within IP
132	SCTP	Stream Control Transmission Protocol
133	FC	Fibre Channel
134	RSVP-E2E-IGNORE	
135	Mobility Header	
136	UDPLite	
137	MPLS-in-IP	
138	manet	
139	HIP	
140	Shim6	
141	WESP	
142	ROHC	
143 – 252	Unassigned	Unassigned
253		Use for experimentation and testing
254		Use for experimentation and testing
255	Reserved	

Further information can be found by researching RFC 5237.

Service Groups

Just like some of the other firewall components, services can also be bundled into groups for ease of administration.

Example Scenario: Using FortiGate services to support Audio/Visual Conferencing

The feature, and the transmitting of data for the purpose of, Tele-conferencing or Audio/Visual Conferencing is covered by a number of standards:

- The IETF standard known as the Binary Floor Control Protocol (BFCP).
- RFC 4582, for SIP-based video devices
- The ITU standard H.239 (for H.323-based video devices)

While these standards have been set up by various authoritative bodies and can take place on different layers of the OSI model, they share common requirements that are addressed by the FortiGate firewall's ability to manage the traffic and the protocols involved. This means that the same ability that make the device RFC 4582 compliant makes it compliant with H.239 as well.

To demonstrate how services and service groups are used we show the setup of a firewall that will need to support the connectivity of a video conferencing unit. The FortiGate does not manipulate or change the content of the traffic but it does allow for the traffic to pass through the device. In this case it allow for only the needed traffic to pass through the device so as to allow the functionality of Audio Visual Conference call but not to allow other traffic through.

The theoretical location for this scenario is a hospital that hosts conferences and lectures from doctors from all over the world, sometimes from multiple locations, using video conferencing technology such as a Polycom Video Conference system. There is a special room set up with dedicated Ethernet connectivity to the Internet. A hospital has a lot of sensitive information going over its network so the setup has to be secure to prevent any chance of penetration.

The approach is fairly simple. The conference room has a dedicated port on the FortiGate (port #7) and its own LAN. We will assume that the interface has already been configured properly. Video conference traffic can come from the Internet to the Polycom in that room and traffic can get out to the Internet, but traffic going to other areas of the hospital network have to go through the FortiGate and traffic going from the Video Conference LAN is thoroughly filtered.

To give an idea of how extensive this can be, we will use an extreme case and include just about all of the services that could be commonly used in one of these setups. The protocols listed here may differ from other setups. It will depend on which features are being used and which equipment is within the network. Always check the documentation that comes with the set up before opening ports into your network.

VIP

In this particular case there is an IP address set aside for the conferencing system so a separate VIP is not needed for every port. One Virtual IP will be created for the system and then only the approved of protocols will be allows through the firewall.

Name	Vid-Conf_Room216
External Interface	wan1
External IP Address/Range	256.87.212.51 – 256.87.212.51
Mapped IP Address/Range	192.168.7.25 – 192.168.7.25
Port Forwarding	not selected

Creating an address for the subnet

In the same way that the VIP was created to identify and direct incoming traffic an address should be created to identify the addresses of computer that will be in the Conference room. This included computers on the LAN as well as the Teleconferencing equipment.

Go to *Firewall Objects -> Address -> Addresses*

Create New

Fill out the fields with the following information:

Category	Address
Name	Port7_subnet
Type	Subnet
Subnet/IP Range	192.168.7.0/255.255.255.0
Interface	port7
Show in address list	checked

Configuring the services

Services already created:

The following are standard services that have already been created by default:

HTTP	TCP 80
SNMP	TCP 161-162/UDP 161-162
LDAP	TCP 389
HTTPS	TCP 443
SYSLOG	UDP 514

Existing Services to be edited:

There are a few services that have already been created for you, but they need to be expanded to accommodate the list of protocols listed for this scenario.

The default h323 contains:

•TCP 1503

•UDP 1719

•TCP 1720

We need to add:

•TCP1719

The default SIP contains:

•UDP 5060

We need to add:

•TCP 5060

To edit an existing service:

- H323

Go to *Firewall Objects -> Service -> Services*

Scroll down to the section: *VoIP, Messaging & Other Applications*

Select *H323*

Select *Edit*

In the Protocol section add the additional protocol:

Protocol Type	TCP
Destination port /Low	1719

Select *OK* to save

- SIP

Select *SIP*

Select *Edit*

In the Protocol section add the additional protocol:

Protocol Type	TCP
Destination port / Low:	5060

Custom Services that need to be created:

There are a number of possible services that may need to be added from scratch rather than editing existing ones. While it is possible to create a single custom service that contains all of the open ports needed, it make more sense to make this modular in case only a small subset of the service needs to be added to another policy.

- Polycom API

Go to *Firewall Objects -> Service -> Services*

Create New

Fill in the fields of the new service with the following information:

Name	Polycom API
Service Type	Firewall
Category	VoIP, Messaging & Other
Protocol Type	TCP/UDP/SCTP
Protocol	TCP/UDP/SCTP
Protocol	TCP

Destination Port - Low:	24
Destination Port - High:	<leave blank>

Select *OK*

- Polycom Endpoints

Go to *Firewall Objects -> Service -> Services*

Create New

Fill in the fields of the new service with the following information:

Name	Polycom Endpoints
Service Type	Firewall
Category	VoIP, Messaging & Other
Protocol Type	TCP/UDP/SCTP
Protocol	TCP
Destination - Low:	3230
Destination - High:	3253

Select *OK*

Other Services to add in the same way:

Table 49:

Name of Service	Category	Protocol & Port #
LDAP secure communications	Authentication	TCP 636
Win 2000 ILS Registration	Network Services	TCP 1002
Gatekeeper discovery	VoIP, Messaging & Other Applications	TCP 1718
Audio Call Control	VoIP, Messaging & Other Applications	TCP 1731
Polycom proprietary Global directory data	VoIP, Messaging & Other Applications	TCP 3601
Polycom People+Content	VoIP, Messaging & Other Applications	TCP 5001
HTTP Server Push	Web Access	TCP 8080

Creating the Service Group

Go to *Firewall Objects -> Service -> Groups*

Create New

Build the Service group by filing in the fields with the following information

Group Name	A-V_Conference
Type	Firewall
Members (click in the drop down menu to add the following services)	•HTTP •SNMP •LDAP •HTTPS •SYSLOG •Polycom API •Polycom Endpoints •LDAP secure communications •Win 2000 ILS Registration •Gatekeeper discovery •Audio Call Control •Polycom proprietary Global directory data •Polycom People+Content •HTTP Server Push

Creating the IPS Security Profile

This is by no means the only way to set up this IPS filter, but it is the way that the fictional System Administrator wants it set up. Yours may be different.

Go to Security *Profiles -> Intrusion Protection -> IPS Sensors.*

Create a new sensor

Name	A-V_Conference-incoming

Select OK

In the newly created sensor, create a new IPS filter.

Sensor Type	Filter Based
Filter Options	Advanced
Severity	• Critical • High • Medium • Low
Target	• Server
OS	• Windows
Application	• IIS • other

Protocol Use the [Show more...] option	• HTTP • LDAP • SIP • SSL • H323
Packet logging	• enabled

Based on these filters there should be somewhere in the neighborhood of 750 signatures that the FortiGate will run traffic against in the IPS engine.

Policies

Incoming Policy

A policy has to be made to allow the traffic to come in from the Internet to connect to the Tele-conferencing server equipment.

Go to *Policy -> Policy -> Policy.*

Create New

Fill out the fields with the following information:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	wan1
Source Address	all
Outgoing Interface	port7
Destination Address	Vid-Conf_Room216
Schedule	always
Service	A-V_Conference
Action	ACCEPT
Enable NAT	<not enabled>
Logging Options	Logging is a good idea but how much will depend on storage capabilities.
Security Profiles	Turn on IPS and choose “A-V_Conference-incoming”
Traffic Shaping, Web cache, WAN Optimization, Disclaimer:	The use of these features will depend on your network environment and should be decided by the network architect, as the decision will largely be based on network bandwidth, usage and importance of Video conferencing compared to other traffic.

Select *OK*.

The policy will then need to be put in the correct position in the sequence of the policies. Because it is a rather focused policy it should be acceptable to place it near the top of the policy order sequence.

Outgoing Policy

A policy has to be made to allow the traffic to leave from the subnet in the conference room to the Internet, not only for the traffic for the Tele-conferencing equipment but for normal traffic of users on the Internet such as web research and email. The traffic is outgoing so there is less of a need for an Intrusion Protection System filter, but check with the network architect in case there is a need for using one of the other security profiles.

Go to *Policy -> Policy -> Policy.*

Create New

Fill out the fields with the following information:

Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port7
Source Address	Port7_subnet
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	any
Action	ACCEPT
Enable NAT	enabled Use Destination Interface Address
Logging Options	Logging is a good idea but how much will depend on storage capabilities.
Security Profiles	<see above>
Traffic Shaping, Web cache, WAN Optimization, Disclaimer:	The use of these features will depend on your network environment and should be decided by the network architect, as the decision will largely be based on network bandwidth, usage and importance of Video conferencing compared to other traffic.

Select *OK*.

The policy will then need to be put in the correct position in the sequence of the policies.

Firewall schedules

Firewall schedules control when policies are in effect. When you add a security policy on a FortiGate unit you need to set a schedule to determine the time frame in which that the policy

will be functioning. While it is not set by default, the normal schedule would be always. This would mean that the policy that has been created is always function and always policing the traffic going through the FortiGate.

The time component of the schedule is based on a 24 hour clock notation or military time as some people would say.

There are two types of schedules: One-time schedules and recurring schedules.

One-Time schedules are in effect only once for the period of time specified in the schedule. This can be useful for testing to limit how long a policy will be in effect in case it is not removed, or it can be used for isolated events such as a conference where you will only need a temporary infrastructure change for a few days.

The time frame for a One-time schedule is configured by using a start time which includes, Year | Month | Day | Hour | Minute and a Stop time which includes the same variables. So while the frequency of the schedule is only once it can last anywhere from 1 minute to multiple years.

Recurring schedules are in effect repeatedly at specified times of specified days of the week. The Recurring schedule is based on a repeating cycle of the days of the week as opposed to every x days or days of the month. This means that you can configure the schedule to be in effect on Tuesday, Thursday, and Saturday but not every 2 days or on odd numbered days of the month.

If a recurring schedule has a stop time that is earlier than the start time, the schedule will take effect at the start time but end at the stop time on the next day. You can use this technique to create recurring schedules that run from one day to the next.

Example

You want to schedule the use of Skype to only between noon (12:00) and 1 p.m. (13:00).

You could create a schedule that allows Skype traffic:

- Starting at Hour:12 and Minute: 00
- Stopping at Hour:13 and Minute: 00
- Set for days of the week: Sunday | Monday |Tuesday |Wednesday | Thursday | Friday | Saturday

Or you could have a schedule that blocks Skype traffic:

- Starting at Hour:13 and Minute: 00 (and goes to the next day)
- Stopping at Hour:12 and Minute: 00
- Set for days of the week: Sunday | Monday |Tuesday |Wednesday | Thursday | Friday | Saturday

Either way is effective for the task but other factors may make one method work better than another in certain situations of it could be just a preference in approach.

Schedule Groups

You can organize multiple firewall schedules into a schedule group to simplify your security policy list. The schedule parameter in the policy configuration does not allow for the entering of multiple schedules into a single policy so if you have a combination of time frames that you want to schedule the policy for then the best approach, rather than making multiple policies is to use a schedule group.

Example

Your Internet policy allows employees to visit Social Media sites from company computers but not during what is considered working hours. The offices are open a few hours before working

hours and the doors are not locked until a few hours after official closing so work hours are from 9 to 5 with a lunch break from Noon to 1:00 p.m.

Your approach is to block the traffic between 9 and noon and between 1:00 p.m. and 5:00 p.m. This means you will need two schedules for a single policy and the schedule group handles this for you.

Schedule groups can contain both recurring and one-time schedules. Schedule groups cannot contain other schedule groups.

Schedule Expiration

The schedule in a security policy enables certain aspects of network traffic to occur for a specific length of time. What it does not do however, is police that time. That is, the policy is active for a given time frame, and as long as the session is open, traffic can continue to flow.

For example, in an office environment, Skype use is allowed between noon and 1pm. During that hour, any Skype traffic continues. As long as that session is open, after the 1pm end time, the Skype conversations can continue, yet new sessions will be blocked. Ideally, the Skype session should close at 1pm.

Using a CLI command you can set the schedule to terminate all sessions when the end time of the schedule is reached. Within the config firewall command enter the command:

```
set schedule-timeout enable
```

By default, this is set to `disable`.

Security profiles

Where security policies provide the instructions to the FortiGate unit for controlling what traffic is allowed through the device, the Security profiles provide the screening that filters the content coming and going on the network. Security profiles enable you to instruct the FortiGate unit about what to look for in the traffic that you don’t want, or want to monitor, as it passes through the device.

A security profile is a group of options and filters that you can apply to one or more firewall policies. Security profiles can be used by more than one security policy. You can configure sets of security profiles for the traffic types handled by a set of security policies that require identical protection levels and types, rather than repeatedly configuring those same security profile settings for each individual security policy.

For example, while traffic between trusted and untrusted networks might need strict antivirus protection, traffic between trusted internal addresses might need moderate antivirus protection. To provide the different levels of protection, you might configure two separate profiles: one for traffic between trusted networks, and one for traffic between trusted and untrusted networks.

Security profiles are available for various unwanted traffic and network threats. Each are configured separately and can be used in different groupings as needed. You configure security profiles in the Security Profiles menu and applied when creating a security policy by selecting the security profile type.

There is a separate handbook for the topic of the Security Profiles, but because the Security Profiles are applied through the Firewall policies it makes sense to have at least a basic idea of what the security profile do and how they integrate into the FortiGate's firewall policies. The following is a listing and a brief description of what the security profiles offer by way of functionality and how they can be configured into the firewall policies.

AntiVirus

Antivirus is used as a catch all term to describe the technology for protection against the transmission of malicious computer code sometimes referred to as malware. As anyone who has listened to the media has heard that the Internet can be a dangerous place filled with malware of various flavours. Currently, the malware that is most common in the Internet, in descending order, is Trojan horses, viruses, worms, adware, back door exploits, spyware and other variations. In recent years, not only has the volume of malicious software become greater than would have been believed when it first appeared but the level of sophistication has risen as well.

The Antivirus Filter works by inspecting the traffic that is about to be transmitted through the FortiGate. To increase the efficiency of effort it only inspects the traffic being transmitted via the protocols that it has been configured to check. Before the data moves across the FortiGate firewall from one interface to another it is checked for attributes or signatures that have been known to be associated with malware. If malware is detected, it is removed.

Web Filtering

Malicious code is not the only thing to be wary of on the Internet. There is also the actual content. While the content will not damage or steal information from your computer there is still a number of reasons that would require protection from it.

In a setting where there are children or other sensitive people using the access provided by a connected computer there is a need to make sure that images or information that is not appropriate is not inadvertently displayed to them. Even if there is supervision, in the time it takes to recognize something that is inappropriate and then properly react can expose those we wish to protect. It is more efficient to make sure that the content cannot reach the screen in the first place.

In an organizational setting, there is still the expectation that organization will do what it can to prevent inappropriate content from getting onto the computer screens and thus provoking an Human Resources incident. There is also the potential loss of productivity that can take place if people have unfiltered access to the Internet. Some organizations prefer to limit the amount of distractions available to tempt their workers away from their duties.

The Web filter works primarily by looking at the destination location request for a HTTP(S) request made by the sending computer. If the URL is on a list that you have configured to list unwanted sites, the connection will be disallowed. If the site is part of a category of sites that you have configured to deny connections to the session will also be denied. You can also configure the content filter to check for specific key strings of data on the actual web site and if any of those strings of data appear the connection will not be allowed.

Application Control

Application Control is designed to allow you to determine what applications are operating on your network and to the also filter the use of these applications as required. Application control is also for outgoing traffic to prevent the use of applications that are against an organization's policy from crossing the network gateway to other networks. An example of this would be the use of proxy servers to circumvent the restrictions put in place using the Web Filtering.

Intrusion Protection (IPS)

Intrusion Prevention System is almost self explanatory. In the same way that there is malware out on the Internet that the network needs to be protected from there are also people out there that take a more targeted approach to malicious cyber activity. No operating system is perfect and new vulnerabilities are being discovered all of the time. An intrusion prevention system is designed to look for activity or behavior that is consistent with attacks against your network.

When attack like behavior is detected it can either be dropped or just monitored depending on the approach that you would like to take.

As new vulnerabilities are discovered they can be added to the IPS database so that the protection is current.

Email Filtering

Spam or unsolicited bulk email is said to account for approximately 90% of the email traffic on the Internet. Sorting through it is both time consuming and frustrating. By putting an email filter on policies that handle email traffic, the amount of spam that users have to deal with can be greatly reduced.

Data Leak Prevention (DLP)

Data Leak Prevention is used to prevent sensitive information from leaving your network. When people think of security in the cyber-world one of the most common images is that of a hacker penetrating your network and making off with your sensitive information, but the other way that you can lose sensitive data is if someone already on the inside of your network sends it out. This does not have to be an act of industrial espionage. It can just be a case of not knowing the policies of the organization or a lack of knowledge of security or laws concerning privacy.

For instance, a company may have a policy that they will not reveal anyone's Social Security number, but an employee emails a number of documents to another company that included a lengthy document that has a Social Security number buried deep within it. There is not malicious intent but if the information got out there could be repercussions.

If an organization has any information in a digital format that it cannot afford for financial or legal reasons, to leave its network, it makes sense to have Data Leak Prevention in place as an additional layer of protection.

VoIP

Voice over IP is essentially the protocols for transmitting voice or other multimedia communications over Internet Protocol networks such as the Internet. The Security Profiles VoIP options apply the SIP Application Level Gateway (ALG) to support SIP through the FortiGate unit. The SIP ALG can also be used to protect networks from SIP-based attacks.

ICAP

Internet Content Adaptation Protocol (ICAP) off loads HTTP traffic to another location for specialized processing. The purpose of this module when triggered is to send the incoming HTTP traffic over to a remote server to be processed thus taking some of the strain off of the resources of the FortiGate unit. The reasons for the specialized process could be anything from more sophisticated Antivirus to manipulation of the HTTP headers and URLs.

EndPoint Control

EndPoint Control makes sure that certain standards are kept. When a computer on the Internet becomes connected to the FortiGate unit by VPN that computer is now part of the same network and there for needs to be subject to the same levels of protection, not only to protect the computer but the network. In the EndPoint Control section you can set the minimum standards for thins like AntiVirus software and VPN software.

Proxy Option Components

Any time a security profile that requires the use of a proxy is enabled the Proxy Options field will be displayed. Certain inspections defined in security profiles require that the traffic be held in proxy while the inspection is carried out and so the Proxy Options are there to define the parameters of how the traffic will be processed and to what level the traffic will be processed. In the same way that there can be multiple security profiles of a single type there can also be a number of unique Proxy Option profiles so that as the requirements for a policy differ from one policy to the next you can also configure a different Proxy Option profile for each individual policy or you can use one profile repeatedly.

The Proxy Options refer to the handling of the following protocols:

- HTTP
- HTTPS
- FTP
- FTPS
- IMAP
- IMAPS
- POP3
- POP3S
- SMTP
- SMTPS
- DNS
- IM
- NNTP

The configuration for each of these protocols is handled separately.

It should also be noted that these configuration apply to only the Security Profiles Proxy-based processes and not the Flow-based processes.

The use of different proxy profiles and profile options

Just like other components of the FortiGate, there is the option for different Proxy Option profiles so that you can be very granular in your control of the workings of the FortiGate. In the case of the Proxy Option profiles the thing that you will want to focus on is the matching up of the correct profile to a firewall policy that is using the appropriate protocols. If you are creating a Proxy Option profile that is designed for policies that control SMTP traffic into your network you only want to configure the settings that apply to SMTP. You do not need or want to configure the HTTP components.

Oversized File Log

This setting is for those that would like to log the occurrence of oversized files being processed. It does not change how they are processed it only enables the FortiGate unit to log that they were either blocked or allowed through. A common practice is to allow larger files through without antivirus processing. This allows you to get an idea of how often this happens and decide on whether or not to alter the settings relating to the treatment of oversized files.

The setting of the threshold for what is considered to be an oversized file is located in the Oversized File / Email Threshold that is found in some of the protocol options for the Proxy Options.

Invalid Certificate Log

This setting enables the logging of occurrences that have occurred in policies governed by the proxy option profile that this setting is enabled in. As stated elsewhere in this document there can be a number of reasons that a web site may have a certificate that registers as being invalid. Because some administrators decide to allow users to access these sites it makes sense to keep track of when it happens. This does not prevent the accessing of web sites with an invalid certificate. It just allows for logging when it happens.

Port

While each of the protocols listed has a default TCP port that is commonly used, the level of granularity of control on the FortiGate firewall allows that the port used by the protocols can be individually modified in each separate Profile.

Comfort Clients

When proxy-based antivirus scanning is enabled, the FortiGate unit buffers files as they are downloaded. Once the entire file is captured, the FortiGate unit begins scanning the file. During the buffering and scanning procedure, the user must wait. After the scan is completed, if no infection is found, the file is sent to the next step in the process flow. If the file is a large one this part of the process can take some time. In some cases enough time that some users may get impatient and cancel the download.

The comfort client feature to mitigates this potential issue by feeding a trickle of data while waiting for the scan to complete so as to let the user know that processing is taking place and that there hasn't been a failure in the transmission. This slow transfer rate continues until the antivirus scan is complete. Once the file has been successfully scanned without any indication of viruses the transfer will proceed at full speed.

If there is evidence of an infection the FortiGate unit caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client had already started. Instead, the download stops and the user is left with a partially downloaded file. If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. The client receives the Infection cache message replacement message as a notification that the download has been blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting is available for HTTP and FTP traffic. If your FortiGate unit supports SSL content scanning and inspection, you can also configure client comforting for HTTPS and FTPS traffic.

Buffering the entire file allows the FortiGate unit to eliminate the danger of missing an infection due to fragmentation because the file is reassembled before examination. Client comforting can send unscanned and therefore potentially infected content to the client. You should only enable client comforting if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

Oversized File/Email Threshold

This is another feature that is related to antivirus scanning. The FortiGate unit has a finite amount of resources that can be used to buffer and scan a file. If a large file such as an ISO image or video file was to be downloaded this could not only overwhelm the memory of the FortiGate, especially if there were other large files being downloaded at the same time, but could exceed it as well. For this reason, how to treat large files needs to be addressed.

A threshold is assigned to determine what should be considered an oversize file or email. This can be set at any size from 1 MB to 50 MB. Any file or email over this threshold will not be

processed by the Antivirus Security Profiles. Once a file is determined to be oversized it must be then determined whether to allow it or to block it.

These settings are not a technical decision but a policy one that will depend on your comfort level with letting files into your network. As there often is, there is a compromise between convenience or ease of use and security. If you want to go for a high peace of mind level you can configure the firewall to block oversized files and thus no files would be coming into the network that have not been scanned. If you are looking for optimizing the memory of the FortiGate unit and making sure that everybody is getting the files they want, you can lower the threshold and allow files that are over the threshold.

It should be noted that in terms of probability that malware is more likely to be found in smaller files than in larger files. A number of administrators take this into account when they lower the default threshold so as to lessen the impact on memory if they see the FortiGate unit going into conserve mode on a regular basis.

Chunked Bypass

The HTTP section allows the enabling of “Chunked Bypass”. This refers to the mechanism in version 1.1 of HTTP that allows a web server to start sending chunks of dynamically generated output in response to a request before actually knowing the actual size of the content. Where dynamically generated content is concerned this means that there is a faster initial response to HTTP requests. From a security stand point it means that the content will not be held in the proxy as an entire file before proceeding.

Allow Fragmented Messages

The specifications of RFC 2046 allow for the breaking up of emails and sending the fragments in parallel to be rebuilt and read at the other end by the mail server. It was originally designed to increase the performance over slower connections where larger email messages were involved. It will depend on your mail configuration if this is even possible for your network but outside of Microsoft Outlook and Outlook Express, not many email clients are set up to break up messages like this. The drawback of allowing this feature is that if malware is broken up between multiple fragments of the message the risk is run that it will not be detected by some antivirus configurations because the code may not all be present at the same time to identify.

Append Email Signature

The Append Email Signature is used when an organization would like to ensure that over and above our in this case underneath the existing personal signatures of the sender, all of the emails going out of their network have the appropriate “boilerplate”, for lack of a better term. These appended emails do not replace existing signatures. They are as the feature states, appended to the email.

Examples could include things like:

- Without prior approval the email should not be forwarded.
- Please be environmentally friendly and don’t print out emails
- For questions regarding the purchasing of our products please call...

It can be anything that the organization would like as long as it is in text format. The use of this feature usually works best in an environment where there is some standardization of what goes into the personal signatures of the senders so that there is no duplication or contradiction of information in the signatures.

While the profile configuration for this is not found in the Security Profiles section but in the Policy Section, it is set in the policy along with the security profiles. This sort of analysis is some times referred to as deep scanning.

Deep Inspection works along the following lines. If your FortiGate unit has the correct chipset it will be able to scan HTTPS traffic in the same way that HTTP traffic can be scanned. The FortiGate firewall will essentially receive the traffic on behalf of the client and open up the encrypted traffic. Once it is finished it re-encrypts the traffic and sends it on to its intended recipient. It is very similar to a man-in-the-middle attack. By enabling this feature, it allows the FortiGate firewall to filter on traffic that is using the HTTPS protocol.

Sometimes the regular web filter can be circumvented by using https:// instead of http:// in the URL and this would prevent that circumvention. However, because when the encrypted traffic is decrypted it has to be re-encrypted with the FortiGate's certificate rather than the original certificate it can cause errors because the name on the certificate does not match the name on the web site.

At one point deep inspection was something that was either turned on or off. Now individual deep inspection profiles can be created depending on the requirements of the policy. Depending on the Inspection Profile, you can:

- Configure which CA certificate will be used to decrypt the SSL encrypted traffic.
- Configure which SSL protocols will be inspected.
- Configure which ports will be associated with which SSL protocols for the purpose of inspection.
- Configure whether or not to allow invalid SSL certificates.
- Configure whether or not SSH traffic will be inspected.

Allow Invalid SSL Certificate

This setting was something that used to be part of the *Proxy Options*, but now that SSL inspection has it's own configuration setting it is configured with those. It might seem like a straight forward decision that the allowing of invalid SSL certificates must be bad and therefore should not be allowed, but there can be some reasons that should be considered. The issues at hand are the reasons to use a SSL certificate and the reasons that a certificate will be considered invalid.

At a purely technical level, a properly formed certificate will encrypt the data so that it can only be read by the intended parties and not be read by anyone sniffing traffic on the network. For this reason, people will often use self-signed certificates. These self signed certificates are free and will encrypt the data just as well as those purchased from any of the big vendors of certificates, but if they are not listed as an approved Certificate Authority (CA) the certificates will be considered invalid.

On the other hand, one of the services the vendors provide is verification of identity of those that purchase their certificates. This means that if you see a valid certificate from a site that identified itself as being from "valid-company.com" that you can be reasonably sure that the site does belong to that company and not a false site masquerading as being part of that company.

Creating a new SSL/SSH Inspection profile

1. Go to *Policy* > *Policy* > *SSL/SSH Inspection*.
2. In the Name field give the profile a name.
3. In the Comments field you can optionally include an brief description of the profile.

SSL Inspection Options

4. Use the drop down menu for the CA Certificate field to choose the SSL Certificate to be used by Policies that are associated with this profile.
5. Choose between
   a. Inspecting all SSL protocol ports -- enable the check box
   b. Enabling only specific SSL protocol ports -- enable which of the following protocol you intend to inspect:
      - HTTPS
      - SMTPS
      - POP3S
      - IMAPS
      - FTPS

      You can optionally edit the TCP/IP port numbers that you expect the traffic to be travelling over.

SSH Inspection Options

6. Choose whether or not to enable SSH Deep Scan. If yes, enable the check box.

   Once the check box is enabled a window will appear to be used in the configuring of:
   - SSH - across any port or only the specified one.
   - Exec - *Block*, *Log* or neither. Select using check boxes.
   - Port-Forward - *Block*, *Log* or neither. Select using check boxes.
   - SSH-Shell - *Block*, *Log* or neither. Select using check boxes.
   - X11-Filter - *Block*, *Log* or neither. Select using check boxes.

Common Options

7. Choose whether to *Allow Invalid SSL Certificates*. If yes, enable the check box.
8. Select *OK*.

The *Enable SSH Deep Scan* feature is enabled by default when creating a new SSL/SSH Inspection profile. There are situations were this feature can cause issues so be sure that you would like it enabled before applying it.

Security policies

One of the foundations upon which a firewall works is the use of policies. These are what bring the other firewall objects and components together into an elegant mechanism for the governing of the traffic going through the network.

This Chapter includes information on the following topics:

Firewall policies

The firewall policy is the axis around which most of the other features of the FortiGate firewall revolve. A large portion of the settings in the firewall at some point will end up relating to or being associated with the firewall policies and the traffic that they govern. Any traffic going through a FortiGate unit has to be associated with a policy. These policies are essentially discrete compartmentalized sets of instructions that control the traffic flow going through the firewall. These instructions control where the traffic goes, how it's processed, if it's processed and even whether or not it's allowed to pass through the FortiGate.

When the firewall receives a connection packet, it analyzes the packet's source address, destination address, and service (by port number). It also registers the incoming interface, the outgoing interface it will need to use and the time of day. Using this information the FortiGate firewall attempts to locate a security policy that matches the packet. If it finds a policy that matches the parameters it then looks at the action for that policy. If it is ACCEPT the traffic is allowed to proceed to the next step. If the Action is DENY or a match cannot be found the traffic is not allowed to proceed.

The 2 basic actions at the initial connection are either ACCEPT or DENY:

- If the Action is ACCEPT, the policy action permits communication sessions. There may be other packet processing instructions, such as requiring authentication to use the policy.

While you may not see it in the configuration there is the implied subset of the ACCEPT Action that include VPN policies, whether they be an IPSec VPN or SSL.

- If the Action is DENY, the policy action blocks communication sessions, and you can optionally log the denied traffic. If no security policy matches the traffic, the packets are dropped. A DENY security policy is needed when it is required to log the denied traffic, also called “violation traffic”.

The policy may contain a number of instructions for the FortiGate firewall in addition to the ACCEPT or DENY actions, some of which are optional. Instructions on how to process the traffic can also include such things as:

- Logging Traffic
- Authentication
- Network Address Translation or Port Address Translation
- Use Virtual IPs or IP Pools
- Caching
- Whether to use address or Identity based rules
- Whether to treat as regular traffic or VPN traffic
- What certificates to use
- Security profiles to apply
- Proxy Options
- Traffic Shaping

As mentioned before, for traffic to flow through the FortiGate firewall there must be a policy that matches its parameters:

- Source Interface
- Destination Interface
- Source Address
- Destination Address
- Service or TCP/IP suite port number
- Schedule and time of the session’s initiation

Without all five of these things matching the traffic will be declined. Each traffic flow requires a policy and the direction is important as well. Just because packets can go from point A to point B on port X does not mean that the traffic can flow from point B to point A on port X. A policy must be configured for each direction.

When designing a policy there is often reference to the traffic flow, but most communication is a two way connection so trying to determine the direction of the flow can be somewhat confusing. If traffic is HTTP web traffic the user sends a request to the web site, but most of the traffic flow will be coming from the web site to the user. Is the traffic flow considered to be from the user to the web site, the web site to the user or in both directions? For the purposes of determining the direction for a policy the important factor is the direction of the initiating communication. The user is sending a request to the web site so this is the initial communication and the web site is just responding to it so the traffic will be from the users network to the Internet.

A case where either side can initiate the communication like between two internal interfaces on the FortiGate unit would be a more likely situation to require a policy for each direction.

What is not expressly allowed is denied

One of the fundamental ideas that can be found in just about any firewall is the rule than anything that is not expressly allowed is by default denied. This is the foundation for any

strategy of protecting your network. Right out of the box, once you have your FortiGate device connected into your network and hooked up with your ISP your network is protected. Nothing is getting out or in so it is not very convenient, but you don't have to worry that between the time you hooked it up and the point that you got all of the polices in place that someone could have gotten in and done something to your resources. The reason that this needs to be kept in mind when designing policies is because you cannot assume that any traffic will be allowed just because it makes sense to do so. If you want any kind of traffic to make it past the FortiGate firewall you need to create a policy that will allow that traffic. To maintain the protection of the network should also make sure that the any policy you create allows only the traffic you intend to go only to where you specifically want it to go and when you want it to go there.

Example

You have a web server on your network that is meant to provide a collaborative work environment web site for your employees and a partner company for a project over the course of the next 3 months.

It is theoretically possible to allow connections into your network to any device on that network for any service and at any time. The problem with this is that we might not want just anybody looking at those resources. Sadly, no matter how much it is wished otherwise, not everybody on the Internet can be trusted. Which means we now have to be very specific in our instructions as to what traffic to allow into the network. Each step that we take towards being more specific as to what we allow means that there is that much more that is not allowed and the level of protection of a resources is directly proportional to the amount of traffic that is not allowed. If somebody can't get at it they can't damage or steal it.

Limiting where the traffic is allowed to go to means that other computers on your network besides the web-server are protected.

- Limiting where the traffic is allowed to come from means that, if feasible, you can limit the systems that can access the web server to just employees or the partner company computers.
- Limiting the services to just web traffic means that a malicious person, even if they were connection from a computer at the partner organization could only use the features of web traffic to do anything malicious.
- Limiting the policy to the time span of the project would mean that even if the IT department forgot to remove the policy after the end of the project than no computer from the other company could be used to do anything malicious through the policy that allowed the traffic.

This is just a very basic example but it shows the underlying principles of how the idea that anything not expressly allowed is by default denied can be used to effectively protect your network.

Policy order

Another important factor in how firewall policies work is the concept of precedence of order or if you prefer a more recognizable term, "first come, first served".

It is highly likely that even after only a relatively small number of policies have been created that there will be some that overlap or are subsets of the parameters that the policies use to determine which policy should be matched against the incoming traffic. When this happens there has to be a method to determine which policy should be applied to the packet. The method which is used by most firewalls it based on the order of the sequence of the policies.

If all of the policies were placed in a sequential list the process to match up the packet would start at the top of the list and work its way down. It would compare information about the packet, specifically these points of information:

1. The interface the packet connected to the FortiGate firewall
2. The source address of the packet

3. The destination address of the packet
4. The interface the packet would need to use to get to the destination address based on the routing table
5. The port the packet is destined for
6. The time that the packet connected to the FortiGate

As soon as the a policy is reached that matched all six (6) of these parameters, the instructions of that policy are applied and the search for any other matching policies is stopped. All subsequent policies are disregarded. Only 1 policy is applied to the packet.

If there is no matching policy among the policies that have been configured for traffic the packet finally drops down to what is always the last policy. It is an implicit policy. One of a few that are referred to by the term “policy0”. This policy denies everything.

The implicit policy is made up of the following settings:

- Incoming Interface: any
- Source Address: any
- Outgoing Interface: any
- Destination Address: any
- Action: DENY

The only setting that is editable in the implicit policy is the logging of violation traffic.

A logical best practice that comes from the knowledge of how this process works is to make sure that the more specific or specialized a policy is, the closer to the beginning of the sequence it should be. The more general a policy is the higher the likelihood that it could include in its range of parameters a more specifically targeted policy. The more specific a policy is, the higher the probability that there is a requirement for treating that traffic in a specific way.

Example

For security reasons there is no FTP traffic allowed out of a specific subnet so there is a policy that states that any traffic coming from that subnet is denied if the service is FTP, so the following policy was created:

Policy #1

Source Interface	Internal1
Source Address	192.168.1.0/24
Outgoing Interface	WAN1
Destination Address	0.0.0.0/0.0.0.0
Service	FTP
Schedule	always
Action	deny

Now as these things usually go it turns out that there has to be an exception to the rule. There is one very secure computer on the subnet that is allowed to use FTP and once the content has been checked it can them be distributed to the other computer on the subnet. So a second firewall policy is created.

Policy #2

Source Interface	Internal1
Source Address	192.168.1.38/32
Outgoing Interface	WAN1
Destination Address	0.0.0.0/0.0.0.0
Service	FTP
Schedule	always
Action	Allow

By default, a policy that has just been created will be placed last in the sequence so that it is less likely to interfere with existing policies before it can be moved to its intended position. If you look at Policy #2 you will notice that it is essentially the same as Policy #1 exempt for the Source Address and the Action. You will also notice that the Source Address of the Policy #2 is a subset of the Source address in policy #1. This means that if nothing further is done, Policy #2 will never see any traffic because the traffic will always be matched by Policy #1 and processed before it has a chance to reach the second policy in the sequence. For both policies to work as intended Policy #2 needs to be moved to before Policy #1 in the sequence.

Exception to policy order (VIPs)

There is a relevant exception to the normal policy order. Policies with VIPs don't appear to behave the same way. Traffic that is handled by VIPs is processed through the associated policy before the traffic is checked against other policies in the usual top down order.

This only appears inconsistent the policy order rule because when handling the traffic, firewall policies are not the first thing checked. VIP translations are checked first, and if there is more than one VIP that the traffic fits, it is handled in the top down order that is followed by policies. If the traffic is not claimed by a policy in the VIP translation phase, it is checked against the routing rules. If it passes the routing checks, the traffic is allowed to be controlled by the polices.

This processing of traffic targeted a VIPs only applies if there is a policy that included the VIP and the traffic matches all of the criteria checks. There is no need to worry about creating VIPs that are not controlled by a policy.

There are security implications associated with this behavior. Administrators could assume that a policy will process traffic before it drops down to a policy with a VIP in it. This can allow traffic to pass through the firewall into a part of the network that it was not intended for, if it was to be allowed in at all. The way to prevent traffic being incorrectly allowed through a policy containing a VIP is to have that policy be more restrictive or to have a separate policy containing the same VIP deny the traffic earlier in the sequence.

As proof of the behavior, look at the following traffic analysis of a packet sent to a VIP. You will see that the packet is translated even before it is allowed to pass through the firewall by a policy.

Viewing Firewall Policies

When you first go into the Policy window, found by going to Policy > Policy > Policy, you will see a table with a menu bar across the top. The menu bar will have the following items:

At the top left

- Create New (with a “+” sign on the left and a downward pointing triangle on the right)
- Clone
- Delete
- Column Settings
- Filter Settings

At the top right

- Section View
- Global View

The items at the top right with their radio buttons represent the 2 potential views that the policies can be displayed in.

The Global View shows all of the policies in the order of their sequence. With the default settings you will be able to see the sequence number in a column close to the left side of the table.

The Section view is similar to the Global View except that as the name implies it is divided into sections. By default the sections are based on the paths between the interfaces. These can be referred to as “interface pairings”. For instance, all of the policies referencing traffic from WAN1 to DMZ will be in one section. The policies referencing traffic from DMZ to WAN1 will be in another section.

The sections are collapsible so that you only need to look at the sections with policies you are interested in. It is possible to add customized subsections within the default sections of interface pairings. This would be useful in a situation where you have a lot of policies and would like to further compartmentalize them by common attributes so that things are easier to find.

The default column headings are:

- [Check box icon]
- Seq.#
- Source
- Destination
- Authentication
- Schedule
- Service
- Action
- Log

The column that are shown are configurable. All but the first 2 can be removed or their position changed. There are also a number of other columns that display information about the policies that can be added. One of the more useful ones that can be added is the ID column. The reason for adding this one is that policies are referenced by their ID number for simplicity and ease of administration. If you are looking in the CLI you will see that the only designation for a policy is its number and if you wish to change the order of a policy you will be asked to move it before or after another policy by referencing its number.

How “Any” policy can remove the Section View

The FortiGate unit will automatically change the view on the policy list page to Global View whenever a policy containing “any” in the Source interface/zone or Destination interface/zone is created. If the Section View is greyed out it is likely that one or more of the policies has “any” as a Source or Destination interface.

With the use of the “any” the policy should go into multiple sections because it could effectively be any of a number of interface pairings. As mentioned, policies are sectioned by using the interface pairings (for example, port1 -> port2) and each section has its own specific policy order. The order in which a policy is checked for matching criteria to a packet’s information is based solely on the position of the policy within its section or within the entire list of policies as a whole but if the policy is in multiple sections at the same time there is no mechanism for placing the policy in a proper order within all of those sections at the same time because it is a manual process and there is no parameter to compare the precedence of one section or policy over the other. Thus a conflict is created. In order to resolve the conflict the FortiGate firewall removes that aspect of the sections so that there is no need to compare and find precedence between the sections and it therefore has only the Global View to work with.

Security policy configuration extensions

When first creating the policy the configuration form will ask for a choice between the policy types of Firewall or VPN, Firewall being the default. Choosing whether or not to leave the selection as Firewall is straight forward. If the policy is not a policy based VPN policy then it is a Firewall policy type.

There are essentially 2 types of VPN connections, Interface Based and Policy Based. In an Interface Based VPN tunnel a logical interface is created that can be seen as an interface by the policies in the same way that any of the physical interfaces can be seen. Therefore to govern the traffic a regular policy will work. The policy based VPN tunnels work slightly different and therefore need a slightly different policy configuration. For a more detail explanation of the difference between the types of VPN tunnels refer to the VPN documentation found in the VPN handbooks or in the VPN section of the Complete Administration Guide.

Once either the Firewall or the VPN type has been chosen there is then a choice between one of subtypes for each of the Policy types. For the Firewall type of policy the subtypes are:

- Address
- User Identity
- Device Identity

The Address subtype refers to policies where access through the FortiGate firewall is dependant on the source location of the addresses of the devices involved in the traffic matched to the policy.

The User Identity subtype refers to polices where access through the FortiGate firewall is dependant on the users credentials or Identity.

The Device Identity subtype refers to policy where access through the FortiGate firewall is dependant on the specific device being used based on the MAC address of the device or belonging to a group of devices that are based on device types or belonging to custom made groups.

For the VPN type the subtypes are:

- IPSec
- SSL-VPN

As expected the two subtypes are the two different types of VPN tunnels that the FortiGate firewall supports in a policy based configuration.

Identity Based Policies

Identity-based security policies, also known as authentication policies, match traffic that requires a supported authentication protocol to trigger the firewall authentication challenge and successfully authenticate network users. Network users authentication can occur using HTTP, HTTPS, FTP, and Telnet protocols as well as through automatic login using NTLM and FSSO, to bypass user intervention.

Identity-based security policies are usually configured for IPSec or SSL VPN traffic since this type of traffic usually requires authentication from network users.

When configuring identity-based policies, you can use schedules to limit network users authentication sessions. For example, example.com has a schedule policy to use P2P applications between noon and 1:00 pm, and a user authentication timeout of 30

minutes. When a user logs in at 12:15 pm, their authentication time logs them off at 12:45 (30 minutes later). You can configure this type of authentication by using the scheduletimeout field in the config firewall policy command in the CLI.

Identity-based policy positioning

With identity-based security policies, positioning is extremely important. For a typical security policy, the FortiGate unit matches the source, destination and service of the policy. If matched, it acts on that policy. If not, the FortiGate unit moves to the next policy.

With identity-based policies, once the FortiGate unit matches the source and destination addresses, it processes the identity sub-rules for the user groups and services. That is, it acts on the authentication and completes the remainder of that policy and goes no further in the policy list.

The way identity based policies work is that once src/dest are matched, it will process the identity based sub-rules (for lack of a better term) around the user groups and services. It will

never process the rest of your rule base. For this reason, unique security policies should be placed before an identity-based policy.

For example, consider the following policies:

DNS traffic goes through successfully as does any HTTP traffic after being authenticated. However, if there was FTP traffic, it would not get through. As the FortiGate unit processes FTP traffic, it skips rule one since it's matching the source, destination and service. When it moves to rule two it matches the source and destination, it determines there is a match and, sees there are also processes the group/service rules, which requires authentication and acts on those rules. Once satisfied, the FortiGate unit will never go to rule three.

In this situation, where you would want FTP traffic to traverse the FortiGate unit, create a security policy specific to the services you require and place it above the authentication policy.

Identity-based sub-policies

When adding authentication to a security policy, you can add multiple authentication rules, or sub-policies. Within these policies you can include additional security profiles, traffic shaping and so on, to take affect on the selected services.

These sub-policies work on the same principle as normal security policies, that is, top down until the criteria has been met. As such, if there is no matching policy within the list, the packet can still be dropped even after authentication is successful.

Identity policies an unauthenticated users

One of the previous drawbacks with User Identity policies is that if traffic from an unauthenticated user enters the policy it will be denied by default because it doesn't match up with any of the user group and therefore falls to policy 0 which denies access to any traffic that reaches it. Allowances have been made so that if you are using User Identity based policies you are not forced to authenticate all users and create a subpolicy for all of the users.

When configuring User Identity policies you can select the option to *Skip this policy for unauthenticated user*. This policy will only apply to user traffic where the user has already authenticated with the FortiGate unit. As the name of the option implies, this policy will not apply to unauthenticated users and any traffic from unauthenticated uses that makes it through the sequence to this policy will continue on the next policy.

The command line syntax for using this feature is:

```
config firewall policy
  edit <id>
    set identity-based enable
    set fall-through-unauthenticated enable
    next
  end
```

Because of this option, User Identity policies can be placed much higher in the sequence than they once were. Now that the policy will no longer interfere with unauthenticated traffic it can be placed so that non user specific policies will not act upon the traffic before it reaches its intended policy.

Device Identity Policies

Device identity policies are designed to assist in accommodating the BYOD trends.

These policies will share many of the same characteristics and field values as the other firewall policies. The point at which a Device Policy defers from other policies on the FortiGate firewall is that when creating one of these policies the criteria that the authentication will be based on is the MAC address of the device making the connection. With the MAC addresses being unique to a specific networkable device there is a great deal of control that can be exercised with these policies.

In cooperation with the MAC scanning capabilities of the FortiGate it is relatively simple to create a profile that will allow access to the wireless network to personal devices such as smart phones, tablets and personal laptops that are brought into work by employees or even contractors and other guests.

The process of authentication is similar to the processes taking place in the Identity based policies. The FortiGate firewall checks the incoming traffic for parameters such as interfaces, addresses, times and services and then matches them with the values associated with the traffic that is associated with the MAC addresses listed in the policy. If everything matches up correctly traffic is allowed to proceed.

The device addresses can be listed my individual MAC addresses, predefined groups based on device type or custom made groupings of the MAC addresses.

VPN Policies

At one point, if you wanted to have secure digital communications between 2 points a private network would be created. This network would only allow the people that were intended to get the communications on it. This is very straightforward if the 2 points are in the same room or even in the same building. It can all be done physically. If you are supposed to be on the secure network

VPNs are an answer to one of today's biggest concerns, how to make digital communications secure between to points that must communicate over the Internet which anybody can have access to

IPSec Policies

IPSec policies allow IPSec VPN traffic access to the internal network from a remote location. These policies include authentication information that authenticates users and user group or groups. These policies specify the following:

- the FortiGate firewall interface that provides the physical connection to the remote VPN gateway, usually an interface connected to the Internet
- the FortiGate firewall interface that connects to the private network
- IP addresses associated with data that has to be encrypted and decrypted
- optional: a schedule that restricts when the VPN can operate, and services (or types of data) that can be sent.

For a route-based (interface mode) VPN, you do not configure an IPSec security policy. Instead, you configure two regular ACCEPT security policies, one for each direction of communication, with the IPSec virtual interface as the source or destination interface, as appropriate.

SSL VPN Policies

SSL VPN security policies are created for permitting SSL VPN clients, web-mode or tunnel-mode, access to the protected network behind the FortiGate unit. These security policies also contain authentication information that will authenticate the users and user group or groups.

Interface Policies

Interface policies are implemented before the “security” policies and are only flow based.

This feature allows you to attach a set of IPS policies with the interface instead of the forwarding path, so packets can be delivered to IPS before entering firewall. This feature is used for following IPS deployments:

- One-Arm: by defining interface policies with IPS and DoS anomaly checks and enabling sniff-mode on the interface, the interface can be used for one-arm IDS;
- IPv6 IPS: IPS inspection can be enabled through interface IPv6 policy. Only IPS signature scan is supported in FortiOS 4.0. IPv6 DoS protection is not supported;
- Scan traffics that destined to FortiGate;
- Scan and log traffics that are silently dropped or flooded by Firewall or Multicast traffic.

IPS sensors can be assigned to an interface policy. Both incoming and outgoing packets are inspected by IPS sensor (signature).

Here is an example of an interface policy,

```
config firewall interface-policy
  edit 1
    set status enable
    set interface "port14"
    set srcaddr "all"
    set dstaddr "all"
    set service "ALL"
    set application-list-status disable
    set ips-sensor-status enable
    set ips-sensor "default"
    set av-profile-status disable
    set webfilter-profile-status disable
    set spamfilter-profile-status disable
    set dlp-sensor-status disable
    set label "Port 14 Interface Policy"
  next
end
```

DoS Protection

Denial of Service (DoS) policies are primarily used to apply DoS anomaly checks to network traffic based on the FortiGate interface it is entering as well as the source and destination addresses. DoS checks are a traffic anomaly detection feature to identify network traffic that does not fit known or common traffic patterns and behavior. A common example of anomalous traffic is the denial of service attack. A denial of service occurs when an attacking system starts an abnormally large number of sessions with a target system. The large number of sessions slows down or disables the target system, so that legitimate users can no longer use it.

DoS policies are similar to firewall policies except that instead of defining the way traffic is allowed to flow, they keep track of certain traffic patterns and attributes and will stop traffic displaying those attributes. Further, DoS policies affect only incoming traffic on a single interface. You can further limit a DoS policy by source address, destination address, and service.

DoS configurations have been changed a couple of times in the past. In FortiOS 4.0, DoS protection is moved to the interface policy, so when it is enabled, it is the first thing checked

when a packet enters FortiGate. Because of this early detection, DoS policies are a very efficient defence that uses few resources. Denial of service attacks, for example, are detected and its packets dropped before requiring security policy look-ups, antivirus scans, and other protective but resource-intensive operations.

A DoS policy examines network traffic arriving at an interface for anomalous patterns usually indicating an attack. This does not mean that all anomalies experience by the firewall are the result of an intentional attack.

Because an improperly configured DoS anomaly check can interfere with network traffic, no DoS checks are preconfigured on a factory default FortiGate unit. You must create your own before they will take effect. Thresholds for newly created sensors are preset with recommended values that you can adjust to meet the needs of your network.

To create a Denial of Service policy determine if it needs to be an IPv4 or IPv6 policy, then go to:

Policy > *Policy* > *DoS Policy* for IPv4.

Policy > *Policy* > *IPv6 DoS Policy* for IPv6.

It is important to know normal and expected network traffic before changing the default anomaly thresholds. Setting the thresholds too low could cause false positives, and setting the thresholds too high could allow otherwise avoidable attacks.

Settings used in configuring DoS

Incoming Interface

The interface to which this security policy applies. It will be the that the traffic is coming into the firewall on.

Source Address

This will be the address that the traffic is coming from and must be a address listed in the Address section of the Firewall Objects. This can include the predefined “all” address which covers any address coming in on any interface. Multiple addresses or address groups can be chosen

Destination Address

This will be the address that the traffic is addressed to. In this case it must be an address that is associated with the firewall itself. For instance it could be one of the interface address of the firewall, a secondary IP address or the interface address assigned to a Virtual IP address. Just like with the Source Address this address must be already configured before being used in the DoS policy.Multiple addresses, virtual IPs or virtual IP groups can be chosen.

Service

While the Service field allows for the use of the ALL service some administrators prefer to optimize the resources of the firewall and only check on the services that will be answered on an interface. Multiple services or service groups can be chosen.

Anomalies

The anomalies can not be configured by the user. They are predefined sensors set up for specific patterns of anomalous traffic

The anomalies that have been predefined for use in the DoS Policies are:

Anomaly Name	Description	Recommended Threshold
tcp_syn_flood	If the SYN packet rate of new TCP connections, including retransmission, to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
tcp_port_scan	If the SYN packet rate of new TCP connections, including retransmission, from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second.
tcp_src_session	If the number of concurrent TCP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
tcp_dst_session	If the number of concurrent TCP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
udp_flood	If the UDP traffic to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
udp_scan	If the number of UDP sessions originating from one source IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
udp_src_session	If the number of concurrent UDP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
udp_dst_session	If the number of concurrent UDP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
icmp_flood	If the number of ICMP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	250 packets per second.
icmp_sweep	If the number of ICMP packets originating from one source IP address exceeds the configured threshold value, the action is executed.	100 packets per second.
icmp_src_session	If the number of concurrent ICMP connections from one source IP address exceeds the configured threshold value, the action is executed.	300 concurrent sessions
icmp_dst_session	If the number of concurrent ICMP connections to one destination IP address exceeds the configured threshold value, the action is executed.	3000 concurrent sessions
ip_src_session	If the number of concurrent IP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.

Anomaly Name	Description	Recommended Threshold
ip_dst_session	If the number of concurrent IP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
sctp_flood	If the number of SCTP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second
sctp_scan	If the number of SCTP sessions originating from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second
sctp_src_session	If the number of concurrent SCTP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions
sctp_dst_session	If the number of concurrent SCTP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions

Status

The status field is enabled to enable the sensor for the associated anomaly. In terms of actions performed there is no difference between disabling a sensor and having the action as “Pass” but by disabling sensors that are not being used for blocking or logging you can save some resources of the firewall that can be better used elsewhere.

Logging

Regardless of whether the traffic is blocked or passed through the anomalous traffic will be logged.

Pass

Allows the anomalous traffic to pass through unimpeded.

Block

For Thresholds based on the number of concurrent sessions blocking the anomaly will not allow more than the number of concurrent sessions set as the threshold.

For rate based thresholds where the threshold is measured in packets per second, the Action setting “Block” prevents the overwhelming of the firewall by anomalous traffic in one of 2 ways. Setting which of those 2 ways will be issued is determined in the CLI.

- continuous - blocks any packets that match the anomaly criteria once the threshold has been reached
- periodical - allows matching anomalous traffic up to the rate set by the threshold.

To set the type of block action for the rate based anomaly sensors:

```
config ips global
   set anomaly-mode continuous
   set anomaly-mode periodical
   end
```

Threshold

The threshold can be either in terms of concurrent session or in packets per second depending on which sensor is being referred to.

One-Arm IDS

Interface-based policy only defines what and how IPS functions are applied to the packets transmitted by the interface. It works no matter if the port is used in a forwarding path or used as an One-Arm device.

To enable One-Arm IDS, the user should first enable sniff-mode on the interface,

```
config system interface
  edit port2
    set ips-sniffer-mode enable
  next
end
```

Once sniff-mode is turned on, both incoming and outgoing packets will be dropped after IPS inspections. The port can be connected to a hub or a switch's SPAN port. Any packet picked up by the interface will still follow the interface policy so different IPS and DoS anomaly checks can be applied.

IPv6 IPS

IPv6 IPS signature scan can be enabled by interface policy. The user can create an normal IPS sensor and assign it to the IPv6 interface policy.

```
config firewall interface-policy6
    edit 1
      set interface "port1"
      set srcaddr6 "all"
      set dstaddr6 "all"
      set service6 "ANY"
      set ips-sensor-status enable
      set ips-sensor "all_default"
    next
  end
```

Traffic Destined to the FortiGate unit

IPS enabled in firewall policies can only inspect the traffic pass through FortiGate unit, not the traffic destined to FortiGate unit. Enabling IPS in interface-policy allows IPS to pick up any packet on the interface so it is able to inspect attacks targeting FGT.

Dropped, Flooded, Broadcast, Multicast and L2 packets

In many evaluation or certification tests, FortiGate firewall is often required to log any packets dropped by the firewall. In most of cases, these packets are of invalid headers so firewall just drops them silently. It is natural to forward all these packets to IPS first so FortiGate firewall is able to generate logs for invalid packets.

Flooded, broadcast and multicast traffics do not reach any of services in the forwarding path. They can be inspected by the interface policy as long as they match the addresses defined.

Potentially, L2 packets can also be sent to IPS for inspection through interface-policy, but it is not enabled.

GUI and CLI

Now in FortiGate, there are two places that IPS can be enabled, in a firewall policy and in an interface policy. In the firewall policy implementation, IPS sensor can be configured in both CLI and GUI. When adding an IPS sensor to an interface policy it must be done through the CLI. There is no GUI input window for the “Interface Policy”. There is however, a DoS Policy section in the GUI.

Local-In Policies

On the FortiGate unit, there are a number of protocols and traffic that is specific to the internal workings of FortiOS. For many of these traffic sources, you can identify a specific port/IP address for this self-originating traffic. The following traffic can be configured to a specific port/IP address:

- SNMP
- Syslog
- alert email
- FortiManager connection IP
- FortiGuard services
- FortiAnalyzer logging
- NTP
- DNS
- Authorization requests such as RADIUS
- FSSO

Security policies control the flow of traffic through the FortiGate unit. The FortiGate unit also includes the option of controlling internal traffic, that is, management traffic.

Each interface includes an allow access configuration to allow management access for specific protocols. Local policies are set up automatically to allow all users all access. Local-in policies takes this a step further, to enable or restrict the user with that access. This also extends beyond the allow access selection.

Local-in policies are configured in the CLI with the commands:

```
config firewall local-in-policy
  edit <policy_number>
    set intf <source_interface>
    set srcaddr <source_address>
    set dstaddr <destination_address>
    set action {accept | deny}
    set service <service name>
    set schedule <schedule_name>
  end
```

For example, you can configure a local-in policy so that only administrators can access the FortiGate unit on weekends from a specific management computer at 192.168.21.12, represented by the address object mgmt-comp1, using SSH on port 3 (192.168.21.77

represented by the address object FG-port3) using the Weekend schedule which defines the time the of access.

```
config firewall local-in-policy
  edit <1>
    set intf port3
    set srcaddr mgmt-comp1
    set dstaddr FG-port3
    set action accept
    set service SSH
    set schedule Weekend
  end
```

You can also disable a policy should there be a requirement to turn off a policy for troubleshooting or other purpose. To disable a policy enter the commands:

```
config firewall local-in-policy
  edit <policy_number>
    set status disable
  end
```

Use the same commands with a status of enable to use the policy again.

Local-in policies are also supported for IPv6 by entering the command

```
config firewall local-in-policy6.
```

Security Policy 0

Any security policy that is automatically added by the FortiGate unit has a policy ID number of zero (0). The most common reasons the FortiGate unit creates this policy is:

- The IPSec policy for FortiAnalyzer (and FortiManager version 3.0) is automatically added when an IPSec connection to the FortiAnalyzer unit or FortiManager is enabled.
- The policy to allow FortiGuard servers to be automatically added has a policy ID number of zero.
- The (default) drop rule that is the last rule in the policy and that is automatically added has a policy ID number of zero.
- When a network zone is defined within a VDOM, the intra-zone traffic set to allow or block is managed by policy 0 if it is not processed by a configured security policy.

This policy can appear in logs but will never appear in the security policy list, and therefore, can never be repositioned in the list.

When viewing the FortiGate firewall logs, you may find a log field entry indicating policyid=0. The following log message example indicates the log field policyid=0 in bold.

```
2008-10-06 00:13:49 log_id=0022013001 type=traffic subtype=violation
pri=warning vd=root SN=179089 duration=0 user=N/A group=N/A rule=0
policyid=0 proto=17 service=137/udp app_type=N/A status=deny
src=10.181.77.73 srcname=10.181.77.73 dst=10.128.1.161
dstname=10.128.1.161 src_int=N/A dst_int="Internal" sent=0 rcvd=0
src_port=137 dst_port=137 vpn=N/A tran_ip=0.0.0.0 tran_port=0
```

Deny Policies

Deny security policies deny traffic that is coming into the network. The FortiGate unit automatically blocks traffic that is associated with a deny security policy.

Deny security policies are usually configured when you need to restrict specific traffic, for example, SSH traffic. Deny security policies can also help when you want to block a service, such as DNS, but allow a specific DNS server.

There is a disparity in the effectiveness of deny policies. Only deny policies that contain VIPs will block traffic directed at those VIPs. Policies with VIPs are processed before other polices, so using a deny policy earlier in the list will not work. For more on this topic, see "Exception to policy order (VIPs)" on page 956.

Accept Policies

Accept security policies accept traffic that is coming into the network. These policies allow traffic through the FortiGate unit, where the packets are scanned, translated if NAT is enabled, and then sent out to its destination.

Accept security policies are the most common security policies that are created in FortiOS. These security policies are basic policies, such as allowing Internet access, as well as complex policies, such as IPSec VPN.

IPv6 Policies

IPv6 security policies are created both for an IPv6 network, and a transitional network. A transitional network is a network that is transitioning over to IPv6, but must still have access to the Internet or must connect over an IPv4 network.

These policies allow for this specific type of traffic to travel between the IPv6 and IPv4 networks. The IPv6 options for creating these policies is hidden by default. You must enable this feature in *System* > *Config* > *Settings*.

Fixed Port

Some network configurations do not operate correctly if a NAT policy translates the source port of packets used by the connection. NAT translates source ports to keep track of connections for a particular service.

From the CLI you can enable fixedport when configuring a security policy for NAT policies to prevent source port translation.

```
config firewall policy
  edit <policy-id>
    ...
    set fixedport enable
    ...
  end
```

However, enabling fixedport means that only one connection can be supported through the firewall for this service. To be able to support multiple connections, add an IP pool, and then select Dynamic IP pool in the policy. The firewall randomly selects an IP address from the IP

pool and assigns it to each connection. In this case, the number of connections that the firewall can support is limited by the number of IP addresses in the IP pool.

Endpoint Security

Endpoint security enforces the use of the FortiClient End Point Security (FortiClient and FortiClient Lite) application on your network. It can also allow or deny endpoints access to the network based on the application installed on them.

By applying endpoint security to a security policy, you can enforce this type of security on your network. FortiClient enforcement can check that the endpoint is running the most recent version of the FortiClient application, that the antivirus signatures are up-to-date, and that the firewall is enabled. An endpoint is usually often a single PC with a single IP address being used to access network services through a FortiGate unit.

With endpoint security enabled on a policy, traffic that attempts to pass through, the FortiGate unit runs compliance checks on the originating host on the source interface. Non-compliant endpoints are blocked. If someone is browsing the web, the endpoints are redirected to a web portal which explains the non-compliance and provides a link to download the FortiClient application installer. The web portal is already installed on the FortiGate unit, as a replacement message, which you can modify if required.

Endpoint Security requires that all hosts using the security policy have the FortiClient Endpoint Security agent installed.

For more information about endpoint security, see the Security Profiles chapter in the FortiOS Handbook.

Traffic Logging

When you enable logging on a security policy, the FortiGate unit records the scanning process activity that occurs, as well as whether the FortiGate unit allowed or denied the traffic according to the rules stated in the security policy. This information can provide insight into whether a security policy is working properly, as well as if there needs to be any modifications to the security policy, such as adding traffic shaping for better traffic performance.

Depending on what the FortiGate unit has in the way of resources, there may be advantages in optimizing the amount of logging taking places. This is why in each policy you are given 3 options for the logging:

- *No Log* - Does not record any log messages about traffic accepted by this policy.
- *Log Security Events* - records only log messages relating to security events caused by traffic accepted by this policy.
- *Log all Sessions* - records all log messages relating to all of the traffic accepted by this policy.

  Depending on the model, if the Log all Sessions option is selected there may be 2 additional options. These options are normally available in the GUI on the higher end models such as the FortiGate 600C or larger.

  - *Generate Logs when Session Starts*
  - *Capture Packets*

You can also use the CLI to enter the following command to write a log message when a session starts:

```
config firewall policy
  edit <policy-index>
    set logtraffic-start
  end
```

Traffic is logged in the traffic log file and provides detailed information that you may not think you need, but do. For example, the traffic log can have information about an application used (web: HTTP.Image), and whether or not the packet was SNAT or DNAT translated. The following is an example of a traffic log message.

2011-04-13

If you want to know more about logging, see the Logging and Reporting chapter in the FortiOS Handbook. If you want to know more about traffic log messages, see the FortiGate Log Message Reference.

Quality of Service

The Quality of Service (QoS) feature allows the management of the level of service and preference given to the various types and sources of traffic going through the firewall so that the traffic that is important to the services and functions connecting through the firewall gets the treatment required to ensure the level of quality that is required.

QoS uses the following techniques:

Traffic policing	Packets are dropped that do not conform to bandwidth limitations
Traffic Shaping	Assigning minimum levels of bandwidth to be allocated to specific traffic flows to guarantee levels of servers or assigning maximum levels of bandwidth to be allocated to specific traffic flows so that they do not impede other flows of traffic.

This helps to ensure that the traffic may consume bandwidth at least at the guaranteed rate by assigning a greater priority queue if the guarantee is not being met. Traffic shaping also ensures that the traffic cannot consume bandwidth greater than the maximum at any given instant in time. Flows that are greater than the maximum rate are subject to traffic policing.

Queuing

Assigning differing levels priority to different traffic flows so that traffic flows that are adversely effected by latency are prevented from being effected by traffic flows that are not subject to the effects of latency. All traffic in a higher priority traffic queue must be completely transmitted before traffic in lower priority queues will be transmitted.

An example of where you would want to use something like this is if you had competing traffic flows of Voice over IP traffic and email traffic. The VoIP traffic is highly susceptible to latency issues.If you have a delay of a few seconds it is quickly noticeable when it is occurring. Email on the other hand can have a time delay of much longer and it is highly unlikely that it will be noticed at all.

By default, the priority given to any traffic is high, so if you want to give one type of traffic priority over all other traffic you will need to lower the priority of all of the other traffic.

Policy Monitor

Once policies have been configured and enabled it is useful to be able to monitor them. To get an overview about what sort of traffic the policies are processing go to Policy > Monitor > Policy Monitor.

The window is separated into two panes.

Upper Pane

The upper pane displays a horizontal bar graph comparing the *Top Policy Usage* based on one of the following criteria:

- Active Sessions
- Bytes
- Packets

The criteria that the displayed graph is based on can be selected from the drop down menu in the upper right corner of the pane. The field name is *Report By:*.

The bars of the graph are interactive to an extent and can be used to drill down for more specific information. If you hover the cursor over the bar of the graph a small popup box will appear displaying more detailed information. If the bar of the graph is selected an entirely new window will be displayed using a vertical bar graph to divide the data that made up the first graph by IP address.

For example if the first graph was reporting usage by active sessions it would include a bar for each of the top polices with a number at the end showing how many sessions were currently going through that policy. If one of the bars of the graph was then selected the new bar graph would show the traffic of that policy separated by either *Source Address*, *Destination Address* or *Destination Port*. As in the other window, the selection for the reported criteria is in the upper right corner of the pane. If the parameter was by source address there would be a bar for each of the IP addresses sending a session through the policy and the end of the bar would show how many sessions.

To go back to the previous window of information in the graphs select the Return link in the upper left of the pane.

Lower Pane

The lower pane contains a spreadsheet of the information that the bar graph will derive their information from. The column headings will include:

- Policy ID
- Source Interface/Zone
- Destination Interface/Zone
- Action
- Active Sessions
- Bytes
- Packets

Network defense

This section describes in general terms the means by which attackers can attempt to compromise your network and steps you can take to protect it. The goal of an attack can be as complex as gaining access to your network and the privileged information it contains, or as simple as preventing customers from accessing your web server. Even allowing a virus onto your network can cause damage, so you need to protect against viruses and malware even if they are not specifically targeted at your network.

The following topics are included in this section:

Monitoring

Monitoring, in the form of logging, alert email, and SNMP, does not directly protect your network. But monitoring allows you to review the progress of an attack, whether afterwards or while in progress. How the attack unfolds may reveal weaknesses in your preparations. The packet archive and sniffer policy logs can reveal more details about the attack. Depending on the detail in your logs, you may be able to determine the attackers location and identity.

While log information is valuable, you must balance the log information with the resources required to collect and store it.

Blocking external probes

Protection against attacks is important, but attackers often use vulnerabilities and network tools to gather information about your network to plan an attack. It is often easier to prevent an attacker from learning important details about your network than to defend against an attack designed to exploit your particular network.

Attacks are often tailored to the hardware or operating system of the target, so reconnaissance is often the first step. The IP addresses of the hosts, the open ports, and the operating systems the hosts are running is invaluable information to an attacker. Probing your network can be as simple as an attacker performing an address sweep or port scan to a more involved operation like sending TCP packets with invalid combinations of flags to see how your firewall reacts.

Address sweeps

An address sweep is a basic network scanning technique to determine which addresses in an address range have active hosts. A typical address sweep involves sending an ICMP ECHO request (a ping) to each address in an address range to attempt to get a response. A response signifies that there is a host at this address that responded to the ping. It then becomes a target for more detailed and potentially invasive attacks.

Address sweeps do not always reveal all the hosts in an address range because some systems may be configured to ignore ECHO requests and not respond, and some firewalls and gateways may be configured to prevent ECHO requests from being transmitted to the destination

network. Despite this shortcoming, Address sweeps are still used because they are simple to perform with software tools that automate the process.

Use the `icmp_sweep` anomaly in a DoS policy to protect against address sweeps.

There are a number of IPS signatures to detect the use of ICMP probes that can gather information about your network. These signatures include `AddressMask, Traceroute, ICMP.Invalid.Packet.Size`, and `ICMP.Oversized.Packet`. Include ICMP protocol signatures in your IPS sensors to protect against these probes/attacks.

Port scans

Potential attackers may run a port scan on one or more of your hosts. This involves trying to establish a communication session to each port on a host. If the connection is successful, a service may be available that the attacker can exploit.

Use the DoS anomaly check for `tcp_port_scan` to limit the number of sessions (complete and incomplete) from a single source IP address to the configured threshold. If the number of sessions exceed the threshold, the configured action is taken.

Use the DoS anomaly check for `udp_scan` to limit UDP sessions in the same way.

Probes using IP traffic options

Every TCP packet has space reserved for eight flags or control bits. They are used for communicating various control messages. Although space in the packet is reserved for all eight, there are various combinations of flags that should never happen in normal network operation. For example, the SYN flag, used to initiate a session, and the FIN flag, used to end a session, should never be set in the same packet.

Attackers may create packets with these invalid combinations to test how a host will react. Various operating systems and hardware react in different ways, giving a potential attackers clues about the components of your network.

The IPS signature `TCP.Bad.Flags` detects these invalid combinations. The default action is pass though you can override the default and set it to *Block* in your IPS sensor.

Configure packet replay and TCP sequence checking

The anti-replay CLI command allows you to set the level of checking for packet replay and TCP sequence checking (or TCP Sequence (SYN) number checking). All TCP packets contain a Sequence Number (SYN) and an Acknowledgement Number (ACK). The TCP protocol uses these numbers for error free end-to-end communications. TCP sequence checking can also be used to validate individual packets.

FortiGate units use TCP sequence checking to make sure that a packet is part of a TCP session. By default, if a packet is received with sequence numbers that fall out of the expected range, the FortiGate unit drops the packet. This is normally a desired behavior, since it means that the packet is invalid. But in some cases you may want to configure different levels of anti-replay checking if some of your network equipment uses non-RFC methods when sending packets.

Configure the anti-replay CLI command:

```
config system global
  set anti-replay {disable | loose | strict}
end
```

You can set anti-replay protection to the following settings:

- `disable` — No anti-replay protection.
- `loose` — Perform packet sequence checking and ICMP anti-replay checking with the following criteria:
- The SYN, FIN, and RST bit can not appear in the same packet.
- The FortiGate unit does not allow more than one ICMP error packet through before it receives a normal TCP or UDP packet.
- If the FortiGate unit receives an RST packet, and check-reset-range is set to strict, the FortiGate unit checks to determine if its sequence number in the RST is within the un-ACKed data and drops the packet if the sequence number is incorrect.
- `strict` — Performs all of the loose checking but for each new session also checks to determine of the TCP sequence number in a SYN packet has been calculated correctly and started from the correct value for each new session. Strict anti-replay checking can also help prevent SYN flooding.

If any packet fails a check it is dropped.

Configure ICMP error message verification

Enable ICMP error message verification to ensure an attacker can not send an invalid ICMP error message.

```
config system global
  check-reset-range {disable | strict}
end
```

- `disable` — the FortiGate unit does not validate ICMP error messages.
- `strict` — enable ICMP error message checking.

If the FortiGate unit receives an ICMP error packet that contains an embedded IP(A,B) | TCP(C,D) header, then if FortiOS can locate the A:C->B:D session it checks to make sure that the sequence number in the TCP header is within the range recorded in the session. If the sequence number is not in range then the ICMP packet is dropped. Strict checking also affects how the anti-replay option checks packets.

Protocol header checking

Select the level of checking performed on protocol headers.

```
config system global
  check-protocol-header {loose | strict}
end
```

- `loose` — the FortiGate unit performs basic header checking to verify that a packet is part of a session and should be processed. Basic header checking includes verifying that the layer-4 protocol header length, the IP header length, the IP version, the IP checksum, IP options are correct, etc.
- `strict` — the FortiGate unit does the same checking as above plus it verifies that ESP packets have the correct sequence number, SPI, and data length.

If the packet fails header checking it is dropped by the FortiGate unit.

Evasion techniques

Attackers employ a wide range of tactics to try to disguise their techniques. If an attacker disguises a known attack in such a way that it is not recognized, the attack will evade your

security and possibly succeed. FortiGate security recognizes a wide variety of evasion techniques and normalizes data traffic before inspecting it.

Packet fragmentation

Information sent across local networks and the Internet is encapsulated in packets. There is a maximum allowable size for packets and this maximum size varies depending on network configuration and equipment limitations. If a packet arrives at a switch or gateway and it is too large, the data it carries is divided among two or more smaller packets before being forwarded. This is called fragmentation.

When fragmented packets arrive at their destination, they are reassembled and read. If the fragments do not arrive together, they must be held until all of the fragments arrive. Reassembly of a packet requires all of the fragments.

The FortiGate unit automatically reassembles fragmented packets before processing them because fragmented packets can evade security measures. Both IP packets and TCP packets are reassembled by the IPS engine before examination.

For example, you have configured the FortiGate unit to block access to the example.org web site. Any checks for example.com will fail if a fragmented packet arrives and one fragment contains `http://www.exa` while the other contains `mple.com/`. Viruses and malware can be fragmented and avoid detection in the same way. The FortiGate unit will reassemble fragmented packets before examining network data to ensure that inadvertent or deliberate packet fragmentation does not hide threats in network traffic.

Non-standard ports

Most traffic is sent on a standard port based on the traffic type. The FortiGate unit recognizes most traffic by packet content rather than the TCP/UDP port and uses the proper IPS signatures to examine it. Protocols recognized regardless of port include DHCP, DNP3, FTP, HTTP, IMAP, MS RPC, NNTP, POP3, RSTP, SIP, SMTP, and SSL, as well as the supported IM/P2P application protocols.

In this way, the FortiGate unit will recognize HTTP traffic being sent on port 25 as HTTP rather than SMTP, for example. Because the protocol is correctly identified, the FortiGate unit will examine the traffic for any enabled HTTP signatures.

Negotiation codes

Telnet and FTP servers and clients support the use of negotiation information to allow the server to report what features it supports. This information has been used to exploit vulnerable servers. To avoid this problem, the FortiGate unit removes negotiation codes before IPS inspection.

HTTP URL obfuscation

Attackers encode HTML links using various formats to evade detection and bypass security measures. For example, the URL www.example.com/cgi.bin could be encoded in a number of ways to avoid detection but still work properly, and be interpreted the same, in a web browser.

The FortiGate prevents the obfuscation by converting the URL to ASCII before inspection.

Table 50: HTTP URL obfuscation types

Encoding type	Example
No encoding	http://www.example.com/cgi.bin/
Decimal encoding	http://www.example.com/cgi.bin/
URL encoding	http://www.example.com/%43%47%49%2E%42%49%4E%2F
ANSI encoding	http://www.example.com/%u0063%u0067%u0069%u002E%u0062%u0069%u006E/
Directory traversal	http://www.example.com/cgi.bin/test/../

HTTP header obfuscation

The headers of HTTP requests or responses can be modified to make the discovery of patterns and attacks more difficult. To prevent this, the FortiGate unit will:

- remove junk header lines
- reassemble an HTTP header that's been folded onto multiple lines
- move request parameters to HTTP POST body from the URL

The message is scanned for any enabled HTTP IPS signatures once these problems are corrected.

HTTP body obfuscation

The body content of HTTP traffic can be hidden in an attempt to circumvent security scanning. HTTP content can be GZipped or deflated to prevent security inspection. The FortiGate unit will uncompress the traffic before inspecting it.

Another way to hide the contents of HTTP traffic is to send the HTTP body in small pieces, splitting signature matches across two separate pieces of the HTTP body. The FortiGate unit reassembles these 'chunked bodies' before inspection.

Microsoft RPC evasion

Because of its complexity, the Microsoft Remote Procedure Call protocol suite is subject to a number of known evasion techniques, including:

- SMB-level fragmentation
- DCERPC-level fragmentation
- DCERPC multi-part fragmentation
- DCERPC UDP fragmentation
- Multiple DCERPC fragments in one packet

The FortiGate unit reassembles the fragments into their original form before inspection.

Defending against DoS attacks

A denial of service is the result of an attacker sending an abnormally large amount of network traffic to a target system. Having to deal with the traffic flood slows down or disables the target system so that legitimate users can not use it for the duration of the attack.

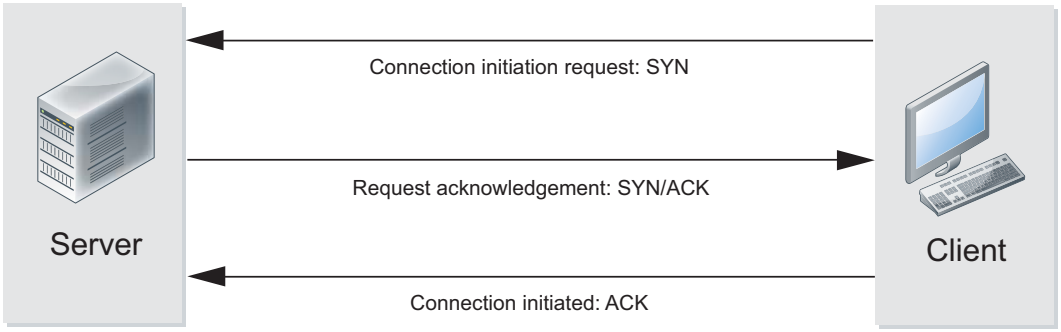
Any network traffic the target system receives has to be examined, and then accepted or rejected. TCP, UDP, and ICMP traffic is most commonly used, but a particular type of TCP traffic is the most effective. TCP packets with the SYN flag are the most efficient DoS attack tool because of how communication sessions are started between systems.

The “three-way handshake”

Communication sessions between systems start with establishing a TCP/IP connection. This is a simple three step process, sometimes called a “three-way handshake,” initiated by the client attempting to open the connection.

1. The client sends a TCP packet with the SYN flag set. With the SYN packet, the client informs the server of its intention to establish a connection.
2. If the server is able to accept the connection to the client, it sends a packet with the SYN and the ACK flags set. This simultaneously acknowledges the SYN packet the server has received, and informs the client that the server intends to establish a connection.
3. To acknowledge receipt of the packet and establish the connection, the client sends an ACK packet.

Figure 172: Establishing a TCP/IP connection



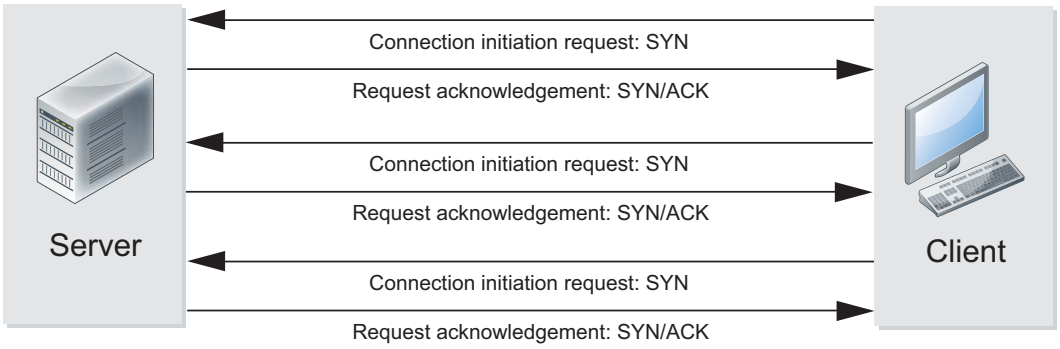
The three-way handshake is a simple way for the server and client to each agree to establish a connection and acknowledge the other party expressing its intent. Unfortunately, the three-way handshake can be used to interfere with communication rather than facilitate it.

SYN flood

When a client sends a SYN packet to a server, the server creates an entry in its session table to keep track of the connection. The server then sends a SYN+ACK packet expecting an ACK reply and the establishment of a connection.

An attacker intending to disrupt a server with a denial of service (DoS) attack can send a flood of SYN packets and not respond to the SYN+ACK packets the server sends in response. Networks can be slow and packets can get lost so the server will continue to send SYN+ACK packets until it gives up, and removes the failed session from the session table. If an attacker sends enough SYN packets to the server, the session table will fill completely, and further connection attempts will be denied until the incomplete sessions time out. Until this happens, the server is unavailable to service legitimate connection requests.

Figure 173:A single client launches a SYN flood attack

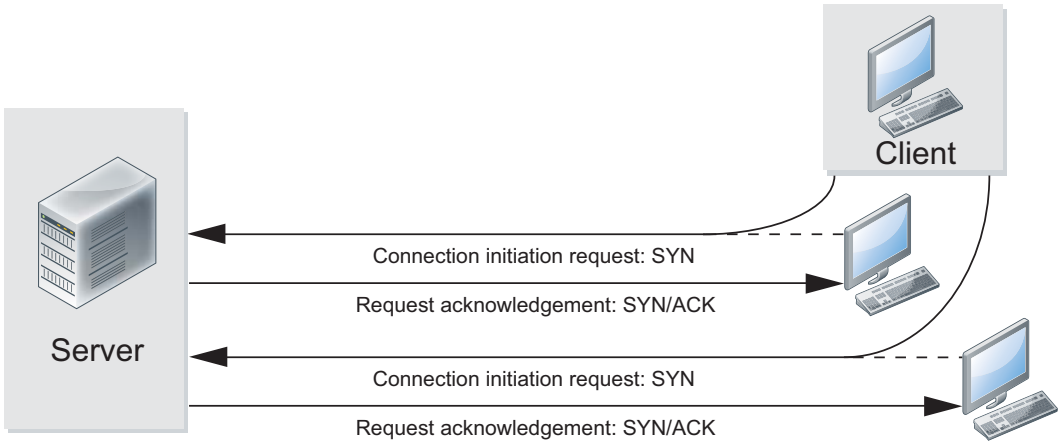


SYN floods are seldom launched from a single address so limiting the number of connection attempts from a single IP address is not usually effective.

SYN spoofing

With a flood of SYN packets coming from a single attacker, you can limit the number of connection attempts from the source IP address or block the attacker entirely. To prevent this simple defense from working, or to disguise the source of the attack, the attacker may spoof the source address and use a number of IP addresses to give the appearance of a distributed denial of service (DDoS) attack. When the server receives the spoofed SYN packets, the SYN+ACK replies will go to the spoofed source IP addresses which will either be invalid, or the system receiving the reply will not know what to do with it.

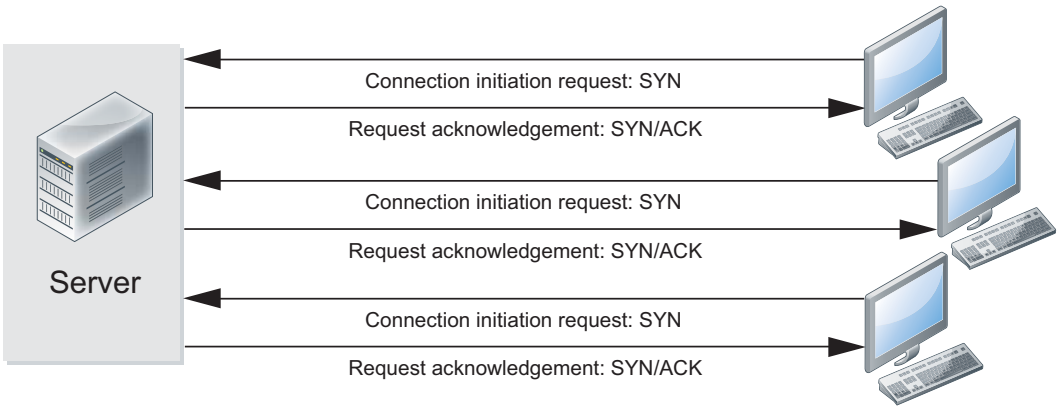
Figure 174:A client launches a SYN spoof attack



DDoS SYN flood

The most severe form of SYN attack is the distributed SYN flood, one variety of distributed denial of service attack (DDoS). Like the SYN flood, the target receives a flood of SYN packets and the ACK+SYN replies are never answered. The attack is distributed across multiple sources sending SYN packets in a coordinated attack.

Figure 175: Multiple attackers launch a distributed SYN flood



The distributed SYN flood is more difficult to defend against because multiple clients are capable of creating a larger volume of SYN packets than a single client. Even if the server can cope, the volume of traffic may overwhelm a point in the network upstream of the targeted server. The only defence against this is more bandwidth to prevent any choke-points.

Configuring the SYN threshold to prevent SYN floods

The preferred primary defence against any type of SYN flood is the DoS anomaly check for `tcp_syn_flood` threshold. The threshold value sets an upper limit on the number of new incomplete TCP connections allowed per second. If the number of incomplete connections exceeds the threshold value, and the action is set to *Pass*, the FortiGate unit will allow the SYN packets that exceed the threshold. If the action is set to *Block*, the FortiGate unit will block the SYN packets that exceed the threshold, but it will allow SYN packets from clients that send another SYN packet.

The tools attackers use to generate network traffic will not send a second SYN packet when a SYN+ACK response is not received from the server. These tools will not “retry.” Legitimate clients will retry when no response is received, and these retries are allowed even if they exceed the threshold with the action set to *Block*.

SYN proxy

FortiGate units with network acceleration hardware, whether built-in or installed in the form of an add-on module, offer a third action for the `tcp_syn_flood` threshold. Instead of *Block* and *Pass*, you can choose to *Proxy* the incomplete connections that exceed the threshold value.

When the `tcp_syn_flood` threshold action is set to *f*, incomplete TCP connections are allowed as normal as long as the configured threshold is not exceeded. If the threshold is exceeded, the FortiGate unit will intercept incoming SYN packets from clients and respond with a SYN+ACK packet. If the FortiGate unit receives an ACK response as expected, it will “replay” this exchange to the server to establish a communication session between the client and the server, and allow the communication to proceed.

Other flood types

UDP and ICMP packets can also be used for DoS attacks, though they are less common. TCP SYN packets are so effective because the target receives them and maintains a session table entry for each until they time out. Attacks using UDP or ICMP packets do not require the same level of attention from a target, rendering them less effective. The target will usually drop the offending packets immediately, closing the session.

Use the `udp_flood` and `icmp_flood` thresholds to defend against these DoS attacks.

DoS policies

DDoS attacks vary in nature and intensity. Attacks aimed at saturating the available bandwidth upstream of your service can only be countered by adding more bandwidth. DoS policies can help protect against DDoS attacks that aim to overwhelm your server resources.

DoS policy recommendations

- Use and configure DoS policies to appropriate levels based on your network traffic and topology. This will help drop traffic if an abnormal amount is received.
- It is important to set a good threshold. The threshold defines the maximum number of sessions/packets per second of normal traffic. If the threshold is exceeded, the action is triggered. Threshold defaults are general recommendations, although your network may require very different values.
- One way to find the correct values for your environment is to set the action to *Pass* and enable logging. Observe the logs and adjust the threshold values until you can determine the value at which normal traffic begins to generate attack reports. Set the threshold above this value with the margin you want. Note that the smaller the margin, the more protected your system will be from DoS attacks, but your system will also be more likely to generate false alarms.

GUI & CLI - What You May Not Know

The Graphic User Interface (GUI) is designed to be as intuitive as possible but there are always a few things that are left out because to put all of that information on the interface would clutter it up to the point where it wouldn't be graphical and intuitive anymore.

This section is made up of knowledge that will make working with the both of the management interfaces easier because you wont have to find out about things like field limitations through trial and error. Some of it has to do with changing in how navigation in the GUI has changed.

The section includes the topics:

Mouse Tricks

In previous version of the firmware much of the navigation, editing or choosing of options in the Web-based Manager was carried out by using the mouse in combination with a number of icons visible on the interface. This version of the firmware makes more extensive use of the right or secondary mouse button as well as the "drag and drop" feature. If you are used to the old Web-based Manager interface you will notice that a number of the options at the top of the display window are not there anymore or there are fewer of them.

To get a feel for the new approach the Policy > Policy > Policy window is a noticeable place to see some of these changes in action.

The different view modes are still in the upper right-hand corner as they were before but now there is no column settings link to move or configure the columns of the window. Now if you wish to reposition a column just use the mouse to click on the column heading and drag it to its new position. If you wish to add a new column just right-click on one of the column headings and a drop down menu will appear with the option "Column Settings". Use the right pointing triangle to expand the "Column Settings" option to see a choice of possible columns for the window you are in. Those already selected will be at the top with a checked box and the available new ones will be at the bottom ready to be selected.

By right or secondary clicking the mouse curser in the cells of the Policy window you will get a drop down menu that is contextual to the column and policy row where you made the clck.For example if you right click in the "Schedule" column for the row that is for policy #5 you will get the option to select a schedule for policy #5 along with a number of other configuration options relating to that policy or its position in the sequence of policies.

You will find this approach used much more frequently through out the Web-based Manager, giving it a more modern and intuitive feel once you learn to use the right mouse button rather than finding a link displayed on the page.

Changing the default column setting on the policy page

The Policy > Policy > Policy window is one of the more important ones in the Web based interface and has the capacity to display a lot of information, but displaying all of that information at the same time makes for a very busy screen. If all of the columns are displayed, depending on the screen size you may have to constantly use the scroll bars to see what you need to look at. The default installation shows some of the more commonly used columns but these list may not consist of the columns that you wish to look at or the order that you wish to view them in. For this reason it is possible, through the CLI to override these settings to establish a new default.

The syntax of the command starts with:

```
config system settings
  set gui-default-policy-columns
```

The rest of the command is a space delimited list that depends on the columns you wish to view and the order you wish to view them in. The possible selection is in the following table.

Table 51: Variables for the gui-default-policy-columns command

Variable Name	Column Heading
#	Sequence Number
policyid	Policy ID
srcintf	Source Interface
dstintf	Destination Interface
srcaddr	Source Addresses
dstaddr	Destination Addresses
schedule	Policy Schedule
service	Policy Services
action	Policy Action
logtraffic	Traffic Logging Status
nat	Policy NAT Status
status	Policy Status
authentication	Authentication Groups
count	Policy Traffic Counter
profile	Security Profiles
vpntunnel	VPN Tunnel
comments	Policy Comment

Example:

If you wanted these columns in this order, Policy ID, Source Addresses, Destination Addresses, Security Profiles, Policy Comment. You would enter the command:

```
config system settings
  set gui-default-policy-columns policyid srcaddr dstaddr profile
       comments
```

Naming Rules and Restrictions

The following are the specific rules that are obeyed by the FortiGate.

Duplicate Name Issues:

- A VLAN cannot have the same name as a physical interface.
- An Address must not have the same name as an Address Group.
- An Address or Address Group must not have the same name as a Virtual IP Address.
- A Service cannot have the same name as a Service Group.
- A VLAN must not have the same name as a VDOM.
- A VLAN or VDOM must not have the same name as a Zone.

Try to make each firewall object name as unique as possible so that it cannot be confused with another object.

Character Restrictions

A name can contain numbers (0-9), uppercase and lowercase letters (A-Z, a-z), spaces, and the special characters - and _. Other characters are not allowed

The special characters < > ( ) # " ' are allowed only in the following fields:

- Passwords
- Replacement message
- Firewall policy description
- IPS customized signature
- Antivirus blocked file pattern
- Web Filter banned word
- Spam filter banned word
- interface PPPoE client user name
- modem dialup account user name
- modem dialup telephone number

Where you would normally be tempted to use spaces in a name try using the "-" or "_". There are a few name fields were it is not an issue but most of them will trigger serious and unpredictable issues if there is a space in the name field of the object.

Length of Fields Restrictions

Most name fields accept 35 characters. The exceptions are:

Table 52: Characters allowed in some fields

Field	Characters allowed
VDOM names	12
VLAN name	15
RADIUS server secret	15
LDAP server common name identifier	15
Admin user password	32
Schedule names	32
Local certificate email	60
Modem dialup account user name, password, phone number fields	63
Firewall policy comments	63
RADIUS, LDAP server domain name	63
IPSec phase 1 local/peer ID	63
IPS custom signature name	63
Spam Filter MIME header name	63
Antivirus file block pattern	63
Local certificate organizational unit, organization, locality, state/province fields	127
IPSec phase 1 pre-shared key or certificate name	127
Web Filter banned word, URL, URL exempt, Pattern fields	127
Spam Filter RBL server name, email address, MIME header body	127
LDAP server distinguished name	128
IPS custom signature	511
Replacement message	1024

Object Tagging and Coloring

For ease of administration and searching the features of object tagging and coloring are available. These features can make it easier to find similar objects in an administrative screen or to search based on common assigned criteria.

Tags

The Tag Management menu provides a central location to view, search and manage tags that you created. Tags are keywords or a term that is assigned to a specific configuration that can be used for searching or filtering purposes. With the Tag Management feature you can:

- Search to find a specific tag
- View where a tag is referenced, for example, a single tag could be referenced in a security policy, predefined signature and application
- Go to where the tag is located, for example, a security policy
- View how many tags are currently unused
- Remove tags.

The Tag Management page also provides a way to easily locate a specific object, such as a security policy, because of how tags work. For example, an SSL VPN security policy is tagged with the keywords SSL VPN, remote, and SSL branch office;

1. From the Tag Management page, enter SSL and the tags for that security policy appear;
2. Select one of the tags and within the Object Usage window, select to go to the SSL VPN security policy.
3. You can view detailed information about what object is using a tag by selecting one of the tags in the rectangular area that contains a grey background. The Object Usage window appears, which displays similar information as when you select a number in the Ref. column.

In the Add Tags window, you can select to add existing tags to the security policy or address list; however, these tags belong to predefined signatures and applications as well as to other security policies and address lists so the tags may not be applicable. You should make sure that the tag is valid for its use when applied to a security policy or other object otherwise it becomes redundant.

Coloring

You will sometimes be given the option of changing the color of the icon that will represent the firewall object you are configuring. You can do this by clicking on the [Change] link. You will be given the option of picking one of 32 colors.

Numeric Values

Numeric values are used to configure various sizes, rates, numeric addresses, or other numeric values. For example, a static routing priority of 10, a port number of 8080, or an IP address of 10.10.10.1. Numeric values can be entered as a series of digits without spaces or commas (for example, 10 or 64400), in dotted decimal format (for example the IP address 10.10.10.1) or as in the case of MAC or IPv6 addresses separated by colons (for example, the MAC address 00:09:0F:B7:37:00). Most numeric values are standard base-10 numbers, but some fields (again such as MAC addresses) require hexadecimal numbers.

Most web-based manager numeric value fields make it easy to add the acceptable number of digits within the allowed range. CLI help includes information about allowed numeric value ranges. Both the web-based manager and the CLI prevent you from entering invalid numbers.

Selecting options from a list

If a configuration field can only contain one of a number of selected options, the web-based manager and CLI present you a list of acceptable options and you can select one from the list. No other input is allowed. From the CLI you must spell the selection name correctly.

Enabling or disabling options

If a configuration field can only be on or off (enabled or disabled) the web-based manager presents a check box or other control that can only be enabled or disabled. From the CLI you can set the option to enable or disable.

To Enable or Disable Optionally Displayed Features

There are a number of features in the web-based manager that can be configured to either be displayed if you are likely to use them or disabled if you have no need to see them. The ones that may be relevant to the function of the Firewall are:

- Central NAT Table
- Dynamic Profile
- Explicit Proxy
- Implicit Firewall Policies
- IPv6
- Load Balance
- Local In Policy
- Object Tagging and Coloring

You can enable or disable these features by going to *System* > *Admin* > *Settings* or by using the following CLI options:

```
config system global
  set gui-ap-profile {disable | enable}
  set gui-central-nat-table {disable | enable}
  set gui-dns-database {disable | enable}
  set gui-dynamic-profile-display {disable | enable}
  set gui-icap {disable | enable}
  set gui-implicit-id-based-policy {disable | enable}
  set gui-implicit-policy {disable | enable}
  set gui-ipsec-manual-key {enable | disable}
  set gui-ipv6 {enable | disable}
  set gui-lines-per-page <gui_lines>
  set gui-load-balance {disable | enable}
  set gui-object-tags {disable | enable}
  set gui-policy-interface-pairs-view {enable | disable}
  set gui-voip-profile {disable | enable}
end
```

Building firewall objects and policies

The other chapters in the Firewall book have so far been concerned primarily with concepts and abstract ideas that are designed you help you understand what is going on with the firewall and what it can do. Now that we have a good grounding in the “what” it is time to get into the “how”.

This section will provide the instructions for the web-based manager (when available) and the CLI for adding and or editing FortiGate firewall objects and then how to put them together when building a policy to govern the traffic flowing through your network. To give some context, scenarios have been included. The instructions here are concerned with the creation of the objects. The inclusion of these objects into firewall policies is not shown in these instructions.

This chapter includes the instructions for building the following:

IPv4 Firewall Addresses

Scenario: Mail Server

You need to create an IPv4 address for the Mail Server on Port1 of your internal network.

- These server is on the network off of port1.
- The IP address is 192.168.1.27
- The subnet mask is 255.255.255.0
- There should be a tag for this address being for a server

Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* > *Address/FQDN.*

Fill out the fields with the following information:

Address Name	Mail_Server
Comments	<Input into this field is optional>
Color	<Changing this value is optional>
Type	Subnet / IP Range
Subnet / IP Range	192.168.1.27/255.255.255.0
Interface	port1
Add Tags	Server

Select *OK.*

Enter the following CLI command:

```
config firewall address
  edit Mail_Server
    set type ipmask
    set subnet 192.168.1.27 255.255.255.255
    set associated-interface port1
    set tags Server
end
```

Scenario: First Floor Network

You need to create an IPv4 address for the subnet of the internal network off of Port1.

- These computers are on the network off of port1.
- The subnet is the range from 192.168.1.1 to 192.168.1.255.
- The subnet mask is 255.255.255.0
- There should be a reference to this being the network for the 1st floor of the building.

Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* > *Address/FQDN.*

Fill out the fields with the following information

Address Name	Internal_Subnet_1
Comments	Network for 1st Floor

Color	<Changing this value is optional>
Type	Subnet / IP Range
Subnet / IP Range	192.168.1.0/24
Interface	port1
Add Tags	<Input into this field is optional>

Select *OK.*

Enter the following CLI command:

```
config firewall address
  edit Internal_Subnet_1
    Set comment "Network for 1st Floor"
    set type ipmask
    set subnet 192.168.1.0/24
    set associated-interface port1
end
```

Scenario: Marketing Department

You need to create an IPv4 address for the address range for a group of computers used by the Marketing Department.

- These computers are on the network off of port1.
- The IP addresses for these computers range from 192.168.1.100 to 192.168.1.115

Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* > *Address/FQDN.*

Fill out the fields with the following information

Address Name	Marketing_computers
Comments	<Input into this field is optional>
Color	<Changing this value is optional>
Type	Subnet / IP Range
Subnet / IP Range	192.168.1.[100-115]
Interface	port1
Add Tags	<Input into this field is optional>

Select *OK.*

Enter the following CLI command:

```
config firewall address
  edit Internal_Subnet_1
    set type iprange
    set start-ip 192.168.1.100
    set end-ip 192.168.1.115
    set associated-interface port1
  end
```

Verification

To verify that the addresses were added correctly:

Go to *Firewall Objects* > *Address* > *Addresses.* Check that the addresses have been added to the address list and that they are correct.

Enter the following CLI command:

```
config firewall address
  edit <the name of the address to verify>
  show full-configuration
```

IPv6 Firewall Addresses

Scenario: Mail Server

You need to create an IPv6 address for the Mail Server on Port1 of your internal network.

- These server is on the network off of port1.
- The IP address is 2001:db8:0:2::20/64
- There should be a tag for this address being for a server

Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* > *IPv6 Address.*

Fill out the fields with the following information

Address Name	Mail_Server
Comments	<Input into this field is optional>
Color	<Changing this value is optional>
IPv6 Address	2001:db8:0:2::20/64
Add Tags	Server

Select *OK.*

Enter the following CLI command:

```
config firewall address6
  edit Mail_Server
    set type ipmask
    set subnet 2001:db8:0:2::20/64
    set associated-interface port1
    set tags Server
  end
```

Scenario: First Floor Network

You need to create an IPv4 address for the subnet of the internal network off of Port1.

- These computers are on the network off of port1.
- The Network uses the IPv6 addresses: fdde:5a7d:f40b:2e9d:xxxx:xxxx:xxxx:xxxx
- There should be a reference to this being the network for the 1st floor of the building.

Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* > *IPv6 Address.*

Fill out the fields with the following information

Field Name	Field Value
Address Name	Internal_Subnet_1
Comments	Network for 1st Floor
Color	<Changing this value is optional>
Type	Subnet / IP Range
Subnet / IP Range	2001:db8:0:2::/64
Interface	port1
Add Tags	<Input into this field is optional>

Select *OK.*

Enter the following CLI command:

```
config firewall address6
  edit Internal_Subnet_1
    Set comment "Network for 1st Floor"
    set subnet 2001:db8:0:2::/64
  end
```

Verification

To verify that the addresses were added correctly:

Go to *Firewall Objects* > *Address* > *Addresses.* Check that the addresses have been added to the address list and that they are correct.

Enter the following CLI command:

```
config firewall address6
  edit <the name of the address that you wish to verify>
    Show full-configuration
```

FQDN address

You have to create a policy that will govern traffic that goes to a site that has a number of servers on the Internet. Depending on the traffic or the possibility that one of the servers is down network traffic can go to any one of those sites. The consistent factor is that they all use the same Fully Qualified Domain Name.

- The FQDN of the web site: example.com
- The number of ISP connections off of the FortiGate firewall: 2

Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* > *Address/FQDN.*

Fill out the fields with the following information

Field Name	Field Value
Address Name	BigWebsite.com
Comments	<Input into this field is optional>
Color	<Changing this value is optional>
Type	FQDN
FQDN	bigwebsite.com
Interface	any
Add Tags	<Input into this field is optional>

Select *OK.*

Enter the following CLI command:

```
config firewall address
  edit BigWebsite.com
    set type fqdn
    set associated-interface any
    set fqdn bigwebsite.com
  end
```

Verification

To verify that the addresses were added correctly:

Go to *Firewall Objects* > *Address* > *Addresses.* Check that the addresses have been added to the address list and that they are correct.

Enter the following CLI command:

```
config firewall address
  edit <the name of the address that you wish to verify>
    Show full-configuration
```

Changing the TTL of a FQDN address

To make sure that the FQDN resolves to the most recent active server you have been asked to make sure that the FortiGate has not cached the address for any longer than 10 minutes.

There is no field for the cached time-to-live in the web-based manager. It is only configurable in the CLI. Enter the following commands:

```
config firewall address
  edit BigWebsite.com
    set cache-ttl 600
  end
```

New Geography-based Address

Your company is US based and has information on its web site that may be considered information that is not allowed to be sent to embargoed countries. In an effort to help reduce the possibility of sensitive information going to those countries you have be asked to set up addresses for those countries so that they can be block in the firewall policies.

- One of the countries you have been asked to block is Cuba
- You have been asked to Tag the addresses so that other administrators will know why they have been created

Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* > *Address/FQDN.*

Fill out the fields with the following information

Field Name	Field Value
Address Name	Cuba
Comments	<Input into this field is optional>
Color	<Changing this value is optional>
Type	Geography
Country	Cuba
Interface	any
Add Tags	Embargo

Select *OK.*

Enter the following CLI command:

```
config firewall address
  edit Cuba
    set type geography
    set country CN
    set interface wan1
  end
```

Wildcard Address

The company has a large network with multiple subnets. Each team has its own subnet in the 172.12.x.x range. To help keep things organized the IT department uses the same host address on each subnet for the servers. For instance the gateways are always.1 or .2. mail servers are always .5 and print servers are always .10.

In this case an address needs to be created for the mail servers for the entire company.

The addresses will be 172.12.0.5, 172.12.1.5, 172.12.2.5, etc.

Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* > *Address/FQDN.*

Fill out the fields with the following information

Address Name	Print_Servers
Comments	<Input into this field is optional>
Color	<Changing this value is optional>
Type	Subnet / IP Range
Subnet / IP Range	172.12.0.5 / 255.255.0.255
Interface	any

Select *OK.*

There will be a pop up window explaining that the address will automatically be converted to a wildcard address and ask if you would like to continue. When you see the address in the editing window you will notice that the type field shows wildcard even though that was not an option before.

Enter the following CLI command:

```
config firewall address
  edit Print_Servers
    Set type wildcard
    Set wildcard 172.12.0.5 255.255.0.255
  end
```

To verify that the addresses were added correctly:

Go to *Firewall Objects* > *Address* > *Addresses.* Check that the addresses have been added to the address list and that they are correct.

Enter the following CLI command:

```
config firewall address
  edit <the name of the address that you wish to verify>
    Show full-configuration
```

IPv4 Address Group

Your company has a small division that is in Denmark that has a number of remote users that need to connect to a resource from either home, office or customer sites. The thing that they have in common is that there are all in Denmark. An address group needs to be created that will allow for this.

The preconfigured addresses to use will consist of:

- Denmark - a geography based address
- Denmark_ISP1 - a IP range of address of an ISP that services Denmark
- Denmark_ISP2 - a IP range of address of another ISP that services Denmark
- Denmark_Division - the FQDN of the Denmark office that uses Dynamic DNS

Go to *Firewall Objects* > *Address* > *Groups* and select *Create New* > *Address Group.*

Fill out the fields with the following information

Group Name	Denmark_Users
Comments	<Input into this field is optional>
Color	<Changing this value is optional>
Members	Denmark Denmark_ISP1 Denmark_ISP2 Denmark_Division

Select *OK.*

Enter the following CLI command:

```
config firewall addrgrp
  edit Denmark_Users
    set member Denmark Denmark_ISP1 Denmark_ISP2 Denmark_Division
  end
```

If you need to edit out a member of an address group in the CLI you need to

To verify that the addresses were added correctly:

Go to *Firewall Objects* > *Address* > *Groups.* Check that the addresses have been added to the address list and that they are correct.

Enter the following CLI command:

```
config firewall addgrp
  edit <the name of the address that you wish to verify>
    Show full-configuration
```

IPv6 Address Group

Create IPv6 address groups from existing IPv6 addresses

Your company has 3 internal servers with IPv6 addresses that it would like to group together for the purposes of a number of policies.

The preconfigured addresses to use will consist of:

- Web_Server-1
- Web_Server-2
- Web_Server-3

Go to *Firewall Objects* > *Address* > *Groups* and select *Create New* > *IPv6 Address Group.*

Fill out the fields with the following information

Group Name	Web_Server_Cluster
Comments	<Input into this field is optional>
Color	<Changing this value is optional>
Members	Web_Server-1 Web_Server-2 Web_Server-3

Select *OK.*

Enter the following CLI command:

```
config firewall addrgrp6
  edit Web_Server_Cluster
    set member Web_Server-1 Web_Server-2 Web_Server-3
  end
```

To verify that the addresses were added correctly:

Go to *Firewall Objects* > *Address* > *Groups.* Check that the addresses have been added to the address list and that they are correct.

Enter the following CLI command:

```
config firewall addgrp6
  edit <the name of the address that you wish to verify>
    Show full-configuration
```

Multicast Address

The company has a large high tech campus that has monitors in many of its meeting rooms. It is common practice for company wide notifications of importance to be done in a streaming video

format with the CEO of the company addressing everyone at once. The video is High Definition quality so takes up a lot of bandwidth. To minimize the impact on the network the network administrators have set things up to allow the use of multicasting to the monitors for these notifications. Now it has to be set up on the FortiGate firewall to allow the traffic.

- The range being used for the multicast is 239.5.0.0 to 239.5.255.255
- The interface on this FortiGate firewall will be on port 4

Go to *Firewall Objects* > *Address* > *Addresses* and select *Create New* > *Address/FQDN.*

Fill out the fields with the following information:

Field	Value
Category	Multicast Address
Name	Meeting_Room_Displays
Color	<optional>
Show in address list	enabled
Multicast IP Range	239.5.0.0-239.5.255.255
Interface	port4
Comments	<optional>

Select *OK.*

Enter the following CLI command:

```
config firewall multicast-address
  edit "meeting_room_display"
    set associated-interface "port9"
    set start-ip 239.5.0.0
    set end-ip 239.5.255.255
    set visibility enable
    next
  end
```

To verify that the address range was added correctly:

Go to *Firewall Objects* > *Address* > *Groups.* Check that the addresses have been added to the address list and that they are correct.

Enter the following CLI command:

```
config firewall multicast-address
  edit <the name of the address that you wish to verify>
    Show full-configuration
```

Service Category

Add a new category to the list of Service Categories

You plan on adding a number of devices such as web cameras that will allow the monitoring of the physical security of your datacenter. A number of non-standard services will have to be created and you would like to keep them grouped together under the heading of “Surveillance”

Go to *Firewall Objects* > *Service* > *Services* and select *Create New* > *Category.*

Fill out the fields with the following information

Name	Surveillance
Comments	For DataCenter Surveillance Devices

Select *OK.*

Enter the following CLI command:

```
config firewall service category
  Edit Surveillance
    Set comment "For DataCenter Surveillance Devices"
  end
```

To verify that the category was added correctly:

Go to *Firewall Objects* > *Service* > *Services.* Select *Create New* > *Custom Service*. Go to the Category Field and use the drop down menu arrow to open the drop down menu. The new category should be displayed.

Enter the following CLI command:

```
config firewall service category
  show
```

This should bring up all of the categories. Check to see that the new one is displayed.

TCP/UDP/SCTP Service

To create and configure a TCP/UDP/STCP protocol type service.

You have set up some new web cams at work that send a constant live feed to a security service. Not only do these cameras have a feed that can be sent offsite they can be remotely managed from a browser or an application.

The ports that need to be opened to use all of the features of the web cams are:

- Management by browser - TCP on port 8000
- Real time video feed - UDP on port 4000
- Connection through vendor application - SCTP on port 1600

The IP address of the offsite service is 256.25.56.12 (Not a valid IP address. Used for example only)

- One service will be needed for the incoming connections
- One service will be needed for the outgoing connections

The IT manager would like the service for the outgoing data stream to be tied to the destination of the Surveillance service site so that service can only be used for that one vendor.

To add the incoming service

Go to *Firewall Objects* > *Service* > *Services* and select *Create New* > *Custom Service*.

Fill out the fields with the following information

Name	WebCam_Connection-incoming
Comments	<Input into this field is optional>
Service Type	Firewall
Color	<Changing this value is optional>
Show in Service List	Check in check box
Category	Surveillance
Protocol Type	TCP/UDP/SCTP
IP/FQDN	<Leave blank>

	Destination Port		**Source Port**	
Protocol	Low	High	Low	High
TCP	8000	8000	1	65535
SCTP	16000	16000	1	65535

The source port range can be left black as the default is 1 to 65635.

Select *OK.*

Enter the following CLI command:

```
config firewall service custom
  edit WebCam_Connection-incoming
    Set protocol TCP/UDP/SCTP
    Set tcp-portrange 8000
    Set sctp-portrange 16000
    Set visibility enable
    end
```

To add the outgoing service

Go to *Firewall Objects* > *Service* > *Services* and select *Create New* > *Custom Service*.

Fill out the fields with the following information

Name	WebCam_Connection-outgoing
Comments	<Input into this field is optional>
Service Type	Firewall
Color	<Changing this value is optional>

Show in Service List	Check in check box
Category	Surveillance
Protocol Type	TCP/UDP/SCTP
IP/FQDN	256.25.56.12

	Destination Port		**Source Port**	
Protocol	Low	High	Low	High
TCP	4000	4000	1	65535

Select *OK.*

Enter the following CLI command:

```
config firewall service custom
  edit WebCam_Connection-incoming
    Set protocol TCP/UDP/SCTP
    Set category Surveillance
    Set udp-portrange 4000
    Set iprange 256.25.56.12
    Set visibility enable
    end
```

To verify that the category was added correctly:

Go to *Firewall Objects* > *Service* > *Services.* Check that the services have been added to the service list and that they are correct.

Enter the following CLI command:

```
config firewall service custom
  edit <the name of the service that you wish to verify>
    Show full-configuration
```

This should bring up all of the details of the service.

ICMP Service

The Security Officer would like to block the use of the traceroute utility through the network. The IT manager insists that ping and other ICMP utility must be allows for the task of diagnosing connectivity, so it is agreed that only traceroute functionality will be blocked.

The ICMP type for traceroute is 30. There is no codes with the type.

Web-based Manager Instructions

Go to Firewall Objects > Service > Services and select *Create New* > *Custom Service*.

Fill out the fields with the following information

Field Name	Field Value
Name	traceroute

Comments	<Input into this field is optional>
Service Type	Firewall
Color	<Changing this value is optional>
Show in Service List	Check in check box
Category	Uncategorized
Protocol Type	ICMP
Type	30
Code	<Leave blank>

Select *OK.*

Enter the following CLI command:

```
config firewall service custom
  edit traceroute
    set protocol ICMP
    set icmptype 30
    set visibility enable
    end
```

To verify that the category was added correctly:

Go to *Firewall Objects* > *Service* > *Services.* Check that the services have been added to the services list and that they are correct.

Enter the following CLI command:

```
config firewall service custom
  edit <the name of the service that you wish to verify>
    show full-configuration
```

ICMPv6 Service

The IT Manager is doing some diagnostics and would like to temporarily block the successful replies of ICMP Node information Responses between 2 IPv6 networks.

The ICMP type for ICMP Node informations responses is 140. The codes for a successful response is 0.

Web-based Manager Instructions

Go to Firewall Objects > Service > Services and select *Create New* > *Custom Service*.

Fill out the fields with the following information

Field Name	Field Value
Name	diagnostic-test1
Comments	<Input into this field is optional>
Service Type	Firewall

Color	<Changing this value is optional>
Show in Service List	Check in check box
Category	Uncategorized
Protocol Type	ICMP6
Type	140
Code	0

Select *OK.*

Enter the following CLI command:

```
config firewall service custom
  edit diagnostic-test1
    set protocol ICMP6
    set icmptype 140
    set icmpcode 0
    set visibility enable
    end
```

To verify that the category was added correctly:

Go to *Firewall Objects* > *Service* > *Services.* Check that the services have been added to the services list and that they are correct.

Enter the following CLI command:

```
config firewall service custom
  edit <the name of the service that you wish to verify>
    show full-configuration
```

Service Group

The company provide email services for a number of different companies. They have a standard list of services that they like to keep open to their customer's email servers, including webmail services. The company prides itself on getting a customer up and going the same day so they use standard templates for everything to make sure nothing is forgotten including the services that are available.
The services include:

- IMAP
- IMAPS
- POP3
- POP3S
- SMTP
- SMTPS
- HTTP
- HTTPS
- Email_Admin - a custom service for administration of the servers

Go to Firewall Objects > Service > Groups and select *Create New*.

Fill out the fields with the following information:

Field	Value
Group Name	Cust_Email_Serv_Template
Comments	(Optional)
Color	(Optional)
Type	Firewall
Members	(click to add...choose from the drop down • IMAP • IMAPS • POP3 • POP3S • SMTP • SMTPS • HTTP • HTTPS • Email_Admin

Select *OK.*

Enter the following CLI command:

```
config firewall service group
  edit Cust_Email_Serv_Template
    set member "IMAP" "IMAPS" "POP3" "POP3S" "SMTP" "SMTPS" "HTTP"
        "HTTPS" "Email_Admin"
    next
  end
```

To verify that the category was added correctly:

Go to *Firewall Objects* > *Service* > *Groups.* Check that the service group has been added to the services list and that it is correct.

Enter the following CLI command:

```
config firewall service group
  edit <the name of the service that you wish to verify>
    show full-configuration
```

Virtual IP address

The company has an web server on the internal network that needs to be accessed from the Internet.

- The internal IP address is 192.168.50.37
- The external IP address is 256.85.94.60 (for example use only. Not a valid IP address)
- The external IP address is assigned by ISP "A" on WAN1
- The port that needs to be mapped is 80

Go to Firewall *Objects* > *Virtual IP*> *Virtual IP* and select *Create New*.

Fill out the fields with the following information.

Field	Value
Name	Web1-VIP
Comments	Virtual IP for the Forum Webserver
Color	<optional>
External Interface	wan1
Type	(This field is only changeable in the CLI
Source Address Filter	<leave blank or default setting>
External IP Address/Range	256.85.94.60
Mapped IP Address/Range	192.168.50.37
Port Forward	enabled
Protocol	TCP
External Service Port	80
Map to Port	80

Select *OK.*

Enter the following CLI command:

```
config firewall vip
  edit Web1-VIP
    set comment "Virtual IP for the Forum Webserver"
    set extintf wan1
    set extip 256.85.94.60
    set mappedip 192.168.50.37
    set portforward enable
    set protocol tcp
    set extport 80
    set mapped port 80
    end
end
```

To verify that the category was added correctly:

Go to *Firewall Objects* > *Virtual IP*> *Virtual IP.* Check that the virtual IP address has been added to the list and that it is correct.

Enter the following CLI command:

```
config firewall vip
  edit <the name of the vip that you wish to verify>
    show full-configuration
```

VIP Group

The company has only a single external IP address but multiple servers with different functions running on its internal LAN that need to be accessed from the Internet.

- The external IP address of the company on wan1 is 256.34.56.149 (for example use only. Not a valid IP address)
- The webserver is on the internal LAN on 192.168.100.86
- The webserver needs to answer on ports 80 443
- The administration of the FortiGate firewall connects on port 4443 instead of 443
- There is are also a separate email server, FTP server, and Terminal Server for specialised applications.
- 2 Virtual IPs have been created to map 256.34.56.149 to 192.168.100.86 on ports 80 and 443. The names are webserver_80 and webserver_443 respectively.

Go to *Firewall Objects* > *Virtual IP*> *Virtual IP* and select *Create New.*

Fill out the fields with the following information.

Field	Value
Group Name	WebServer_Grp
Comments	(Optional)
Color	(Optional)
Interface	wan1

Move the Following “Available VIPs:” to the “Members” field:

- “webserver_80”
- “webserver_443”

Enter the following CLI command:

```
config firewall vipgrp
  edit WebServer_Grp
    set member “webserver_80” “webserver_443”
    next
  end
```

To verify that the category was added correctly:

Go to *Firewall Objects* > *Virtual IP*> *Group.* Check that the virtual IP address group has been added to the list and that it is correct.

Enter the following CLI command:

```
config firewall vipgrp
  edit <the name of the vip that you wish to verify>
    show full-configuration
```

IP Pool

Your company has an application server on the internal network that sends out regular data updates to an offsite service. In order to make the service site more secure, they only accept connections from predefined IP address. If the external IP address of the FortiGate firewall interface were used that would mean that the service would be accepting sessions from just about any user in the network so a separate IP address need so be assigned for the Network Address Translation.

- The external address that will be used is one that has been assigned to the company by the ISP on WAN2
- The address is 256.100.42.129 (for example use only. Not a valid IP address)

Note: the ARP interface cannot be set in the Web-based Manager but as this is the only path that the traffic will be coming from the outside this should not be an issue. The setting has been included in the CLI instructions so that you will now how to set it in a situation where you want the ARP replies to be answered only on a specific interface.

Go to *Firewall Objects* > *Virtual IP* > *IP Pools*

Fill out the fields with the following information:

Field	Value
Name	App_Server1
Comments	Addresses assignment for this server only.
Type	One-to-One
External IP Range/Subnet2	256.100.42.129
ARP Reply	enabled

Select *OK*

Enter the following CLI command:

```
config firewall ippool
  edit App_Server1
    set comments ''Addresses assignment for this server only."
    set type one-to-one
    set arp-reply enable
    set arp-intf wan2
    set startip 256.100.42.129
    set endip 256.100.42.129
    end
```

To verify that the category was added correctly:

Go to *Firewall Objects* > *Virtual IP* > *IP Pools*

Check that the IP Pool has been added to the list of IP Pools and that the listed settings are correct.

Enter the following CLI command:

```
config firewall ippool
  edit <the name of the IP Pool you wish to verify>
    show full-configuration
```

Central NAT Table

The company has a server on the Development LAN that needs to communicate with a server at a remote site over the Internet. One of the restrictions on the communications between these systems is that the IP address and source port must be specific.

- The traffic going out on to the Internet must be NATed
- The traffic is coming from a server with the IP address 192.168.150.86
- An address called “app-server” has been created for the address 192.168.150.86 on the port1 interface
- The external interface must be 256.23.45.67
- An address called "app-server-ext" has been created for the address 256.23.45.67 on the wan1 interface
- The originating traffic from the server originates in the port range from 2000 to 3000
- The remote site requires that the source TCP port must be within the 12000 to 13000 range

The original address and Translated Address fields require values that are address names that are listed in the address section of Firewall Objects.

Go to *Policy* > *Policy* > *Central NAT Table.*

Create a new NAT table

Fill out the fields with the following information:

Field	Value
Source Address	app-server
Translated Address	app-server-ext
Original Source Port	2000
Translated Port	12000-13000

Select *OK*

Enter the following CLI command:

```
config firewall central-nat
  edit 0
    set orig-addr app-server
    set nat-ippool app-server-ext
    set orig-port 2000
    set nat-port 12000-13000
    next
  end
```

To verify that the table was added correctly:

Go to *Policy* > *Policy*> *Central NAT Table*

Check that the table has been added to the list of Central NAT Tables and that the listed settings are correct.

Enter the following CLI command:

```
config firewall central-nat
  show full-configuration
```

Verify that the listing of tables includes the one that you have just configured, with the correct settings.

When configuring the Central NAT in the GUI you may notice that only those addresses which have been configured to be associated with *any* interface are displayed in the drop down menu for choosing a Source Address and yet the CLI will allow any address to be used, not just those associated with *any* interface. This is because by default the policies in the GUI use a function of cross referencing which addresses are allowed based on which interface is involved in the policy.When combined with the aspect of Central NAT that doesn't restrict to a specific interface. This means the only addresses will be allowed are those associated with the *any* interface. The CLI does not have this cross referencing function which is why the CLI seems less restrictive. However, more care must be taken when using the CLI to make sure that appropriate addresses are used.

Firewall Schedule - Recurring

The Company wants to allow the use of Facebook by employees, but only during none business hours and the lunch break.

- The business hours are 9:00 p.m. to 6:00 p.m.
- The Lunch break is 12:00 p.m. to 1:00 p.m.
- The plan is to create a schedule to cover the morning business hours and the afternoon business hours and block access to the Facebook web site during that time.

Go to *Firewall Objects* > *Schedule* > *IP Recurring.*

Create a new schedule

Fill out the fields with the following information:

Field	Value
Name	Morning_Business_Hours
Day of the Week	
Sunday	disabled
Monday	enabled
Tuesday	enabled
Wednesday	enabled
Thursday	enabled
Friday	enabled
Saturday	disabled

Start Time:	Hour:	09	Minute:	00
Stop Time:	Hour:	12	Minute:	00

Select *OK*

Enter the following CLI command:

```
config firewall schedule recurring
  edit Morning_Business_Hours
    set day monday tuesday wednesday thursday friday
    set start 09:00
    set end 12:00
    end
```

Create a second new schedule.

Field	Value
Name	Afternoon_Business_Hours
Day of the Week	
Sunday	disabled
Monday	enabled
Tuesday	enabled
Wednesday	enabled
Thursday	enabled

Field	Value
Friday	enabled
Saturday	disabled

Start Time:	Hour:	13	Minute:	00
Stop Time:	Hour:	18	Minute:	00

Select *OK*

Enter the following CLI command:

```
config firewall schedule recurring
  edit Afternoon_Business_Hours
    set day monday tuesday wednesday thursday friday
    set start 13:00
    set end 18:00
    end
```

To verify that the schedule was added correctly:

Go to *Firewall Objects* > *Schedule* > *Recurring*

Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.

Enter the following CLI command:

```
config firewall schedule recurring
  edit <the name of the schedule you wish to verify>
    show full-configuration
```

Firewall Schedule - One-time

The company wants to change over their web site image to reference the new year. They have decided to take this opportunity to do some hardware upgrades as well. Their web site is business oriented so they have determined that over New Year's Eve there will be very limited traffic.

- They are going to need a maintenance window of 2 hours bracketing midnight on New Year's Eve.

Go to *Firewall Objects* > *Schedule* > *One-time.*

Create a new schedule

Fill out the fields with the following information:

	Year	Month	Day	Hour	Minute
Start	2012	12	31	23	00
Stop	2013	1	1	1	00

Select *OK*

Enter the following CLI command:

```
config firewall schedule onetime
  edit maintenance_window
    set start 23:00 2012/12/31
    set end 01:00 2013/01/01
    next
  end
```

To verify that the schedule was added correctly:

Go to *Firewall Objects* > *Schedule* > *One-time*

Check that the schedule with the name you used has been added to the list of recurring schedules and that the listed settings are correct.

Enter the following CLI command:

```
config firewall schedule onetime
  edit <the name of the schedule you wish to verify>
    show full-configuration
```

Schedule Group

In order to make the administration of the policies easier a group needs to be created.

Go to *Firewall Objects* > *Schedule* > *Groups.*

Create a new group

Fill out the fields with the following information:

Field	Value
Group Name	Business_Hours
Available Schedules	Morning_Business_Hours
	Afternoon_Business_Hours

Use arrows to move schedules from the “Members” field to the “Available Schedules:” field

Select *OK*

Enter the following CLI command:

```
config firewall service group
  edit Business_Hours
    set member Morning_Business_Hours Afternoon_Business _ours
    end
```

To verify that the schedule was added correctly:

Go to *Firewall Objects* > *Schedule* > *Groups*

Check that the schedule group with the name you used has been added to the list of schedule groups.

Enter the following CLI command:

```
config firewall service group
  edit <the name of the schedule group you wish to verify>
    show full-configuration
```

Proxy Option

The company will be using a number of the Security Profiles features on various policies but wants to use as few profiles as possible to make administration simpler. The decision has been made to have two profiles, the default one and a single customized one that will be a combination of the settings required to cover the situations that will not be covered by the default profile.

The company profile will have the following parameters:

- There are no FTP servers running on the site so there is no need for FTP.
- The company will use the Fortinet supplied default certificate called “Fortinet_CA_SSLProxy”
- The company will only be doing inspecting of SSL over HTTP, SMTP and IMAP.
- The company has a non-standard IMAP implementation the uses ports 1143 and 1993 for IMAP and IMAPS respectively.
- Deep Scanning is to be enabled on any SSL traffic regardless of port and the traffic logged but nothing is blocked.
- The Comfort Clients is to be used with a ratio of 1 byte for every 15 seconds.
- There is a lot of varied email traffic so there is to be no blocking of emails due to size beyond the settings on the mail servers.
- The Security Officer insists that invalid SSL certificates not be allowed.

Go to Policy > Policy > Proxy Options

Create a new profile

Fill out the fields with the following information:

Field	Value
Name	example_standard
Comments	<optional>

Protocol Port Mapping:

Enable	Protocol	Inspection Ports
enabled	HTTP	Specify and <leave on default setting.>
enabled	SMTP	Specify and <leave on default setting.>
enabled	POP3	Specify and <leave on default setting.>
enabled	IMAP	Specify and 1143
not enabled	FTP	
enabled	NNTP	Specify and <leave on default setting.>

Enable	Protocol	Inspection Ports
enabled	MAPI	<leave on default setting.>
enabled	DNS	<leave on default setting.>

SSL Inspection Options

CA Certificate:“Fortinet_CA_SSLProxy” from drop down menu

Inspect All Ports: Not enabled

Enable	Protocol	Inspection Port(s)
enabled	HTTPS	<leave as default>
enabled	SMTPS	<leave as default>
enabled	POP3S	<leave as default>
enabled	IMAPS	1993
	FTPS	

SSH Inspection Options

Enable SSH Deep Scan: enabled

Protocol	Inspection Ports
SSH	Any
Exec	Block: not enabled | Log: enabled
Port-Forward	Block: not enabled | Log: enabled
SSH-Shell	Block: not enabled | Log: enabled
x11-Filter	Block: not enabled | Log: enabled

Common Options

Field	Value
Comfort Clients	enabled
• Interval (Seconds)	15
• Amount(bytes)	1
Block Oversized File/Email	not enabled
• Threshold(MB)	not enabled
Allow Invalid SSL Certificates	not enabled

Web Options

Field	Value
Enabled Chunked Bypass	not enabled
Add Fortinet Bar	not enabled
• Communication Port	<leave as default>

Email Options

Field	Value
Allow Fragmented Messages	not enabled
Append Signature (SMTP)	not enabled
Email Signature Text	not enabled

Select *OK*

Enter the following CLI command:

```
config firewall profile-protocol-options
  edit example_standard
    config http
      set options clientcomfort no-content-summary
      set comfort-interval 15
      next
    config https
      set status enable
      set options clientcomfort no-content-summary
      set comfort-interval 15
      next
    config ftp
      set status disable
      set options clientcomfort no-content-summary splice
      set comfort-interval 15
      next
    config ftps
      set options clientcomfort no-content-summary splice
      set comfort-interval 15
      next
    config imap
      set ports "1143"
      set options fragmail no-content-summary
      next
    config imaps
      set ports "1993"
      set status enable
      set options fragmail no-content-summary
      next
    config mapi
      set options fragmail no-content-summary
      next
    config pop3
      set options fragmail no-content-summary
      next
    config pop3s
      set status enable
      set options fragmail no-content-summary
      next
    config smtp
      set options fragmail no-content-summary splice
      next
    config smtps
      set status enable
      set options fragmail no-content-summary splice
      next
```

```
config nntp
   set options no-content-summary splice
   next
config ssh
   set inspect-all enable
   set log x11-filter ssh-shell exec port-forward
   next
end
```

Oversized Files

A couple of variations on the example could have to do with the processing of oversized files at a level other than the default setting. The ways that it can be approached are:

1. Set a non default threshold size and block the files
2. Set a non default threshold size and not scan the files over the threshold but allow them to pass through the FortiGate firewall.

In the following instructions:

- We will just use 2 MB as the new threshold.
- In the CLI instructions we will limit the configuration to just the HTTP settings for the purposes of brevity and simplicity.

Option 1

Option 1 can be done in the GUI.

Go to Policy > Policy > Proxy Options

Create a new profile

Fill out the fields with the following information:

Common Options

Field	Value
Comfort Clients	enabled
• Interval (Seconds)	15
• Amount(bytes)	1
Block Oversized File/Email	enabled
• Threshold(MB)	2
Allow Invalid SSL Certificates	not enabled

Select *OK*

Enter the following CLI command:

```
config firewall profile-protocol-options
  edit example_standard
    config http
      set options clientcomfort no-content-summary oversize
      set oversize-limit 2
      set comfort-interval 15
      next
    end
```

Option 2

Option 2 can only be done in the CLI.

Enter the following CLI command:

```
config firewall profile-protocol-options
  edit example_standard
    config http
      set options clientcomfort no-content-summary
      set oversize-limit 2
      set comfort-interval 15
      next
    end
```

Firewall Address Policy

A policy must be created to all traffic from one of the subnets off of the FortiGate out to the Internet.

- The traffic needs to be NATed
- The Internal subnet that needs to be connected is connected to port 1
- The subnet is from 192.168.1.1 to 192.168.1.255
- There is a user defined address for this subnet named “lan_192.168.1.x”
- The policy is for general Internet access over wan1.
- The IT manager would like to keep an eye on the kinds of sites that users are going to so for the time being even allowed traffic will be logged.
- To prevent the spread of malware even the outgoing traffic will be screened for viruses using the “basic_outgoing_av” profile that has already been defined by the IT Manager.
- There is no schedule restriction on access to the Internet so the schedule is the predefined “always”.
- There is no restrictions yet on what protocols are allowed so the predefines services should be used.
- In order to prevent any HR issues a webfilter has been defined by the IT manager that blocks access to inappropriate sites. The profile is called “basic_web_filter”

Go to *Policy* > *Policy* > *Policy.*

Create a new policy

Fill out the fields with the following information:

Field	Value
Policy Type	Firewall
Policy Subtype	Address
Incoming Interface	port1
Source Address	lan_192.168.1.x
Outgoing Interface	wan1
Destination Address	all
Schedule	always
Service	ALL
Action	Accept
Enable NAT	enable
Use Destination Interface Address	enable
Log Allowed Traffic	enable
Enable WebCache	not enabled
Enable WAN Optimization	not enabled
Traffic Shaping	enabled

Security Profiles

Security Profiles	Status	Profile Name
AntiVirus	ON	basic_outgoing_av
Web Filter	ON	basic_web_filter
Application Control	OFF	(option should be greyed out)
IPS	OFF	(option should be greyed out)
Email Filter	OFF	(option should be greyed out)
DLP Sensor	OFF	(option should be greyed out)
VoIP	OFF	(option should be greyed out)
ICAP	OFF	(option should be greyed out)

Select *OK*

Enter the following CLI command:

```
config firewall policy
  edit 0
    set srcintf port1
    set dstintf wan1
    set srcaddr lan_192.168.1.x
    set dstaddr "all
    set action accept
    set schedule always
    set service ALL
    set logtraffic enable
    set nat enable
    set natip 0.0.0.0 0.0.0.0
    set utm-status enable
    set av-profile basic_outgoing_av
    set webfilter-profile basic_web_filter
    next
  end
```

Firewall User Identity Policy

There is a Server on the Internal LAN that is used as a resource by sales people that are out on the road and at home. The sales people and their administrator are the only ones that are allowed access to the server “SalesServer”. Because of the importance of the data on the server it needs to be backed up on a regular bases and to make sure that all of the files are available for backup no one is allowed access during the scheduled backup time.

- Firewall User Group has been created: “sales”. This is a group defined for more than one purpose.
- Firewall User has been created: “jsmith”, who is the administrator. “jsmith” is not a member of the sales group and can’t be placed in it because of other resources that the group has access to.
- A Virtual IP has been defined for the server “SalesServer” mapped from an external address to an internal address on port9. Port forwarding is enabled on TCP port 443 for the application that the sales people use.
- The schedule “Non-Maintenance_Window” has been created (between 2 a.m. and 3 a.m.) by starting the window at 3:00 and stopping at 2:00 (If the stop time is set earlier than the start time, the stop time will be during the next day).
- Because there is access from the Internet to the internal network the company’s HTTPS Server IPS profile, called “Protect_HTTPS_Server” will be enabled.

Go to *Policy* > *Policy* > *Policy.*

Create a new policy

Fill out the fields with the following information:

Field	Value
Policy Type	Firewall
Policy Subtype	User Identity

Field	Value
Incoming Interface	wan1
Source Address	all
Outgoing Interface	port9
Enable NAT	not enabled
Enable Web cache	not enabled
Enable WAN Optimization	not enabled
Certificate	No Certificate
Firewall	enabled
Fortinet Single Sign-On	not enabled
WiFi Singe Sign-on	not enabled
NTLM Authentications	not enabled
Customize Authentication Messages	(optional)
Add tag	(optional)
Comments	(optional)

In the Configure Authentication Rules section, create a new Authentication rule by filling out the fields with the following information.

Field	Value
Destination Address	SalesServer (virtual IP address)
Group(s)	sales
User(s)	jsmith
Schedule	Non-Maintenance_Window
Service	HTTPS
Action	(automatically assigned value of “ACCEPT”
Log Allowed Traffic	(optional)
Traffic Shaping	(optional)

In the Security Profiles Section:

Enable and select the security profiles as follows:

Security Profiles	Status	Profile Name
AntiVirus	OFF	(option should be greyed out)
Web Filter	OFF	(option should be greyed out)
Application Control	OFF	(option should be greyed out)
IPS	ON	Protect_HTTPS_Server
Email Filter	OFF	(option should be greyed out)
DLP Sensor	OFF	(option should be greyed out)
VoIP	OFF	(option should be greyed out)
ICAP	OFF	(option should be greyed out)

Select *OK*

Enter the following CLI command:

```
config firewall policy
  edit 0
    set srcintf "wan1"
    set dstintf "port9"
    set srcaddr "all"
    set action accept
    set identity-based enable
      config identity-based-policy
        edit 1
          set schedule "Non-Maintenance_Window"
          set utm-status enable
          set profile-type single
          set groups "sales"
          set users "jsmith"
          set dstaddr "SalesServer"
          set service "HTTPS"
          set ips-sensor "Protect_HTTPS_Server"
          next
        end
```

Firewall Device Identity Policy

The company is instituting a BYOD pilot project. They are going to be letting employee's personal devices connect through a wireless network. Most will only be allowed only to the Internet but some will have access to the Internal LAN.

- The wireless interface the users will be connecting on is "WiFi".
- The source address has been defined as the DCHP scope assigned to the wireless network, "Internal_wireless".
- The Internal Network is on the interface designated as "LAN"
- There is no need to NAT the traffic.
- The AntiVirus Profile to be used is "Internal-AV", already defined.
- The Application Profile to be used is "Internal-AC", already defined.
- The IPS Profile to be used is "Internal-IPS", already defined.
- The Device group for this policy is "IT_Personnel_phones".
- The IT team is a trusted group that will be accessing practically everything so the schedule will be the predefined "always" and the Service will be the predefined "ALL".
- While the IT team is trusted the company would like to verify that they are compliant with the Endpoint profile so the check for this must be enabled on the policy.

Go to *Policy* > *Policy* > *Policy.*

Create a new policy

Fill out the fields with the following information:

Field	**Value**
Policy Type	Firewall
Policy Subtype	Device Identity
Incoming Interface	wifi
Source Address	all
Outgoing Interface	port9
Enable NAT	not enabled
Customize Authentication Messages	(optional)
Add tag	(optional)
Comments	(optional)

In the Configure Authentication Rules section, create a new Authentication rule by filling out the fields with the following information.

Field	Value
Destination Address	Internal_Network
Device	IT_Personnel_Phones
Compliant with Endpoint Profile	enable
Schedule	always
Service	ALL
Action	(automatically assigned value of “ACCEPT”
Log Allowed Traffic	(optional)
Traffic Shaping	(optional)

In the Security Profile Section:

Enable and select the security profiles as follows:

Security Profiles	Status	Profile Name
AntiVirus	ON	Internal-AV
Web Filter	OFF	(option should be greyed out)
Application Control	ON	Internal-AC
IPS	ON	Internal-IPS
Email Filter	OFF	(option should be greyed out)
DLP Sensor	OFF	(option should be greyed out)
VoIP	OFF	(option should be greyed out)
ICAP	OFF	(option should be greyed out)

Select *OK*

Enter the following CLI command:

```
config firewall policy
  edit 0
    set srcintf "wifi"
    set dstintf "LAN"
    set srcaddr "Internal_wireless"
    set action accept
    set identity-based enable
    set identity-from device
      config identity-based-policy
        edit 1
          set schedule always
          set utm-status enable
          set dstaddr Internal_Network
          set service ALL
          set devices IT_Personnel_phones
          set endpoint-compliance enable
          set av-profile Internal-AV
          set ips-sensor Internal-IPS
          set application-list Internal-AC
          next
        end
```

DoS Policy

The company wishes to protect against Denial of Service attach. They have chosen some where they wish to block the attacks of the incidence goes above a certain threshold and for some others they are just trying to get a baseline of activity for those types of attacks so they are letting the traffic pass through without action.

- The interface to the Internet is on WAN1
- There is no requirement to specify which addresses are being protected or protected from.
- The protection is to extend to all services.
- The TCP attacks are to be blocked
- The UDP, ICMP, and IP attacks are to be recorded but not blocked.
- The tcp_syn_flood attach's threshold is to be changed from the default to 1000

Go to *Policy* > *Policy* > *DoS Policy.*

Create a new policy

Fill out the fields with the following information:

Field	Value
Incoming Interface	wan1
Source Address	all

Field	Value
Destination Addresses	all
Service	ALL

Anomalies

Name	Status	Logging	Action	Threshold
tcp_syn_flood	enabled	enabled	Block	1000
tcp_port_scan	enabled	enabled	Block	<default value>
tcp_src_session	enabled	enabled	Block	<default value>
tcp_dst_session	enabled	enabled	Block	<default value>
udp_flood	enabled	enabled	Pass	<default value>
udp_scan	enabled	enabled	Pass	<default value>

      edit "icmp_src_session"
        set status enable
        set log enable
        next
      edit "icmp_dst_session"
        set status enable
        set log enable
        next
      edit "ip_src_session"
        set status enable
        set log enable
        next
      edit "ip_dst_session"
        set status enable
        set log enable
        next
      end
    next
end
```

Multicast forwarding

Multicasting (also called IP multicasting) consists of using a single multicast source to send data to many receivers. Multicasting can be used to send data to many receivers simultaneously while conserving bandwidth and reducing network traffic. Multicasting can be used for one-way delivery of media streams to multiple receivers and for one-way data transmission for news feeds, financial information, and so on.

Also RIPv2 uses multicasting to share routing table information, OSPF uses multicasting to send hello packets and routing updates, Enhanced Interior Gateway Routing Protocol (EIGRP) uses multicasting to send routing information to all EIGRP routers on a network segment and the Bonjour network service uses multicasting for DNS.

A FortiGate unit can operate as a Protocol Independent Multicast (PIM) version 2 router. FortiGate units support PIM sparse mode (RFC 4601) and PIM dense mode (RFC 3973) and can service multicast servers or receivers on the network segment to which a FortiGate unit interface is connected. Multicast routing is not supported in transparent mode (TP mode).

To support PIM communications, the sending/receiving applications and all connecting PIM routers in between must be enabled with PIM version 2. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations. To enable source-to-destination packet delivery, either sparse mode or dense mode must be enabled on the PIM-router interfaces. Sparse mode routers cannot send multicast messages to dense mode routers. In addition, if a FortiGate unit is located between a source and a PIM router, two PIM routers, or is connected directly to a receiver, you must create a security policy manually to pass encapsulated (multicast) packets or decapsulated data (IP traffic) between the source and destination.

A PIM domain is a logical area comprising a number of contiguous networks. The domain contains at least one Boot Strap Router (BSR), and if sparse mode is enabled, a number of Rendezvous Points (RPs) and Designated Routers (DRs). When PIM is enabled on a FortiGate unit, the FortiGate unit can perform any of these functions at any time as configured.

Sparse mode

Initially, all candidate BSRs in a PIM domain exchange bootstrap messages to select one BSR to which each RP sends the multicast address or addresses of the multicast group(s) that it can service. The selected BSR chooses one RP per multicast group and makes this information available to all of the PIM routers in the domain through bootstrap messages. PIM routers use the information to build packet distribution trees, which map each multicast group to a specific RP. Packet distribution trees may also contain information about the sources and receivers associated with particular multicast groups.

When a FortiGate unit interface is configured as a multicast interface, sparse mode is enabled on it by default to ensure that distribution trees are not built unless at least one downstream receiver requests multicast traffic from a specific source. If the sources of multicast traffic and their receivers are close to each other and the PIM domain contains a dense population of active receivers, you may choose to enable dense mode throughout the PIM domain instead.

An RP represents the root of a non-source-specific distribution tree to a multicast group. By joining and pruning the information contained in distribution trees, a single stream of multicast

packets (for example, a video feed) originating from the source can be forwarded to a certain RP to reach a multicast destination.

Each PIM router maintains a Multicast Routing Information Base (MRIB) that determines to which neighboring PIM router join and prune messages are sent. An MRIB contains reverse-path information that reveals the path of a multicast packet from its source to the PIM router that maintains the MRIB.

To send multicast traffic, a server application sends IP traffic to a multicast group address. The locally elected DR registers the sender with the RP that is associated with the target multicast group. The RP uses its MRIB to forward a single stream of IP packets from the source to the members of the multicast group. The IP packets are replicated only when necessary to distribute the data to branches of the RP's distribution tree.

To receive multicast traffic, a client application can use Internet Group Management Protocol (IGMP) version 1 (RFC 1112), 2 (RFC 2236), or 3 (RFC 3376) control messages to request the traffic for a particular multicast group. The locally elected DR receives the request and adds the host to the multicast group that is associated with the connected network segment by sending a join message towards the RP for the group. Afterward, the DR queries the hosts on the connected network segment continually to determine whether the hosts are active. When the DR no longer receives confirmation that at least one member of the multicast group is still active, the DR sends a prune message towards the RP for the group.

FortiOS supports PIM sparse mode multicast routing for IPv6 multicast (multicast6) traffic and is compliant with RFC 4601: Protocol Independent Multicast - Sparse Mode (PIM-SM). You can use the following command to configure IPv6 PIM sparse multicast routing.

```
config router multicast6
  set multicast-routing {enable | disable}
    config interface
      edit <interface-name>
        set hello-interval <1-65535 seconds>
        set hello-holdtime <1-65535 seconds>
      end
    config pim-sm-global
      config rp-address
        edit <index>
          set ipv6-address <ipv6-address>
        end
```

The following diagnose commands for IPv6 PIM sparse mode are also available:

```
diagnose ipv6 multicast status
diagnose ipv6 multicast vif
diagnose ipv6 multicast mroute
```

Dense mode

The packet organization used in sparse mode is also used in dense mode. When a multicast source begins to send IP traffic and dense mode is enabled, the closest PIM router registers the IP traffic from the multicast source (S) and forwards multicast packets to the multicast group address (G). All PIM routers initially broadcast the multicast packets throughout the PIM domain to ensure that all receivers that have requested traffic for multicast group address G can access the information if needed.

To forward multicast packets to specific destinations afterward, the PIM routers build distribution trees based on the information in multicast packets. Upstream PIM routers depend

on prune/graft messages from downstream PIM routers to determine if receivers are actually present on directly connected network segments. The PIM routers exchange state refresh messages to update their distribution trees. FortiGate units store this state information in a Tree Information Base (TIB), which is used to build a multicast forwarding table. The information in the multicast forwarding table determines whether packets are forwarded downstream. The forwarding table is updated whenever the TIB is modified.

PIM routers receive data streams every few minutes and update their forwarding tables using the source (S) and multicast group (G) information in the data stream. Superfluous multicast traffic is stopped by PIM routers that do not have downstream receivers—PIM routers that do not manage multicast groups send prune messages to the upstream PIM routers. When a receiver requests traffic for multicast address G, the closest PIM router sends a graft message upstream to begin receiving multicast packets.

FortiGate units operating in NAT mode can also be configured as multicast routers. You can configure a FortiGate unit to be a Protocol Independent Multicast (PIM) router operating in Sparse Mode (SM) or Dense Mode (DM).

Multicast IP addresses

Multicast uses the Class D address space. The 224.0.0.0 to 239.255.255.255 IP address range is reserved for multicast groups. The multicast address range applies to multicast groups, not to the originators of multicast packets. Table 53 lists reserved multicast address ranges and describes what they are reserved for:

Table 53: Reserved Multicast address ranges

Reserved Address Range	Use	Notes
224.0.0.0 to 224.0.0.255	Used for network protocols on local networks. For more information, see RFC 1700.	In this range, packets are not forwarded by the router but remain on the local network. They have a Time to Live (TTL) of 1. These addresses are used for communicating routing information.
224.0.1.0 to 238.255.255.255	Global addresses used for multicasting data between organizations and across the Internet. For more information, see RFC 1700.	Some of these addresses are reserved, for example, 224.0.1.1 is used for Network Time Protocol (NTP).
239.0.0.0 to 239.255.255.255	Limited scope addresses used for local groups and organizations. For more information, see RFC 2365.	Routers are configured with filters to prevent multicasts to these addresses from leaving the local system.

Creating multicast security policies requires multicast firewall addresses. You can add multicast firewall addresses by going to *Firewall Objects* > *Address* > *Addresses* and selecting *Create New* > *Multicast Address*. The factory default configuration includes multicast addresses for Bonjour(224.0.0.251-224.0.0.251, EIGRP (224.0.0.10-224.0.0.100), OSPF (224.0.0.5-224.0.0.60), all_hosts (224.0.0.1-224.0.0.1), and all_routers (224.0.0.2-224.0.0.2).

PIM Support

A FortiGate unit can be configured to support PIM by going to *Router* > *Dynamic* > *Multicast* and enabling multicast routing. You can also enable multicast routing using the `config router multicast` CLI command. When PIM is enabled, the FortiGate unit allocates memory to manage mapping information. The FortiGate unit communicates with neighboring PIM routers to acquire mapping information and if required, processes the multicast traffic associated with specific multicast groups.

The end-user multicast client-server applications must be installed and configured to initiate Internet connections and handle broadband content such as audio/video information.

Client applications send multicast data by registering IP traffic with a PIM-enabled router. An end-user could type in a class D multicast group address, an alias for the multicast group address, or a call-conference number to initiate the session.

Rather than sending multiple copies of generated IP traffic to more than one specific IP destination address, PIM-enabled routers encapsulate the data and use the one multicast group address to forward multicast packets to multiple destinations. Because one destination address is used, a single stream of data can be sent. Client applications receive multicast data by requesting that the traffic destined for a certain multicast group address be delivered to them — end-users may use phone books, a menu of ongoing or future sessions, or some other method through a user interface to select the address of interest.

A class D address in the 224.0.0.0 to 239.255.255.255 range may be used as a multicast group address, subject to the rules assigned by the Internet Assigned Numbers Authority (IANA). All class D addresses must be assigned in advance. Because there is no way to determine in advance if a certain multicast group address is in use, collisions may occur (to resolve this problem, end-users may switch to a different multicast address).

To configure a PIM domain

1. If you will be using sparse mode, determine appropriate paths for multicast packets.
2. Make a note of the interfaces that will be PIM-enabled. These interfaces may run a unicast routing protocol.
3. If you will be using sparse mode and want multicast packets to be handled by specific (static) RPs, record the IP addresses of the PIM-enabled interfaces on those RPs.
4. Enable PIM version 2 on all participating routers between the source and receivers. On FortiGate units, use the `config router multicast` command to set global operating parameters.
5. Configure the PIM routers that have good connections throughout the PIM domain to be candidate BSRs.
6. If sparse mode is enabled, configure one or more of the PIM routers to be candidate RPs.
7. If required, adjust the default settings of PIM-enabled interface(s).

Multicast forwarding and FortiGate units

In both transparent mode and NAT mode you can configure FortiGate units to forward multicast traffic.

For a FortiGate unit to forward multicast traffic you must add FortiGate multicast security policies. Basic multicast security policies accept any multicast packets at one FortiGate

interface and forward the packets out another FortiGate interface. You can also use multicast security policies to be selective about the multicast traffic that is accepted based on source and destination address, and to perform NAT on multicast packets.

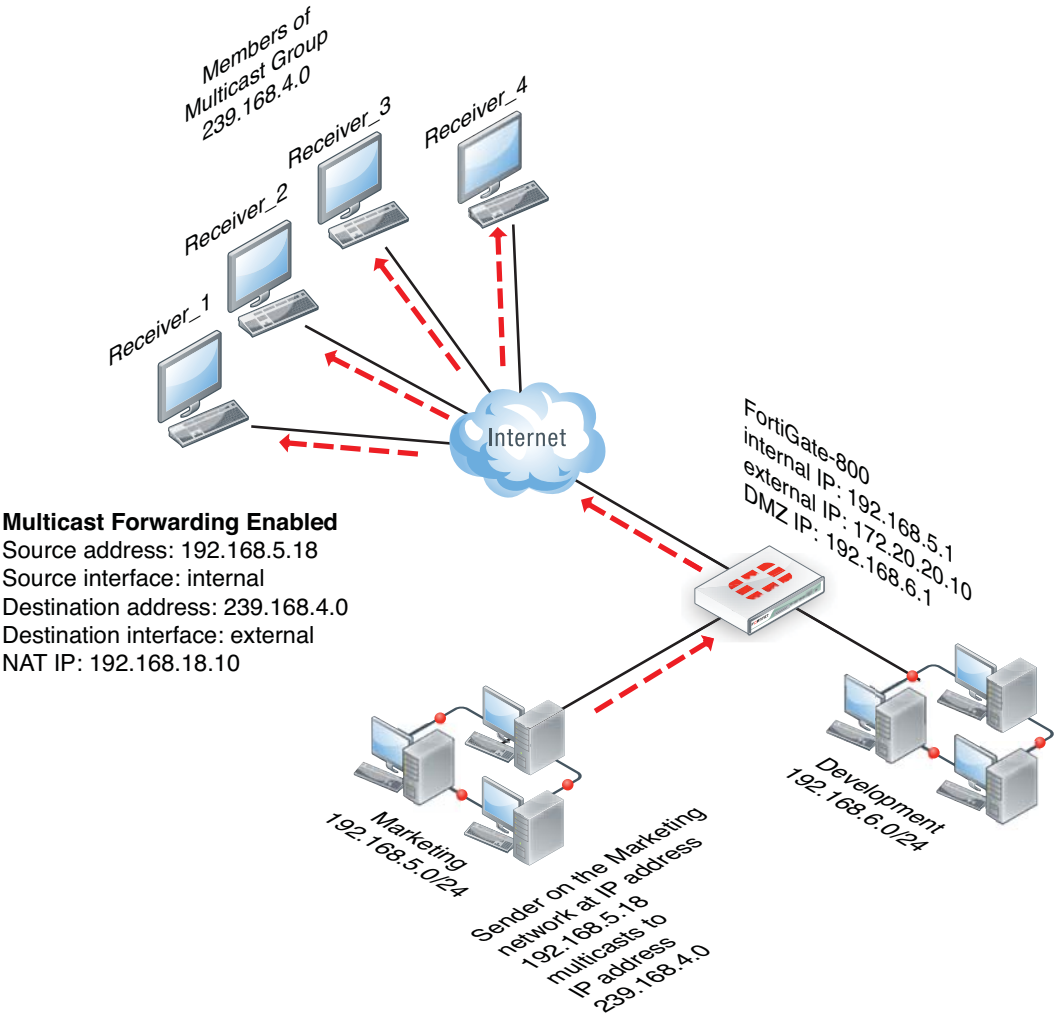
In the example shown in Figure 176, a multicast source on the Marketing network with IP address 192.168.5.18 sends multicast packets to the members of network 239.168.4.0. At the FortiGate unit, the source IP address for multicast packets originating from workstation 192.168.5.18 is translated to 192.168.18.10. In this example, the FortiGate unit is not acting as a multicast router.

Multicast forwarding and RIPv2

RIPv2 uses multicast to share routing table information. If your FortiGate unit is installed on a network that includes RIPv2 routers, you must configure the FortiGate unit to forward multicast packets so that RIPv2 devices can share routing data through the FortiGate unit. No special FortiGate configuration is required to share RIPv2 data, you can simply use the information in the following sections to configure the FortiGate unit to forward multicast packets.

RIPv1 uses broadcasting to share routing table information. To allow RIPv1 packets through a FortiGate unit you can add standard security policies. Security policies to accept RIPv1 packets can use the ANY predefined firewall service or the RIP predefined firewall service.

Figure 176: Example multicast network including a FortiGate unit that forwards multicast packets



Configuring FortiGate multicast forwarding

You configure FortiGate multicast forwarding from the Command Line Interface (CLI). Two steps are required:

- Adding multicast security policies
- Enabling multicast forwarding

  This second step is only required if your FortiGate unit is operating in NAT mode. If your FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

There is sometimes a confusion between the terms “forwarding” and “routing”. These two functions should not be taking place at the same time.

It is mentioned that multicast-forward should be enabled when the FortiGate unit is in NAT mode and that this will forward any multicast packet to all interfaces. However, this parameter should **NOT** be enabled when the FortiGate unit operates as a multicast router (i.e. with a routing protocol enabled. It should only be enabled when there is no routing protocols activated.

Adding multicast security policies

You need to add security policies to allow packets to pass from one interface to another. Multicast packets require multicast security policies. You add multicast security policies from the CLI using the `config firewall multicast-policy` command. As with unicast security policies, you specify the source and destination interfaces and optionally the allowed address ranges for the source and destination addresses of the packets.

You can also use multicast security policies to configure source NAT and destination NAT for multicast packets.

Keep the following in mind when configuring multicast security policies:

- The matched forwarded (outgoing) IP multicast source IP address is changed to the configured IP address.
- Source and Destination interfaces are optional. If left blank, then the multicast will be forwarded to ALL interfaces.
- Source and Destination addresses are optional. If left un set, then it will mean ALL addresses.
- The `nat` keyword is optional. Use it when source address translation is needed.

Enabling multicast forwarding

Multicast forwarding is enabled by default. In NAT mode you must use the `multicast-forward` keyword of the `system settings` CLI command to enable or disable multicast forwarding. When `multicast-forward` is enabled, the FortiGate unit forwards any multicast IP packets in which the TTL is 2 or higher to all interfaces and VLAN interfaces except the receiving interface. The TTL in the IP header will be reduced by 1. Even though the multicast packets are forwarded to all interfaces, you must add security policies to actually allow multicast packets through the FortiGate. In our example, the security policy allows multicast packets received by the internal interface to exit to the external interface.

Enabling multicast forwarding is only required if your FortiGate unit is operating in NAT mode. If your FortiGate unit is operating in transparent mode, adding a multicast policy enables multicast forwarding.

Enter the following CLI command to enable multicast forwarding:

```
config system settings
  set multicast-forward enable
end
```

If multicast forwarding is disabled and the FortiGate unit drops packets that have multicast source or destination addresses.

You can also use the `multicast-ttl-notchange` keyword of the `system settings` command so that the FortiGate unit does not increase the TTL value for forwarded multicast packets. You should use this option only if packets are expiring before reaching the multicast router.

```
config system settings
  set multicast-ttl-notchange enable
end
```

In transparent mode, the FortiGate unit does not forward frames with multicast destination addresses. Multicast traffic such as the one used by routing protocols or streaming media may need to traverse the FortiGate unit, and should not be interfere with the communication. To

avoid any issues during transmission, you can set up multicast security policies. These types of security policies can only be enabled using the CLI.

The CLI parameter multicast-skip-policy must be disabled when using multicast security policies. To disable enter the command

```
config system settings
  set multicast-skip-policy disable
end
```

In this simple example, no check is performed on the source or destination interfaces. A multicast packet received on an interface is flooded unconditionally to all interfaces on the forwarding domain, except the incoming interface.

To enable the multicast policy

```
config firewall multicast-policy
  edit 1
    set action accept
end
```

In this example, the multicast policy only applies to the source port of WAN1 and the destination port of Internal.

To enable the restrictive multicast policy

```
config firewall multicast-policy
  edit 1
    set srcintf wan1
    set dstinf internal
    set action accept
end
```

In this example, packets are allowed to flow from WAN1 to Internal, and sourced by the address 172.20.120.129. This address needs to be configured as an address objct. For simplicity we will assume that this address is represented by the address object "example-addr_A".

To enable the restrictive multicast policy

```
config firewall multicast-policy
  edit 1
    set srcintf wan1
    set srcaddr example-addr_A
    set dstinf internal
    set action accept
end
```

This example shows how to configure the multicast security policy required for the configuration shown. This policy accepts multicast packets that are sent from a PC with IP address 192.168.5.18, which will be represented by the address objct "example-addr_X", to destination address range 239.168.4.0, which will be represented by the address object "example-addr_Y". The policy allows the multicast packets to enter the internal interface and then exit the external

interface. When the packets leave the external interface their source address is translated to 192.168.18.10.

```
config firewall multicast-policy
  edit 5
    set srcaddr example-addr_X
    set srcintf internal
    set destaddr example-addr_Y
    set dstintf external
    set nat 192.168.18.10
end
```

This example shows how to configure a multicast security policy so that the FortiGate unit forwards multicast packets from a multicast Server with an IP 10.10.10.10, represented by address object "example-addr_C", is broadcasting to address 225.1.1.1, represented by address object "example-addr_D". This Server is on the network connected to the FortiGate DMZ interface.

```
config firewall multicast-policy
  edit 1
    set srcintf DMZ
    set srcaddr example-addr_C
    set dstintf Internal
    set dstaddr example-addr_D
    set action accept
  edit 2
    set action deny
end
```

Multicast routing examples

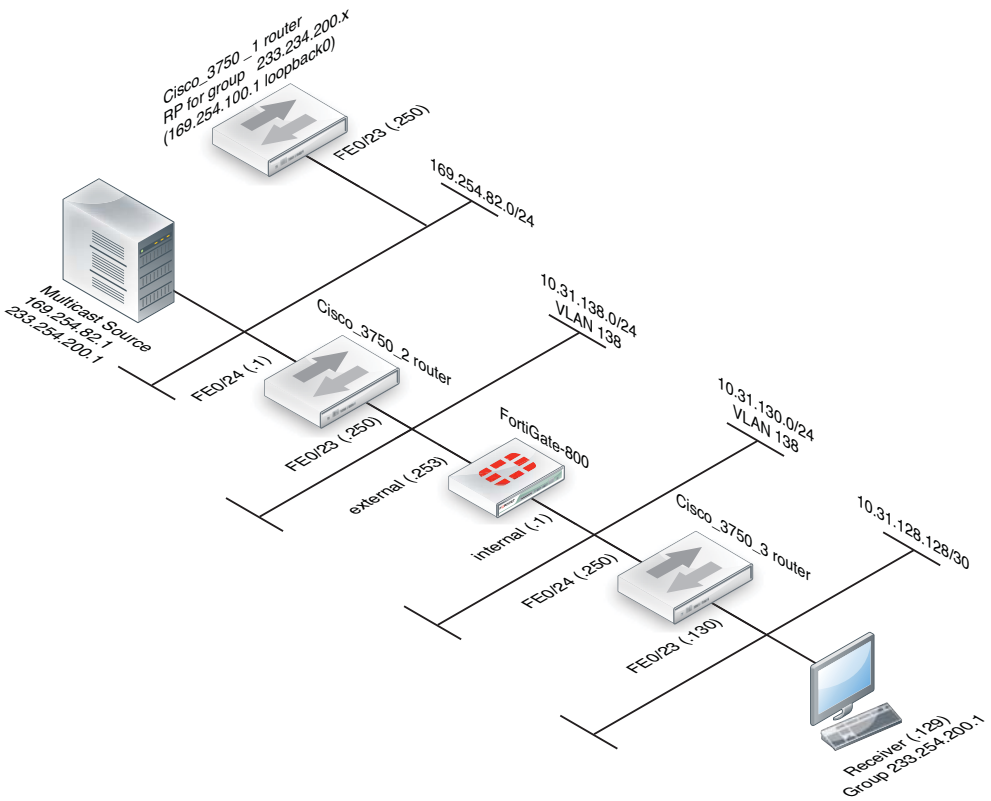
This section contains the following multicast routing configuration examples and information:

- Example FortiGate PIM-SM configuration using a static RP
- FortiGate PIM-SM debugging examples
- Example multicast destination NAT (DNAT) configuration
- Example PIM configuration that uses BSR to find the RP

Example FortiGate PIM-SM configuration using a static RP

The example Protocol Independent Multicast Sparse Mode (PIM-SM) configuration shown in Figure 177 has been tested for multicast interoperability using PIM-SM between Cisco 3750 switches running 12.2 and a FortiGate-800 running FortiOS v3.0 MR5 patch 1. In this configuration, the receiver receives the multicast stream when it joins the group 233.254.200.1.

Figure 177: Example FortiGate PIM-SM topology



The configuration uses a statically configured rendezvous point (RP) which resides on the Cisco_3750_1. Using a bootstrap router (BSR) was not tested in this example. See “Example PIM configuration that uses BSR to find the RP” on page 1055 for an example that uses a BSR.

Configuration steps

The following procedures show how to configure the multicast configuration settings for the devices in the example configuration.

- Cisco_3750_1 router configuration
- Cisco_3750_2 router configuration
- To configure the FortiGate-800 unit
- Cisco_3750_3 router configuration

Cisco_3750_1 router configuration

```

To configure the FortiGate-800 unit

1. Configure the internal and external interfaces.
   - Internal

   Go to *System* > *Network* > *Interfaces.*

   Select the internal interface

   Verify the following settings:

Type:	Physical Interface
Addressing mode:	Manual
IP/Network Mask:	10.31.138.253 255.255.255.0
Administrative Access:	PING

   Select *OK*

   - **External**

   Go to *System* > *Network* > *Interfaces.*

   Select the external interface

   Verify the following settings:

Type:	Physical Interface
Addressing mode:	Manual
IP/Network Mask:	10.31.130.253 255.255.255.0
Administrative Access:	HTTPS and PING

   Select *OK.*

2. Add a firewall addresses.

   Go to *Firewall Objects* > *Address* > *Addresses.*

   - RP

   Select *Create New*.

   Use the following settings:

Category:	Address
Name:	RP
Type:	Subnet
Subnet/IP Range:	169.254.100.1/32
Interface:	Any

   Select *OK*.

   - Multicast source subnet

   Select *Create New*.

   Use the following settings:

Category:	Address
Name:	multicast_source_subnet
Type:	Subnet
Subnet/IP Range:	169.254.82.0/24
Interface:	Any

   Select *OK*.

3. Add destination multicast address

   Go to *Firewall Objects* > *Address* > *Addresses.*

   Select *Create New*.

   Use the following settings:

Category:	Multicast Address
Name:	Multicast_stream
Type:	Broadcast Subnet
Broadcast Subnet:	233.254.200.0/24
Interface:	Any

   Select OK.

4. Add standard security policies to allow traffic to reach the RP.

   Go to Policy > Policy > Policy

   - 1st policy

   Select *Create New*

   Use the following settings:

Policy Type:	Firewall
Policy Subtype:	Address
Incoming Interfac:	internal
Source Address:	all
Outgoing Interface:	external
Destination Address:	RP
Schedule:	always
Service:	ALL
Action:	ACCEPT

   Select *OK*.

   - 2nd policy

   Select *Create New*

   Use the following settings:

Policy Type:	Firewall
Policy Subtype:	Address
Incoming Interfac:	external
Source Address:	RP
Outgoing Interface:	internal
Destination Address:	all
Schedule:	always
Service:	ALL
Action:	ACCEPT

   Select *OK*.

5. Add the multicast security policy.
   Go to Policy > Policy > Multicast Policy
   Select *Create New*
   Use the following settings:

Incoming Interface:	external
Source Address:	multicast_source_subnet
Outgoing Interface:	internal
Destination Address:	multicast_stream
Protocol:	Any
Action:	ACCEPT

   Select *OK*.

6. Add an access list. (CLI only)

```
config router access-list
  edit Source-RP
    config rule
      edit 1
        set prefix 233.254.200.0 255.255.255.0
        set exact-match disable
      next
    end
```

7. Add some static routes.
   Go to *Router* > *Static* > *Static Routes*.
   - Route 1

   Select *Create New*.
   Use the following settings:

Destination IP/Mask:	0.0.0.0/0.0.0.0
Device:	internal
Gateway:	10.31.130.250

   Select *OK*.
   - Route 2

   Select *Create New*.
   Use the following settings:

Destination IP/Mask:	169.254.0.0/16
Device:	external
Gateway:	10.31.138.250

   Select *OK*.

8. Configure multicast routing.

   Go to *Router* > *Dynamic* > *Multicast*.

   Add the following Static Rendezvous Point(s):

   - 169.254.100.1

- Route 1

  Select *Create New*.

  Use the following settings:

Interface:	internal
PIM Mode:	Sparse Mode
DR Priority:	<not needed in this scenario>
RP Candidate:	<not needed in this scenario>
RP Candidate Priority:	<not needed in this scenario>

  Select *OK.*

- Route 2

  Select *Create New*.

  Use the following settings:

Interface:	external
PIM Mode:	Sparse Mode
DR Priority:	
RP Candidate:	
RP Candidate Priority:	

  Select *OK.*

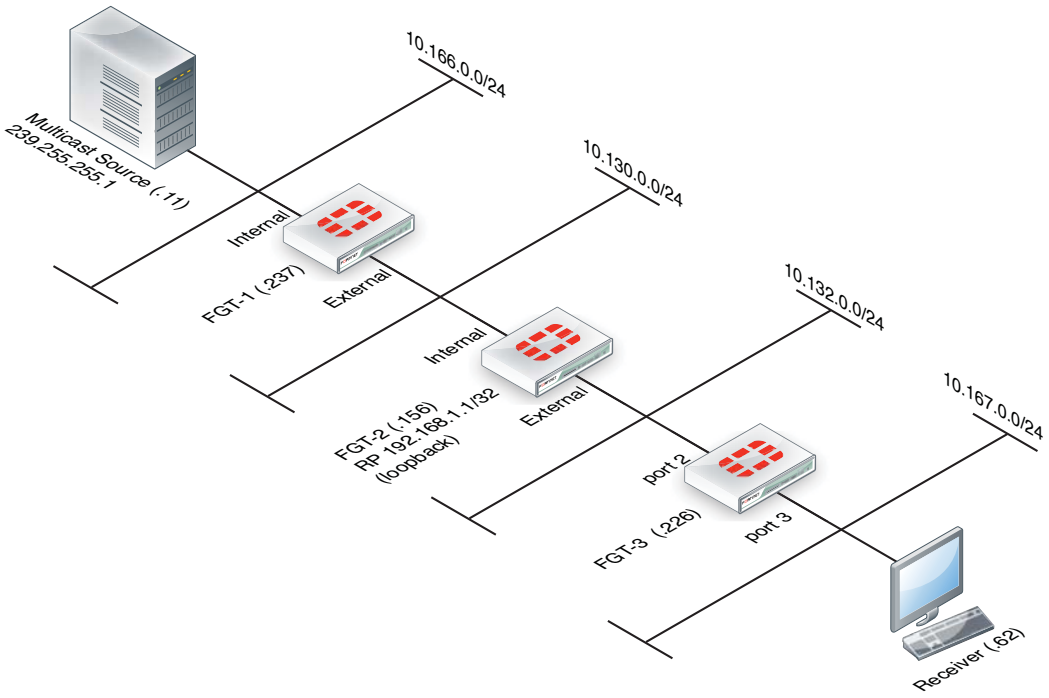
FortiGate PIM-SM debugging examples

Using the example topology shown in Figure 178 you can trace the multicast streams and states within the three FortiGate units (FGT-1, FGT-2, and FGT-3) using the debug commands described in this section. The command output in this section is taken from FortiGate unit when the multicast stream is flowing correctly from source to receiver.

Figure 178:PIM-SM debugging topology



Checking that the receiver has joined the required group

From the last hop router, FGT-3, you can use the following command to check that the receiver has correctly joined the required group.

```
FGT-3 # get router info multicast igmp groups
IGMP Connected Group Membership
Group Address    Interface            Uptime   Expires  Last Reporter
239.255.255.1    port3                00:31:15 00:04:02 10.167.0.62
```

Only 1 receiver is displayed for a particular group, this is the device that responded to the IGMP query request from the FGT-3. If a receiver is active the expire time should drop to approximately 2 minutes before being refreshed.

Checking the PIM-SM neighbors

Next the PIM-SM neighbors should be checked. A PIM router becomes a neighbor when the PIM router receives a PIM hello. Use the following command to display the PIM-SM neighbors of FGT-3.

```
FGT-3 # get router info multicast pim sparse-mode neighbour
Neighbor          Interface          Uptime/Expires    Ver   DR
Address Priority/Mode
10.132.0.156      port2              01:57:12/00:01:33 v2    1 /
```

Checking that the PIM router can reach the RP

The rendezvous point (RP) must be reachable for the PIM router (FGT-3) to be able to send the *,G join to request the stream. This can be checked for FGT-3 using the following command:

```
FGT-3 # get router info multicast pim sparse-mode rp-mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/4, Static
    RP: 192.168.1.1
         Uptime: 07:23:00
```

Viewing the multicast routing table (FGT-3)

The FGT-3 unicast routing table can be used to determine the path taken to reach the RP at 192.168.1.1. You can then check the stream state entries using the following commands:

```
FGT-3 # get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 1
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
```

(*,*,RP) Entries	This state may be reached by general joins for all groups served by a specified RP.
(*,G) Entries	State that maintains the RP tree for a given group.
(S,G) Entries	State that maintains a source-specific tree for source S and group G.
(S,G,rpt) Entries	State that maintains source-specific information about source s on the RP tree for G. For example, if a source is being received on the source-specific tree, it will normally have been pruned off the RP tree.
FCR	The FCR state entries are for tracking the sources in the <*, G> when <S, G> is not available for any reason, the stream would typically be flowing when this state exists.

Breaking down each entry in detail:

```
(*, 239.255.255.1)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: JOINED
 Local:
     port3
 Joined:
 Asserted:
FCR:
```

The RP will always be listed in a *,G entry, the RPF neighbor and interface index will also be shown. In this topology these are the same in all downstream PIM routers. The state is active so the upstream state is joined.

In this case FGT-3 is the last hop router so the IGMP join is received locally on port3. There is no PIM outgoing interface listed for this entry as it is used for the upstream PIM join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.132.0.156
RPF idx: port2
SPT bit: 1
Upstream State: JOINED
 Local:
 Joined:
 Asserted:
 Outgoing:
     port3
```

This is the entry for the SPT, no RP IS listed. The `S,G` stream will be forwarded out of the stated outgoing interface.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 10.132.0.156
RPF idx: port2
Upstream State: NOT PRUNED
 Local:
 Pruned:
 Outgoing:
```

The above `S,G,RPT` state is created for all streams that have both a `S,G` and a `*,G` entry on the router. This is not pruned in this case because of the topology, the RP and source are reachable over the same interface.

Although not seen in this scenario, assert states may be seen when multiple PIM routers exist on the same LAN which can lead to more than one upstream router having a valid forwarding state. Assert messages are used to elect a single forwarder from the upstream devices.

Viewing the PIM next-hop table

The PIM next-hop table is also very useful for checking the various states, it can be used to quickly identify the states of multiple multicast streams

```
FGT-3 # get router info multicast pim sparse-mode next-hop
Flags: N = New, R = RP, S = Source, U = Unreachable
Destination     Type  Nexthop   Nexthop         Nexthop  Metric Pref
     Refcnt
                         Num     Addr            Ifindex

------------------------------------------------------------------
10.166.0.11     ..S.  1         10.132.0.156    9 21     110    3
192.168.1.1     .R..  1         10.132.0.156    9 111    110    2
```

Viewing the PIM multicast forwarding table

Also you can check the multicast forwarding table showing the ingress and egress ports of the multicast stream.

```
FGT-3 # get router info multicast table

IP Multicast Routing Table
Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed
Timers: Uptime/Stat Expiry
Interface State: Interface (TTL threshold)

(10.166.0.11, 239.255.255.1), uptime 04:02:55, stat expires 00:02:25
Owner PIM-SM, Flags: TF
  Incoming interface: port2
  Outgoing interface list:
    port3 (TTL threshold 1)
```

Viewing the kernel forwarding table

Also the kernel forwarding table can be verified, however this should give similar information to the above command:

```
FGT-3 # diag ip multicast mroute
grp=239.255.255.1 src=10.166.0.11 intf=9 flags=(0x10000000)[  ]
     status=resolved
        last_assert=2615136 bytes=1192116 pkt=14538 wrong_if=0 num_ifs=1
         index(ttl)=[6(1),]
```

Viewing the multicast routing table (FGT-2)

If you check the output on FGT-2 there are some small differences:

```
  FGT-2 # get router info multicast pim sparse-mode table
  IP Multicast Routing Table

  (*,*,RP) Entries: 0
  (*,G) Entries: 1
  (S,G) Entries: 1
  (S,G,rpt) Entries: 1
  FCR Entries: 0

  (*, 239.255.255.1)
  RP: 192.168.1.1
  RPF nbr: 0.0.0.0
  RPF idx: None
  Upstream State: JOINED
   Local:
   Joined:
       external
   Asserted:
  FCR:
```

The *,G entry now has a joined interface rather than local because it has received a PIM join from FGT-3 rather than a local IGMP join.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 10.130.0.237
RPF idx: internal
SPT bit: 1
Upstream State: JOINED
 Local:
 Joined:
     external
 Asserted:
 Outgoing:
     external
```

The S,G entry shows that we have received a join on the external interface and the stream is being forwarded out of this interface.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 192.168.1.1
RPF nbr: 0.0.0.0
RPF idx: None
Upstream State: PRUNED
 Local:
 Pruned:
 Outgoing:
     External
```

The S,G,RPT is different from FGT-3 because FGT-2 is the RP, it has pruned back the SPT for the RP to the first hop router.

Viewing the multicast routing table (FGT-1)

FGT-1 again has some differences with regard to the PIM-SM states, there is no *,G entry because it is not in the path of a receiver and the RP.

```
FGT-1_master #  get router info multicast pim sparse-mode table
IP Multicast Routing Table

(*,*,RP) Entries: 0
(*,G) Entries: 0
(S,G) Entries: 1
(S,G,rpt) Entries: 1
FCR Entries: 0
```

Below the S,G is the SPT termination because this FortiGate unit is the first hop router, the RPF neighbor always shows as 0.0.0.0 because the source is local to this device. Both the joined and outgoing fields show as external because the PIM join and the stream is egressing on this interface.

```
(10.166.0.11, 239.255.255.1)
RPF nbr: 0.0.0.0
RPF idx: None
SPT bit: 1
Upstream State: JOINED
```

```
Local:
Joined:
    external
Asserted:
Outgoing:
    external
```

The stream has been pruned back from the RP because the end-to-end SPT is flowing, there is no requirement for the stream to be sent to the RP in this case.

```
(10.166.0.11, 239.255.255.1, rpt)
RP: 0.0.0.0
RPF nbr: 10.130.0.156
RPF idx: external
Upstream State: RPT NOT JOINED
 Local:
 Pruned:
Outgoing:
```

Example multicast destination NAT (DNAT) configuration

The example topology shown in Figure 179 and described below shows how to configure destination NAT (DNAT) for two multicast streams. Both of these streams originate from the same source IP address, which is 10.166.0.11. The example configuration keeps the streams separate by creating 2 multicast NAT policies.

In this example the FortiGate units in Figure 179 have the following roles:

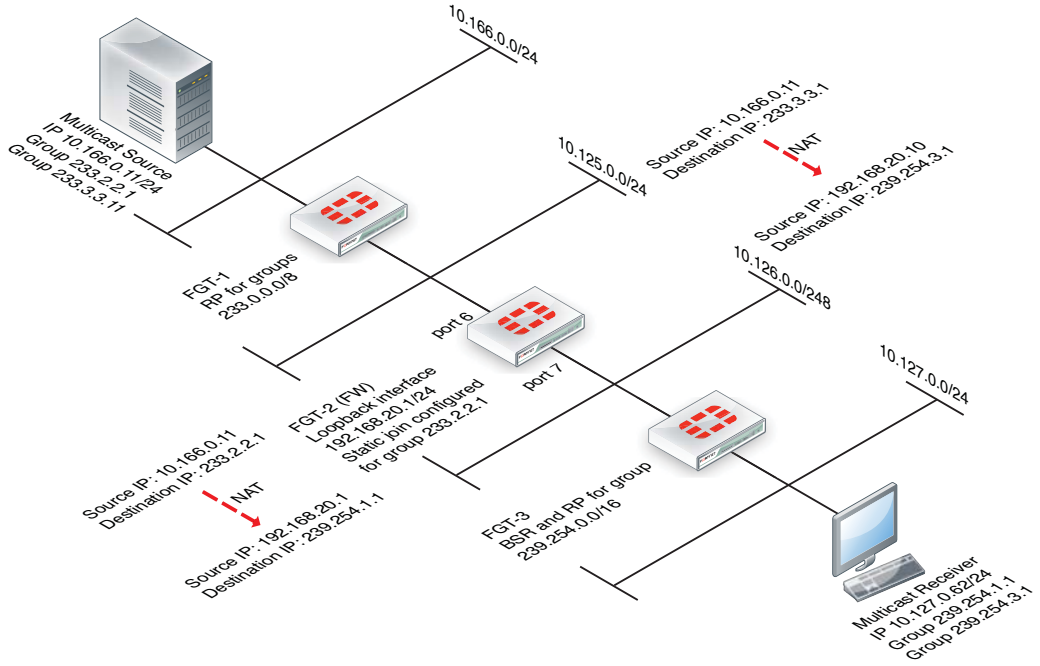
- FGT-1 is the RP for dirty networks, 233.0.0.0/8.
- FGT-2 performs all firewall and DNAT translations.
- FGT-3 is the RP for the clean networks, 239.254.0.0/16.
- FGT-1 and FGT-3 are functioning as PM enabled routers and could be replaced can be any PIM enabled router.

This example only describes the configuration of FGT-2.

FGT-2 performs NAT so that the receivers connected to FGT-3 receive the following translated multicast streams.

- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.2.2.1; FGT-3 translates the source and destination IPs to 192.168.20.1 and 239.254.1.1
- If the multicast source sends multicast packets with a source and destination IP of 10.166.0.11 and 233.3.3.1; FGT-3 translates the source and destination IPs to 192.168.20.10 and 239.254.3.1

Figure 179: Example multicast DNAT topology



To configure FGT-2 for DNAT multicast

1. Add a loopback interface. In the example, the loopback interface is named `loopback`.

```
config system interface
  edit loopback
    set vdom root
    set ip 192.168.20.1 255.255.255.0
    set type loopback
  next
end
```

2. Add PIM and add a unicast routing protocol to the loopback interface as if it was a normal routed interface. Also add static joins to the loopback interface for any groups to be translated.

```
config router multicast
  config interface
    edit loopback
      set pim-mode sparse-mode
        config join-group
          edit 233.2.2.1
          next
          edit 233.3.3.1
          next
        end
    next
```

3. In this example, to add firewall multicast policies, different source IP addresses are required so you must first add an IP pool:

```
config firewall ippool
  edit Multicast_source
    set endip 192.168.20.20
    set interface port6
    set startip 192.168.20.10
  next
end
```

4. Add the translation security policies.

   Policy 2, which is the source NAT policy, uses the actual IP address of port6. Policy 1, the DNAT policy, uses an address from the IP pool.

```
config firewall multicast-policy
  edit 1
    set dnat 239.254.3.1
    set dstaddr example-addr_P
    set dstintf loopback
    set nat 192.168.20.10
    set srcaddr example-addr_Q
    set srcintf port6
  next
  edit 2
    set dnat 239.254.1.1
    set dstaddr example-addr_R
    set dstintf loopback
    set nat 192.168.20.1
    set srcaddr example-addr_Q
    set srcintf port6
  next
end
```

5. Add a firewall multicast policy to forward the stream from the loopback interface to the physical outbound interface.

   This example is an any/any policy that makes sure traffic accepted by the other multicast policies can exit the FortiGate unit.

```
config firewall multicast-policy
  edit 3
    set dstintf port7
    set srcintf loopback
  next
end
```

Example PIM configuration that uses BSR to find the RP

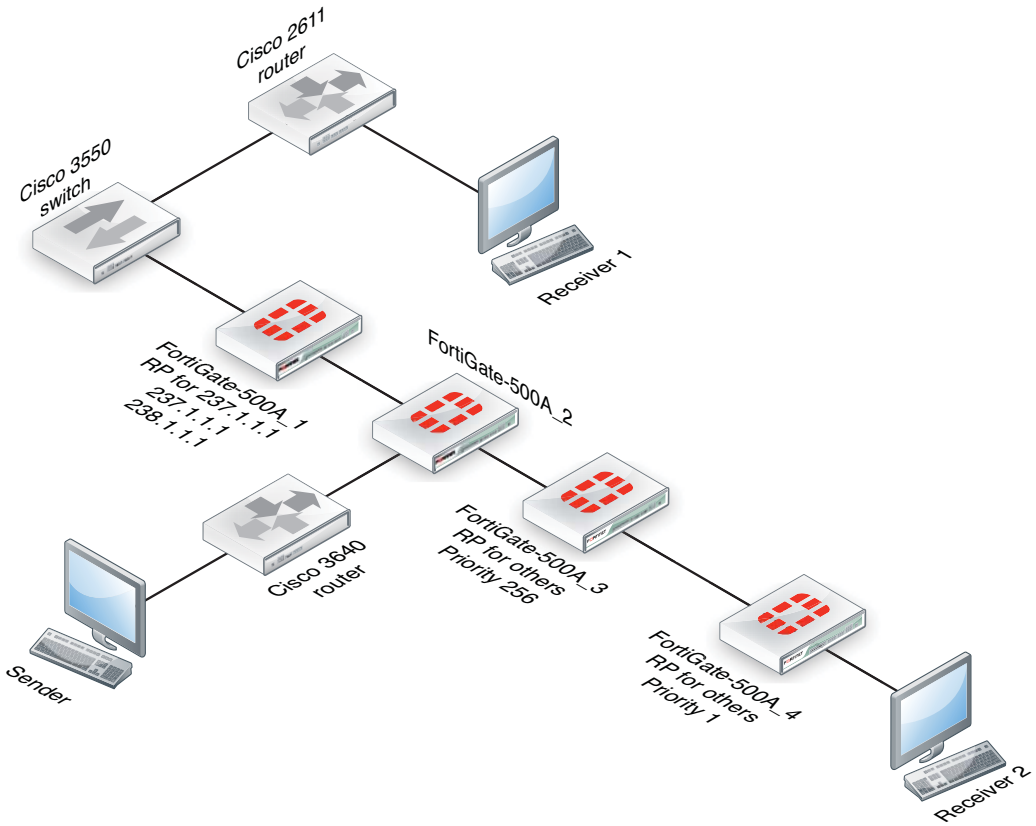
This example shows how to configure a multicast routing network for a network consisting of four FortiGate-500A units (FortiGate-500A_1 to FortiGate-550A_4, see Figure 180). A multicast sender is connected to FortiGate-500A_2. FortiGate-500A_2 forwards multicast packets in two directions to reach Receiver 1 and Receiver 2.

The configuration uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface `lo0` must join the 236.1.1.1 group (source).

This example describes:

- Commands used in this example
- Configuration steps
- Example debug commands

Figure 180:PIM network topology using BSR to find the RP



Commands used in this example

This example uses CLI commands for the following configuration settings:

- Adding a loopback interface (lo0)
- Defining the multicast routing
- Adding the NAT multicast policy

Adding a loopback interface (lo0)

Where required, the following command is used to define a loopback interface named `lo0`.

```
config system interface
  edit lo0
    set vdom root
    set ip 1.4.50.4 255.255.255.255
    set allowaccess ping https ssh snmp http telnet
    set type loopback
  next
end
```

Defining the multicast routing

In this example, the following command syntax is used to define multicast routing. The example uses a Boot Start Router (BSR) to find the Rendezvous Points (RPs) instead of using static RPs. Under interface configuration, the loopback interface `lo0` must join the 236.1.1.1 group (source).

```
config router multicast
  config interface
    edit port6
      set pim-mode sparse-mode
    next
    edit port1
      set pim-mode sparse-mode
    next
    edit lo0
      set pim-mode sparse-mode
      set rp-candidate enable
        config join-group
          edit 236.1.1.1
          next
        end
      set rp-candidate-priority 1
    next
  end
set multicast-routing enable
  config pim-sm-global
    set bsr-allow-quick-refresh enable
    set bsr-candidate enable
    set bsr-interface lo0
    set bsr-priority 200
  end
end
```

Adding the NAT multicast policy

In this example, the incoming multicast policy does the address translation. The NAT address should be the same as the IP address of the of loopback interface. The DNAT address is the translated address, which should be a new group.

```
config firewall multicast-policy
  edit 1
    set dstintf port6
    set srcintf lo0
  next
  edit 2
    set dnat 238.1.1.1
    set dstintf lo0
    set nat 1.4.50.4
    set srcintf port1
next
```

Configuration steps

In this sample, FortiGate-500A_1 is the RP for the group 228.1.1.1, 237.1.1.1, 238.1.1.1, and FortiGate-500A_4 is the RP for the other group which has a priority of1. OSPF is used in this example to distribute routes including the loopback interface. All firewalls have full mesh security policies to allow any to any.

- In the FortiGate-500A_1 configuration, the NAT policy translates source address 236.1.1.1 to 237.1.1.1
- In the FortiGate-500A_4, configuration, the NAT policy translates source 236.1.1.1 to 238.1.1.1
- Source 236.1.1.1 is injected into network as well.

The following procedures include the CLI commands for configuring each of the FortiGate units in the example configuration.

To configure FortiGate-500A_1

1. Configure multicast routing.

```
config router multicast
  config interface
    edit port5
      set pim-mode sparse-mode
    next
    edit port4
      set pim-mode sparse-mode
    next
    edit lan
      set pim-mode sparse-mode
    next
    edit port1
      set pim-mode sparse-mode
    next
    edit lo999
      set pim-mode sparse-mode
    next
```

```
      edit lo0
        set pim-mode sparse-mode
        set rp-candidate enable
        set rp-candidate-group 1
      next
    end
  set multicast-routing enable
    config pim-sm-global
      set bsr-candidate enable
      set bsr-interface lo0
    end
  end
```

2. Add multicast security policies.

```
  config firewall multicast-policy
    edit 1
      set dstintf port5
      set srcintf port4
    next
    edit 2
      set dstintf port4
      set srcintf port5
    next
    edit 3
    next
  end
```

3. Add router access lists.

```
  config router access-list
    edit 1
      config rule
        edit 1
          set prefix 228.1.1.1 255.255.255.255
          set exact-match enable
        next
        edit 2
          set prefix 237.1.1.1 255.255.255.255
          set exact-match enable
        next
        edit 3
          set prefix 238.1.1.1 255.255.255.255
          set exact-match enable
        next
      end
    next
  end
```

To configure FortiGate-500A_2

1. Configure multicast routing.

```
config router multicast
  config interface
    edit "lan"
      set pim-mode sparse-mode
   next
   edit "port5"
     set pim-mode sparse-mode
   next
   edit "port2"
     set pim-mode sparse-mode
   next
   edit "port4"
     set pim-mode sparse-mode
   next
   edit "lo_5"
     set pim-mode sparse-mode
       config join-group
         edit 236.1.1.1
         next
       end
     next
   end
  set multicast-routing enable
end
```

2. Add multicast security policies.

```
config firewall multicast-policy
  edit 1
    set dstintf lan
    set srcintf port5
  next
  edit 2
    set dstintf port5
    set srcintf lan
  next
  edit 4
    set dstintf lan
    set srcintf port2
  next
  edit 5
    set dstintf port2
    set srcintf lan
  next
  edit 7
    set dstintf port1
    set srcintf port2
  next
  edit 8
```

```
      set dstintf port2
      set srcintf port1
    next
    edit 9
      set dstintf port5
      set srcintf port2
    next
    edit 10
      set dstintf port2
      set srcintf port5
    next
    edit 11
      set dnat 237.1.1.1
      set dstintf lo_5
      set nat 5.5.5.5
      set srcintf port2
    next
    edit 12
      set dstintf lan
      set srcintf lo_5
    next
    edit 13
      set dstintf port1
      set srcintf lo_5
    next
    edit 14
      set dstintf port5
      set srcintf lo_5
    next
    edit 15
      set dstintf port2
      set srcintf lo_5
    next
    edit 16
    next
  end
```

To configure FortiGate-500A_3

1. Configure multicast routing.

```
  config router multicast
    config interface
      edit port5
        set pim-mode sparse-mode
      next
      edit port6
        set pim-mode sparse-mode
      next
      edit lo0
        set pim-mode sparse-mode
```

```
        set rp-candidate enable
        set rp-candidate-priority 255
      next
      edit lan
        set pim-mode sparse-mode
      next
    end
  set multicast-routing enable
    config pim-sm-global
      set bsr-candidate enable
      set bsr-interface lo0
    end
  end
```

2. Add multicast security policies.

```
  config firewall multicast-policy
    edit 1
      set dstintf port5
      set srcintf port6
    next
    edit 2
      set dstintf port6
      set srcintf port5
    next
    edit 3
      set dstintf port6
      set srcintf lan
    next
    edit 4
      set dstintf lan
      set srcintf port6
    next
    edit 5
      set dstintf port5
      set srcintf lan
    next
    edit 6
      set dstintf lan
      set srcintf port5
    next
  end
```

To configure FortiGate-500A_4

1. Configure multicast routing.

```
config router multicast
  config interface
    edit port6
      set pim-mode sparse-mode
    next
    edit lan
      set pim-mode sparse-mode
    next
    edit port1
      set pim-mode sparse-mode
    next
    edit lo0
      set pim-mode sparse-mode
      set rp-candidate enable
        config join-group
          edit 236.1.1.1
          next
        end
      set rp-candidate-priority 1
    next
  end
set multicast-routing enable
  config pim-sm-global
   set bsr-allow-quick-refresh enable
    set bsr-candidate enable
    set bsr-interface lo0
    set bsr-priority 1
  end
end
```

2. Add multicast security policies.

```
config firewall policy
  edit 1
    set srcintf lan
    set dstintf port6
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 2
    set srcintf port6
    set dstintf lan
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
```

```
    set service ANY
  next
  edit 3
    set srcintf port1
    set dstintf port6
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 4
    set srcintf port6
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 5
    set srcintf port1
    set dstintf lan
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 6
    set srcintf lan
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 7
    set srcintf port1
    set dstintf port1
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ANY
  next
  edit 8
    set srcintf port6
```

```
        set dstintf lo0
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 9
        set srcintf port1
        set dstintf lo0
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
    edit 10
        set srcintf lan
        set dstintf lo0
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ANY
    next
 end
```

Example debug commands

You can use the following CLI commands to view information about and status of the multicast configuration. This section includes `get` and `diagnose` commands and some sample output.

```
get router info multicast pim sparse-mode table 236.1.1.1
get router info multicast pim sparse-mode neighbor
  Neighbor        Interface        Uptime/Expires    Ver   DR
     Address                                              Priority/
     Mode
     83.97.1.2        port6           02:22:01/00:01:44 v2    1 / DR

diagnose ip multicast mroute
  grp=236.1.1.1 src=19.2.1.1 intf=7 flags=(0x10000000)[  ]
     status=resolved
             last_assert=171963 bytes=1766104 pkt=1718 wrong_if=1
     num_ifs=2
             index(ttl)=[6(1),10(1),]

Chapter 8 Hardware Acceleration

This FortiOS Handbook chapter contains the following sections:

Hardware acceleration overview describes the capabilities of FortiGate content processors (CPs), security processors (SPs) and network processors (NPs). This chapter also describes how to determine the hardware acceleration components installed in your FortiGate unit and contains some configuration details and examples.

NP6 Acceleration describes the FortiGate NP6 network processor.

FortiGate NP6 architectures contains details about the network processing architectures of FortiGate units that contain NP6 processors.

NP4 Acceleration describes the FortiGate NP4 network processor.

FortiGate NP4 architectures contains details about the network processing architectures of FortiGate units that contain NP4 processors.

Hardware acceleration overview

All FortiGate models have specialized acceleration hardware that can offload resource intensive processing from main processing (CPU) resources. All FortiGate units include specialized content processors (CPs) that accelerate a wide range of important security processes such as virus scanning, attack detection, encryption and decryption. Many FortiGate models also contain security processors (SPs) that accelerate processing for specific security features such as IPS and network processors (NPs) that offload processing of high volume network traffic.

This chapter contains the following topics:

Content processors (CP4, CP5, CP6 and CP8)

All FortiGate units contain FortiASIC Content Processors (CPs) that accelerate many common resource intensive security related processes. CPs work at the system level with tasks being offloaded to them as determined by the main CPU. Capabilities of the CPs vary by model. Newer FortiGate units include CP8 processors. Older CP versions still in use in currently operating FortiGate models include the CP4, CP5, and CP6.

CP8 capabilities

The CP8 content processor provides the following services:

- IPS signature matching acceleration
- High performance VPN bulk data engine
  - IPSEC and SSL/TLS protocol processor
  - DES/3DES/AES in accordance with FIPS46-3/FIPS81/FIPS197
  - ARC4 in compliance with RC4
  - MD5/SHA-1/SHA256 with RFC1321 and FIPS180
  - HMAC in accordance with RFC2104/2403/2404 and FIPS198
- Key Exchange Processor support high performance IKE and RSA computation
  - Public key exponentiation engine with hardware CRT support
  - Primarily checking for RSA key generation
  - Handshake accelerator with automatic key material generation
  - Random Number generator compliance with ANSI X9.31
  - Sub public key engine (PKCE) to support up to 4094 bit operation directly
- Message authentication module offers high performance cryptographic engine for calculating SHA256/SHA1/MD5 of data up to 4G bytes (used by many applications)
- PCI express Gen 2 four lanes interface
- Cascade Interface for chip expansion

CP6 capabilities

- Dual content processors
- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321 and FIPS180
- HMAC in accordance with RFC2104/2403/2404 and FIPS198
- IPsec protocol processor
- High performance IPsec engine
- Random Number generator compliance with ANSI X9.31
- Key exchange processor for high performance IKE and RSA computation
- Script Processor
- SSL/TLS protocol processor for SSL content scanning and SSL acceleration

CP5 capabilities

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC with RFC1321/2104/2403/2404 and FIPS180/FIPS198
- IPsec protocol processor
- High performance IPSEC Engine
- Random Number generator compliant with ANSI X9.31
- Public Key Crypto Engine supports high performance IKE and RSA computation
- Script Processor

CP4 capabilities

- FIPS-compliant DES/3DES/AES encryption and decryption
- SHA-1 and MD5 HMAC
- IPSEC protocol processor
- Random Number generator
- Public Key Crypto Engine
- Content processing engine
- ANSI X9.31 and PKCS#1 certificate support

Determining the content processor in your FortiGate unit

Use the `get hardware status` CLI command to determine which content processor your FortiGate unit contains. The output looks like this:

```
get hardware status
Model name: FortiGate-100D
ASIC version: CP8
ASIC SRAM: 64M
CPU: Intel(R) Atom(TM) CPU D525   @ 1.80GHz
Number of CPUs: 4
RAM: 1977 MB
Compact Flash: 15331 MB /dev/sda
Hard disk: 15272 MB /dev/sda
USB Flash: not available
Network Card chipset: Intel(R) PRO/1000 Network Connection (rev.0000)
Network Card chipset: bcm-sw Ethernet driver 1.0 (rev.)
```

The ASIC version line lists the content processor model number.

Viewing SSL acceleration status

You can view the status of SSL acceleration using the following command:

```
get vpn status ssl hw-acceleration-status
Acceleration hardware detected: kxp=on cipher=on
```

Disabling CP offloading

If you want to completely disable offloading to CP processors for test purposes or other reasons, you can do so in security policies. Here are some examples:

For IPv4 security policies.

```
config firewall policy
  edit 1
    set auto-asic-offload disable
  end
```

For IPv6 security policies.

```
config firewall policy6
  edit 1
    set auto-asic-offload disable
  end
```

For multicast security policies.

```
config firewall multicast-policy
  edit 1
    set auto-asic-offload disable
  end
```

Security processors (SPs)

FortiGate Security Processing (SP) modules, such as the SP3 but also including the XG2, XE2, FE8, and CE4, work at both the interface and system level to increase overall system performance by accelerating specialized security processing. You can configure the SP to favor IPS over firewall processing in hostile high-traffic environments. The following security processors are available:

- The SP3 is built into the FortiGate-5101B and provides IPS acceleration. No special configuration is required. All IPS traffic is accelerated by the built-in SP3 processors.
- The FMC-XG2 is an FMC module with two 10Gb/s SPF+ interfaces that can be used on FortiGate-3950B and FortiGate-3951B units.
- The FortiGate-3140B also contains a built-in XG2 using ports 19 and 20.
- The ADM-XE2 is a dual-width AMC module with two 10Gb/s interfaces that can be used on FortiGate-3810A and FortiGate-5001A-DW systems.
- The ADM-FE8 is a dual-width AMC module with eight 1Gb/s interfaces that can be used with the FortiGate-3810A.
- The ASM-CE4 is a single-width AMC module with four 10/100/1000 Mb/s interfaces that can be used on FortiGate-3016B and FortiGate-3810A units.

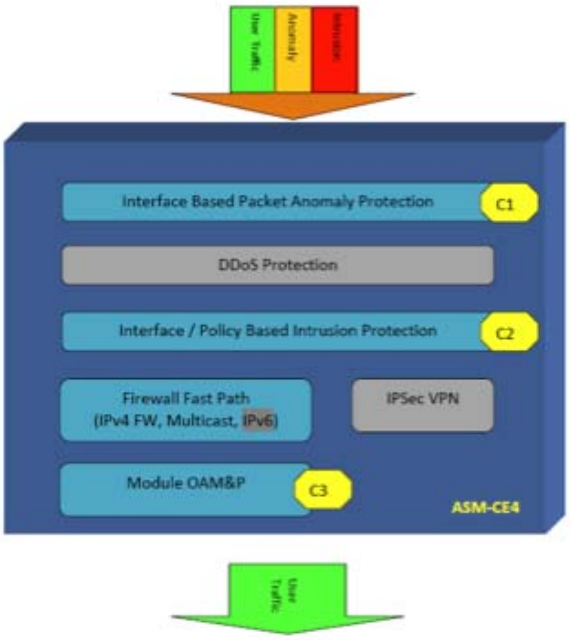
SP Processing Flow

SP processors provide an integrated high performance fast path multilayer solution for both intrusion protection and firewall functions. The multilayered protection starts from anomaly checking at packet level to ensure each packet is sound and reasonable. Immediately after that, a sophisticated set of interface based packet anomaly protection, DDoS protection, policy based intrusion protection, firewall fast path, and behavior based methods are employed to prevent DDoS attacks from the rest of system.

Then the packets enter an interface/policy based intrusion protection system,

where each packet is evaluated against a set of signatures. The end result is streams of user packets that are free of anomaly and attacks, entering the fast path system for unicast or multicast fast path forwarding.

Figure 181:SP processing flow



Displaying information about security processing modules

You can display information about installed SP modules using the CLI command

```
diagnose npu spm
```

For example, for the FortiGate-5101C:

```
FG-5101C # diagnose npu spm list
Available SP Modules:

ID Model        Slot     Interface
0  xh0          built-in port1, port2, port3, port4
                         base1, base2, fabric1, fabric2
                         eth10, eth11, eth12, eth13
                         eth14, eth15, eth16, eth17
                         eth18, eth19
```

You can also use this command to get more info about SP processing. This example shows how to display details about how the module is processing sessions using the syn proxy.

```
diagnose npu spm dos synproxy <sp_id>
```

This is a partial output of the command:

```
Number of proxied TCP connections :                 0
Number of working proxied TCP connections :         0
Number of retired TCP connections :                 0
Number of valid TCP connections :                   0
Number of attacks, no ACK from client :             0
Number of no SYN-ACK from server :                  0
Number of reset by server (service not supportted): 0
Number of establised session timeout :              0
Client timeout setting :                            3 Seconds
Server timeout setting :                            3 Seconds
```

Network processors (NP1, NP2, NP3, NP4 and NP6)

FortiASIC network processors work at the interface level to accelerate traffic by offloading traffic from the main CPU. Current models contain NP4 and NP6 network processors. Older FortiGate models include NP1 network processors (also known as FortiAccel, or FA2) and NP2 network processors.

The traffic that can be offloaded, maximum throughput, and number of network interfaces supported by each varies by processor model:

- NP6 supports offloading of most IPv4 and IPv6 traffic, IPsec VPN encryption, CAPWAP traffic, and multicast traffic. The NP6 has a capacity of 40 Gbps through 4 x 10 Gbps interfaces or 3 x 10 Gbps and 16 x 1 Gbps interfaces. For details about the NP6 processor, see “NP6 Acceleration” on page 1082 and for information about FortiGate models with NP6 processors, see “FortiGate NP6 architectures” on page 1089.
- NP4 supports offloading of most IPv4 firewall traffic and IPsec VPN encryption. The NP4 has a capacity of 20 Gbps through 2 x 10 Gbps interfaces. For details about NP4 processors, see “NP4 Acceleration” on page 1093 and for information about FortiGate models with NP4 processors, see “FortiGate NP4 architectures” on page 1105.
- NP2 supports IPv4 firewall and IPsec VPN acceleration. The NP2 has a capacity of 2 Gbps through 2 x 10 Gbps interfaces or 4 x 1 Gbps interfaces.
- NP1 supports IPv4 firewall and IPsec VPN acceleration with 2 Gbps capacity. The NP1 has a capacity of 2 Gbps through 2 x 1 Gbps interfaces.
  - The NP1does not support frames greater than 1500 bytes. If your network uses jumbo frames, you may need to adjust the MTU (Maximum Transmission Unit) of devices connected to NP1ports.Maximum frame size for NP2, NP4, and NP6 processors is 9000 bytes.
  - For both NP1 and NP2 network processors, ports attached to a network processor cannot be used for firmware installation by TFTP.

Session that require proxy-based and flow based security features (for example, virus scanning, IPS, application control and so on) are not fast pathed and must be processed by the CPU.

Determining the network processors installed on your FortiGate unit

Use the following command to list the NP6 processors in your FortiGate unit:

```
diagnose npu np6 port-list
```

To list other network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu <model> list
```

`<model>` can be `legacy`, `np1`, `np2` or `np4`.

The output lists the interfaces that have the specified processor. For example, for a FortiGate-5001B:

```
get hardware npu np4 list
ID     Model          Slot       Interface
0      On-board                  port1 port2 port3 port4
                                 fabric1 base1 npu0-vlink0 npu0-vlink1
1      On-board                  port5 port6 port7 port8
                                 fabric2 base2 npu1-vlink0 npu1-vlink1
```

The `npu0-vlink0`, `npu1-vlink1` etc interfaces are used for accelerating inter-VDOM links.

How NP hardware acceleration alters packet flow

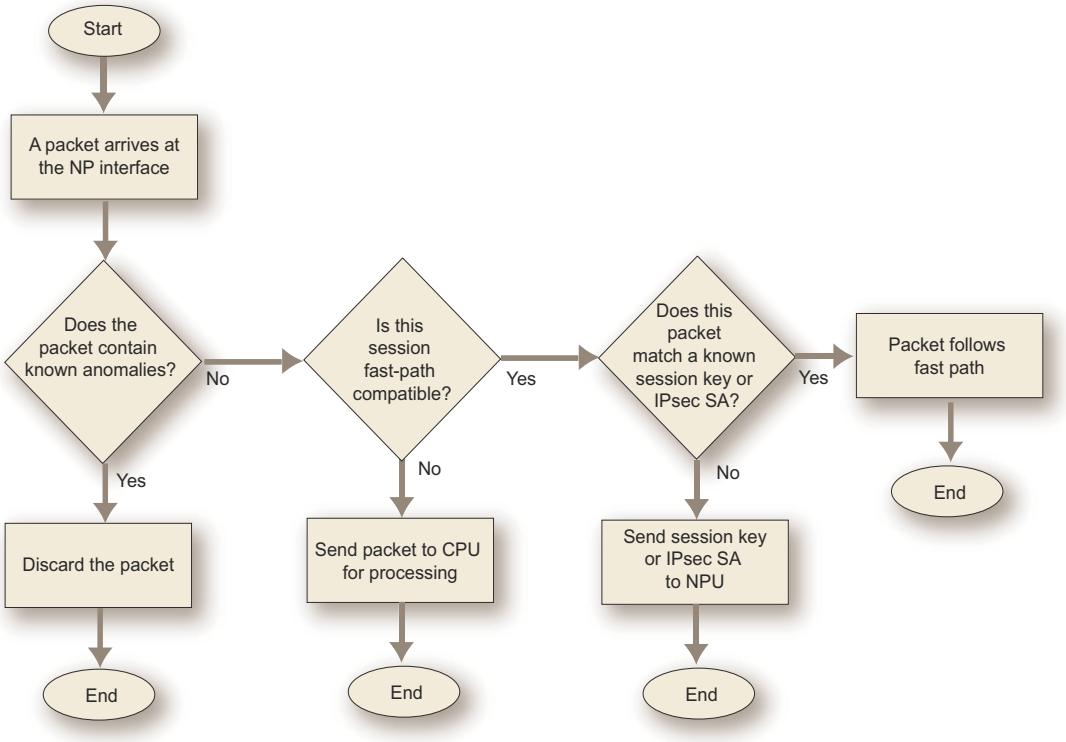
NP hardware acceleration generally alters packet flow as follows:

1. Packets initiating a session pass to the FortiGate unit's main processing resources (CPU).
2. The FortiGate unit assesses whether the session matches fast path (offload) requirements.

   To be suitable for offloading, traffic must possess only characteristics that can be processed by the fast path. The list of requirements depends on the processor, see "NP6 session fast path requirements" on page 1083 or "NP4 session fast path requirements" on page 1094.

   If the session can be fast pathed, the FortiGate unit sends the session key or IPsec security association (SA) and configured firewall processing action to the appropriate network processor.
3. Network processors continuously match packets arriving on their attached ports against the session keys and SAs they have received.
   - If a network processor's network interface is configured to perform hardware accelerated anomaly checks, the network processor drops or accepts packets which match the configured anomaly patterns. These checks are separate from and in advance of anomaly checks performed by IPS, which is not compatible with network processor offloading. See "Offloading NP pre-IPS anomaly detection" on page 1076.
   - The network processor next checks for a matching session key or SA. If a matching session key or SA is found, and if the packet meets packet requirements, the network processor processes the packet according to the configured action and then sends the resulting packet. This is the actual offloading step. Performing this processing on the NP processor improves overall performance because the NP processor is optimized for this task. As well, overall FortiGate performance is improved because the CPU has fewer sessions to process.

Figure 182:NP network processor packet flow



- If a matching session key or SA is not found, or if the packet does not meet packet requirements, the packet cannot be offloaded. The network processor sends the data to the FortiGate unit's CPU, which processes the packet.

Encryption and decryption IPsec traffic originating from the FortiGate can utilize network processor encryption capabilities. See "Configuring NP accelerated VPN encryption/decryption offloading" on page 1078.

Packet forwarding rates vary by the percentage of offloadable processing and the type of network processing required by your configuration, but are independent of frame size. For optimal traffic types, network throughput can equal wire speed.

NP processors and traffic logging and monitoring

Except for the NP6, network processors do not count offloaded packets, and offloaded packets are not logged by traffic logging and are not included in traffic statistics and traffic log reports.

NP6 processors support per-session traffic and byte counters, Ethernet MIB matching, and reporting through messages resulting in traffic statistics and traffic log reporting.

NP session offloading in HA active-active configuration

Network processors can improve network performance in active-active (load balancing) high availability (HA) configurations, even though traffic deviates from general offloading patterns, involving more than one network processor, each in a separate FortiGate unit. No additional offloading requirements apply.

Once the primary FortiGate unit's main processing resources send a session key to its network processor(s), network processor(s) on the primary unit can redirect any subsequent session

traffic to other cluster members, reducing traffic redirection load on the primary unit's main processing resources.

As subordinate units receive redirected traffic, each network processor in the cluster assesses and processes session offloading independently from the primary unit. Session key states of each network processor are not part of synchronization traffic between HA members.

Configuring NP HMAC check offloading

Hash-based Message Authentication Code (HMAC) checks offloaded to network processors by default. You can enter the following command to disable this feature:

```
configure system global
  set ipsec-hmac-offload disable
end
```

Offloading NP pre-IPS anomaly detection

Network interfaces associated with a port attached to a network processor can be configured to offload anomaly checking. This anomaly checking happens before other offloading and separately from and in advance of DoS policy anomaly checking. Using the following command, each FortiGate interface can have a different anomaly checking configuration.

```
config system interface
  edit <port-name>
    set fp-anomaly <anomalies>
  end
```

where `<anomalies>` can be one, more than one or all of the following:

Anomaly	Description
drop_icmp_frag	Drop ICMP fragments to pass.
drop_icmpland	Drop ICMP Land.
drop_ipland	Drop IP Land.
drop_iplsrr	Drop IP with Loose Source Record Route option.
drop_iprr	Drop IP with Record Route option.
drop_ipsecurity	Drop IP with Security option.
drop_ipssrr	Drop IP with Strict Source Record Route option.
drop_ipstream	Drop IP with Stream option.
drop_iptimestamp	Drop IP with Timestamp option.
drop_ipunknown_option	Drop IP with malformed option.
drop_ipunknown_prot	Drop IP with Unknown protocol.
drop_tcp_fin_noack	Drop TCP FIN with no ACT flag set to pass.
drop_tcp_no_flag	Drop TCP with no flag set to pass.
drop_tcpland	Drop TCP Land.

Anomaly	Description
drop_udpland	Drop UDP Land.
drop_winnuke	Drop TCP WinNuke.
pass_icmp_frag	Allow ICMP fragments to pass.
pass_icmpland	Allow ICMP Land to pass.
pass_ipland	Allow IP land to pass.
pass_iplsrr	Allow IP with Loose Source Record Route option to pass.
pass_iprr	Allow IP with Record Route option to pass.
pass_ipsecurity	Allow IP with Security option to pass.
pass_ipssrr	Allow IP with Strict Source Record Route option to pass.
pass_ipstream	Allow IP with Stream option to pass.
pass_iptimestamp	Allow IP with Timestamp option to pass.
pass_ipunknown_option	Allow IP with malformed option to pass.
pass_ipunknown_prot	Allow IP with Unknown protocol to pass.
pass_tcp_fin_noack	Allow TCP FIN with no ACT flag set to pass.
pass_tcp_no_flag	Allow TCP with no flag set to pass.
pass_tcpland	Allow TCP Land to pass.
pass_udpland	Allow UDP Land to pass.
pass_winnuke	Allow TCP WinNuke to pass.

Example

You might configure an NP4 to drop packets with TCP WinNuke or unknown IP protocol anomalies, but to pass packets with an IP time stamp, using hardware acceleration provided by the network processor.

```
config system interface
  edit port1
    set fp-anomaly drop_winnuke drop_ipunknown_prot pass_iptimestamp
  end
```

Software switch interfaces and NP processors

FortiOS supports creating a software switch by grouping two or more FortiGate physical interfaces into a single virtual or software switch interface. All of the interfaces in this virtual switch act like interfaces in a hardware switch in that they all have the same IP address and can be connected to the same network. You create a software switch interface from the CLI using the command `config system switch-interface`.

The software switch is a bridge group of several interfaces, and the FortiGate CPU maintains the mac-port table for this bridge. As a result of this CPU involvement, traffic processed by a software switch interface is not offloaded to network processors.

Configuring NP accelerated VPN encryption/decryption offloading

Network processing unit (`npu`) settings configure offloading behavior for IPsec VPN. Configured behavior applies to all network processors contained by the FortiGate unit itself or any installed AMC modules.

```
config system npu
  set enc-offload-antireplay {enable | disable}
  set dec-offload-antireplay {enable | disable}
  set offload-ipsec-host {enable | disable}
end
```

Variables	Description	Default
`enc-offload-antireplay {enable | disable}`	Enable or disable offloading of IPsec encryption. This option is used only when replay detection is enabled in Phase 2 configuration. If replay detection is disabled, encryption is always offloaded.	disable
`dec-offload-antireplay {enable | disable}`	Enable or disable offloading of IPsec decryption. This option is used only when replay detection is enabled in Phase 2 configuration. If replay detection is disabled, decryption is always offloaded.	enable
`offload-ipsec-host {enable | disable}`	Enable or disable offloading of IPsec encryption of traffic from local host (FortiGate unit). **Note:** For this option to take effect, the FortiGate unit must have previously sent the security association (SA) to the network processor.	disable

Example

You could configure the offloading of encryption and decryption for an IPsec SA that was sent to the network processor.

```
config system npu
  set enc-offload-antireplay enable
  set dec-offload-antireplay enable
  set offload-ipsec-host enable
end
```

Checking that traffic is offloaded by NP processors

A number of diagnose commands can be used to verify that traffic is being offloaded.

Using the packet sniffer

Use the packet sniffer to verify that traffic is offloaded. Offloaded traffic is not picked up by the packet sniffer so if you are sending traffic through the FortiGate unit and it is not showing up on the packet sniffer you can conclude that it is offloaded.

```
diag sniffer packet port1 <option>
```

Checking the firewall session offload tag

Use the `diagnose sys session list` command to display sessions. If the output for a session includes the `npu info` field you should see information about session being offloaded. If the output doesn't contain an `npu info` field then the session has not been offloaded.

```
diagnose sys session list
session info: proto=6 proto_state=01 duration=34 expire=3565
     timeout=3600 flags=00000000 sockflag=00000000 sockport=0
     av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
ha_id=0 policy_dir=0 tunnel=/
state=may_dirty npu
statistic(bytes/packets/allow_err): org=295/3/1 reply=60/1/1
     tuples=2
orgin->sink: org pre->post, reply pre->post dev=48->6/6->48
     gwy=10.1.100.11/11.11.11.1
hook=pre dir=org act=noop
     172.16.200.55:56453->10.1.100.11:80(0.0.0.0:0)
hook=post dir=reply act=noop
     10.1.100.11:80->172.16.200.55:56453(0.0.0.0:0)
pos/(before,after) 0/(0,0), 0/(0,0)
misc=0 policy_id=1 id_policy_id=0 auth_info=0 chk_client_info=0 vd=4
serial=0000091c tos=ff/ff ips_view=0 app_list=0 app=0

     ipid=23/1, vlan=32779/0
```

Verifying IPsec VPN traffic offloading

The following commands can be used to verify IPsec VPN traffic offloading to NP processors.

```
diagnose vpn ipsec status
NP1/NP2/NP4_0/sp_0_0:
        null:    0       0
        des:     0       0
        3des:    4075    4074
        aes:     0       0
        aria:    0       0
        seed:    0       0
        null:    0       0
        md5:     4075    4074
        sha1:    0       0
        sha256:  0       0
        sha384:  0       0
        sha512:  0       0

diagnose vpn tunnel list

Controlling IPS NPx and CPx acceleration

You can use the following commands to enale or disable acceleration of IPS processing by NPx and CPx processors:

```
config ips global
  set np-accel-mode {none | basic}
  set cp-accel-mode {none | basic | advanced}
end
```

The network processor (NP) acceleration modes are:

`none`: Network Processor acceleration disabled

`basic`: Basic Network Processor acceleration enabled

The content processor (CP) acceleration modes are:

`none`: Content Processor acceleration disabled

`basic`: Basic Content Processor acceleration enabled

`advanced`: Advanced Content Processor acceleration enabled

NP6 Acceleration

NP6 network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP6 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP6 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP6 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP6 processor plus the network processing load is removed from the CPU. In addition the NP6 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

Session keys (and IPsec SA keys) are stored in the memory of the NP6 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP6. There is no dependence on getting the right pair of interfaces since the offloading is done by the receiving NP6. The key to making this possible is the Integrated Switch Fabric (ISF) that connects the NP6s and the FortiGate unit interfaces together. The ISF allows any port connectivity. All ports and NP6s can communicate with each other over the ISF.

There are no special ingress and egress fast path requirements as long as traffic enters and exits on interfaces connected to the same ISF and the NP6 processors. All FortiGate models with NP6 processors connect all interfaces and NP6 processors to the same ISF (except management interfaces) so this should not ever be a problem.

There are at least two limitations to keep in mind:

- The capacity of each NP6 processor. An individual NP6 processor can support between 10 and 16 million sessions. This number is limited by the amount of memory the processor has. Once an NP6 processor hits its session limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP6 processors. To be able to do this you need to be aware of which interfaces connect to which NP6 processors and distribute incoming traffic accordingly.
- Some FortiGate units may use some NP6 processors for special functions. For example, ports 25 to 32 of the FortiGate-3700D can be used for low latency offloading. See “FortiGate-3700D fast path architecture” on page 1091 for more information.

This chapter contains the following topics:

NP6 session fast path requirements

NP6 processors can offload the following traffic and services:

- IPv4 and IPv6 traffic and NAT64 and NAT46 traffic (as well as IPv4 and IPv6 versions of the following traffic types where appropriate)
- TCP, UDP, ICMP and SCTP traffic
- IPSec VPN traffic, and offloading of IPsec encryption/decryption (including SHA2-256 and SHA2-512)
- Anomaly-based intrusion prevention, checksum offload and packet defragmentation
- SIT and IPv6 Tunnelling sessions
- Multicast traffic (including Multicast over IPsec)
- CAPWAP and wireless bridge traffic tunnel encapsulation to enable line rate wireless forwarding from FortiAP devices
- Traffic shaping and priority queuing for both shared and per IP traffic shaping. An NP6 processor has 16 million queues for traffic shaping and statistics counting.
- Syn proxying
- Inter-VDOM link traffic

Sessions that are offloaded must be fast path ready. For a session to be fast path ready it must meet the following criteria:

- Layer 2 type/length must be 0x0800 for IPv4 or 0x86dd for IPv6 (IEEE 802.1q VLAN specification is supported)
- Link aggregation between any network interfaces sharing the same network processor(s) may be used (IEEE 802.3ad specification is supported)
- Layer 3 protocol can be IPv4 or IPv6
- Layer 4 protocol can be UDP, TCP, ICMP, or SCTP
- In most cases, Layer 3 / Layer 4 header or content modification sessions that require a session helper can be offloaded.
- Local host traffic (originated by the FortiGate unit) can be offloaded
- Application layer content modification is not supported (the firewall policy that accepts the session must not include virus scanning, web filtering, DLP, application control, IPS, email filtering, SSL/SSH inspection, VoIP or ICAP)

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See "Offloading NP pre-IPS anomaly detection" on page 1076.

If a session or is not fast path ready, the FortiGate unit will not send the session key or IPsec SA key to the NP6 processor. Without the session key, all session key lookup by a network processor for incoming packets of that session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key or IPsec SA key to the network processor. Session key or IPsec SA key lookups then succeed for subsequent packets from the known session or IPsec SA.

Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.
- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for network processors' network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

Mixing fast path and non-fast path traffic

If packet requirements are not met, an individual packet will be processed by the FortiGate CPU regardless of whether other packets in the session are offloaded to the NP6.

Also, in some cases, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing. For example, VoIP control packets may not be offloaded but VoIP data packets (voice packets) may be offloaded.

Viewing your FortiGate NP6 processor configuration

Use the following command to view the NP6 processor configuration of your FortiGate unit:

```
diagnose npu np6 port-list
```

For example output of this command for different FortiGate models, see "FortiGate NP6 architectures" on page 1089.

Increasing NP6 offloading capacity using link aggregation groups (LAGs)

NP6 processors can offload sessions received by interfaces in link aggregation (LAG) groups. You can use link aggregation groups to offload more traffic that would exceed the capacity of a single FortiGate interface. For example, if you want to offload sessions on a 30 GB link you can add three 10-GB interfaces to a LAG group and send 30 GB of traffic to the LAG group.

Just like with normal interfaces, traffic accepted by a LAG group is offloaded by the NP6 processor connected to the interfaces in the LAG group that receive the traffic to be offloaded. If all interfaces in a LAG group are connected to the same NP6 processor, traffic received by the LAG group is offloaded by that NP6 processor. The amount of traffic that can be offloaded is limited by the capacity of the NP6 processor.

LAG groups can include interfaces connected to more than one NP6 processor. For example, a adding a second NP6 processor to a LAG group effectively doubles the offloading capacity of the LAG group. Adding a third further increases capacity. Using LAG groups allows you to increase offloading capacity for incoming traffic by sharing the traffic load across multiple NP6 processors. This increase in capacity is supported by the integrated switch fabric that allows the NP6 processors to share session information.

The increase in offloading capacity may not actually be doubled by adding a second NP6 processor to a LAG group. Traffic and load conditions and other factors may limit the actual achieved offloading result.

Configuring Inter-VDOM link acceleration with NP6 processors

FortiGate units with NP6 processors include inter-VDOM links that can be used to accelerate inter-VDOM link traffic.

- For a FortiGate unit with two NP6 processors there are two accelerated inter-VDOM links, each with two interfaces:
  - npu0_vlink
    - npu0_vlink0
    - npu0_vlink1
  - npu1_vlink
    - npu1_vlink0
    - npu1_vlink1

These interfaces are visible from the GUI and CLI. For a FortiGate unit with NP6 interfaces, enter the following CLI command to display the NP6-accelerated inter-VDOM links:

```
get system interface
...
== [ npu0_vlink0 ]
name: npu0_vlink0   mode: static   ip: 0.0.0.0 0.0.0.0   status: down
     netbios-forward: disable   type: physical   sflow-sampler: disable
     explicit-web-proxy: disable    explicit-ftp-proxy: disable
     mtu-override: disable   wccp: disable   drop-overlapped-fragment:
     disable    drop-fragment: disable
== [ npu0_vlink1 ]
name: npu0_vlink1   mode: static   ip: 0.0.0.0 0.0.0.0   status: down
     netbios-forward: disable   type: physical   sflow-sampler: disable
     explicit-web-proxy: disable    explicit-ftp-proxy: disable
     mtu-override: disable   wccp: disable   drop-overlapped-fragment:
     disable    drop-fragment: disable
== [ npu1_vlink0 ]
name: npu1_vlink0   mode: static   ip: 0.0.0.0 0.0.0.0   status: down
     netbios-forward: disable   type: physical   sflow-sampler: disable
     explicit-web-proxy: disable    explicit-ftp-proxy: disable
     mtu-override: disable   wccp: disable   drop-overlapped-fragment:
     disable    drop-fragment: disable
== [ npu1_vlink1 ]
name: npu1_vlink1   mode: static   ip: 0.0.0.0 0.0.0.0   status: down
     netbios-forward: disable   type: physical   sflow-sampler: disable
     explicit-web-proxy: disable    explicit-ftp-proxy: disable
     mtu-override: disable   wccp: disable   drop-overlapped-fragment:
     disable    drop-fragment: disable
...
```

By default the interfaces in each inter-VDOM link are assigned to the root VDOM. To use these interfaces to accelerate inter-VDOM link traffic, assign each interface in the pair to the VDOMs that you want to offload traffic between. For example, if you have added a VDOM named New-VDOM to a FortiGate unit with NP4 processors, you can go to *System* > *Network* > *Interfaces* and edit the *npu0-vlink1* interface and set the *Virtual Domain* to *New-VDOM*. This results in an accelerated inter-VDOM link between root and New-VDOM. You can also do this from the CLI:

```
config system interface
  edit npu0-vlink1
    set vdom New-VDOM
end
```

Using VLANs to add more accelerated Inter-VDOM links

You can add VLAN interfaces to the accelerated inter-VDOM links to create inter-VDOM links between more VDOMs. For the links to work, the VLAN interfaces must be added to the same inter-VDOM link, must be on the same subnet, and must have the same VLAN ID.

For example, to accelerate inter-VDOM link traffic between VDOMs named Marketing and Engineering using VLANs with VLAN ID 100 go to *System* > *Network* > *Interfaces* and select *Create New* to create the VLAN interface associated with the Marketing VDOM:

Name	Marketing-link
Type	VLAN
Interface	npu0_vlink0
VLAN ID	100
Virtual Domain	Marketing
IP/Network Mask	172.20.120.12/24

Create the inter-VDOM link associated with Engineering VDOM:

Name	Engineering-link
Type	VLAN
Interface	npu0_vlink1
VLAN ID	100
Virtual Domain	Engineering
IP/Network Mask	172.20.120.22/24

Or do the same from the CLI:

```
config system interface
  edit Marketing-link
    set vdom Marketing
    set ip 172.20.120.12/24
    set interface npu0_vlink0
    set vlanid 100
  next
  edit Engineering-link
    set vdom Engineering
    set ip 172.20.120.22/24
    set interface npu0_vlink1
    set vlanid 100
```

Confirm that the traffic is accelerated

Use the following CLI commands to obtain the interface index and then correlate them with the session entries. In the following example traffic was flowing between new accelerated inter-VDOM links and physical ports port1 and port 2 also attached to the NP6 processor.

```
diagnose ip address list
IP=172.31.17.76->172.31.17.76/255.255.252.0 index=5 devname=port1

FortiGate NP6 architectures

Many FortiGate models can offload some types of network traffic processing from main processing resources to specialized network processors. If your network has a significant volume of traffic that is suitable for offloading, this hardware acceleration can significantly improve your network throughput.

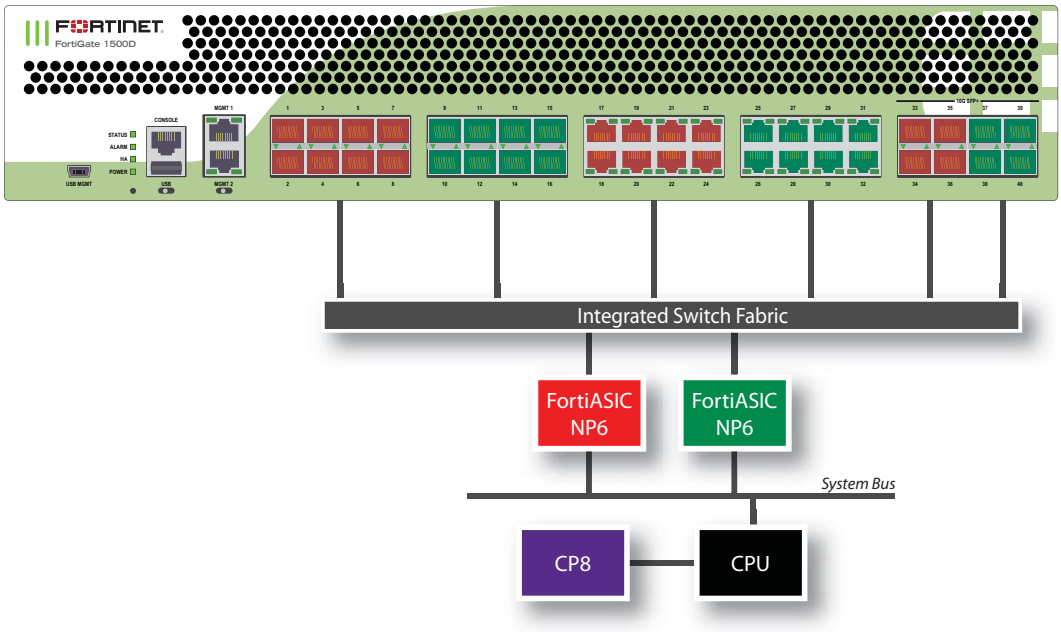
This chapter shows the fastpath architecture for the following FortiGate units:

- FortiGate-1500D fast path architecture
- FortiGate-3700D fast path architecture

FortiGate-1500D fast path architecture

The FortiGate-1500D features two NP6 processors.

- Eight SFP 1Gb interfaces (port1-port8), eight RJ-45 Ethernet ports (port17-24) and four SFP+ 10Gb interfaces (port33-port36) share connections to the first NP6 processor.
- Eight SFP 1Gb interfaces (port9-port16), eight RJ-45 Ethernet ports (port25-32) and four SFP+ 10Gb interfaces (port37-port40) share connections to the second NP6 processor.



You can use the following command to display the FortiGate-1500D NP6 configuration. The command output shows two NP6s named NP6_0 and NP6_1. The output also shows the interfaces (ports) connected to each NP6.

```

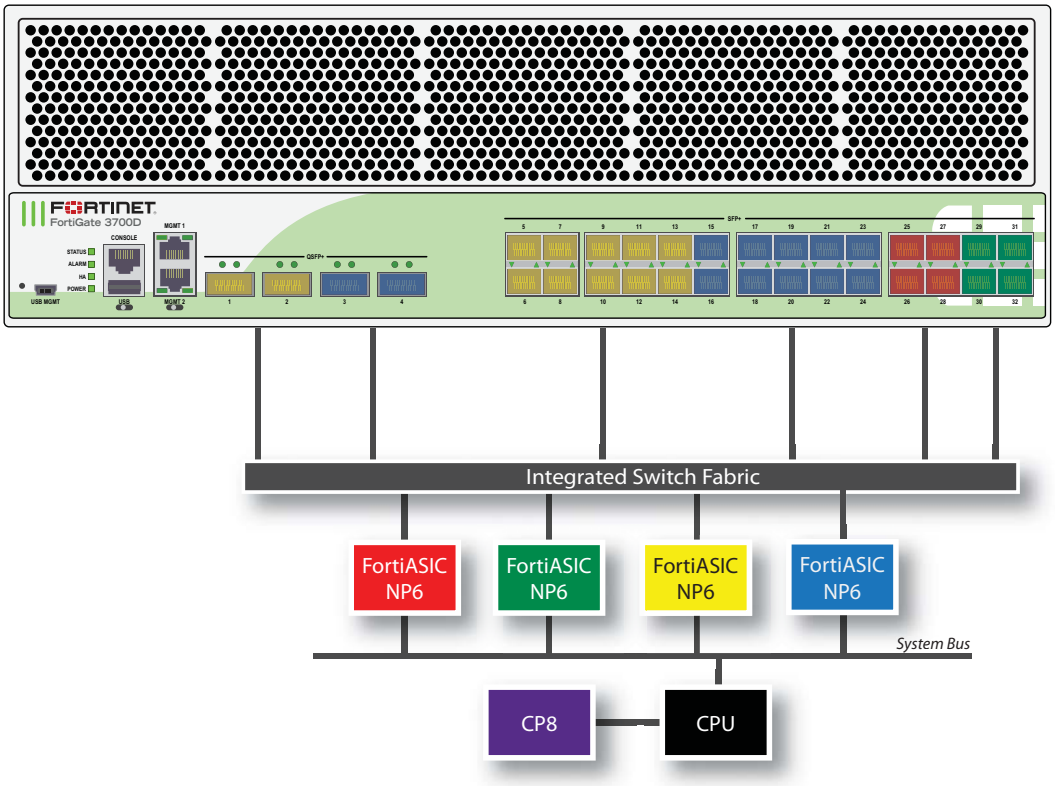
FortiGate-3700D fast path architecture

The FortiGate-3700D features four NP6 processors.

- Port25 through port28, SFP+ 10Gb interfaces, share connections to the first NP6 processor.
- Port29 through port32, SFP+ 10Gb interfaces, share connections to the second NP6 processor.
- Ten SFP+ 10Gb interfaces, port5 through port14, and two 40Gb QSFP interfaces, port1 and port2 share connections to the third NP6 processor.
- Ten SFP+ 10Gb interfaces, port15 through port24, and two 40Gb QSFP interfaces, port3 and port4 share connections to the fourth NP6 processor.



Ports 25 to 32 can be used for low latency offloading. As long as traffic enters and exits the FortiGate-3700D through ports connected to the same NP6 processor and using these low latency ports the traffic will be offloaded and have lower latency that other NP6 offloaded traffic. Latency is reduced by bypassing the integrated switch fabric. Specifically:

- Port25 through port28, share connections to the first NP6 processor so sessions entering one of these ports and exiting through another will experience low latency
- Port29 through port32, share connections to the second NP6 processor so sessions entering one of these ports and exiting through another will experience low latency

You can use the following command to display the FortiGate-3700D NP6 configuration. The command output shows four NP6s named NP6_0, NP6_1, NP6_2, and NP6_3. The output also shows the interfaces (ports) connected to each NP6.

```

NP4 Acceleration

NP4 network processors provide fastpath acceleration by offloading communication sessions from the FortiGate CPU. When the first packet of a new session is received by an interface connected to an NP4 processor, just like any session connecting with any FortiGate interface, the session is forwarded to the FortiGate CPU where it is matched with a security policy. If the session is accepted by a security policy and if the session can be offloaded its session key is copied to the NP4 processor that received the packet. All of the rest of the packets in the session are intercepted by the NP4 processor and fast-pathed out of the FortiGate unit to their destination without ever passing through the FortiGate CPU. The result is enhanced network performance provided by the NP4 processor plus the network processing load is removed from the CPU. In addition, the NP4 processor can handle some CPU intensive tasks, like IPsec VPN encryption/decryption.

Session keys (and IPsec SA keys) are stored in the memory of the NP4 processor that is connected to the interface that received the packet that started the session. All sessions are fast-pathed and accelerated, even if they exit the FortiGate unit through an interface connected to another NP4. The key to making this possible is the Integrated Switch Fabric (ISF) that connects the NP4s and the FortiGate unit interfaces together. The ISF allows any port connectivity. All ports and NP4s can communicate with each other over the ISF.

There are no special ingress and egress fast path requirements because traffic enters and exits on interfaces connected to the same ISF. Most FortiGate models with multiple NP4 processors connect all interfaces and NP4 processors to the same ISF (except management interfaces) so this should not ever be a problem.

There is one limitation to keep in mind; the capacity of each NP4 processor. An individual NP4 processor has a capacity of 20 Gbps (10 Gbps ingress and 10 Gbps egress). Once an NP4 processor hits its limit, sessions that are over the limit are sent to the CPU. You can avoid this problem by as much as possible distributing incoming sessions evenly among the NP4 processors. To be able to do this you need to be aware of which interfaces connect to which NP4 processors and distribute incoming traffic accordingly.

Some FortiGate units contain one NP4 processor with all interfaces connected to it and to the ISF. As a result, offloading is supported for traffic between any pair of interfaces.

Some FortiGate units include NP4Lite processors. These network processors have the same functionality and limitations as NP4 processors but with about half the performance. NP4lite processors can be found in mid-range FortiGate models such as the FortiGate-200D and 240D.

This chapter contains the following topics:

Viewing your FortiGate's NP4 configuration

To list the NP4 network processors on your FortiGate unit, use the following CLI command.

```
get hardware npu np4 list
```

The output lists the interfaces that have NP4 processors. For example, for a FortiGate-5001C:

```
get hardware npu np4 list
ID     Model          Slot       Interface
0      On-board                  port1 port2 port3 port4
                                 fabric1 base1 npu0-vlink0 npu0-vlink1
1      On-board                  port5 port6 port7 port8
                                 fabric2 base2 npu1-vlink0 npu1-vlink1
```

Depending on the product, NP4 network processors may or may not be directly connected to each other on the circuit board through an EEI (Enhanced Extension Interface).

Directly connected network processors have an EEI, and can pass traffic between them without involving the FortiGate unit's main processing resources.

Indirectly connected network processors have no EEI, and cannot pass traffic between them without involving the FortiGate unit's main processing resources.

Sessions can only be offloaded if both the source and destination port are connected to the same network processor or directly (EEI) connected network processor pair.

For information about the network processors in specific FortiGate models, see "FortiGate NP4 architectures" on page 1105.

NP4lite CLI commands (disabling NP4Lite offloading)

If your FortiGate unit includes an NP4Lite processor the following commands will be available:

- Use the following command to disable or enable NP4Lite offloading. By default NP4lite offloading is enabled. If you want to disable NP4Lite offloading to diagnose a problem enter:

  ```
  diagnose npu nplite fastpath disable
  ```

  This command disables NP4Lite offloading until your FortiGate reboots. You can also re-enable offloading by entering the following command:

  ```
  diagnose npu nplite fastpath enable
  ```

- NP4lite debug command. Use the following command to debug NP4Lite operation:

  ```
  diagnose npl npl_debug {<parameters>}
  ```

Configuring NP4 traffic offloading

Offloading traffic to a network processor requires that the FortiGate unit configuration and the traffic itself is suited to hardware acceleration. There are requirements for path the sessions and the individual packets.

NP4 session fast path requirements

Sessions must be fast path ready. Fast path ready session characteristics are:

- Layer 2 type/length must be 0x0800 (IEEE 802.1q VLAN specification is supported); link aggregation between any network interfaces sharing the same network processor(s) may be used (IEEE 802.3ad specification is supported)
- Layer 3 protocol must be IPv4

- Layer 4 protocol must be UDP, TCP or ICMP
- Layer 3 / Layer 4 header or content modification must not require a session helper (for example, SNAT, DNAT, and TTL reduction are supported, but application layer content modification is not supported)
- Firewall policies must not include proxy-based or flow-based security features (antivirus, web filtering, email filtering, IPS, application control, or DLP)
- Origin must not be local host (the FortiGate unit)

If you disable anomaly checks by Intrusion Prevention (IPS), you can still enable hardware accelerated anomaly checks using the `fp-anomaly` field of the `config system interface` CLI command. See "Offloading NP pre-IPS anomaly detection" on page 1076.

If a session is not fast path ready, the FortiGate unit will not send the session key to the network processor(s). Without the session key, all session key lookup by a network processor for incoming packets of that session fails, causing all session packets to be sent to the FortiGate unit's main processing resources, and processed at normal speeds.

If a session is fast path ready, the FortiGate unit will send the session key to the network processor(s). Session key lookup then succeeds for subsequent packets from the known session.

Packet fast path requirements

Packets within the session must then also meet packet requirements.

- Incoming packets must not be fragmented.
- Outgoing packets must not require fragmentation to a size less than 385 bytes. Because of this requirement, the configured MTU (Maximum Transmission Unit) for network processors' network interfaces must also meet or exceed the network processors' supported minimum MTU of 385 bytes.

If packet requirements are not met, an individual packet will use FortiGate unit main processing resources, regardless of whether other packets in the session are offloaded to the specialized network processor(s).

In some cases, due to these requirements, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing.

For example, FTP uses two connections: a control connection and a data connection. The control connection requires a session helper, and cannot be offloaded, but the data connection does not require a session helper, and can be offloaded. Within the offloadable data session, fragmented packets will not be offloaded, but other packets will be offloaded.

Some traffic types differ from general offloading requirements, but still utilize some of the network processors' encryption and other capabilities. Exceptions include IPsec traffic and active-active high availability (HA) load balanced traffic.

Mixing fast path and non-fast path traffic

If packet requirements are not met, an individual packet will be processed by the FortiGate CPU regardless of whether other packets in the session are offloaded to the NP4.

Also, in some cases, a protocol's session(s) may receive a mixture of offloaded and non-offloaded processing. For example, FTP control packets may not be offloaded but FTP data packets (voice packets) may be offloaded.

NP4 traffic shaping offloading

Accelerated Traffic shaping is supported with the following limitations.

- NP4 processors support policy-based traffic shaping. However, fast path traffic and traffic handled by the FortiGate CPU (slow path) are controlled separately, which means the policy setting on fast path does not consider the traffic on the slow path.
- The port based traffic policing as defined by the inbandwidth and outbandwidth CLI commands is not supported.
- DSCP configurations are supported.
- 4QoS in general is not supported.

You can also use the traffic shaping features of the FortiGate unit's main processing resources by disabling the NP4 acceleration. See "Disabling CP offloading" on page 1070.

NP4 IPsec VPN offloading

NP4 processors improve IPsec tunnel performance by offloading IPsec encryption and decryption.

Requirements for hardware accelerated IPsec encryption or decryption are a modification of general offloading requirements. Differing characteristics are:

- Origin can be local host (the FortiGate unit)
- In Phase 1 configuration, Local Gateway IP must be specified as an IP address of a network interface for a port attached to a network processor
- SA must have been received by the network processor
- in Phase 2 configuration:
  - encryption algorithm must be DES, 3DES, AES-128, AES-192, AES-256, or null
  - authentication must be MD5, SHA1, or null
  - if encryption is null, authentication must not also be null
  - if replay detection is enabled, `enc-offload-antireplay` must also be `enable` in the CLI

If replay detection is enabled in the Phase 2 configuration, you can enable or disable IPsec encryption and decryption offloading from the CLI. Performance varies by those CLI options and the percentage of packets requiring encryption or decryption. For details, see "Configuring NP accelerated VPN encryption/decryption offloading" on page 1078.

To apply hardware accelerated encryption and decryption, the FortiGate unit's main processing resources must first perform Phase 1 negotiations to establish the security association (SA). The SA includes cryptographic processing instructions required by the network processor, such as which encryption algorithms must be applied to the tunnel. After ISAKMP negotiations, the FortiGate unit's main processing resources send the SA to the network processor, enabling the network processor to apply the negotiated hardware accelerated encryption or decryption to tunnel traffic.

Possible accelerated cryptographic paths are:

- IPsec decryption offload
  - Ingress ESP packet > Offloaded decryption > Decrypted packet egress (fast path)
  - Ingress ESP packet > Offloaded decryption > Decrypted packet to FortiGate unit's main processing resources

- IPsec encryption offload
  - Ingress packet > Offloaded encryption > Encrypted (ESP) packet egress (fast path)
  - Packet from FortiGate unit's main processing resources > Offloaded encryption > Encrypted (ESP) packet egress

NP4 IPsec VPN offloading configuration example

Hardware accelerated IPsec processing, involving either partial or full offloading, can be achieved in either tunnel or interface mode IPsec configurations.

To achieve offloading for both encryption and decryption:

- In Phase 1 configuration's Advanced section, Local Gateway IP must be specified as an IP address of a network interface associated with a port attached to a network processor. (In other words, if Phase 1's Local Gateway IP is Main Interface IP, or is specified as an IP address that is not associated with a network interface associated with a port attached to a network processor, IPsec network processing is not offloaded.)
- In Phase 2 configuration's P2 Proposal section, if the checkbox "Enable replay detection" is enabled, `enc-offload-antireplay` and `dec-offload-antireplay` must be set to `enable` in the CLI.
- `offload-ipsec-host` must be set to `enable` in the CLI.

This section contains example IPsec configurations whose IPsec encryption and decryption processing is hardware accelerated by an NP4 unit contained in a FortiGate-5001B at both ends of the VPN tunnel.

Hardware accelerated IPsec VPN does not require both tunnel endpoints to have the same network processor model. However, if hardware is not symmetrical, the packet forwarding rate is limited by the slower side.

Figure 183: Example network topology for offloaded IPsec processing

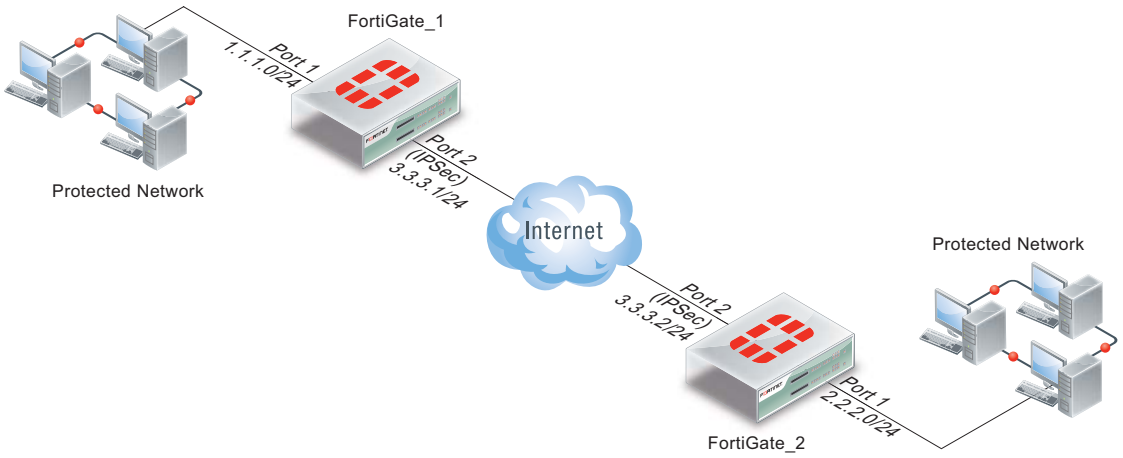

Table 54: Example ports and IP addresses for offloaded IPsec processing

	FortiGate_1		FortiGate_2	
	Port	**IP**	**Port**	**IP**
IPsec tunnel	FortiGate-5001B port 2	3.3.3.1/24	FortiGate-5001B port 2	3.3.3.2/24
Protected network	FortiGate-5001B port 1	1.1.1.0/24	FortiGate-5001B port 1	2.2.2.0/24

This section includes the following topics:

Accelerated policy mode IPsec configuration

The following steps create a hardware accelerated policy mode IPsec tunnel between two FortiGate-5001B units, each containing two NP4 processors, the first of which will be used.

To configure hardware accelerated policy mode IPsec

1. On FortiGate_1, go to *VPN* > *IPsec* > *Auto Key (IKE)*.
2. Configure Phase 1.

   For tunnel mode IPsec and for hardware acceleration, specifying the Local Gateway IP is required.

   Select *Advanced*. In the Local Gateway IP section, select *Specify* and type the VPN IP address 3.3.3.2, which is the IP address of FortiGate_2's FortiGate-ASM-FB4 module port 2.
3. Configure Phase 2.
4. Select *Enable replay detection*.
5. Use the following command to enable offloading antireplay packets:

```
config system npu
  set enc-offload-antireplay enable
end
```

   For details on encryption and decryption offloading options available in the CLI, see "Configuring NP accelerated VPN encryption/decryption offloading" on page 1078.

6. Go to *Policy* > *Policy* > *Policy*.
7. Configure a policy to apply the Phase 1 IPsec tunnel you configured in step 2 to traffic between FortiGate-5001B ports 1 and 2.
8. Go to *Router* > *Static* > *Static Route*.
9. Configure a static route to route traffic destined for FortiGate_2's protected network to VPN IP address of FortiGate_2's VPN gateway, 3.3.3.2, through the FortiGate-5001B port2.

   You can also configure the static route using the following CLI command:

```
config router static
  edit 2
    set device "AMC-SW1/2"
    set dst 2.2.2.0 255.255.255.0
    set gateway 3.3.3.2
  end
```

10. On FortiGate_2, go to *VPN* > *IPsec* > *Auto Key (IKE)*.
11. Configure Phase 1.

    For tunnel mode IPsec and for hardware acceleration, specifying the Local Gateway IP is required.

    Select Advanced. In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.1, which is the IP address of FortiGate_1's port2.
12. Configure Phase 2.
13. Select *Enable replay detection*.
14. Use the following command to enable offloading antireplay packets:

```
config system npu
  set enc-offload-antireplay enable
end
```

    For details on encryption and decryption offloading options available in the CLI, see "Configuring NP accelerated VPN encryption/decryption offloading" on page 1078.
15. Go to *Policy* > *Policy* > *Policy*.
16. Configure a policy to apply the Phase 1 IPsec tunnel you configured in step 9 to traffic between FortiGate-5001B ports 1 and 2.
17. Go to *Router* > *Static* > *Static Route*.
18. Configure a static route to route traffic destined for FortiGate_1's protected network to VPN IP address of FortiGate_1's VPN gateway, 3.3.3.1, through the FortiGate-5001B port2.

    You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "AMC-SW1/2"
    set dst 1.1.1.0 255.255.255.0
    set gateway 3.3.3.1
  end
```

19. Activate the IPsec tunnel by sending traffic between the two protected networks.

    To verify tunnel activation, go to *VPN* > *Monitor* > *IPsec Monitor*.

Accelerated interface mode IPsec configuration

The following steps create a hardware accelerated interface mode IPsec tunnel between two FortiGate units, each containing a FortiGate-ASM-FB4 module.

To configure hardware accelerated interface mode IPsec

1. On FortiGate_1, go to *VPN* > *IPsec* > *Auto Key (IKE)*.
2. Configure Phase 1.

   For interface mode IPsec and for hardware acceleration, the following settings are required.

   - Select Advanced.
   - Enable the checkbox “Enable IPsec Interface Mode.”
   - In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.2, which is the IP address of FortiGate_2’s port 2.
3. Configure Phase 2.
4. Select *Enable replay detection*.
5. Use the following command to enable offloading antireplay packets:

   ```
   config system npu
     set enc-offload-antireplay enable
   end
   ```

   For details on encryption and decryption offloading options available in the CLI, see “Configuring NP accelerated VPN encryption/decryption offloading” on page 1078.
6. Go to *Policy* > *Policy* > *Policy*.
7. Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 2 to traffic leaving from or arriving on FortiGate-ASM-FB4 module port 1.
8. Go to *Router* > *Static* > *Static Route*.
9. Configure a static route to route traffic destined for FortiGate_2’s protected network to the Phase 1 IPsec device, `FGT_1_IPsec`.

   You can also configure the static route using the following CLI commands:

   ```
   config router static
     edit 2
       set device "FGT_1_IPsec"
       set dst 2.2.2.0 255.255.255.0
     end
   ```
10. On FortiGate_2, go to *VPN* > *IPsec* > *Auto Key (IKE)*.
11. Configure Phase 1.

    For interface mode IPsec and for hardware acceleration, the following settings are required.

    - Enable the checkbox “Enable IPsec Interface Mode.”
    - In the Local Gateway IP section, select Specify and type the VPN IP address 3.3.3.1, which is the IP address of FortiGate_1’s FortiGate-5001B port 2.
12. Configure Phase 2.
13. Select *Enable replay detection*.
14. Use the following command to enable offloading antireplay packets:

    ```
    config system npu
      set enc-offload-antireplay enable
    end
    ```

    For details on encryption and decryption offloading options available in the CLI, see “Configuring NP accelerated VPN encryption/decryption offloading” on page 1078.
15. Go to *Policy* > *Policy* > *Policy*.
16. Configure two policies (one for each direction) to apply the Phase 1 IPsec configuration you configured in step 9 to traffic leaving from or arriving on FortiGate-5001B port 1.
17. Go to *Router* > *Static* > *Static Route*.

18. Configure a static route to route traffic destined for FortiGate_1's protected network to the Phase 1 IPsec device, `FGT_2_IPsec`.

    You can also configure the static route using the following CLI commands:

```
config router static
  edit 2
    set device "FGT_2_IPsec"
    set dst 1.1.1.0 255.255.255.0
    next
  end
```

19. Activate the IPsec tunnel by sending traffic between the two protected networks.

    To verify tunnel activation, go to *VPN* > *Monitor* > *IPsec Monitor*.

Configuring Inter-VDOM link acceleration with NP4 processors

FortiGate units with NP4 processors include inter-VDOM links that can be used to accelerate inter-VDOM link traffic.

- For a FortiGate unit with two NP4 processors there are also two inter-VDOM links, each with two interfaces:
  - npu0-vlink
    - npu0-vlink0
    - npu0-vlink1
  - npu1-vlink
    - npu1-vlink0
    - npu1-vlink1

These interfaces are visible from the GUI and CLI. For a FortiGate unit with NP4 interfaces, enter the following CLI command (output shown for a FortiGate-5001B):

```
get hardware npu np4 list
ID     Model          Slot       Interface
0      On-board                  port1 port2 port3 port4
                                 fabric1 base1 npu0-vlink0 npu0-vlink1
1      On-board                  port5 port6 port7 port8
                                 fabric2 base2 npu1-vlink0 npu1-vlink1
```

By default the interfaces in each inter-VDOM link are assigned to the root VDOM. To use these interfaces to accelerate inter-VDOM link traffic, assign each interface in a pair to the VDOMs that you want to offload traffic between. For example, if you have added a VDOM named New-VDOM to a FortiGate unit with NP4 processors, you can go to *System* > *Network* > *Interfaces* and edit the *npu0-vlink1* interface and set the *Virtual Domain* to *New-VDOM*. This results in an inter-VDOM link between root and New-VDOM. You can also do this from the CLI:

```
config system interface
  edit npu0-vlink1
    set vdom New-VDOM
end
```

Using VLANs to add more accelerated Inter-VDOM links

You can add VLAN interfaces to the accelerated inter-VDOM links to create inter-VDOM links between more VDOMs. For the links to work, the VLAN interfaces must be added to the same inter-VDOM link, must be on the same subnet, and must have the same VLAN ID.

For example, to accelerate inter-VDOM link traffic between VDOMs named Marketing and Engineering using VLANs with VLAN ID 100 go to *System* > *Network* > *Interfaces* and select *Create New* to create the VLAN interface associated with the Marketing VDOM:

Name	Marketing-link
Type	VLAN
Interface	npu0-vlink0
VLAN ID	100
Virtual Domain	Marketing
IP/Network Mask	172.20.120.12/24

Create the inter-VDOM link associated with Engineering VDOM:

Name	Engineering-link
Type	VLAN
Interface	npu0-vlink1
VLAN ID	100
Virtual Domain	Engineering
IP/Network Mask	172.20.120.22/24

Or do the same from the CLI:

```
config system interface
  edit Marketing-link
    set vdom Marketing
    set ip 172.20.120.12/24
    set interface npu0-vlink0
    set vlanid 100
  next
  edit Engineering-link
    set vdom Engineering
    set ip 172.20.120.22/24
    set interface npu0-vlink1
    set vlanid 100
```

Confirm that the traffic is accelerated

Use the following CLI commands to obtain the interface index and then correlate them with the session entries. In the following example traffic was flowing between new accelerated inter-VDOM links and physical ports port1 and port 2 also attached to the NP4 processor.

```
diagnose ip address list
IP=172.31.17.76->172.31.17.76/255.255.252.0 index=5 devname=port1
IP=10.74.1.76->10.74.1.76/255.255.252.0 index=6 devname=port2

FortiGate NP4 architectures

This chapter shows the NP4 architecture for the following FortiGate units:

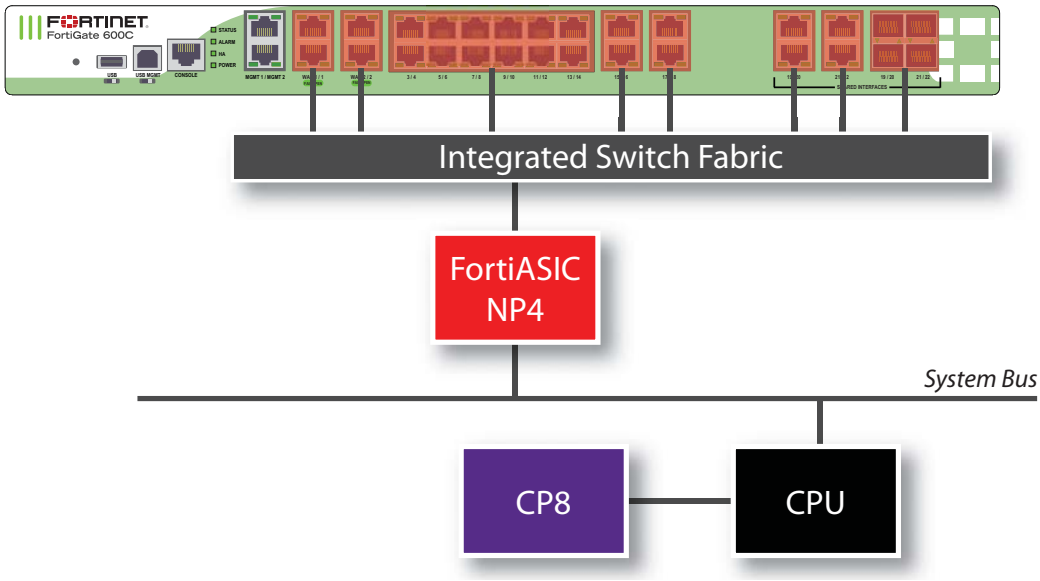
- FortiGate-600C
- FortiGate-800C
- FortiGate-1000C
- FortiGate-1240B
- FortiGate-3040B
- FortiGate-3140B
- FortiGate-3140B — load balance mode
- FortiGate-3240C
- FortiGate-3600C
- FortiGate-3950B and FortiGate-3951B
- FortiGate-5001C
- FortiGate-5001B

And includes the following reference information:

- Setting switch-mode mapping on the ADM-XD4

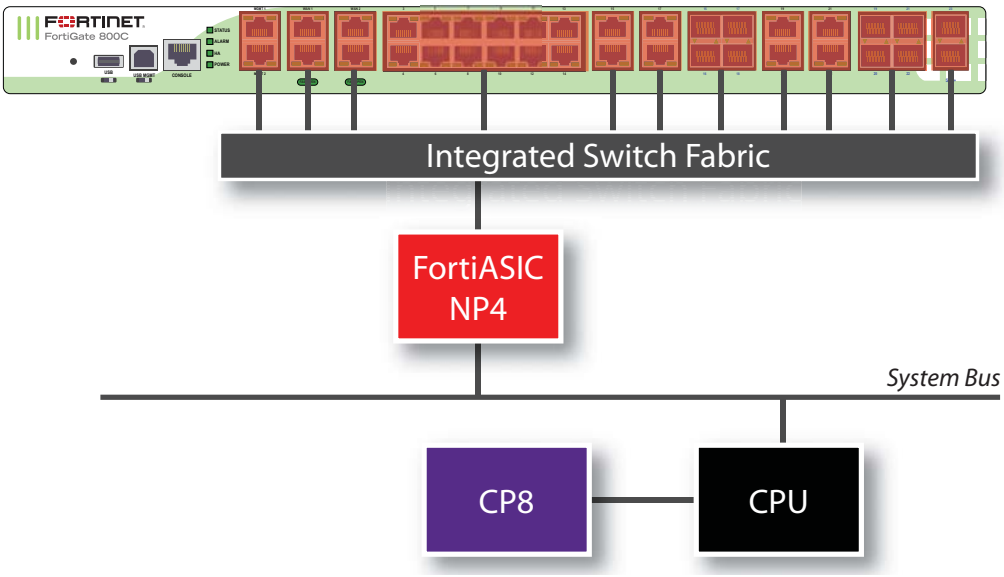
FortiGate-600C

The FortiGate-600C features one NP4 processor. All the ports are connected to this NP4 over the Integrated Switch Fabric. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are four 1Gb SFP interface ports duplicating the port19-port22 connections.



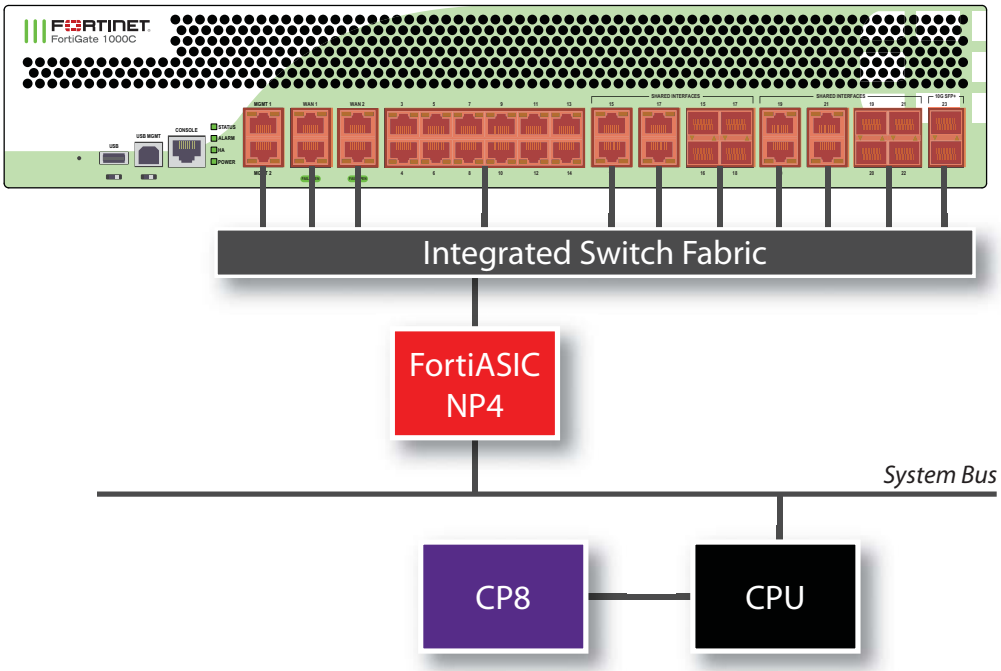
FortiGate-800C

The FortiGate-800C features one NP4 processor. All the ports are connected to this NP4. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are eight 1Gb SFP interface ports duplicating the port15-18 and port19-port22 connections. There are also two 10Gb SFP+ ports, port23 and port24.



FortiGate-1000C

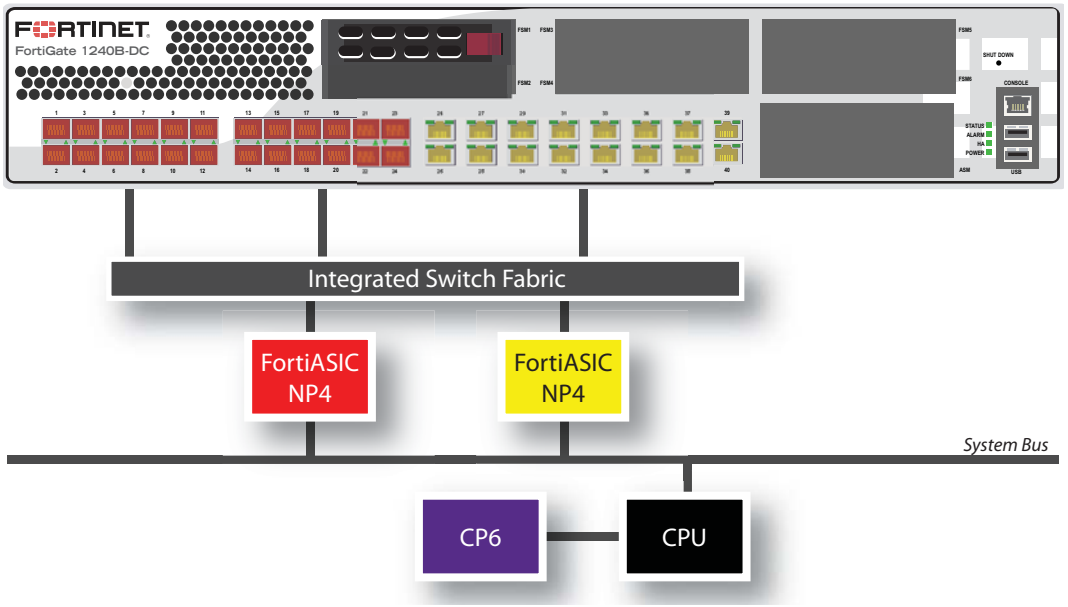
The FortiGate-1000C features one NP4 processor. All the ports are connected to this NP4. Port1 and port2 are dual failopen redundant RJ-45 ports. Port3-port22 are RJ-45 ethernet ports, and there are eight 1Gb SFP interface ports duplicating the port15-18 and port19-port22 connections. There are also two 10Gb SFP+ ports, port23 and port24.



FortiGate-1240B

The FortiGate-1240B features two NP4 processors:

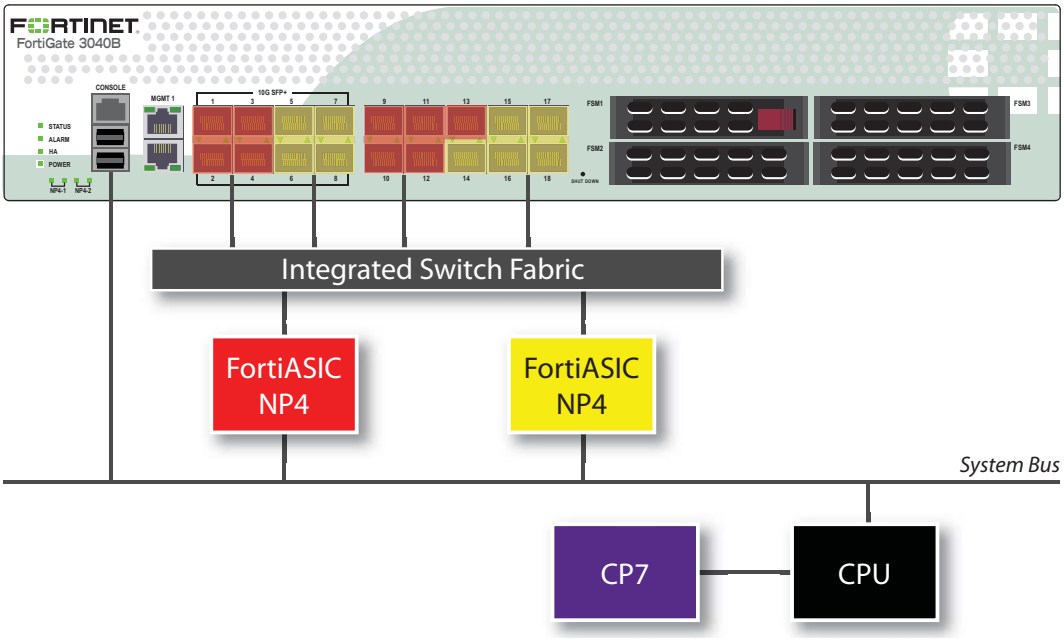
- Port1-port24 are 1Gb SFP interfaces connected to one NP4 processor.
- Port25-port40 are RJ-45 ethernet ports, connected to the other NP4 processor.



FortiGate-3040B

The FortiGate-3040B features two NP4 processors:

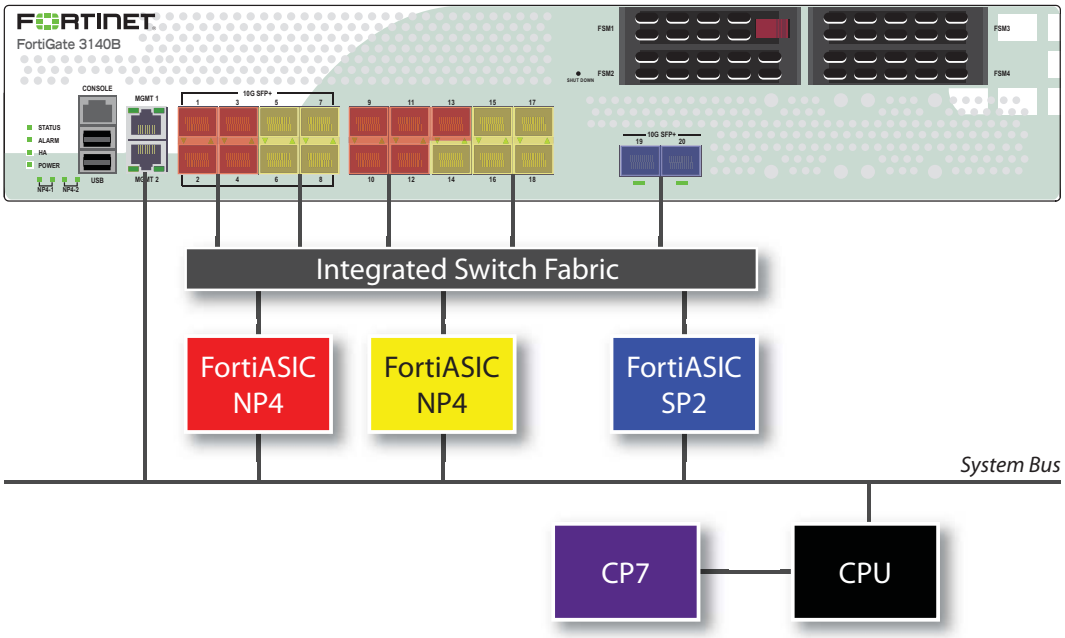
- The 10Gb interfaces, port1, port2, port3, port4, and the 1Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10Gb interfaces, port5, port6, port7, port8, and the 1Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.



FortiGate-3140B

The FortiGate-3140B features two NP4 processors and one SP2 processor:

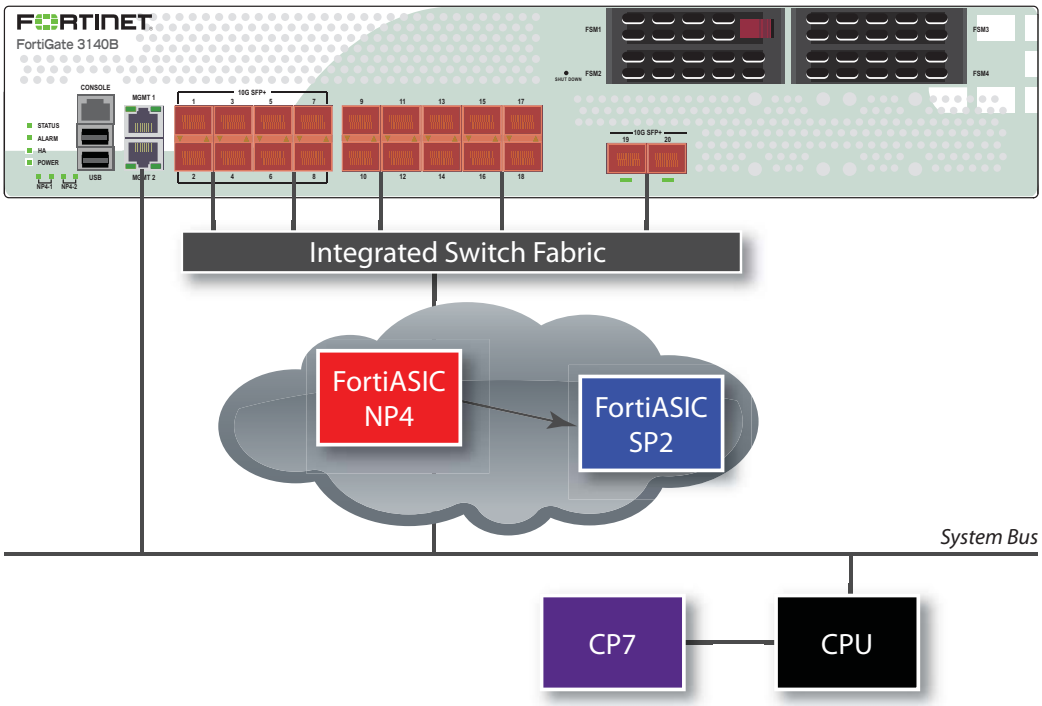
- The 10Gb interfaces, port1, port2, port3, port4, and the 1Gb interfaces, port9, port10, port11, port12, port13, share connections to one NP4 processor.
- The 10Gb interfaces, port5, port6, port7, port8, and the 1Gb interfaces, port14, port15, port16, port17, port18, share connections to the other NP4 processor.
- The 10Gb interfaces, port19 and port20, share connections to the SP2 processor.



FortiGate-3140B — load balance mode

The FortiGate-3140B load balance mode allows you increased flexibility in how you use the interfaces on the FortiGate unit. When enabled, traffic between any two interfaces (excluding management and console) is accelerated. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.



To enable this feature, issue this CLI command.

```
config system global
  set sp-load-balance enable
end
```

The FortiGate unit will then restart.

To return to the default mode, issue this CLI command.

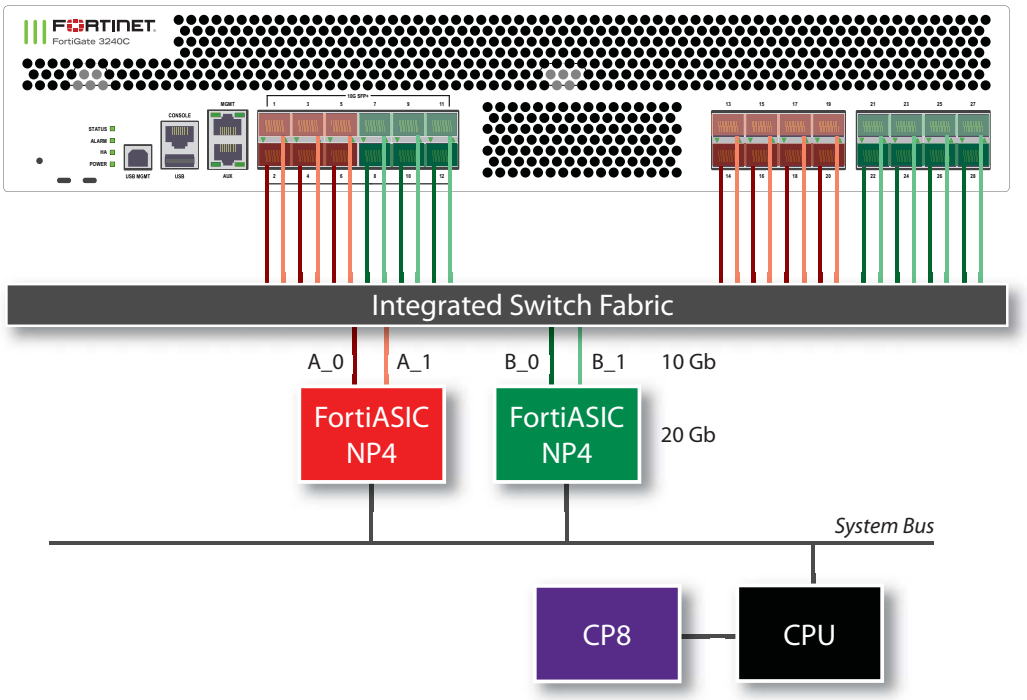
```
config system global
  set sp-load-balance disable
end
```

FortiGate-3240C

The FortiGate-3240C features two NP4 processors:

- The 10Gb interfaces, port1 through port6, and the 1Gb interfaces, port13 through port20, share connections to one NP4 processor.
- The 10Gb interfaces, port7 through port12, and the 1Gb interfaces, port21 through port28, share connections to the other NP4 processor.

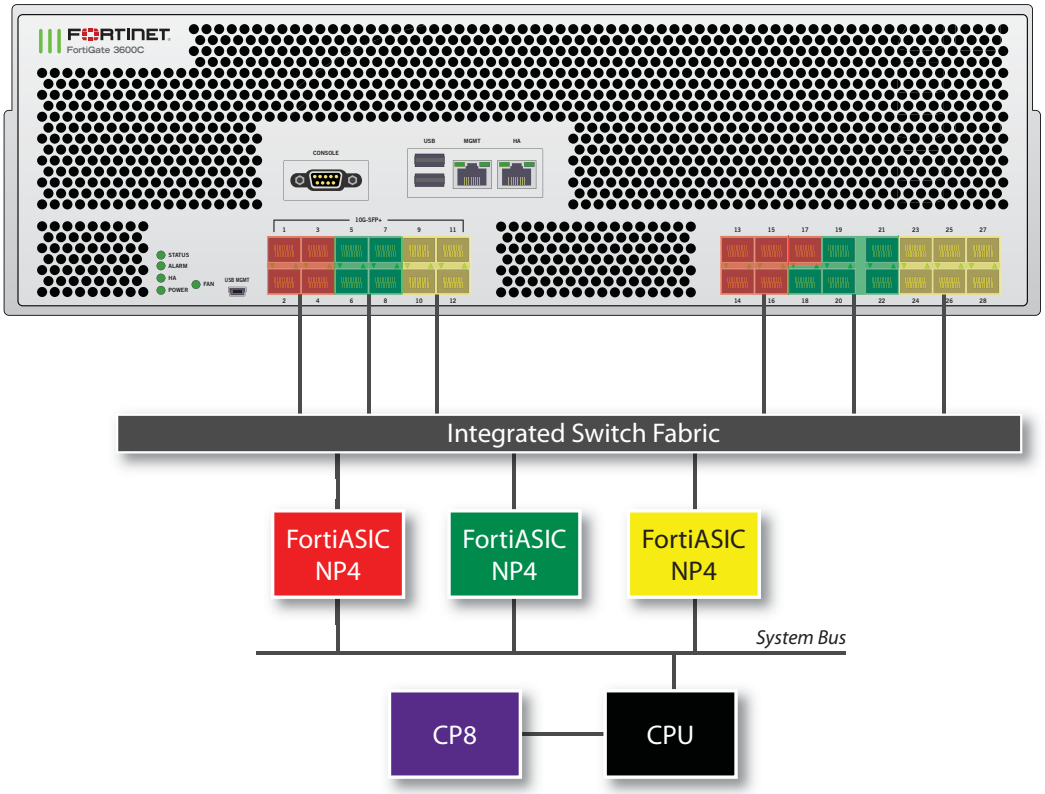
In addition to the ports being divided between the two NP4 processors, they are further divided between the two connections to each processor. Each NP4 can process 20 Gb of network traffic per second and each of two connections to each NP4 can move 10Gb of data to the processor per second, so the ideal configuration would have no more than 10 Gb of network traffic to each connection of each NP4 at any time.



FortiGate-3600C

The FortiGate-3600C features three NP4 processors:

- The 10Gb interfaces, port1-port4, and the 1Gb interfaces, port13-port17, share connections to one NP4 processor.
- The 10Gb interfaces, port5-port8, and the 1Gb interfaces, port18-port22 share connections to the second NP4 processor.
- The 10Gb interfaces, port9-port12, and the 1Gb interfaces, port23-port28 share connections to the third NP4 processor.



XAUI interfaces

Each NP4 processor connects to the integrated switch fabric through two XAUI interfaces: XAUI0 and XAUI1. On each NP4 processor all of the odd numbered interfaces use XAU0 and all of the even numbered interfaces use XAUI1:

NPU1

XAUI0 = port1,port3,port13, port15, port17

XAUI1 = port2, port4, port14, port16

NPU2

XAUI0 = port5, port7, port18, port20, port22

XAUI1 = port6, port8, port19, port21

NPU3

XAUI0 = port9, port11, port23, port25, port27

XAUI1 = port10, port12, port24, port26, port28

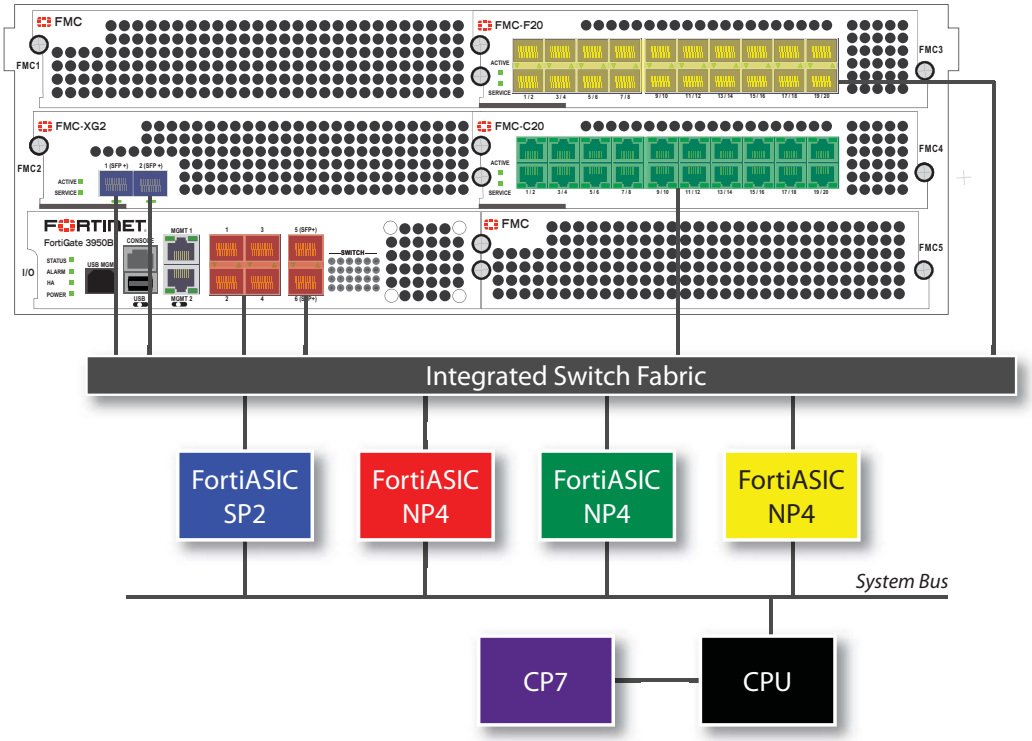
Usually you do not have to be concerned about the XAUI interface mapping. However, if an NP4 interface is processing a very high amount of traffic you should distribute that traffic among both of the XAUI interfaces connected to it. So if you have a very high volume of traffic flowing between two networks you should connect both networks to the same NP4 processor but to different XAUI links. So between even and an add numbered FortiGate-3600C ports. For example, you could connect one network to port5 and the other network to port6. In this configuration, the second NP4 processor would handle traffic acceleration and both XAUI interfaces would be processing traffic.

FortiGate-3950B and FortiGate-3951B

The FortiGate-3950B features one NP4 processor. The 1Gb SPF interfaces, port1, port2, port3, port4, and the 10Gb SPF+ interfaces, port5, port6, share connections to one NP4 processor. The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

You can add additional FMC interface modules. The diagram below shows a FortiGate-3950B with three modules installed: an FMC-XG2, an FMC-F20, and an FMC-C20.

- The FMC-XG2 has one SP2 processor. The 10Gb SPF+ interfaces, port1 and port2, share connections to the processor.
- The FMC-F20 has one NP4 processor and the twenty 1Gb SPF interfaces, port1 through port20, share connections to the NP4 processor.
- The FMC-C20 has one NP4 processor and the twenty 10/100/1000 interfaces, port1 through port20, share connections to the NP4 processor.



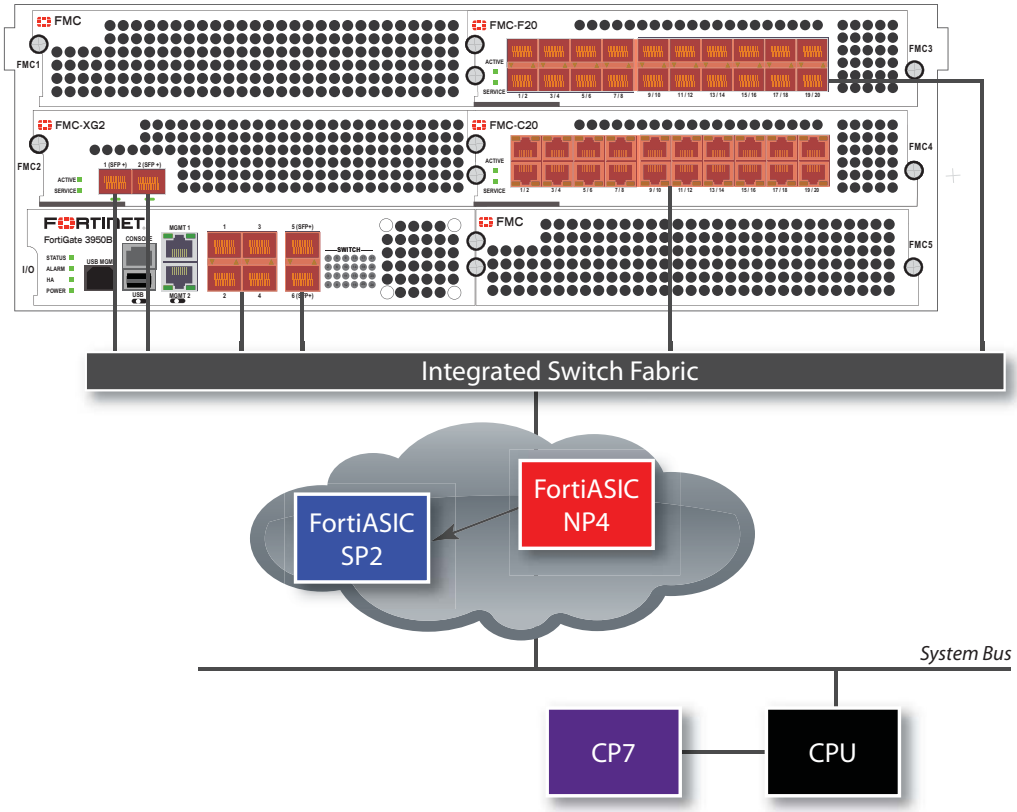
FortiGate-3950B and FortiGate-3951B — load balance mode

Adding one or more FMC-XG2 modules to your FortiGate-3950B allows you to enable load balance mode. This feature allows you increased flexibility in how you use the interfaces on the FortiGate unit. The FortiGate-3951B is similar to the FortiGate-3950B, except it trades one FMC slot for four FSM slots. The network interfaces available on each model are identical.

When enabled, traffic between any two interfaces (excluding management and console) is accelerated whether they are the six interfaces on the FortiGate-3950B itself, or on any installed FMC modules. Traffic is not limited to entering and leaving the FortiGate unit in specific interface groupings to benefit from NP4 and SP2 acceleration. You can use any pair of interfaces.

Security acceleration in this mode is limited, however. Only IPS scanning is accelerated in load balance mode.

Figure 184: The FortiGate-3950B in load balance mode



To enable this feature, issue this CLI command.

```
config system global
  set sp-load-balance enable
end
```

The FortiGate unit will then restart.

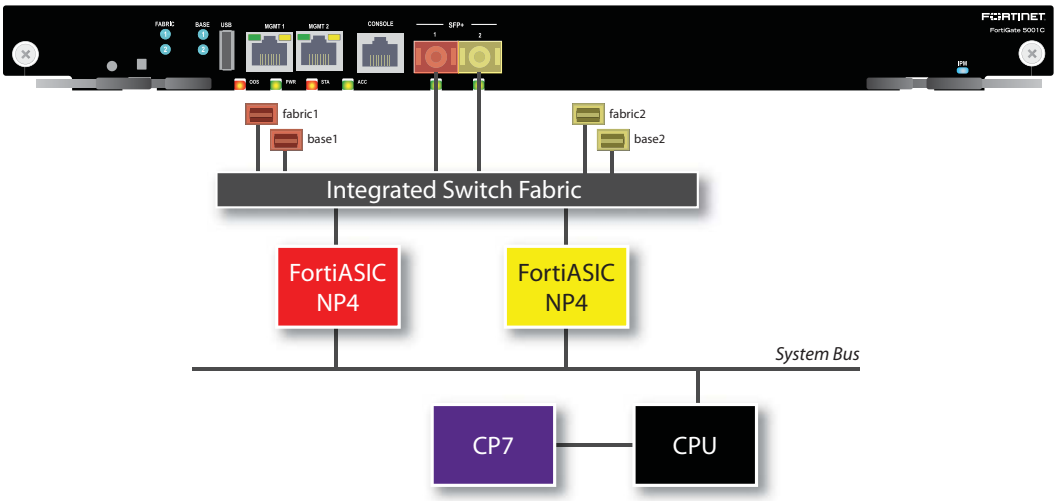
To return to the default mode, issue this CLI command.

```
config system global
  set sp-load-balance disable
end
```

FortiGate-5001C

The FortiGate-5001C board includes two NP4 processors connected to an integrated switch fabric:

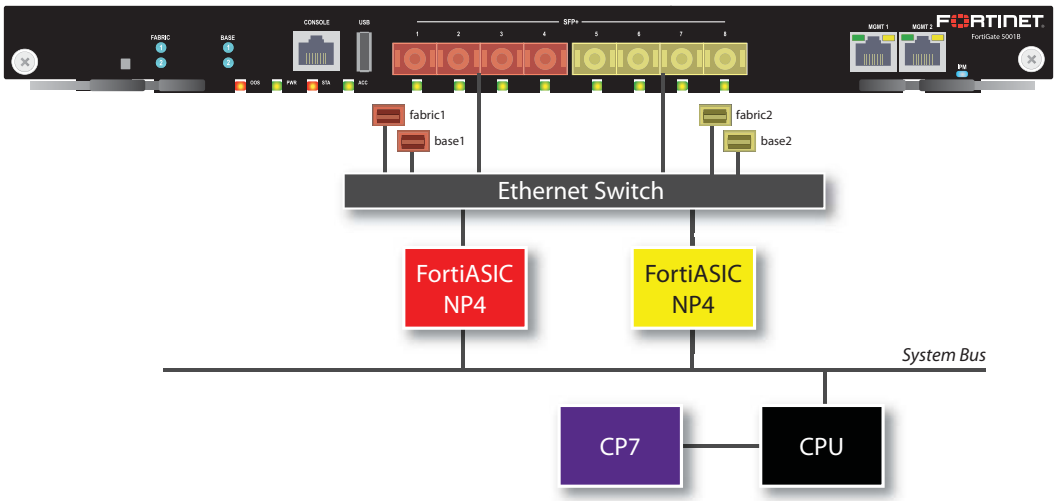
- The port1, fabric1, and base1 interfaces are connected to one NP4 processor.
- The port2, fabric2, and base2 interfaces are connected to the other NP4 processor.



FortiGate-5001B

The FortiGate-5001B board includes two NP4 connected to an Ethernet switch. Traffic between interfaces that use the same NP4 processor experiences the highest acceleration since the FortiGate-5001B does not include an integrated switch fabric.

- The port1, port2, port3, port4, fabric1 and base1 interfaces are connected to one NP4 processor.
- The port5, port6, port7, port8, fabric2 and base2 interfaces are connected to the other NP4 processor.

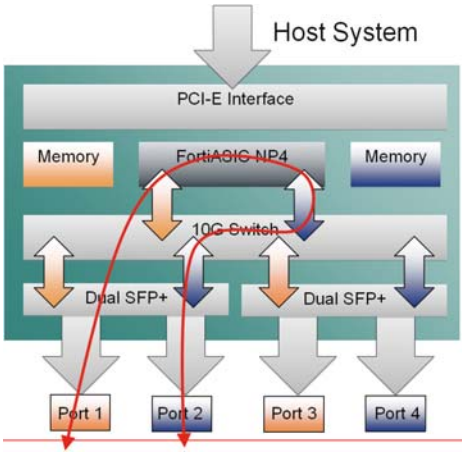


For example, for maximum NP4 acceleration of traffic received on port1 the traffic must exit the FortiGate-5001B board on port2, port3, port4, or fabric1. Also, for maximum acceleration of traffic received on port5 the traffic must exit the FortiGate-5001B board on port6, port7, port8, or fabric2.

Setting switch-mode mapping on the ADM-XD4

The ADM-XD4 SP has four 10Gb/s ports, but the NP4 processor it contains has only two 10Gb/s ports. The external ports you use are important to optimize the SP for your application.

Figure 185:ADM-XD4 mapping mode



Ports 1 and 3 share one NP4 processor and ports 2 and 4 share the other. Performance ports sharing the same NP4 processor is far better than when forcing network data to move between NP4 processors by using one port from each, for example ports 1 and 2 or ports 3 and 4.

Chapter 9 High Availability for FortiOS 5.0

This FortiOS Handbook chapter contains the following sections:

Solving the High Availability problem describes the high availability problem and introduces the FortiOS solutions described in this document (FGCP, VRRP, and standalone session synchronization).

An introduction to the FGCP introduces the FGCP clustering protocol and many of its features and terminology.

Configuring and connecting HA clusters describes configuring HA clusters and contains HA clustering configuration examples.

Virtual clusters describes configuring HA virtual clusters and contains virtual clustering configuration examples.

Full mesh HA describes configuring FortiGate Full mesh HA and contains a full mesh HA configuration example.

Operating a cluster describes how to operate a cluster and includes detailed information about how various FortiGate systems operate differently in a cluster.

HA and failover protection describes in detail how FortiGate HA device failover, link failover, and session failover work.

HA and load balancing describes in detail how FortiGate HA active-active load balancing load balances sessions.

HA with FortiGate-VM and third-party products describes how FortiGate units interact with third-party products.

VRRP describes FortiOS support of the Virtual Router Redundancy Protocol (VRRP) and its use for high availability.

FortiGate Session Life Support Protocol (FGSP) describes the FortiGate standalone session synchronization feature and its use for high availability.

Configuring FRUP describes how to set up a FortiGate Redundant UTM Protocol (FRUP) cluster consisting of two FortiGate-100D units.

•

Solving the High Availability problem

The basic high availability (HA) problem for TCP/IP networks and security gateways is keeping network traffic flowing. Uninterrupted traffic flow is a critical component for online systems and media because critical business processes quickly come to a halt when the network is down.

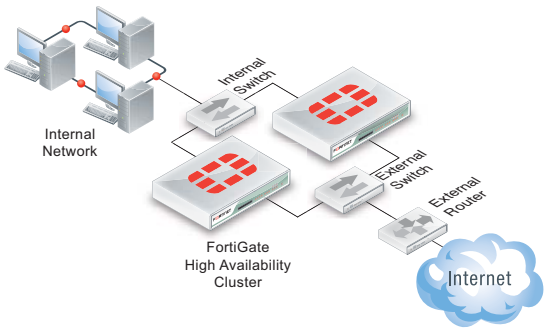
The security gateway is a crucial component of most networks since all traffic passes through it. A standalone network security gateway is a single point of failure that is vulnerable to any number of software or hardware problems that could compromise the device and bring all traffic on the network to a halt.

A common solution to the high availability problem is to eliminate the security gateway as single point of failure by introducing redundancy. With two or more redundant security gateways, if one fails, the remaining one or more gateways keep the traffic flowing. FortiOS provides four redundancy solutions: industry standard VRRP as well as three proprietary solutions: FortiGate Cluster Protocol (FGCP) high availability, FortiGate Session Life Support Protocol (FGSP) high availability, and the Fortinet Redundant UTM protocol (FRUP) high availability.

You can combine more than one high availability solution into a single configuration. A common reason for doing this could be to add VRRP to an FGCP or FGSP configuration.

A strong and flexible High availability solution is required for many mission-critical firewall and UTM applications. Each FortiOS high availability solution can be fine tuned to fit into many different network scenarios.

FortiGate Cluster Protocol (FGCP)

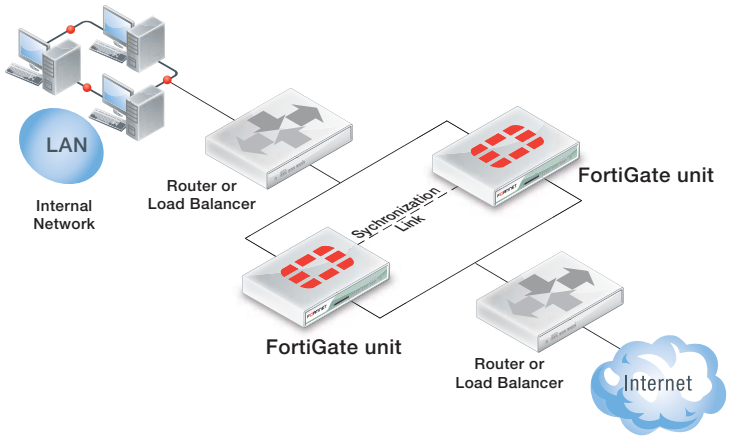


FGCP HA provides a solution for two key requirements of critical enterprise networking components: enhanced reliability and increased performance. Enhanced reliability is achieved through device failover protection, link failover protection, and remote link failover protection. Also contributing to enhanced reliability is session failover protection for most IPv4 and IPv6 sessions including TCP, UDP, ICMP, IPsec VPN, and NAT sessions. Increased performance is achieved though active-active HA load balancing. Extended FGCP features include full mesh HA and virtual clustering. You can also fine tune the performance of the FGCP to change how a cluster forms and shares information among cluster units and how the cluster responds to failures.

When configured onto your network an FGCP cluster appears to be a single FortiGate unit operating in NAT/Route or Transparent mode and configuration synchronization allows you to configure a cluster in the same way as a standalone FortiGate unit. If a failover occurs, the cluster recovers quickly and automatically and also sends administrator notifications so that the problem that caused the failure can be corrected and any failed equipment restored.

The FGCP is compatible with most network environments and most networking equipment. While initial configuration is relatively quick and easy, a large number of tools and configuration options are available to fine tune the cluster for most situations.

FortiGate Session Life Support Protocol (FGSP)



In a network that already includes load balancing (either with load balancers or routers) for traffic redundancy, two identical FortiGate units can be integrated into the load balancing configuration using the FortiGate Session Life Support Protocol (FGSP). The external load balancers or routers can distribute sessions among the FortiGate units and the FGSP performs session synchronization of IPv4 and IPv6 TCP, UDP, ICMP, expectation, and NAT sessions to keep the session tables of both FortiGate units synchronized.

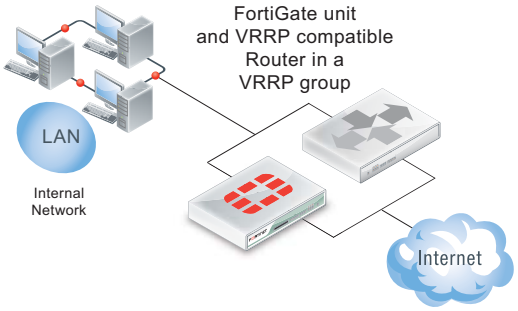
If one of the FortiGate units fails, session failover occurs and active sessions fail over to the unit that is still operating. This failover occurs without any loss of data. As well, the external load balancers or routers detect the failover and re-distribute all sessions to the unit that is still operating.

Load balancing and session failover is done by external routers or load balancers and not by the FGSP. The FortiGate units just perform session synchronization which allows session failover to occur without packet loss.

The FGSP also includes configuration synchronization, allowing you to make configuration changes once for both FortiGate units instead of requiring duplicate configuration changes on each unit. Settings that identify the FortiGate unit to the network, for example, interface IP addresses and BGP neighbor settings, are not synchronized so each FortiGate unit maintains its identity on the network. These settings must be configured separately for each FortiGate unit.

In previous versions of FortiOS the FGSP was called TCP session synchronization or standalone session synchronization. However, the FGSP has been expanded to include configuration synchronization and session synchronization of connectionless sessions, expectation sessions, and NAT sessions.

VRRP



FortiGate units can function as master or backup Virtual Router Redundancy Protocol (VRRP) routers and can be quickly and easily integrated into a network that has already deployed VRRP. A FortiGate unit can be integrated into a VRRP group with any third-party VRRP devices and VRRP can provide redundancy between multiple FortiGate units.

In a VRRP configuration, when a FortiGate unit operating as the master unit fails, a backup unit takes its place and continues processing network traffic. If the backup unit is a FortiGate unit, the network continues to benefit from FortiOS security features. If the backup unit is a router, after a failure traffic will continue to flow, but FortiOS security features will be unavailable until the FortiGate unit is back on line. You can include different FortiGate models in the same VRRP group.

FortiOS supports VRRP between two or more FortiGate units and between FortiGate units and third-party routers that support VRRP. Using VRRP you can assign VRRP routers as master or backup routers. The master router processes traffic and the backup routers monitor the master router and can begin forwarding traffic if the master fails. Similar to the FGCP you can configuration VRRP between multiple FortiGate units to provide redundancy. You can also create a VRRP group with a FortiGate units and any routers that support VRRP.

In a VRRP configuration that consists of one FortiGate unit and one router, normally the FortiGate unit would be the master and all traffic would be processed by the FortiGate unit. If the FortiGate unit fails, all traffic switches to the router. Network connectivity is maintained even though FortiGate security features will be unavailable until the FortiGate unit can is back on line.

Fortinet redundant UTM protocol (FRUP)

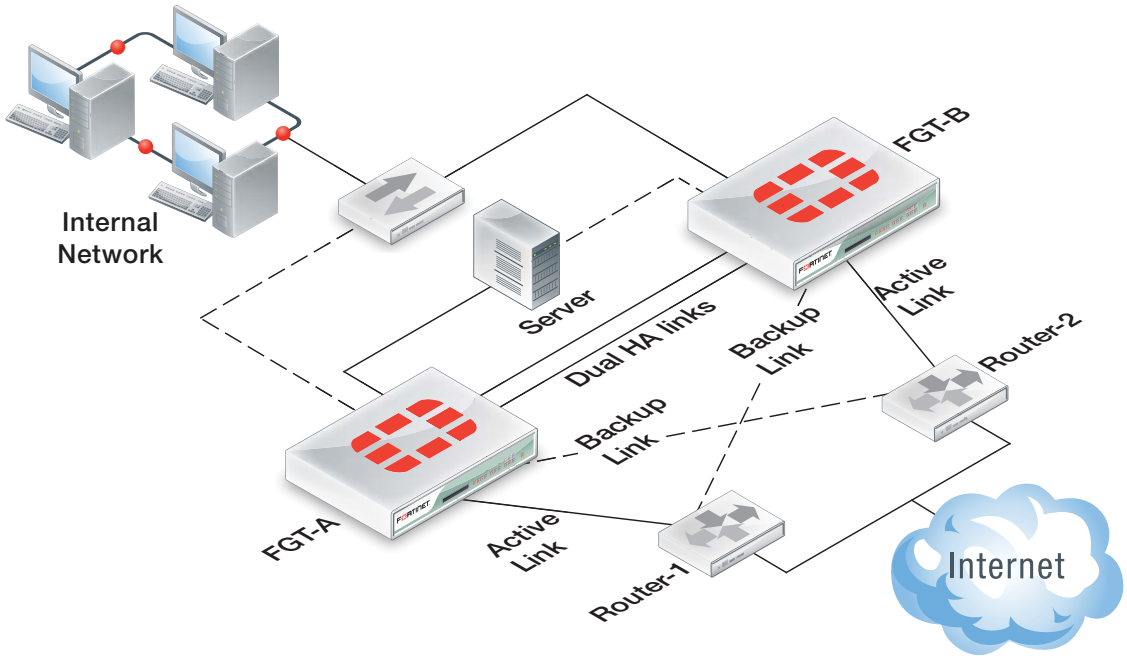
An extension to the FGCP combines switching HA and firewall HA into a single unified design. This feature is available on the FortiGate-100D and will be expanded to other models in future releases.

A FRUP setup consists of 2 (and only 2) identical FortiGate-100D units. The setup supports dual redundant HA links between the units for sharing session and configuration data.

FRUP requires redundant external routers where:

- One FortiGate unit has a primary connection to one of the routers and a backup connection to the other.
- The other FortiGate unit has the opposite configuration.

See “Configuring FRUP” on page 1380 for an example configuration.



An introduction to the FGCP

A FortiGate HA cluster consists of two to four FortiGate units configured for HA operation. Each FortiGate unit in a cluster is called a cluster unit. All cluster units must be the same FortiGate model with the same FortiOS firmware build installed. All cluster units must also have the same hardware configuration (for example, the same AMC modules installed in the same slots, the same number of hard disks and so on) and be running in the same operating mode (NAT/Route mode or Transparent mode).

You can create an FGCP cluster of up to four FortiGate units.

In addition the cluster units must be able to communicate with each other through their heartbeat interfaces. This heartbeat communication is required for the cluster to be created and to continue operating. Without it, the cluster acts like a collection of standalone FortiGate units.

On startup, after configuring the cluster units with the same HA configuration and connecting their heartbeat interfaces, the cluster units use the FortiGate Clustering Protocol (FGCP) to find other FortiGate units configured for HA operation and to negotiate to create a cluster. During cluster operation, the FGCP shares communication and synchronization information among the cluster units over the heartbeat interface link. This communication and synchronization is called the FGCP heartbeat or the HA heartbeat. Often, this is shortened to just heartbeat.

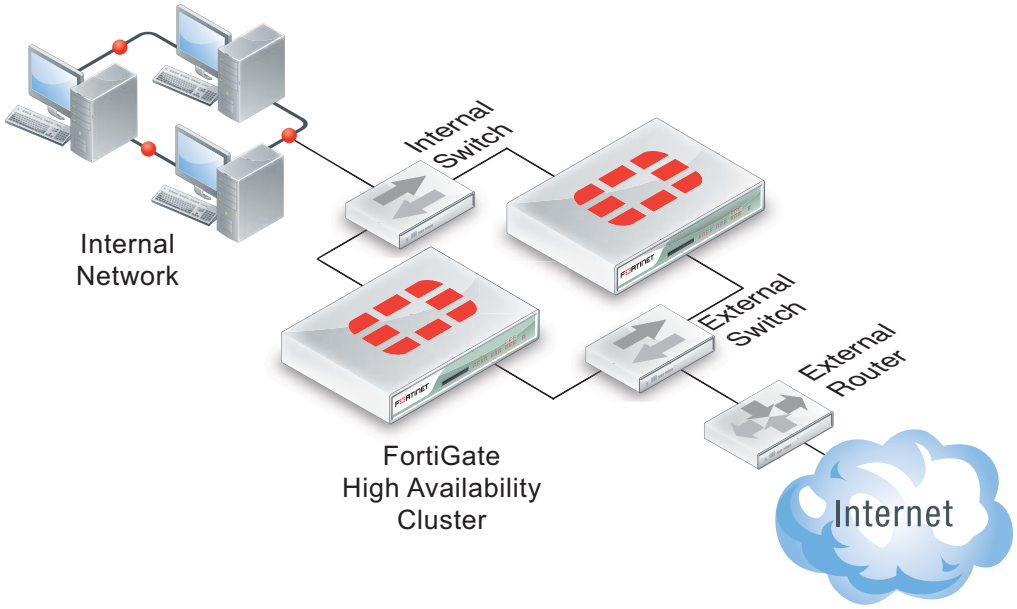
The cluster uses the FGCP to select the primary unit, and to provide device, link and session failover. The FGCP also manages the two HA modes; active-passive (failover HA) and active-active (load balancing HA).

This chapter describes.

About the FGCP

FortiGate HA is implemented by configuring two or more FortiGate units to operate as an HA cluster. To the network, the HA cluster appears to function as a single FortiGate unit, processing network traffic and providing normal security services such as firewalling, security services, Unified Threat Management (UTM) and VPN services.

Figure 186:HA cluster installed between an internal network and the Internet



Inside the cluster the individual FortiGate units are called cluster units. These cluster units share state and configuration information. If one cluster unit fails, the other units in the cluster automatically replace that unit, taking over the work that the failed unit was doing. After the failure, the cluster continues to process network traffic and provide normal FortiGate services with virtually no interruption.

Every FortiGate cluster contains one primary unit (also called the master unit) and one or more subordinate units (also called slave or backup units). The primary unit controls how the cluster operates. The role that the subordinate units play depends on the mode in which the cluster operates: (Active-Passive (AP) or Active-Active (AA) (see “Active-passive HA (failover protection)” on page 1128 and “Active-active HA (load balancing and failover protection)” on page 1129).

The ability of an HA cluster to continue providing firewall services after a failure is called failover. FGCP failover means that your network does not have to rely on one FortiGate unit to continue functioning. You can install additional units and form an HA cluster.

A second HA feature, called load balancing, can be used to increase performance. A cluster of FortiGate units can increase overall network performance by sharing the load of processing network traffic and providing security services. The cluster appears to your network to be a single device, adding increased performance without changing your network configuration.

Virtual clustering extends HA features to provide failover protection and load balancing for Virtual Domains (VDOMs). See “Virtual clusters” on page 1217.

FortiGate models that support redundant interfaces can be configured to support full mesh HA. Full mesh HA is a method of reducing the number of single points of failure on a network that includes an HA cluster. For details about full mesh HA, see “Full mesh HA” on page 1239.

FGCP failover protection

The FGCP provides IP/MAC takeover for failover protection by assigning virtual MAC addresses to the primary cluster unit and then sending gratuitous ARP packets from the primary unit interfaces to reprogram the network.

Failover times can be less than a second under optimal conditions. You can fine tune failover performance for your network by adjusting cluster status checking timers, routing table update timers, and wait timers.

An HA cluster fails over if the primary unit fails (a device failure) or experiences a link failure. The cluster can detect link failures for connections to the primary unit using port monitoring and for connections between downstream network components using remote IP monitoring. To compensate for a link failover, the cluster maintains active links to keep traffic flowing between high-priority networks. Port and remote IP monitoring can be fine tuned without disrupting cluster operation.

Session Failover

FGCP session failover maintains TCP, SIP and IPsec VPN sessions after a failure. You can also configure session failover to maintain UDP and ICMP sessions. Session failover does not failover multicast, or SSL VPN sessions. Session failover may not be required for all networks because many TCP/IP, UDP, and ICMP protocols can resume sessions on their own. Supporting session failover adds extra overhead to cluster operations and can be disabled to improve cluster performance if it is not required.

Load Balancing

Active-active HA load balances resource-intensive virus scanning, web filtering, intrusion protection, Application Control, email filtering and Data Leak Prevention operations among all cluster units to provide better performance than a standalone FortiGate unit. If network traffic consists of mainly TCP sessions, the FGCP can also load balance all TCP sessions to improve TCP performance in some network configurations. You can also load balance UDP sessions. You can use accelerated FortiGate interfaces to also accelerate HA load balancing and HA load balancing schedules can be adjusted to optimize performance for the traffic mix on your network. Weighted load balancing can be used to control the relative amount of sessions processed by each cluster unit.

Virtual Clustering

Virtual clustering is an extension of the FGCP for a cluster of 2 FortiGate units operating with multiple VDOMS enabled. Not only does virtual clustering provide failover protection for a multiple VDOM configuration, but a virtual cluster can load balance traffic between the cluster units. Load balancing with virtual clustering is quite efficient and load balances all traffic (not just UTM and TCP traffic). Its possible to fine tune virtual clustering load balancing in real time to actively optimize load sharing between the cluster units without affecting the smooth operation of the cluster.

Full Mesh HA

High availability improves the reliability of a network by replacing a single point of failure (a singe FortiGate unit) with a cluster that can maintain network traffic if one of the cluster units fails. However, in a normal cluster configuration, single points of failure remain. Full mesh HA removes these single points of failure by allowing you to connect redundant switches to each cluster interface. Full mesh HA is achieved by configuring 802.3ad aggregate or redundant interfaces on the FortiGate unit and connecting redundant switches to these interfaces. Configuration is a relatively simple extension of the normal aggregate/redundant interface and HA configurations.

Cluster Management

FortiOS HA provides a wide range of cluster management features:

- Automatic continuous configuration synchronization. You can get a cluster up and running almost as quickly as a standalone FortiGate unit by performing a few basic steps to configure HA settings and minimal network settings on each cluster unit. When the cluster is operating you can configure FortiGate features such as firewalling, content inspection, and VPN in the same way as for a standalone FortiGate unit. All configuration changes (even complex changes such as switching to multiple VDOM mode or from NAT/Route to Transparent mode) are synchronized among all cluster units.
- Firmware upgrades/downgrades. Upgrading or downgrading cluster firmware is similar to upgrading or downgrading standalone FortiGate firmware. The Firmware is uploaded once to the primary unit and the cluster automatically upgrades or downgrades all cluster units in one operation with minimal or no service interruption.
- Individual cluster unit management. In some cases you may want to manage individual cluster units. You can do so from cluster CLI by navigating to each cluster unit. You can also use the reserved management interface feature to give each cluster unit its own IP address and default route. You can use the reserved management interfaces and IP addresses to connect to the GUI and CLI of each cluster unit and configure an SNMP server to poll each cluster unit.
- Removing and adding cluster units. In one simple step any unit (even the primary unit) can be removed from a cluster and given a new IP address. The cluster keeps operating as it was; the transition happening without interrupting cluster operation. A new unit can also be added to an operating cluster without disrupting network traffic. All you have to do is connect the new unit and change its HA configuration to match the cluster's. The cluster automatically finds and adds the unit and synchronizes its configuration with the cluster.
- Debug and diagnose commands. An extensive range of debug and diagnose commands can be used to report on HA operation and find and fix problems.
- Logging and reporting. All cluster units can be configured to record all log messages. These message can be stored on the individual cluster units or sent to a FortiAnalyzer unit. You can view all cluster unit log messages by logging into any cluster unit.
- FortiManager support. FortiManager understands FortiOS HA and automatically recognizes when you add a FortiOS cluster to the FortiManager configuration.

Synchronizing the configuration (and settings that are not synchronized)

The FGCP uses a combination of incremental and periodic synchronization to make sure that the configuration of all cluster units is synchronized to that of the primary unit. This means that in most cases you only have to make a configuration change once to have it synchronized to all cluster units.

Some configuration settings are not synchronized to support some aspects of FortiGate operation. The following settings are not synchronized among cluster units:

- The FortiGate unit host name. Allows you to identify cluster units.
- HA override ("HA override" on page 1138).
- HA device priority ("Primary unit selection and device priority" on page 1136).
- Virtual cluster 1 and Virtual cluster 2 device priorities ("Virtual clustering and load balancing or VDOM partitioning" on page 1218)
- The HA priority (`ha-priority`) setting for a ping server or dead gateway detection configuration ("Remote link failover" on page 1325).
- The system interface settings of the FortiGate interface that becomes the HA reserved management interface ("Managing individual cluster units using a reserved management interface" on page 1254).
- The default route for the reserved management interface, set using the `ha-mgt-interface-gateway` option of the `config system ha` command ("Managing individual cluster units using a reserved management interface" on page 1254).
- The dynamic weighted load balancing thresholds and high and low watermarks ("Dynamically optimizing weighted load balancing according to how busy cluster units are" on page 1350).

Configuring FortiGate units for FGCP HA operation

Each FortiGate unit in the cluster must have the same HA configuration. Once the cluster is connected, you can configure it in the same way as you would configure a standalone FortiGate unit. The following procedures set the HA mode to active-passive and set the HA password to HA_pass.

Make sure your FortiGate interfaces are configured with static IP addresses. If any interface gets its address using DHCP you will not be able to configure HA.

To configure a FortiGate unit for HA operation - web-based manager

1. Power on the FortiGate unit to be configured.
2. Log into the web-based manager.
3. On the Dashboard *System Information* dashboard widget, beside *Host Name* select *Change*.
4. Enter a new Host Name for this FortiGate unit.

   Changing the host name makes it easier to identify individual cluster units when the cluster is operating.

5. Go to *System* > *Config* > *HA* and change the following settings:

Mode	Active-Passive
Group Name	Example_cluster
Password	HA_pass The password must be the same for all FortiGate units in the cluster.

   You can accept the default configuration for the remaining HA options and change them later, once the cluster is operating.

6. Select *OK*.

   The FortiGate unit negotiates to establish an HA cluster. When you select *OK* you may temporarily lose connectivity with the FortiGate unit as the HA cluster negotiates and the FGCP changes the MAC address of the FortiGate unit interfaces (see "Cluster virtual MAC addresses" on page 1300). To be able to reconnect sooner, you can update the ARP table of your management PC by deleting the ARP table entry for the FortiGate unit (or just deleting all ARP table entries). You may be able to delete the ARP table of your management PC from a command prompt using a command similar to `arp -d`.

7. Power off the FortiGate unit.

8. Repeat this procedure for all of the FortiGate units in the cluster.

   Once all of the units are configured, continue with "Connecting a FortiGate HA cluster" on page 1127.

To configure a FortiGate unit for HA operation - CLI

1. Power on the FortiGate unit to be configured.
2. Log into the CLI.
3. Enter the following command to change the FortiGate unit host name.

```
config system global
  set hostname Example1_host
end
```

   Changing the host name makes it easier to identify individual cluster units when the cluster is operating.
