# Introduction

This guide details the steps required to configure a Layer 7 load balance server in FortiADC. It covers the common concept for configuration of load balance profile, load balance method and load balance pool. For other optional features information, please also refer to the relevant deployment guide.

# Server load balance

# **Server Load Balance overview**

FortiADC provides two options for configuring virtual servers—Basic Mode and Advanced Mode. In this document we will provide a step by step example for you to deploy load balance based on Advanced mode.

## Example

1. Configure a load-balance real server.

Go to Server Load Balance > Real Server Pool, and click the Real Server tab.

🚍 Real Server	×
Name	
Required config name. No spaces.

Save Cancel	

2. Configure a load-balance pool

Go to Server Load Balance > Real Server Pool, click the Real Server Pool tab.

- Set name, address type and Health Check as desired.
- If your real web server is using an http server, leave Real Server SSL Profile as NONE. If your real web server uses an https server, set Real Server SSL Profile as desired.

For all detailed setting please check CLI reference config load-balance pool.

For Pool member weight, please see below:

PoolAssigns relative preference among members—higher values are preferred and are assignedmemberconnections more frequently. The default is 1. The valid range is 1 to 256.weightAll load balancing methods consider weight. Servers are dispatched requests proportional to their<br/>weight, relative to the sum of all weights.

The following example shows the effect of weight on Round Robin: RealServer1-weight: 1, RealServer2-weight: 2, RealServer3-weight: 3; If there are in total 60 connections coming to thevirtual server, there should be 10 connections to RealServer1, 20 connections to RealServer2, 30 connections to RealServer3.

For other methods, weight functions as a tie-breaker. For example, with the Least Connection algorithm, requests are sent to the server with the least connections. If the number of connections is equal, the request is sent to the server with the greater weight.

### Example

RealServer A, Weight 1, 1 connection ReaServer B, Weight 2, 1 connection The next request is sent to RealServer B.

3. Config load-balance Method. The system includes predefined configuration objects for all supported load balancing methods, and there is no need to create additional configuration objects. You may choose to do so, however, for various reasons.

### Go to Server Load Balance > application resources, click the LB Method tab.

For detailed settings please check the CLI reference config load-balance method.

4. Configure a load-balance Profile.

A profile is a configuration object that defines how you want the FortiADC virtual server to handle traffic for specific protocols.

The system includes predefined configuration objects for all supported load balancing profile, and there is no need to create additional configuration objects. You may choose to do so, however, for various reasons.

Go to Server Load Balance > application resources, click the Application Profile tab.
