FortiOS 7.6.2 Administration Guide
01-762-1034716-20250325

TABLE OF CONTENTS

Change Log **28**
Getting started **30**
Summary of steps 31
Setting up FortiGate for management access 32
Completing the FortiGate Setup wizard 33
Configuring basic settings 33
Registering FortiGate 38
Configuring a firewall policy 39
Backing up the configuration 39
Troubleshooting your installation 40
Using the GUI 42
Connecting using a web browser 42
Menus 42
Tables 43
Entering values 48
GUI-based global search 50
Loading artifacts from a CDN 51
Accessing additional support resources 52
Command palette 52
Recovering missing graphical components 57
Using the CLI 58
Connecting to the CLI 59
CLI basics 62
Command syntax 68
Subcommands 70
Permissions 73
Configuration and management 73
FortiExplorer Go 74
Migrating a configuration with FortiConverter 74
Accessing Fortinet Developer Network 80
Terraform: FortiOS as a provider 83
Product registration with FortiCare 88
FortiCare and FortiGate Cloud login 88
FortiCare Register button 90
Transfer a device to another FortiCloud account 92
Deregistering a FortiGate 93
FortiGate models 94
Differences between models 94
Low encryption models 95
LEDs 95
Proxy-related features not supported on FortiGate 2 GB RAM models 98
FGR-70F/FGR-70F-3G4G GPIO/DIO module 99
Dashboards and Monitors **102**
Using dashboards 102
Using widgets 104

Widgets 106
Viewing device dashboards in the Security Fabric 108
Creating a fabric system and license dashboard 109
Example 109
Dashboards 110
Resetting the default dashboard template 111
Status dashboard 111
Security dashboard 115
Network dashboard 116
Assets & Identities 126
WiFi dashboard 135
Monitors 141
Non-FortiView monitors 141
FortiView monitors 141
FortiView monitors 142
Adding FortiView monitors 143
Using the FortiView interface 146
Enabling FortiView from devices 149
FortiView sources 152
FortiView Sessions 153
FortiView Top Source and Top Destination Firewall Objects monitors 155
Viewing top websites and sources by category 156
Cloud application view 159
Application risk levels 168
Network 170
Interfaces 170
Interface settings 173
Physical interface 203
VLAN 204
Aggregation and redundancy 219
Loopback interface 229
Software switch 230
Hardware switch 232
Zone 238
Virtual wire pair 240
Enhanced MAC VLAN 247
VXLAN 250
DNS 289
Important DNS CLI commands 289
DNS domain list 294
FortiGate DNS server 296
DDNS 313
DNS latency information 317
DNS over TLS and HTTPS 319
Transparent conditional DNS forwarder 323
Interfaces in non-management VDOMs as the source IP address of the DNS conditional forwarding server 328
DNS session helpers 330

DNS troubleshooting 331
Explicit and transparent proxies 333
Explicit web proxy 334
FTP proxy 338
Transparent proxy 342
Proxy policy addresses 344
Proxy policy security profiles 351
Explicit proxy authentication 356
Transparent web proxy forwarding 362
Transparent web proxy forwarding over IPv6 366
Upstream proxy authentication in transparent proxy mode 369
Multiple dynamic header count 371
Restricted SaaS access 374
Explicit proxy and FortiGate Cloud Sandbox 382
Proxy chaining 385
WAN optimization SSL proxy chaining 390
Agentless NTLM authentication for web proxy 398
Multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers 402
Learn client IP addresses 403
Explicit proxy authentication over HTTPS 404
mTLS client certificate authentication 406
CORS protocol in explicit web proxy when using session-based, cookie-enabled, and captive portal-enabled SAML authentication 412
Display CORS content in an explicit proxy environment 415
HTTP connection coalescing and concurrent multiplexing for explicit proxy 417
Secure explicit proxy 419
Secure explicit proxy with client certificates 422
Explicit proxy logging 424
Configuring fast fallback for explicit proxy 434
Forward HTTPS requests to a web server without the need for an HTTP CONNECT message 438
Specifying outgoing interface and VRF for a web proxy forward server or isolator server 440
Isolator servers in proxy policies 442
DHCP servers and relays 445
Default DHCP server for entry-level FortiGates 446
Basic configuration 446
DHCP options 450
DHCP addressing mode on an interface 458
VCI pattern matching for DHCP assignment 461
DHCP shared subnet 463
Multiple DHCP relay servers 465
DHCP smart relay on interfaces with a secondary IP 466
FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses 469
Static routing 469
Routing concepts 470
Policy routes 484

Equal cost multi-path 487
Dual internet connections 492
Dynamic routing 497
RIP 498
OSPF 520
BGP 538
BFD 597
Routing objects 607
Multicast 618
Multicast routing and PIM support 618
Configuring multicast forwarding 620
Using IPS inspection for multicast UDP traffic 627
Including denied multicast sessions in the session table 630
FortiExtender 631
WAN extension mode 631
LAN extension mode 632
Maximum FortiExtender devices supported per mode 632
Adding a FortiExtender 632
LTE modems 634
Automatic LTE connection establishment 635
Direct IP support for LTE/4G 635
Cellular interface support for IPv6 638
Active SIM card switching 641
Airplane mode and LTE/BLE 649
Upgrade LTE modem firmware directly from FortiGuard 651
LLDP reception 653
Virtual routing and forwarding 656
Implementing VRF 656
VRF routing support 657
Route leaking between VRFs with BGP 667
Route leaking between multiple VRFs 670
VRF with IPv6 681
IBGP and EBGP support in VRF 685
Support cross-VRF local-in and local-out traffic for local services 687
Support specific VRF ID for local-out traffic 690
NetFlow 697
Verification and troubleshooting 699
NetFlow templates 700
NetFlow on FortiExtender and tunnel interfaces 712
Allow multiple NetFlow collectors 716
Netflow sampling New 722
Filter NetFlow sampling New 724
sFlow 729
Configuring sFlow 729
Link monitor 735
Link monitor with route updates 736
Enable or disable updating policy routes when link health monitor fails 737
Add weight setting on each link health monitor server 740

SLA link monitoring for dynamic IPsec and SSL VPN tunnels 743
IPv6 746
IPv6 overview 747
IPv6 quick start 747
Neighbor discovery proxy 751
IPv6 address assignment 753
NAT66, NAT46, NAT64, and DNS64 768
DHCPv6 relay 781
IPv6 tunneling 782
IPv6 Simple Network Management Protocol 794
Dynamic routing in IPv6 797
IPv6 configuration examples 799
FortiGate LAN extension 854
Example CLI configuration 854
Example GUI configuration 861
DHCP client mode for inter-VDOM links 866
FortiGate secure edge to FortiSASE 867
WiFi access point with internet connectivity 871
SCTP packets with zero checksum on the NP7 platform 879
Industrial Connectivity 880
Sample configuration to convert IEC 60870-5-101 serial to IEC 60870-5-104 TCP/IP transport 882
Sample configuration to convert Modbus serial to Modbus TCP 883
Diagnostics 884
Using the packet capture tool 884
Using the debug flow tool 889
SD-WAN 893
SD-WAN overview 893
SD-WAN components and design principles 893
SD-WAN designs and architectures 896
SD-WAN quick start 897
Configuring the SD-WAN interface 898
Adding a static route 899
Selecting the implicit SD-WAN algorithm 900
Configuring firewall policies for SD-WAN 900
Link monitoring and failover 901
Results 902
Configuring SD-WAN in the CLI 905
SD-WAN members and zones 908
Topology 908
Configuring SD-WAN member interfaces 909
Configuring SD-WAN zones 911
Using SD-WAN zones 912
Specify an SD-WAN zone in static routes and SD-WAN rules 914
Defining a preferred source IP for local-out egress interfaces on SD-WAN members 919
Specify SD-WAN zones in some policies 921
SD-WAN Setup wizard 924

Performance SLA 931
Performance SLA overview 932
Link health monitor 937
Monitoring performance SLA 940
Passive WAN health measurement 944
Passive monitoring of TCP metrics 950
Passive health-check measurement by internet service and application 954
Mean opinion score calculation and logging in performance SLA health checks 959
Embedded SD-WAN SLA information in ICMP probes 962
SD-WAN application monitor using FortiMonitor 1002
Classifying SLA probes for traffic prioritization 1007
FortiGuard SLA database for SD-WAN performance SLA 1012
SD-WAN rules 1017
SD-WAN rules overview 1018
Implicit rule 1026
Automatic strategy 1030
Manual strategy 1031
Best quality strategy 1035
Lowest cost (SLA) strategy 1038
Load balancing strategy 1045
SD-WAN traffic shaping and QoS 1045
SDN dynamic connector addresses in SD-WAN rules 1051
Application steering using SD-WAN rules 1053
DSCP tag-based traffic steering in SD-WAN 1066
ECMP support for the longest match in SD-WAN rule matching 1073
Override quality comparisons in SD-WAN longest match rule matching 1076
Internet service and application control steering 1079
Use maximize bandwidth to load balance traffic between ADVPN shortcuts 1089
Use SD-WAN rules to steer multicast traffic 1096
Use SD-WAN rules for WAN link selection with load balancing 1117
Advanced routing 1125
Local out traffic 1125
Using BGP tags with SD-WAN rules 1132
BGP multiple path support 1135
Controlling traffic with BGP route mapping and service rules 1138
Applying BGP route-map to multiple BGP neighbors 1146
Using multiple members per SD-WAN neighbor configuration 1152
VPN overlay 1158
ADVPN 2.0 edge discovery and path management 1159
ADVPN and shortcut paths 1189
Active dynamic BGP neighbor triggered by ADVPN shortcut 1203
SD-WAN monitor on ADVPN shortcuts 1214
Hold down time to support SD-WAN service strategies 1215
Adaptive Forward Error Correction 1217
Dual VPN tunnel wizard 1221
Duplicate packets on other zone members 1222
Duplicate packets based on SD-WAN rules 1225
Interface based QoS on individual child tunnels based on speed test results 1227
SD-WAN in large scale deployments 1230

Keeping sessions in established ADVPN shortcuts while they remain in SLA 1242
SD-WAN multi-PoP multi-hub large scale design and failover 1249
Using a single IKE elector in ADVPN to match all SD-WAN control plane traffic 1268
SD-WAN Overlay-as-a-Service 1276
Advanced configuration 1278
SD-WAN with FGCP HA 1278
Configuring SD-WAN in an HA cluster using virtual VLAN switch 1285
Configuring SD-WAN in an HA cluster using internal hardware switches 1289
SD-WAN configuration portability 1293
SD-WAN segmentation over a single overlay 1299
SD-WAN segmentation over a single overlay using IPv6 1315
Matching BGP extended community route targets in route maps 1323
Copying the DSCP value from the session original direction to its reply direction 1328
SD-WAN cloud on-ramp 1332
Configuring the VPN overlay between the HQ FortiGate and cloud FortiGate-VM 1333
Configuring the VPN overlay between the HQ FortiGate and AWS native VPN gateway 1337
Configuring the VIP to access the remote servers 1341
Configuring the SD-WAN to steer traffic between the overlays 1344
Verifying the traffic 1348
SD-WAN Network Monitor service 1355
CLI speed test 1356
GUI speed test 1357
Scheduled interface speed test 1358
Hub and spoke speed tests 1359
Running speed tests from the hub to the spokes in dial-up IPsec tunnels 1363
Running speed tests from spokes to the hub in dial-up IPsec tunnels 1370
Speed test usage 1378
Speed test examples 1380
Troubleshooting SD-WAN 1386
Tracking SD-WAN sessions 1386
Understanding SD-WAN related logs 1387
SD-WAN related diagnose commands 1390
Using SNMP to monitor health check 1395
Zero Trust Network Access 1400
Zero Trust Network Access introduction 1400
ZTNA application gateway and IP/MAC based access control 1400
ZTNA telemetry, tags, and policy enforcement 1401
Application gateway 1401
Basic ZTNA configuration components 1402
Basic ZTNA configuration 1403
Establish device identity and trust context with FortiClient EMS 1415
SSL certificate based authentication 1424
Full versus simple ZTNA policies 1426
Types of security posture tags 1432
ZTNA advanced configurations 1437

Access control of unmanageable and unknown devices 1437
HTTP2 connection coalescing and concurrent multiplexing for ZTNA 1443
Fabric integration with FortiGSLB 1446
ZTNA agentless web-based application access 1450
ZTNA configuration examples 1460
ZTNA HTTPS access proxy example 1461
ZTNA HTTPS access proxy with basic authentication example 1472
ZTNA TCP forwarding access proxy example 1480
ZTNA TCP forwarding access proxy with FQDN example 1487
ZTNA SSH access proxy example 1490
ZTNA application gateway with SAML authentication example 1497
ZTNA application gateway with SAML and MFA using FortiAuthenticator example 1502
Secure LDAP connection from FortiAuthenticator with zero trust tunnel example 1519
ZTNA IP MAC based access control example 1520
ZTNA IPv6 examples 1528
ZTNA Zero Trust application gateway example 1534
ZTNA SaaS application access control with Inline CASB 1535
ZTNA application gateway with KDC to access shared drives 1542
Custom replacement message for ZTNA virtual hosts 1548
ZTNA troubleshooting and debugging commands 1551
Troubleshooting usage and output 1552
ZTNA troubleshooting scenarios 1556
ZTNA access control 1557
IP/MAC based access control 1558
Other useful CLI commands 1561
Policy and Objects 1562
Policies 1562
Firewall policy 1563
NGFW policy 1586
Local-in policy 1605
DoS policy 1621
Access control lists 1629
Interface policies 1630
Source NAT 1631
Destination NAT 1658
Examples and policy actions 1682
Address objects 1744
Address Types 1745
Address Group 1747
Subnet 1747
Dynamic policy — Fabric devices 1748
IP range 1751
FQDN addresses 1751
Using wildcard FQDN addresses in firewall policies 1752
Geography based addresses 1755
IPv6 geography-based addresses 1758

Wildcard addressing 1760
Interface subnet 1761
Address group 1763
Address folders 1763
Allow empty address groups 1765
Address group exclusions 1766
FSSO dynamic address subtype 1767
ClearPass integration for dynamic address objects 1771
FortiNAC tag dynamic address 1774
FortiVoice tag dynamic address 1777
MAC address-based policies 1781
ISDB well-known MAC address list 1783
IPv6 MAC addresses and usage in firewall policies 1785
RSSO dynamic address subtype 1787
ISDB record for SOCaaS 1789
Protocol options 1792
Log oversized files 1792
RPC over HTTP 1792
Protocol port mapping 1792
Common options 1793
Web options 1794
Email options 1794
Stripping the X-Forwarded-For value in the HTTP header 1794
Traffic shaping 1798
Configuration methods 1798
Traffic shaping policy 1800
Traffic shaping policies 1800
Traffic shaping profiles 1810
Traffic shapers 1821
Global traffic prioritization 1838
DSCP matching and DSCP marking 1841
Examples 1849
Internet Services 1867
Using Internet Service in a policy 1868
Using custom Internet Service in policy 1872
Using extension Internet Service in policy 1874
Global IP address information database 1877
IP reputation filtering 1879
Internet service groups in policies 1880
Allow creation of ISDB objects with regional information 1887
Internet service customization 1889
Look up IP address information from the Internet Service Database page 1890
Internet Service Database on-demand mode 1891
Enabling the ISDB cache in the FortiOS kernel 1894
Apply FQDN address groups within the ISDB 1895
Security Profiles 1899
Inspection modes 1899
Flow mode inspection (default mode) 1900

Proxy mode inspection 1900
Inspection mode feature comparison 1901
Antivirus 1905
Antivirus introduction 1905
Advanced configurations 1932
Configuration examples 1955
Web filter 1965
Web filter introduction 1966
Advanced CLI configuration 1996
Configuration examples 2016
Video filter 2024
Configuring a video filter profile 2024
YouTube API key 2025
Filtering based on FortiGuard categories 2026
Filtering based on YouTube channel 2030
Filtering based on title 2032
Filtering based on description 2034
Configuring a video filter keyword list 2035
Replacement messages displayed in blocked videos 2037
DNS filter 2038
DNS filter behavior in proxy mode 2039
FortiGuard DNS rating service 2040
Configuring a DNS filter profile 2040
FortiGuard category-based DNS domain filtering 2045
Botnet C&C domain blocking 2049
DNS safe search 2052
Local domain filter 2055
DNS translation 2059
Applying DNS filter to FortiGate DNS server 2064
DNS inspection with DoT and DoH 2065
DNS over QUIC and DNS over HTTP3 for transparent and local-in DNS modes 2069
Troubleshooting for DNS filter 2074
Application control 2077
Configuring an application sensor 2078
Application matching signature priority 2079
Basic category filters and overrides 2080
Excluding signatures in application control profiles 2084
Port enforcement check 2086
Protocol enforcement 2087
SSL-based application detection over decrypted traffic in a sandwich topology 2089
Matching multiple parameters on application control signatures 2090
Application signature dissector for DNP3 2093
Domain fronting protection 2093
Inline CASB 2095
Inline CASB examples 2096
Intrusion prevention 2113
Signature-based defense 2116

Configuring an IPS sensor 2119
IPS configuration options 2122
SCTP filtering capabilities 2128
Diameter protocol inspection 2130
IPS signature filter options 2134
IPS with botnet C&C IP blocking 2138
IPS signatures for the operational technology security service 2142
IPS sensor for IEC 61850 MMS protocol 2144
IPS Modbus TCP decoder 2145
File filter 2147
Configuring a file filter profile 2149
Supported file types 2153
Email filter 2155
Protocol comparison between email filter inspection modes 2156
Configuring an email filter profile 2156
Local-based filters 2157
FortiGuard-based filters 2165
Third-party-based filters 2167
Filtering order 2168
Protocols and actions 2170
Configuring webmail filtering 2171
Spam email header 2172
VoIP solutions 2173
General use cases 2173
NAT46 and NAT64 for SIP ALG 2178
SIP message inspection and filtering 2186
SIP ALG and SIP session helper 2192
SIP pinholes 2198
SIP over TLS 2200
Voice VLAN auto-assignment 2201
Scanning MSRP traffic 2203
ICAP 2207
ICAP configuration example 2208
ICAP response filtering 2211
Secure ICAP clients 2213
ICAP scanning with SCP and FTP 2214
Domain name in XFF with ICAP 2217
Selective forwarding to ICAP server 2222
Web application firewall 2224
Protecting a server running web applications 2225
Data loss prevention 2227
Protocol comparison between DLP inspection modes 2228
Archiving 2228
Logging and blocking files by file name 2228
DLP techniques 2229
Basic DLP settings 2230
Advanced DLP configurations 2235
DLP fingerprinting 2238

FortiGuard DLP service 2243
Sensitivity labels 2247
Exact data matching 2251
DLP examples 2258
Virtual patching 2288
OT and IoT device detection 2289
Virtual patching profiles 2289
Virtual patching signatures 2291
License and entitlement information 2292
OT virtual patching basic examples 2294
OT and IoT virtual patching on NAC policies 2300
SSL & SSH Inspection 2303
Configuring an SSL/SSH inspection profile 2304
Certificate inspection 2307
Deep inspection 2310
Protecting an SSL server 2313
Handling SSL offloaded traffic from an external decryption device 2314
SSH traffic file scanning 2317
Redirect to WAD after handshake completion 2319
HTTP/2 support in proxy mode SSL inspection 2320
Define multiple certificates in an SSL profile in replace mode 2321
Disabling the FortiGuard IP address rating 2323
Block or allow ECH TLS connections 2324
Custom signatures 2334
Configuring custom signatures 2334
Blocking applications with custom signatures 2335
Filters for application control groups 2338
Application groups in traffic shaping policies 2341
Overrides 2345
Web rating override 2345
Using local and remote categories 2354
Web profile override 2356
IP ban 2360
IP ban using the CLI 2361
IP ban using security profiles 2362
Configuring the persistency for a banned IP list 2364
Profile groups 2366
IPsec VPN 2369
General IPsec VPN configuration 2369
Network topologies 2370
Phase 1 configuration 2370
Phase 2 configuration 2396
VPN security policies 2400
Blocking unwanted IKE negotiations and ESP packets with a local-in policy 2403
Configurable IKE port 2405
IPsec VPN IP address assignments 2408
Renaming IPsec tunnels 2411
Site-to-site VPN 2414

FortiGate-to-FortiGate 2414
FortiGate-to-third-party 2466
Remote access 2492
FortiGate as dialup client 2492
FortiClient as dialup client 2502
Add FortiToken multi-factor authentication 2509
Add LDAP user authentication 2510
iOS device as dialup client 2511
IKE Mode Config clients 2518
IPsec VPN with external DHCP service 2524
L2TP over IPsec 2527
Tunneled Internet browsing 2531
Dialup IPsec VPN with certificate authentication 2538
SAML-based authentication for FortiClient remote access dialup IPsec VPN clients 2547
Enhancing IPsec security using EMS SN verification 2567
IPsec split DNS 2568
Dialup IPsec VPN using custom TCP port 2568
IPsec DNS suffix 2577
Aggregate and redundant VPN 2578
Manual redundant VPN configuration 2579
OSPF with IPsec VPN for network redundancy 2582
IPsec VPN in an HA environment 2589
Packet distribution and redundancy for aggregate IPsec tunnels 2595
Packet distribution for aggregate dial-up IPsec tunnels using location ID 2606
Packet distribution for aggregate static IPsec tunnels in SD-WAN 2611
Packet distribution for aggregate IPsec tunnels using weighted round robin 2616
Redundant hub and spoke VPN 2618
ADVPN 2623
IPsec VPN wizard hub-and-spoke ADVPN support 2624
ADVPN with BGP as the routing protocol 2628
ADVPN with OSPF as the routing protocol 2638
ADVPN with RIP as the routing protocol 2648
UDP hole punching for spokes behind NAT 2658
Fabric Overlay Orchestrator 2662
Prerequisites 2662
Network topology 2663
Using the Fabric Overlay Orchestrator 2663
SPA easy configuration key for FortiSASE 2681
Other VPN topics 2683
VPN and ASIC offload 2684
Encryption algorithms 2694
Fragmenting IP packets before IPsec encapsulation 2702
Configure DSCP for IPsec tunnels 2703
Defining gateway IP addresses in IPsec with mode-config and DHCP 2705
FQDN support for remote gateways 2707
Windows IKEv2 native VPN with user certificate 2709
IPsec IKE load balancing based on FortiSASE account information 2723
IPsec SA key retrieval from a KMS server using KMIP 2725

IPsec key retrieval with a QKD system using the ETSI standardized API ... 2737
Securely exchange serial numbers between FortiGates connected with IPsec VPN ... 2742
Multiple interface monitoring for IPsec ... 2746
Encapsulate ESP packets within TCP headers ... 2753
Cross-validation for IPsec VPN ... 2760
Resuming sessions for IPsec tunnel IKE version 2 ... 2762
VPN IPsec troubleshooting ... 2766
Understanding VPN related logs ... 2766
IPsec related diagnose commands ... 2768
SSL VPN ... 2775
SSL VPN to dial-up VPN migration ... 2776
SSL VPN best practices ... 2776
Tunnel mode ... 2777
Web mode ... 2778
Security best practices ... 2779
SSL VPN security best practices ... 2779
SSL VPN settings ... 2780
Authentication ... 2782
Authorization ... 2783
SSL VPN quick start ... 2786
SSL VPN split tunnel for remote user ... 2786
Connecting from FortiClient VPN client ... 2790
Set up FortiToken multi-factor authentication ... 2792
Connecting from FortiClient with FortiToken ... 2793
SSL VPN tunnel mode ... 2794
SSL VPN full tunnel for remote user ... 2794
SSL VPN tunnel mode host check ... 2798
SSL VPN split DNS ... 2802
Split tunneling settings ... 2805
Augmenting VPN security with ZTNA tags ... 2806
Enhancing VPN security using EMS SN verification ... 2819
SSL VPN web mode ... 2819
Web portal configurations ... 2821
Quick Connection tool ... 2824
SSL VPN bookmarks ... 2826

Change Log

Date	Change Description
2025-01-28	Initial release.
2025-01-31	Added Enhancing SIP reliability in 464XLAT environments on page 848, Selective forwarding to ICAP server on page 2222, and ZTNA agentless web-based application access on page 1450.
2025-02-04	Updated IPS signature filter options on page 2134 and FortiGate VM unique certificate on page 3654.
2025-02-05	Updated print tablesize on page 4356.
2025-02-13	Added Hairpin NAT on page 1694, IPsec DNS suffix on page 2577, and FortiGate StateRamp support on page 3591. Updated DNS translation on page 2059, FortiClient as dialup client on page 2502, IKE Mode Config clients on page 2518, and Asset Identity Center page on page 3792.
2025-02-21	Updated Mirroring SSL traffic in policies on page 1698 and Using FortiSandbox inline scanning with antivirus on page 1934.
2025-02-27	Added Spam email header on page 2172 and Single FortiGuard license for FortiGate A-P HA cluster on page 3359. Updated Configuring an external feed on page 4072.
2025-02-28	Added FortiGuard error logs on page 4354.
2025-03-04	Added Disable all cloud communication on page 3594 and Variables in actions on page 3917.
2025-03-06	Added Isolator servers in proxy policies on page 442. Updated Explicit web proxy on page 334 and Transparent proxy on page 342.
2025-03-10	Updated SAML-based authentication for FortiClient remote access dialup IPsec VPN clients on page 2547 and Licensing in air-gap environments on page 3588.
2025-03-19	Updated QinQ 802.1Q in 802.1ad on page 216, QinQ 802.1Q in 802.1Q on page 217, Using wildcard FQDN addresses in firewall policies on page 1752 and Block access to LLM applications using keywords and FQDN on page 2273.
2025-03-25	Added Configuring SD-WAN in an HA cluster using virtual VLAN switch on page 1285. Updated Types of security posture tags on page 1432.
2025-03-27	Updated ARP table on page 4346.
2025-04-01	Updated FortiExplorer Go on page 74, Certificates on page 3596, and Single FortiGuard license for FortiGate A-P HA cluster on page 3359.
2025-04-10	Updated UTM inspection on asymmetric traffic in FGSP on page 3458.

Date	Change Description
2025-04-16	Updated Trusted platform module support on page 3289.
2025-05-12	Added Apply FQDN address groups within the ISDB on page 1895. Updated Using Internet Service in a policy on page 1868.

Getting started

FortiOS is the operating system that runs on Fortinet's FortiGate Next-Generation Firewall (NGFW). It supports different platforms, including:

- Physical appliances
- Hypervisors
- Cloud computing platforms

FortiOS delivers security as a hybrid mesh firewall that spans a meshed topology of on-prem and cloud environments. With FortiGuard's AI-powered security services, FortiOS provides protection across the attack surface with IPS, advanced malware protection, web security, inline malware prevention, data loss prevention, and more.

In addition, FortiOS is central to the SD-WAN solution by providing SD-WAN functionality and intelligence in a single FortiGate, a mesh of FortiGates, or integrated into a SASE environment. It is also central to the Zero Trust Network Access (ZTNA) solution by making policy decisions and applying policy enforcement based on security posture input.

Use the following resources to get started with FortiOS:

Task	Documentation links
Follow the steps to set up a new FortiGate	See Summary of steps on page 31. If you are migrating a configuration from another vendor to FortiGate, see the Migration section of the Best Practices guide or use the FortiConverter service.
Learn about best practices for FortiOS	Review Basic configuration in the Best Practices guide.
Learn about new FortiOS features	See FortiOS New Features and FortiOS Release Notes > New Features section.
Learn about standard practices for deploying a solution or an architecture	Go to Best Practices | 4-D Resources and review the document categories.
Review information about FortiOS releases, including resolved and known issues	See FortiOS Release Notes.

For the latest information about FortiOS 7.6, see the latest patch version of the Administration Guide.

Summary of steps

These steps summarize how to get your FortiGate up and running by using the GUI. For information about the Command Line Interface (CLI), see Using the CLI on page 58.

1. Set up your FortiGate for initial management access with the GUI. See Setting up FortiGate for management access on page 32.

For more information	Go to
Physical appliances, such as FortiGate	Go to FortiGate/FortiOS Hardware Guides to view QuickStart Guides for all supported FortiGate models.
Hypervisors, such as FortiGate-VM on ESXi, KVM, Hyper-V, and so on.	Go to FortiGate Public Cloud or FortiGate Private Cloud and follow the deployment section of the administration guide for your hypervisor, for example, Microsoft Hyper-V Administration Guide > Deployment.

   Depending on the topology and FortiGate model, internet access may not yet be configured for the FortiGate. If no internet access, you cannot yet register the FortiGate with Fortinet until later in the setup.
2. In the GUI, follow the *FortiGate Setup* wizard to change the hostname, change the password, and specify a default layout for the FortiOS dashboards. See Completing the FortiGate Setup wizard on page 33.
3. Complete the basic configuration steps for FortiOS. After this step, all FortiGate models should have internet access. See Configuring basic settings on page 33.
4. Register FortiGate with Fortinet by using your FortiCare/FortiCloud account with Fortinet Technical Support (https://support.fortinet.com). See Registering FortiGate on page 38.
5. Configure a policy for the FortiGate to give clients behind FortiGate access to the internet. See Configuring a firewall policy on page 39.
6. Back up the configuration. See Backing up the configuration on page 39.
7. If necessary, troubleshoot the installation. See Troubleshooting your installation on page 40.

After completing the Getting started section, next steps can include:

- Getting familiar with the FortiOS GUI and CLI:
  - See Using the GUI on page 42.
  - See Using the CLI on page 58.
- Configuring FortiOS features. The following table lists a few of the features available with FortiOS. Many additional features are available:

For	Go to
Security profiles	See antivirus, IPS, web filter, and application control.
VPN	See IPsec VPN on page 2369.
Fortinet Security Fabric	See Fortinet Security Fabric on page 3697.
User & Authentication	See User & Authentication on page 2990.

Setting up FortiGate for management access

After you receive your FortiGate, open the box, connect the cables for management and internet access, and use a management computer to access the FortiOS GUI.

For information about setting up FortiGate on hypervisors, such as FortiGate-VM on ESXi, KVM, Hyper-V, and so on, go to FortiGate Public Cloud or FortiGate Private Cloud and follow the deployment section of the administration guide for your hypervisor and cloud computing platform, for example, Microsoft Hyper-V Administration Guide > Deployment.

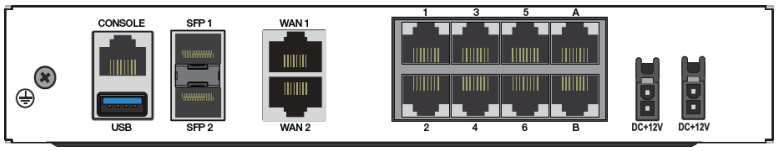
To set up FortiGate for initial management access:

1. Unpack the FortiGate box, and locate the following items:
   - FortiGate device
   - Power cable
   - Ethernet cable

   You will also need to provide the following items:
   - Second Ethernet cable. Only one Ethernet cable is provided to connect the FortiGate to a management computer. Locate a second Ethernet cable to connect the FortiGate to a port for internet access.
   - Management computer to access the FortiOS GUI
2. Use the power cable to connect the FortiGate to a power source.
3. Use one Ethernet cable to connect the management port on the FortiGate to a management computer.

   The default interface used for management differs from model to model. On most units with a single dedicated management port, the port is named MGMT. On units with multiple management ports, the names MGMT1 and MGMT2 are used. On units without dedicated management ports, port1 is used for initial management access, and the port can be part of a virtual switch group.

   The following example is for a FortiGate 80F, which uses port1 for initial management access. For information about your FortiGate hardware model, go to FortiGate/FortiOS Hardware Guides.



4. Use a second Ethernet cable to connect the WAN on the FortiGate to an upstream router, switch, or modem with access to the internet.

   On some FortiGate models, dedicated WAN interface(s) labeled WAN1, WAN2, and so on are available. If no dedicated WAN interfaces are present, select an interface of your choice for the WAN connection.

   Internet access is available when the FortiGate model has addressing mode set to DHCP by default on the WAN interface, and the WAN interface is connected to a network with a DHCP server assigning the correct IP and gateway for internet access. If these conditions are not met, then internet access is not available after connecting your WAN interface. See Configuring basic settings on page 33.

5. On the management computer, assign an address in the 192.168.1.0/24 network.
6. In a web browser, go to https://192.168.1.99 and enter the default user name, `admin`, and leave the password field blank.

   By default, the management interface or the internal interface is configured to allow HTTPS access with the IP address 192.168.1.99.

   The GUI is displayed in your browser.
7. Watch the video and complete the FortiGate Setup wizard. See Completing the FortiGate Setup wizard on page 33.

Completing the FortiGate Setup wizard

After logging in to FortiOS, you can access a FortiOS video as well as a FortiGate Setup wizard to help you get familiar with the product.

To complete the FortiGate Setup wizard:

1. After logging in to the FortiOS GUI, a FortiOS 7.6 What's new video is presented. Watch the video, and then click *OK* to proceed.

   The *FortiGate Setup* wizard is displayed to help you set up the FortiGate by completing the following steps:
   - Register with FortiCare
   - Specify a hostname
   - Dashboard setup
   - Change your password
2. Click *Begin* to start the wizard.

   The *Register with FortiCare* page is displayed.
3. If the FortiGate has internet access, register with FortiCare, and click *OK*.

   If internet access is not yet set up for the FortiGate, you cannot complete registration. Click *Later* to skip this step and proceed to the next step.

   The *Specify Hostname* page is displayed.
4. Specify a name for the FortiGate, and click *OK*.

   The *Change your Password* page is displayed.
5. Change the password for the admin account for the FortiGate, and click *OK*.

   The *Dashboard Setup* page is displayed.
6. Choose what dashboards to display by default in FortiOS, and click *OK*.

   The *FortiGate Setup* is complete, and the FortiOS GUI is displayed.

Configuring basic settings

Complete the following basic settings on the FortiGate to get the device up and running

1. Plan interface usage for MGMT, WAN, and LAN access, and configure the interfaces. See Planning and configuring the MGMT, WAN, and LAN interfaces on page 34.
2. Configure the default route. See Configuring the default route on page 36.

3. Configure the hostname if not done when completing the *FortiGate Setup* wizard. See Configuring the hostname on page 37.
4. Ensure internet and FortiGuard connectivity. See Ensuring internet and FortiGuard connectivity on page 37.
5. Use the default certificate for HTTPs administrative access. See Using the default certificate for HTTPS administrative access on page 37.

After configuring the basic settings, the FortiGate can access the internet and communicate with FortiGuard. Next, you can register the FortiGate with Fortinet. See Registering FortiGate on page 38. Firewall policies are also ready to be configured using the WAN and LAN interfaces.

Planning and configuring the MGMT, WAN, and LAN interfaces

On a typical deployment where the FortiGate NGFW is configured as an edge firewall, the administrator typically sets up access control between the LAN and WAN interface, and permanent management access either through in-band management or out-of-band management. The following sections outline steps to plan and configure your management, WAN, and LAN interfaces

Management access

So far the new FortiGate setup has been completed over a management interface, which is either a dedicated MGMT port named MGMT or MGMT1 or a port on the internal switch interface.

What interface to use for FortiGate management can depend on the FortiGate model. Some FortiGate models have a dedicated MGMT interface and some do not:

- Mid-size and high-end FortiGate models typically have a dedicated MGMT interface, and you can use the MGMT interface for FortiGate management. There is also a separate management network for accessing the FortiGate and other devices on the network. This is called out-of-band management.
- Desktop FortiGate models typically do not have a dedicated MGMT interface. In this case, you might be using the Internal or LAN interface for FortiGate management. There is no dedicated management network, and the management traffic is shared with internal traffic. This is called in-band management.

Following is a summary of what FortiGate models typically support in-band and out-of-band management:

FortiGate model	MGMT interface	In-band management	Out-of-band management
Desktop models	No	Recommended	Not supported*
Mid-size models	Yes	Supported	Recommended
High-end models	Yes	Supported	Recommended

*Although natively the FortiGate does not support out-of-band management, you can pick an unused interface and configure it as a dedicated interface for out-of-band management.

WAN interface

Similar to the management interface, some models have an interface labelled WAN, WAN1, or WAN2, and other models do not. On models with dedicated WAN interface(s), the interfaces are also configured as DHCP clients.

Therefore, if a DHCP server is present in the WAN network that points to the correct internet gateway, then internet access is available without further configuration.

On models without dedicated WAN interfaces, or in situations where you choose to configure the WAN interface statically, select an interface for WAN access. Connect the interface to your upstream router, L3 switch, or modem. Then use the following steps to configure your WAN interface.

To configure a WAN interface in the GUI:

1. Go to *Network* > *Interfaces*. Select an interface and click *Edit*.
2. (Optional) Enter an *Alias*, such as WAN.
3. In the *Address* section, enter the *IP/Netmask*.
4. In *Administrative Access* section, select the access options as needed. For a WAN interface, it is recommended to only allow *PING*.
5. Click *OK*.

To configure a WAN interface in the CLI:

```
config system interface
    edit "port2"
        set ip 203.0.113.99 255.255.255.0
        set allowaccess ping
        set alias "WAN"
    next
end
```

LAN interface

On desktop and some mid-range models, a set of ports are grouped together by default in virtual switch mode for LAN access. The virtual switch interface may be called internal or lan, and it helps facilitate connecting endpoints directly to the FortiGate on the same L2 switching network.

Endpoints connected this way will also share the same access control configured for the internal or lan interface.

On models that lack a default LAN interface, or when you choose to configure a LAN interface manually, select an interface for LAN access. Connect this interface to an internal switch that connects to your LAN network. Then use the following steps to configure your LAN interface.

To configure a LAN interface in the GUI:

1. Go to *Network* > *Interfaces*. Select an interface and click *Edit*.
2. (Optional) Enter an *Alias*, such as LAN.
3. In the *Address* section, enter the *IP/Netmask*.
4. In *Administrative Access* section, select the access options as needed, such as *PING*. For in-band management, you may also want to allow administrative access for HTTPS and SSH.
5. Optionally, enable *DHCP Server* and configure as needed.
6. Click *OK*.

To configure a LAN interface in the CLI:

```
config system interface
  edit "port1"
    set ip 192.168.10.99 255.255.255.0
    set allowaccess ping https ssh
    set alias "LAN"
  next
end
config system dhcp server
    edit 1
        set dns-service default
        set default-gateway 192.168.10.99
        set netmask 255.255.255.0
        set interface "port1"
        config ip-range
            edit 1
                set start-ip 192.168.10.2
                set end-ip 192.168.10.254
            next
        end
    next
end
```

Configuring the default route

Setting the default route enables the FortiGate to route traffic through this interface and default gateway when no specific routes are found for a particular destination. The gateway address should be your upstream router or L3 switch that the FortiGate is connected to. Set the interface to be the WAN interface that the gateway is connected to.

If the WAN interface uses DHCP for address assignment, the default route may already be learned from the DHCP server, and this step is not needed.

To configure the default route in the GUI:

1. Go to *Network* > *Static Routes* and click *Create New*.
2. Leave the destination subnet as *0.0.0.0/0.0.0.0*. This is known as a default route, since it would match any IPv4 address.
3. Enter the *Gateway Address*.
4. Select an *Interface*.
5. Click *OK*.

To configure the default route in the CLI:

```
config router static
    edit 0
        set gateway 203.0.113.1
        set device port2
```

```
    next
end
```

Configuring the hostname

Setting the FortiGate's hostname assists with identifying the device, and it is especially useful when managing multiple FortiGates. Choose a meaningful hostname as it is used in the CLI console, SNMP system name, device name for FortiGate Cloud, and to identify a member of an HA cluster.

To configure the hostname in the GUI:

1. Go to *System* > *Settings*.
2. Enter a name in the *Host name* field.
3. Click *Apply*.

To configure the hostname in the CLI:

```
config system global
    set hostname 200F_YVR
end
```

Ensuring internet and FortiGuard connectivity

This step is not necessary for the configuration; however, it is necessary in order to keep your FortiGate up to date against the latest threats. Updates are provided to FortiGates that are registered and make a request to the FortiGuard network to verify if there are any more recent definitions.

Use `execute ping <domain.tld>` to ensure the DNS resolution is able to resolve the following FortiGuard servers:

- fds1.fortinet.com
- service.fortiguard.net
- update.fortiguard.net

You also need to ensure the necessary ports are permitted outbound in the event your FortiGate is behind a filtering device. Refer to the Ports and Protocols document for more information.

Using the default certificate for HTTPS administrative access

By default, the FortiGate uses the Fortinet_GUI_Server certificate for HTTPS administrative access. Administrators should download the CA certificate and install it on their PC to avoid warnings in their browser. See Using the default certificate for HTTPS administrative access on page 3292 for more information.

Registering FortiGate

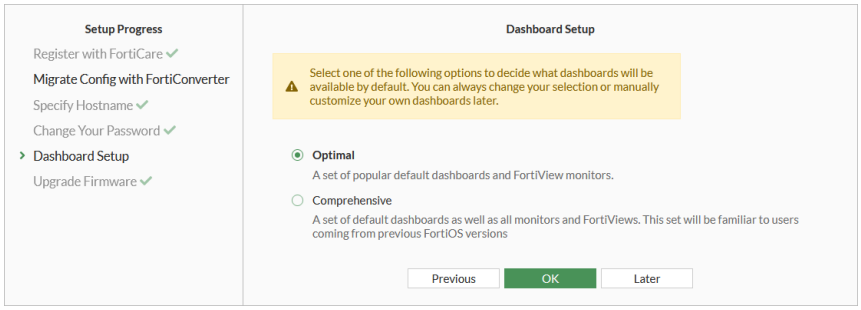
The FortiGate, and then its service contract, must be registered to have full access to Fortinet Customer Service and Support, and FortiGuard services. The FortiGate can be registered in either the FortiGate GUI or the FortiCloud support portal. The service contract can be registered from the FortiCloud support portal.

The service contract number is needed to complete registrations on the FortiCloud support portal. You can find this 12-digit number in the email that contains your service registration document (sent from do-not-reply-contract@fortinet.com) in the service entitlement summary.

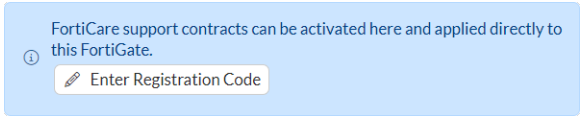
To register your FortiGate in the GUI:

1. Connect to the FortiGate GUI. A dialog box appears, which indicates the steps you should take to complete the setup of your FortiGate. These steps could include one or more of the following:
   a. *Register with FortiCare*
   b. *Migrate Config with FortiConverter*
   c. *Specify Hostname*
   d. *Dashboard Setup*
   e. *Change Your Password*
   f. *Upgrade Firmware*

   If you completed the Configuring basic settings on page 33, the hostname and password steps are already marked as complete (checkmark). If you chose to deploy the latest firmware, the *Upgrade Firmware* step is marked as complete.
2. Click *Begin* to complete the dashboard setup. Two options appear (*Optimal* and *Comprehensive*).



3. Select the desired setting and click *OK*. The *Dashboard > Status* page opens. Note that the licenses are grayed out because the device or virtual machine is not registered.
4. Go to *System > FortiGuard* and click *Enter Registration Code*.



5. Enter the contract registration code from your service registration document.
6. Click *OK*.

To register the FortiGate on the FortiCloud support portal:

FortiGates can be registered with the Register More button in the Products views. For details, see Registering assets in the FortiCloud Account Services Asset Management guide.

Configuring a firewall policy

When devices are behind FortiGate, you must configure a firewall policy on FortiGate to grant the devices access to the internet. In other words, a firewall policy must be in place for any traffic that passes through a FortiGate.

To create a firewall policy in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Click *Create New*. The *New Policy* pane is displayed.
3. Enter a Name and configure the following necessary settings:

Schedule	always
Action	ACCEPT
Incoming Interface	LAN (port1)
Outgoing Interface	WAN (port2)
Source	Source IPv4 address name and address group names
Destination	Destination IPv4 address name and address group names
Service	All

4. Click *Save*.

Backing up the configuration

Once you successfully configure the FortiGate, it is extremely important that you back up the configuration. In some cases, you may need to reset the FortiGate to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device must be recreated, unless a backup can be used to restore it.

You can back up the configuration in FortiOS or YAML format. You have the option to save the configuration file in FortiOS format to various locations including the local PC and USB key.

To back up the configuration in FortiOS format using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration* > *Backup*.
2. Direct the backup to your *Local PC* or to a *USB Disk*.
   The *USB Disk* option will not be available if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.

3. If VDOMs are enabled, indicate whether the scope of the backup is the entire FortiGate configuration (*Global*) or only a specific VDOM configuration (*VDOM*).

   If backing up a VDOM configuration, select the VDOM name from the list.
4. Enable *Encryption*.

   This is recommended to secure your backup configurations and prevent unauthorized parties from reloading your configuration.
5. Enter a password, and enter it again to confirm it. This password will be required to restore the configuration.
6. Click *OK*.
7. When prompted, select a location on the PC or USB disk to save the configuration file. The configuration file will have a .conf extension.

To back up the configuration in YAML format using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration* > *Backup*.
2. Direct the backup to your *Local PC* or to a *USB Disk*.
3. Select *YAML* for the *File format*.
4. Click *OK*.

Troubleshooting your installation

If your FortiGate does not function as desired after installation, try the following troubleshooting tips:

1. **Check for equipment issues**

   Verify that all network equipment is powered on and operating as expected. Refer to the QuickStart Guide for information about connecting your FortiGate to the network.
2. **Check the physical network connections**

   Check the cables used for all physical connections to ensure that they are fully connected and do not appear damaged, and make sure that each cable connects to the correct device and the correct Ethernet port on that device.
3. **Verify that you can connect to the internal IP address of the FortiGate**

   Connect to the GUI from the FortiGate's internal interface by browsing to its IP address. From the PC, try to ping the internal interface IP address; for example, `ping 192.168.1.99`. If you cannot connect to the internal interface, verify the IP configuration of the PC. If you can ping the interface but can't connect to the GUI, check the settings for administrative access on that interface. Alternatively, use SSH to connect to the CLI, and then confirm that HTTPS has been enabled for Administrative Access on the interface.
4. **Check the FortiGate interface configurations**

   Check the configuration of the FortiGate interface connected to the internal network (under *Network* > *Interfaces*) and check that *Addressing mode* is set to the correct mode.
5. **Verify the security policy configuration**

   Go to *Policy & Objects* > *Firewall Policy* and verify that the internal interface to Internet-facing interface security policy has been added and is located near the top of the policy list. Check the *Active Sessions* column to ensure that traffic has been processed (if this column does not appear, right-click on the table

header and select *Active Sessions*). If you are using NAT mode, check the configuration of the policy to make sure that *NAT* is enabled and that *Use Outgoing Interface Address* is selected.

6. **Verify the static routing configuration**

   Go to *Network* > *Static Routes* and verify that the default route is correct. Go to *Monitor* > *Routing Monitor* and verify that the default route appears in the list as a static route. Along with the default route, you should see two routes shown as *Connected*, one for each connected FortiGate interface.

7. **Verify that you can connect to the Internet-facing interface's IP address**

   Ping the IP address of the Internet-facing interface of your FortiGate. If you cannot connect to the interface, the FortiGate is not allowing sessions from the internal interface to Internet-facing interface. Verify that PING has been enabled for *Administrative Access* on the interface.

8. **Verify that you can connect to the gateway provided by your ISP**

   Ping the default gateway IP address from a PC on the internal network. If you cannot reach the gateway, contact your ISP to verify that you are using the correct gateway.

9. **Verify that you can communicate from the FortiGate to the Internet**

   Access the FortiGate CLI and use the command `execute ping 8.8.8.8`. You can also use the `execute traceroute 8.8.8.8` command to troubleshoot connectivity to the Internet.

10. **Verify the DNS configurations of the FortiGate and the PCs**

    Check for DNS errors by pinging or using traceroute to connect to a domain name; for example: `ping www.fortinet.com`.

    If the name cannot be resolved, the FortiGate or PC cannot connect to a DNS server and you should confirm that the DNS server IP addresses are present and correct.

11. **Confirm that the FortiGate can connect to the FortiGuard network**

    Once the FortiGate is on your network, you should confirm that it can reach the FortiGuard network. First, check the *Licenses* widget to make sure that the status of all FortiGuard services matches the services that you have purchased. Go to *System* > *FortiGuard*, and, in the Filtering section, click *Test Connectivity*. After a few minutes, the GUI should indicate a successful connection. Verify that your FortiGate can resolve and reach FortiGuard at `service.fortiguard.net` by pinging the domain name. If you can reach this service, you can then verify the connection to FortiGuard servers by running the command `diagnose debug rating`. This displays a list of FortiGuard IP gateways you can connect to, as well as the following information:

    - `Weight`: Based on the difference in time zone between the FortiGate and this server
    - `RTT`: Return trip time
    - `Flags`: D (IP returned from DNS), I (Contract server contacted), T (being timed), F (failed)
    - `TZ`: Server time zone
    - `Curr Lost`: Current number of consecutive lost packets
    - `Total Lost`: Total number of lost packets

12. **Use FortiExplorer Go if you cannot connect to the FortiGate over Ethernet**

    If you cannot connect to the FortiGate GUI or CLI, you may be able to connect using FortiExplorer Go. Refer to the FortiExplorer Go User Guide for more details.

13. **Contact Fortinet Support for assistance**

If you require further assistance, visit the Fortinet Support website.

Using the GUI

This section presents an introduction to the graphical user interface (GUI) on your FortiGate.

The following topics are included in this section:

- Connecting using a web browser
- Menus
- Tables
- Entering values
- GUI-based global search
- Loading artifacts from a CDN on page 51
- Accessing additional support resources on page 52
- Command palette on page 52
- Recovering missing graphical components on page 57

For information about using the dashboards, see Dashboards and Monitors on page 102.

Connecting using a web browser

In order to connect to the GUI using a web browser, an interface must be configured to allow administrative access over HTTPS or over both HTTPS and HTTP. By default, an interface has already been set up that allows HTTPS access with the IP address 192.168.1.99.

Browse to https://192.168.1.99 and enter your username and password. If you have not changed the admin account's password, use the default user name, `admin`, and leave the password field blank.

The GUI will now display in your browser, and you will be required to provide a password for the administrator account.

To use a different interface to access the GUI:

1. Go to *Network* > *Interfaces* and edit the interface you wish to use for access. Take note of its assigned IP address.
2. In *Administrative Access*, select *HTTPS*, and any other protocol you require. You can also select *HTTP*, although this is not recommended as the connection is insecure.
3. Click *OK*.
4. Browse to the IP address using your chosen protocol.

   The GUI will now be displayed in your browser.

Menus

If you believe your FortiGate model supports a menu that does not appear in the GUI, go to *System* > *Feature Visibility* and ensure the feature is enabled. For more information, see Feature visibility on page 3595.

The GUI contains the following main menus, which provide access to configuration options for most FortiOS features:

Dashboard	The dashboard displays various widgets and monitors that display important system information and allow you to configure some system options. For more information, see Dashboards and Monitors on page 102.
Network	Options for networking, including configuring system interfaces and routing options. For more information, see Network on page 170.
Policy & Objects	Configure firewall policies, protocol options, and supporting content for policies, including schedules, firewall addresses, and traffic shapers. For more information, see Policy and Objects on page 1562.
Security Profiles	Configure your FortiGate's security features, including Antivirus, Web Filter, and Application Control. For more information, see Security Profiles on page 1899.
VPN	Configure options for IPsec and SSL virtual private networks (VPNs). For more information, see IPsec VPN on page 2369 and SSL VPN on page 2775.
User & Authentication	Configure user accounts, groups, and authentication methods, including external authentication and single sign-on (SSO).
WiFi & Switch Controller	Configure the unit to act as a wireless network controller, managing the wireless Access Point (AP) functionality of FortiWiFi and FortiAP units. On certain FortiGate models, this menu has additional features allowing for FortiSwitch units to be managed by the FortiGate. For more information, see Wireless configuration on page 3184 and Switch Controller on page 3185.
System	Configure system settings, such as administrators, HA, FortiGuard, and certificates. For more information, see System on page 3186.
Security Fabric	Access the physical topology, logical topology, automation, and settings of the Fortinet Security Fabric. For more information, see Fortinet Security Fabric on page 3697.
Log & Report	Configure logging and alert email as well as reports. For more information, see Log and Report on page 4123.

Tables

Many GUI pages contain tables of information that can be filtered and customized to display specific information in a specific way. Some tables allow content to be edited directly on that table, or rows to be copied and pasted.

Filters

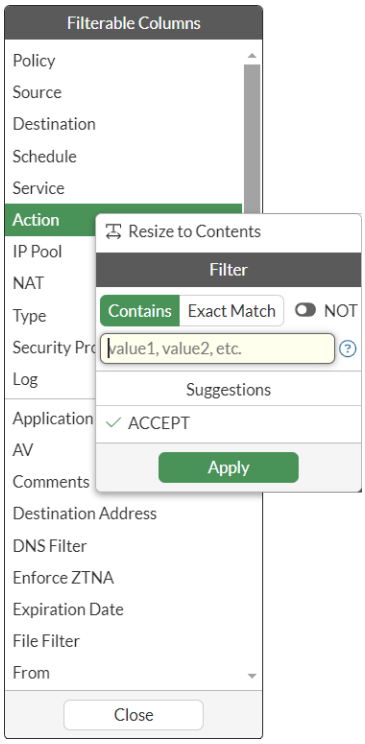
Filters are used to locate a specific set of information or content in a table. They can be particularly useful for locating specific log entries. The filtering options vary, depending on the type of information in the table.

Depending on the table content, you can apply filters using the filter bar, a column filter, or based on a cell's content. Some tables allow filtering based on regular expressions.

Administrators with read and write access can define filters. Multiple filters can be applied at one time.

To manually create a filter:

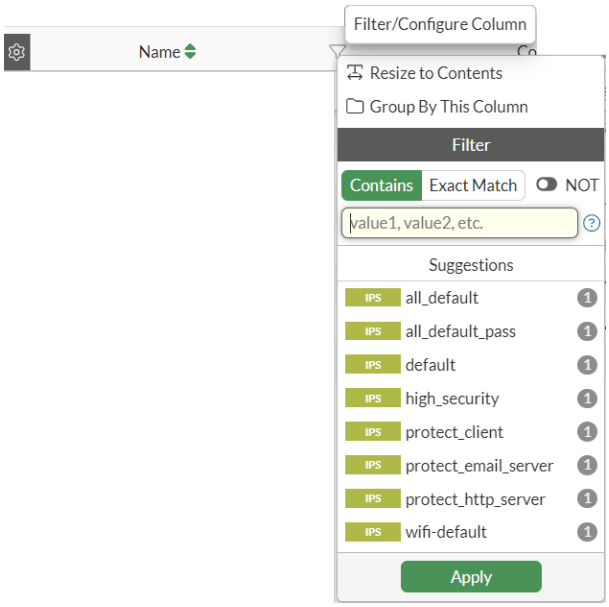
1. Click the add filter button, , in the table search bar. A list of the fields available for filtering is shown.
2. Select the field to filter by.
3. Enter the value to filter by, adding modifiers as needed.



4. Click *Apply*.

To create a column filter:

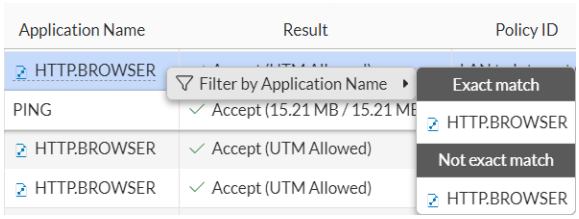
1. Click the filter icon on the right side of the column header.



2. Choose a filter type from the available options.
3. Enter the filter text, or select from the available values.
4. Click *Apply*.

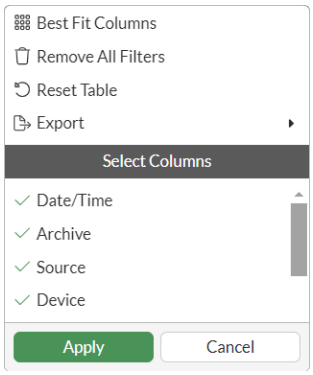
To create a filter based on a cell's content:

1. Right-click a cell in the table.
2. Select *Filter by [column name]* and configure a filtering option from the menu.



To remove all filters:

1. Right-click a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Select *Remove All Filters*.

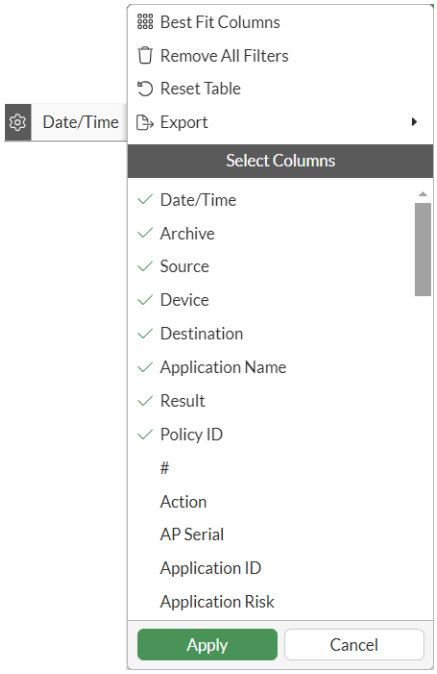


Column settings

Columns can be rearranged, resized, and added or removed from tables.

To add or remove columns:

1. Right-click a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.



2. Select columns to add or remove.
3. Click *Apply*.

To rearrange the columns in a table:

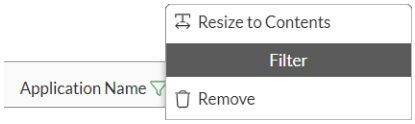
1. Click and drag the column header.

To resize a column:

1. Click and drag the right border of the column header.

To resize a column to fit its contents:

1. Click filter icon on the right side of the column header and select *Resize to Contents*.



To resize all of the columns in a table to fit their content:

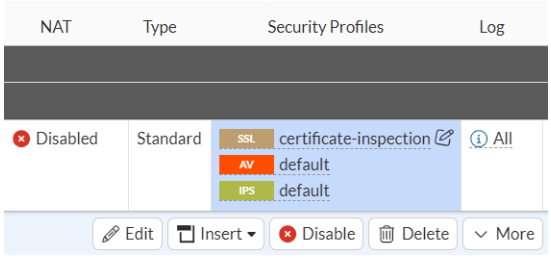
1. Right-click a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Click *Best Fit Columns*.

To reset a table to its default view:

1. Right-click a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Click *Reset Table*.

Editing objects

In some tables, parts of a configuration can be edited directly in the table. For example, you can add security profiles to an existing firewall policy. For the firewall policy, click the *Security Profiles* cell to display, and then click the edit icon.

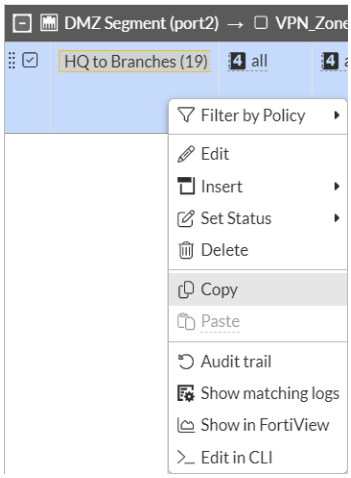


Copying rows

In some tables, rows can be copied and pasted using the right-click menu. For example, a policy can be duplicated.

To copy a row:

1. Right-click the policy, and select *Copy*.



2. Right-click the policy, and select *Paste* > *Above* or *Paste* > *Below*.

Entering values

Numerous fields in the GUI and CLI require text strings or numbers to be entered when configuring the FortiGate. When entering values in the GUI, you will be prevented from entering invalid characters, and a warning message will be shown explaining what values are not allowed. If invalid values are entered in a CLI command, the setting will be rejected when you apply it.

- Text strings on page 48
- Numbers on page 50

Text strings

Text strings are used to name entities in the FortiGate configuration. For example, the name of a firewall address, administrator, or interface are all text strings.

The following characters cannot be used in text strings, as they present cross-site scripting (XSS) vulnerabilities:

- " - double quotes
- ' - single quote
- > - greater than
- < - less than

Most GUI text fields prevent XSS vulnerable characters from being added.

VDOM names and hostnames can only use numbers (0-9), letters (a-z and A-Z), dashes, and underscores.

The `tree` CLI command can be used to view the number of characters allowed in a name field. For example, entering the following commands show that a firewall address name can contain up to 79 characters, while its FQDN can contain 255 characters:

```
# tree firewall address
-- [address] --*name    (79)
             |- uuid
             |- subnet
             |- type
             |- route-tag       (0,4294967295)
             |- sub-type
             |- clearpass-spt
             |- [macaddr] --*macaddr    (127)

             +- fabric-object
```

Numbers

Numbers are used to set sizes, rates, addresses, port numbers, priorities, and other such numeric values. They can be entered as a series of digits (without commas or spaces), in a dotted decimal format (such as IP addresses), or separated by colons (such as MAC addresses). Most numeric values use base 10 numbers, while some use hexadecimal values.

Most GUI and CLI fields prevent invalid numbers from being entered. The CLI help text includes information about the range of values allowed for applicable settings.

GUI-based global search

The global search option in the GUI allows users to search for keywords appearing in objects and navigation menus to quickly access the object and configuration page. Click the magnifying glass icon in the top-left corner of the banner to access the global search.

The global search includes the following features:

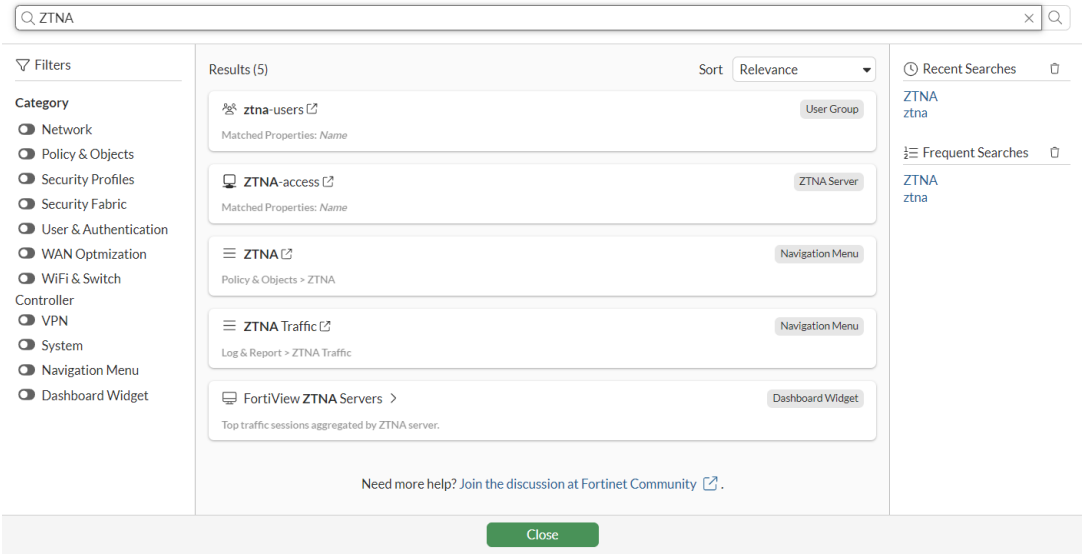
- Keep a history of frequent and recent searches
- Sort results by relevance (by search weight), or alphabetically in increasing or decreasing order
- Search by category
- Search in Security Fabric members (accessed by the Security Fabric members dropdown menu in the banner)
- Search for dashboard widgets and monitors, and preview the widget or go directly to the monitor dashboard if it exists.

Examples

In this example, searching for the word *ZTNA* yields the following results:

- A ZTNA server, user group, and SAML SSO server that have the *ZTNA* in the *Name* field.
- Various ZTNA tag.
- ZTNA navigation tree items: *Policy & Objects* > *ZTNA* and *Log & Report* > *ZTNA Traffic*.
- The FortiView ZTNA Servers dashboard widget.

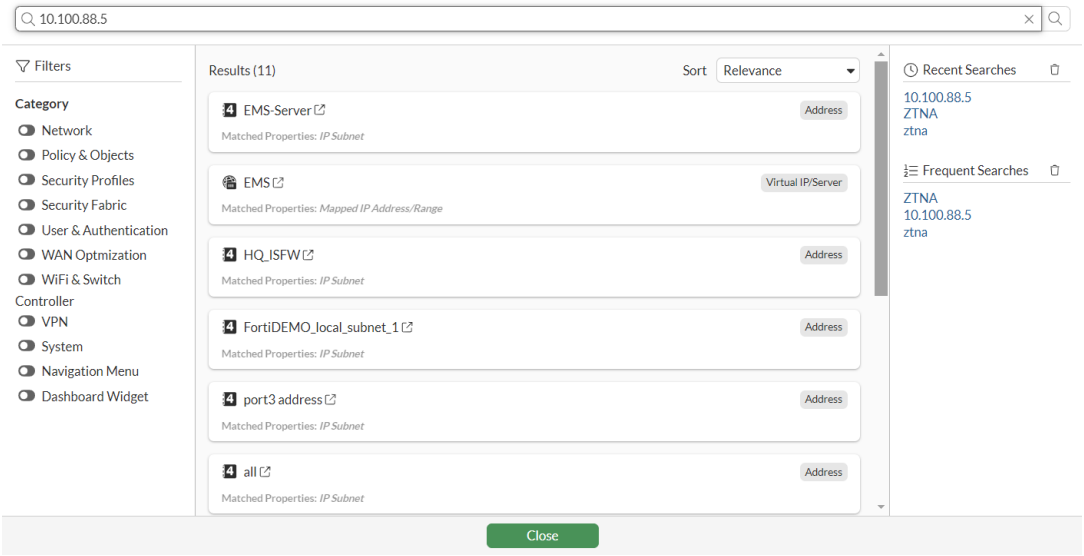
CMDB objects have a higher search weight (50) than navigation objects (20), so the navigation menus and widgets appears at the bottom of the results when sorting by relevance.



In this example, searching for the address *10.100.88.5* yields the following results:

- Various address objects that have a subnet of 10.100.88.5.
- A Virtual IP/Server object, *EMS*, that has a mapped IP address/range with 10.100.88.5.
- Address objects that have IP subnets of 0.0.0.0/0, which the search term falls into.
- Address group objects that contains members addresses that have IP subnets of 0.0.0.0/0.

Sorting by *Relevance* displays address objects that are more closely matched at the top (10.100.88.5), and more loosely matched at the bottom (0.0.0.0).



Loading artifacts from a CDN

To improve GUI performance, loading static GUI artifacts cached in CDN (content delivery network) servers closer to the user instead of the FortiGate can be enabled. This allows the GUI to load more quickly with less

latency for administrators who are accessing the FortiGate remotely. Upon failure, the files fall back to loading from the FortiGate. The CDN is only used after successful administrator logins.

To configure loading static GUI files from a CDN:

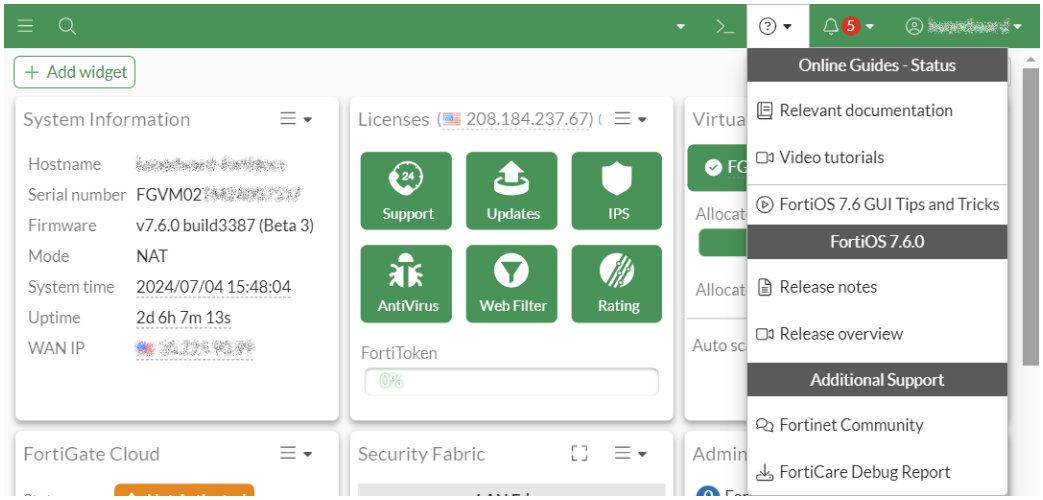
```
config system global
    set gui-cdn-usage {enable | disable}
end
```

Accessing additional support resources

Additional support resources can be accessed from the GUI to troubleshoot issues and get the most out of FortiOS. Online guides, FortiOS documentation, and additional support can now be accessed straight from the help menu.

To access support resources:

1. Click *Help* in the top menu. A dropdown menu is displayed.



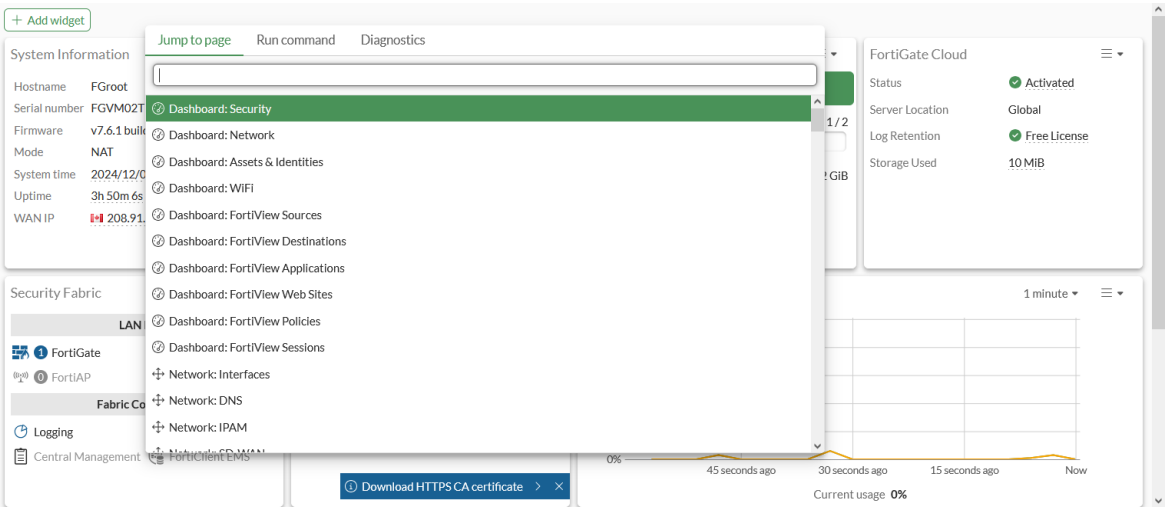
2. Select the support resource you are looking for:
   - *Online Guides* lists resources for help documentation and videos.
   - *FortiOS <version>* contains release information.
   - *Additional Support* contains a link to Fortinet Community and access to download the *FortiCare Debug Report*.

Command palette

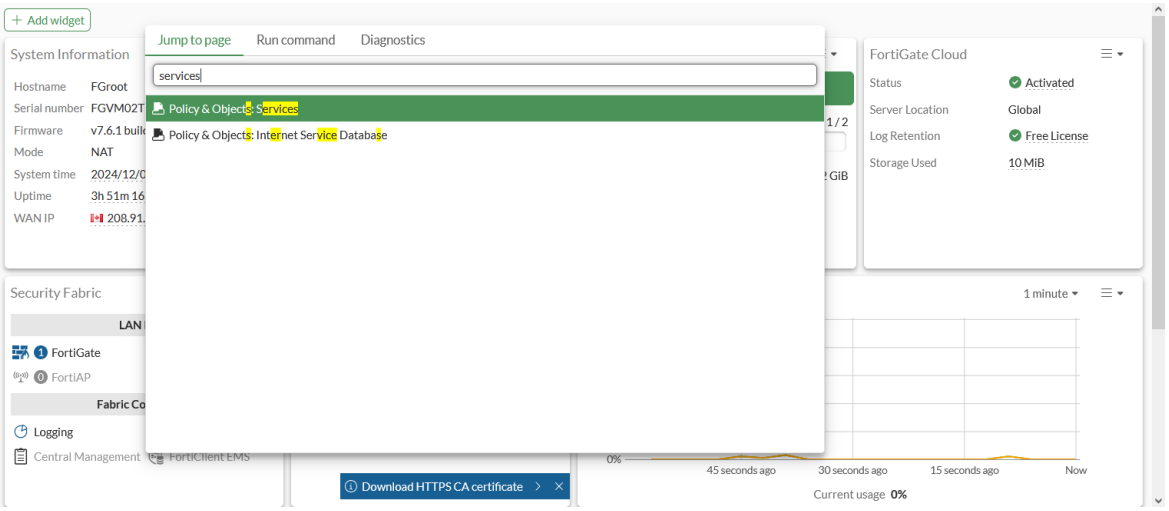
The command palette is a keyboard shortcut menu that can be used to quickly navigate to GUI pages, run specific actions like opening the CLI console and restoring a system configuration, and running troubleshooting or debug commands like `get system status` and `show arp table`.

To navigate to a new GUI page using the command palette:

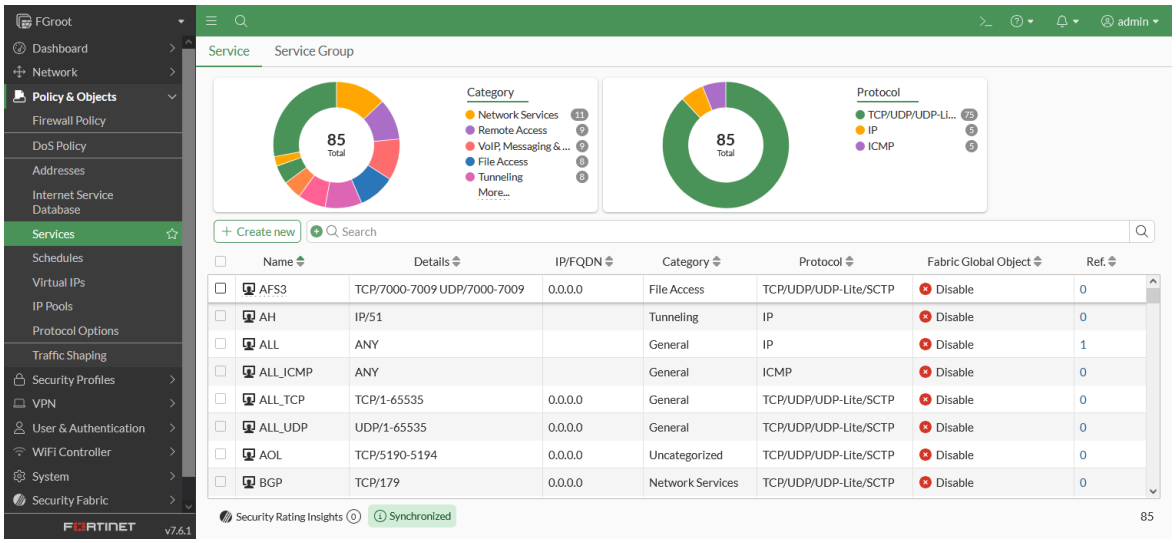
1. Press `ctrl+p` (or `cmd+p` for Mac). The command palette is displayed with available navigation links.



2. Enter the required destination, or browse the list for it.



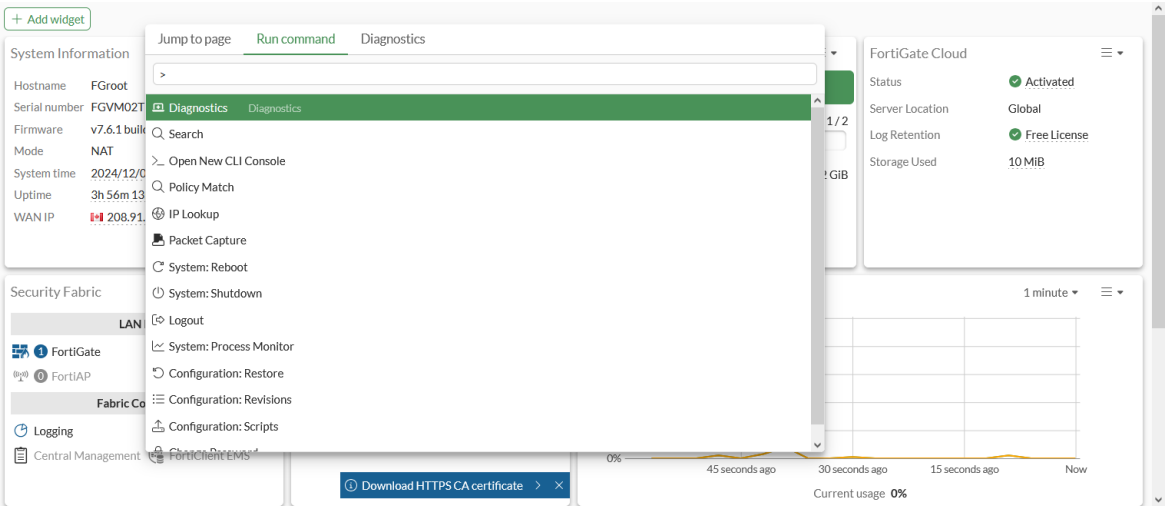
3. Click on the location to jump to the select GUI page.



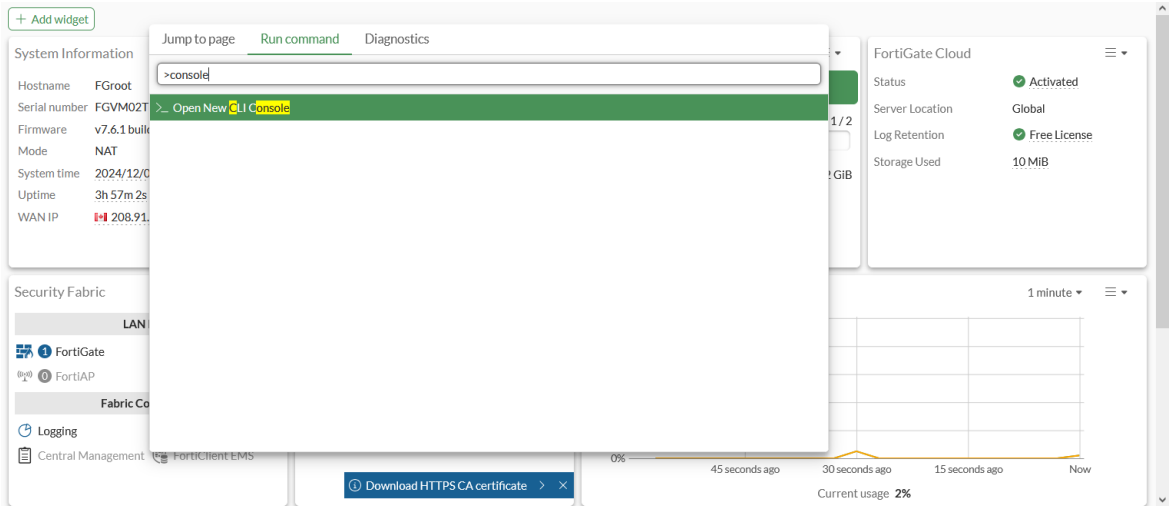
To activate an action using the command palette:

1. Press `ctrl+p` (or `cmd+p` for Mac) and then enter a `>`, or select the *Run command* tab. On supported browsers, `ctrl+shift+p` (or `cmd+shift+p` for Mac) can be used.

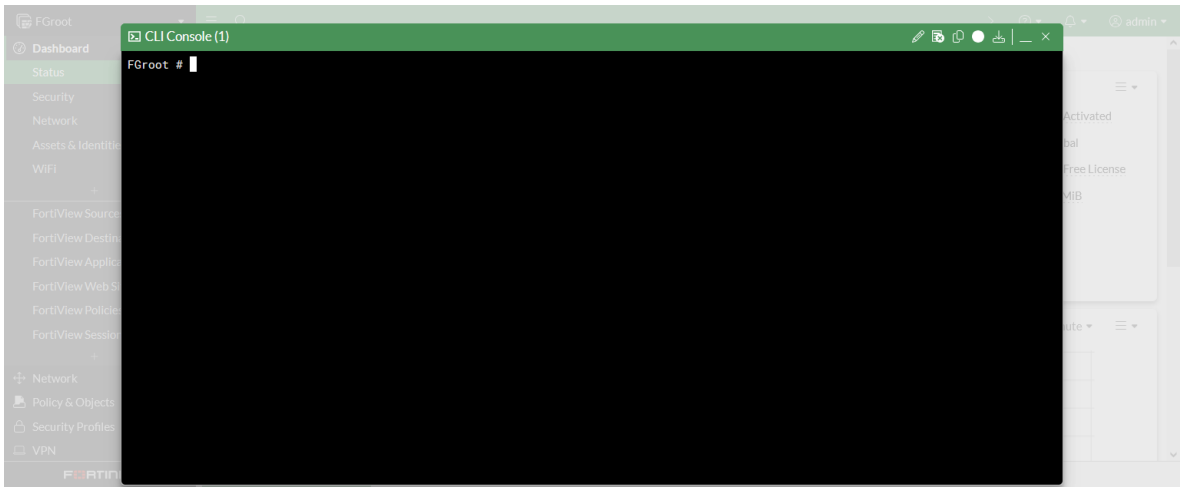
   The command palette is displayed with a runnable command list.



2. Enter the command key word, or browse the list for the command.

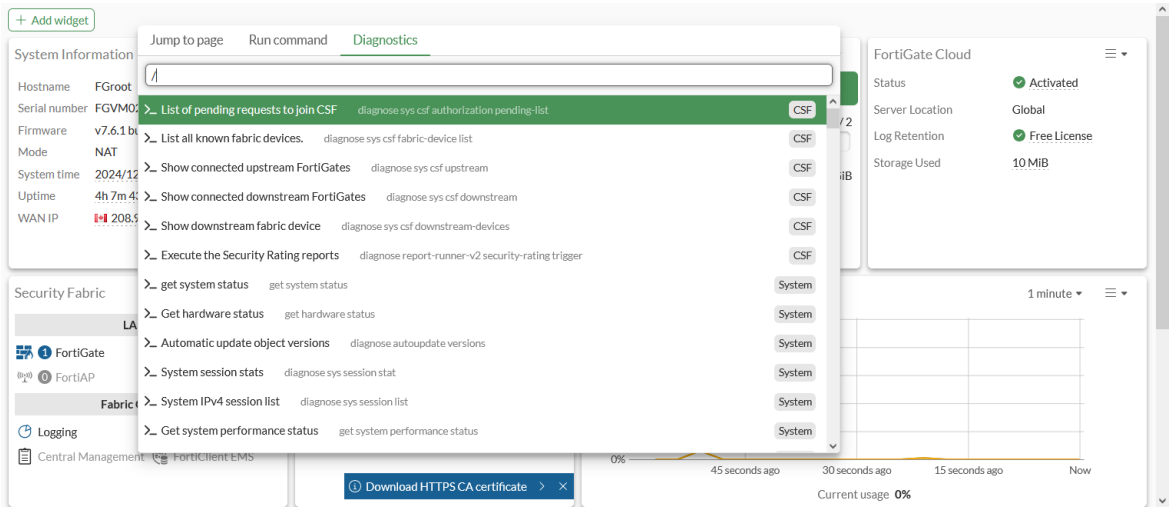


3. Click the result, or press `Enter`, to run the action.

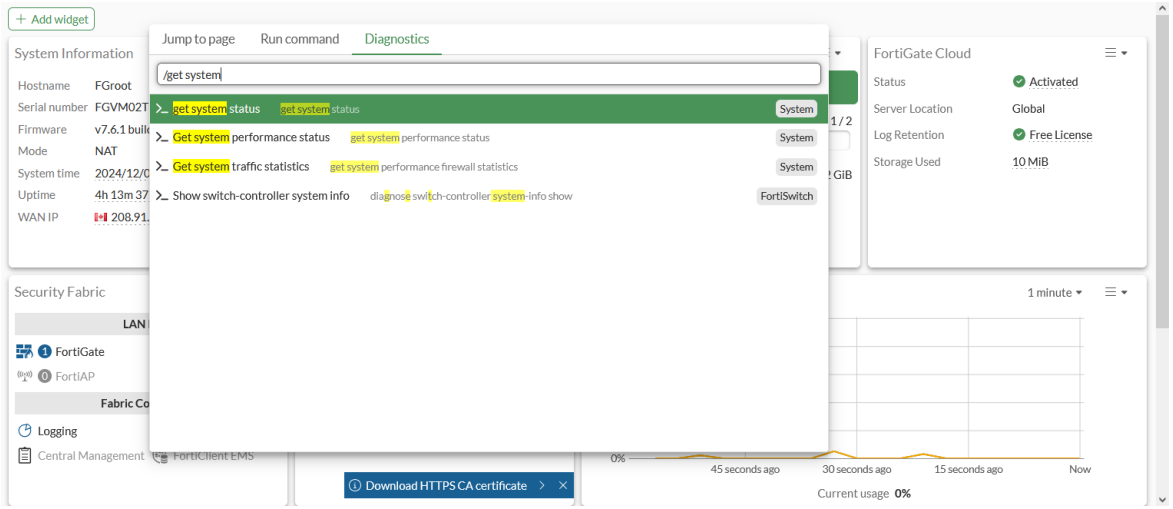


To use the Diagnostics command palette:

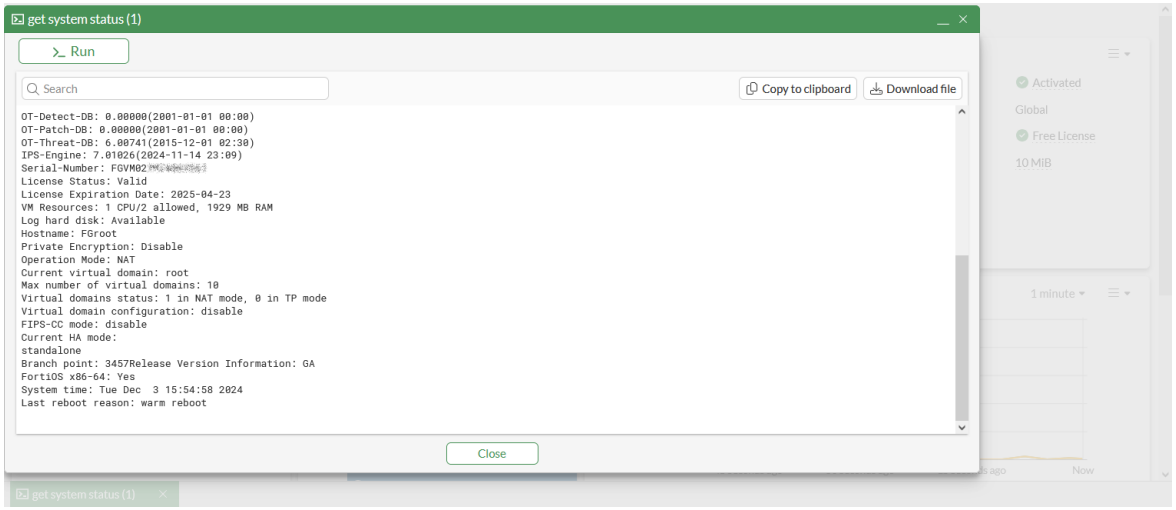
1. Press `ctrl+p` (or `cmd+p` for Mac) and then enter a `/`, or select the *Diagnostics* tab.



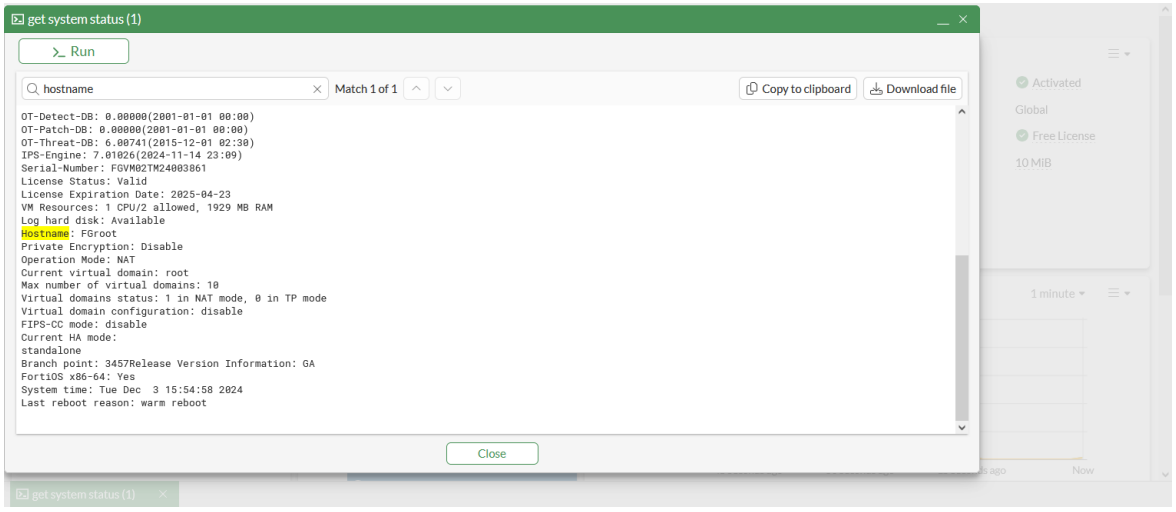
2. Enter the command name, or browse the list for the command.



3. Click the result, or press `Enter`, to run the command.



4. Enter a search string in the search field to search the command output.

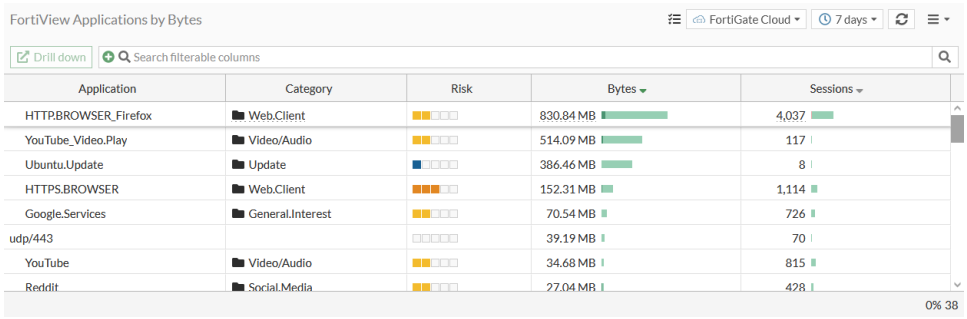


5. Click *Copy to clipboard* to copy the output to the clipboard, or *Download the file* to download the output as a text file.
6. Click *Run* to run the command again.

Recovering missing graphical components

Errors can sometimes cause the application icons, or other minor graphical components, to no longer show up in the GUI.

For example, in the *FortiView Applications* monitor, the icons could be missing from the *Application* column.



The `diagnose fortiguard-resources update` command can be used to delete cached files and force downloads of the FortiGuard resource, including icons.

Command	Downloaded resource
`diagnose fortiguard-resources update sprite-map`	Application icon sprite map (CSS & PNG).
`diagnose fortiguard-resources update sprite-isdb`	Application icon sprite ISDB (CSS & PNG).
`diagnose fortiguard-resources update app-info <id>`	Application info for a given ID.
`diagnose fortiguard-resources update ips-information <id>`	IPS information for a given ID.
`diagnose fortiguard-resources update wf-categories`	Web filter categories.
`diagnose fortiguard-resources update app-categories`	Application categories.
`diagnose fortiguard-resources update prefix-links`	Prefix links.
`diagnose fortiguard-resources update static-links`	Static links.
`diagnose fortiguard-resources update fortigate-end-of-support`	FortiGate product life cycle information.
`diagnose fortiguard-resources update fortiswitch-end-of-support`	FortiSwitch product life cycle information.
`diagnose fortiguard-resources update fortiap-end-of-support`	FortiAP product life cycle information.
`diagnose fortiguard-resources update fortiextender-end-of-support`	FortiExtender product life cycle information.

To recover missing application icons:

1. Run the update command:

```
# diagnose fortiguard-resources update sprite-isdb
Deleted cached resource file: sprite-isdb.css
Deleted cached resource file: sprite-isdb.png
Deleted cached resource file: sprite_map_front.css
Request URL: "https://globalproductapi.fortinet.net/v1/ref?key=spritemap&f=fos&v=2"
Host "globalproductapi.fortinet.net" resolved to "209.52.38.140"

Performing HTTP request...

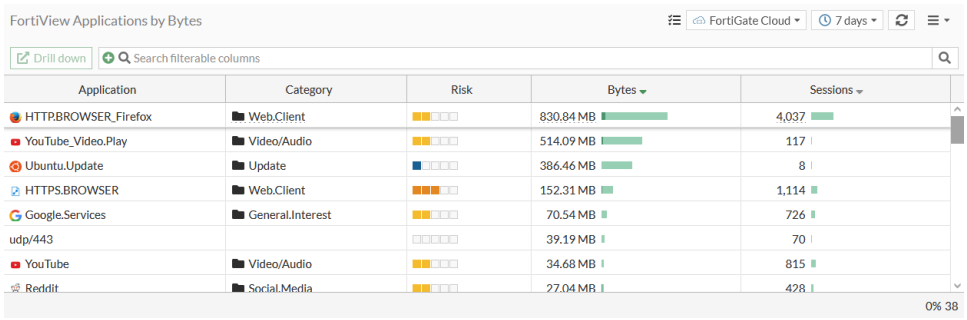
```

2. Refresh the browser window. You might also need to clear your browser cache.



Using the CLI

The Command Line Interface (CLI) can be used in lieu of the GUI to configure the FortiGate. Some settings are not available in the GUI, and can only be accessed using the CLI.

This section briefly explains basic CLI usage. For information about the CLI config commands, see the FortiOS CLI Reference.

- Connecting to the CLI on page 59
- CLI basics on page 62

- Command syntax on page 68
- Subcommands on page 70
- Permissions on page 73

Connecting to the CLI

You can connect to the CLI using a direct console connection, SSH, the FortiExplorer Go app, or the CLI console in the GUI.

You can access the CLI outside of the GUI in three ways:

- Console connection: Connect your computer directly to the console port of your FortiGate.
- SSH access: Connect your computer through any network interface attached to one of the network ports on your FortiGate.
- FortiExplorer Go: Connect your device to the FortiExplorer Go app on your device to configure, manage, and monitor your FortiGate. See the FortiExplorer Go User Guide for details.

To open a CLI console, click the _> icon in the top right corner of the GUI. The console opens on top of the GUI. It can be minimized and multiple consoles can be opened. On many GUI pages, the CLI console can be opened with that pages specific commands already shown by clicking *Edit in CLI* in the right-side gutter.

To edit policies and objects directly in the CLI, right-click on the element and select *Edit in CLI*.

Console connection

A direct console connection to the CLI is created by directly connecting your management computer or console to the FortiGate using its DB-9 or RJ-45 console port.

Direct console access to the FortiGate may be required if:

- You are installing the FortiGate for the first time and it is not configured to connect to your network.
- You are restoring the firmware using a boot interrupt. Network access to the CLI will not be available until after the boot process has completed, making direct console access the only option.

To connect to the FortiGate console, you need:

- A console cable to connect the console port on the FortiGate to a communications port on the computer. Depending on your device, this is one of:
  - null modem cable (DB-9 to DB-9)
  - DB-9 to RJ-45 cable (a DB-9-to-USB adapter can be used)
  - USB to RJ-45 cable
- A computer with an available communications port
- Terminal emulation software

To connect to the CLI using a direct console connection:

1. Using the console cable, connect the FortiGate unit's console port to the serial communications (COM) port on your management computer.

2. Start a terminal emulation program on the management computer, select the COM port, and use the following settings:

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

3. Press *Enter* on the keyboard to connect to the CLI.
4. Log in to the CLI using your username and password (default: *admin* and no password).
   You can now enter CLI commands, including configuring access to the CLI through SSH.

SSH access

SSH access to the CLI is accomplished by connecting your computer to the FortiGate using one of its network ports. You can either connect directly, using a peer connection between the two, or through any intermediary network.

If you do not want to use an SSH client and you have access to the GUI, you can access the CLI through the network using the CLI console in the GUI.

SSH must be enabled on the network interface that is associated with the physical network port that is used.

If your computer is not connected either directly or through a switch to the FortiGate, you must also configure the FortiGate with a static route to a router that can forward packets from the FortiGate to the computer. This can be done using a local console connection, or in the GUI.

To connect to the FortiGate CLI using SSH, you need:

- A computer with an available serial communications (COM) port and RJ-45 port
- An appropriate console cable
- Terminal emulation software
- A network cable
- Prior configuration of the operating mode, network interface, and static route.

To enable SSH access to the CLI using a local console connection:

1. Using the network cable, connect the FortiGate unit's port either directly to your computer's network port, or to a network through which your computer can reach the FortiGate.
2. Note the number of the physical network port.
3. Using direct console connection, connect and log into the CLI.
4. Enter the following command:

```
config system interface
    edit <interface_str>
        append allowaccess ssh
    next
end
```

Where `<interface_str>` is the name of the network interface associated with the physical network port, such as `port1`.

5. Confirm the configuration using the following command to show the interface's settings:

```
show system interface <interface_str>
```

For example:

```
show system interface port1
    config system interface
        edit "port1"
            set vdom "root"
            set ip 192.168.1.99 255.255.255.0
            set allowaccess ping https ssh
            set type hard-switch
            set stp enable
            set role lan
            set snmp-index 6
        next
    end
```

Connecting using SSH

Once the FortiGate is configured to accept SSH connections, use an SSH client on your management computer to connect to the CLI.

The following instructions use PuTTy. The steps may vary in other terminal emulators.

To connect to the CLI using SSH:

1. On your management computer, start PuTTy.
2. In the *Host Name (or IP address)* field, enter the IP address of the network interface that you are connected to and that has SSH access enabled.
3. Set the port number to 22, if it is not set automatically.
4. Select *SSH* for the *Connection type*.
5. Click *Open*. The SSH client connect to the FortiGate.

   The SSH client may display a warning if this is the first time that you are connecting to the FortiGate and its SSH key is not yet recognized by the SSH client, or if you previously connected to the FortiGate using a different IP address or SSH key. This is normal if the management computer is connected directly to the FortiGate with no network hosts in between.
6. Click *Yes* to accept the FortiGate's SSH key.

   The CLI displays the log in prompt.
7. Enter a valid administrator account name, such as `admin`, then press *Enter*.
8. Enter the administrator account password, then press *Enter*.

The CLI console shows the command prompt (FortiGate hostname followed by a #). You can now enter CLI commands.

If three incorrect log in or password attempts occur in a row, you will be disconnected. If this occurs, wait for one minute, then reconnect and attempt to log in again.

CLI basics

Basic features and characteristics of the CLI environment provide support and ease of use for many CLI tasks.

Help

Press the question mark (?) key to display command help and complete commands.

- Press the question mark (?) key at the command prompt to display a list of the commands available and a description of each command.
- Enter a command followed by a space and press the question mark (?) key to display a list of the options available for that command and a description of each option.
- Enter a command followed by an option and press the question mark (?) key to display a list of additional options available for that command option combination and a description of each option.
- Enter a question mark after entering a portion of a command to see a list of valid complete commands and their descriptions. If there is only one valid command, it will be automatically filled in.

Shortcuts and key commands

Shortcut key	Action
?	List valid complete or subsequent commands. If multiple commands can complete the command, they are listed with their descriptions.
Tab	Complete the word with the next available match. Press multiple times to cycle through available matches.
Up arrow or Ctrl + P	Recall the previous command. Command memory is limited to the current session.
Down arrow, or Ctrl + N	Recall the next command.
Left or Right arrow	Move the cursor left or right within the command line.
Ctrl + A	Move the cursor to the beginning of the command line.
Ctrl + E	Move the cursor to the end of the command line.
Ctrl + B	Move the cursor backwards one word.

Shortcut key	Action
Ctrl + F	Move the cursor forwards one word.
Ctrl + D	Delete the current character.
Ctrl + C	Abort current interactive commands, such as when entering multiple lines. If you are not currently within an interactive command such as `config` or `edit`, this closes the CLI connection.
\ then Enter	Continue typing a command on the next line for a multiline command. For each line that you want to continue, terminate it with a backslash (\ ). To complete the command, enter a space instead of a backslash, and then press *Enter*.

Command tree

Enter `tree` to display the CLI command tree. To capture the full output, connect to your device using a terminal emulation program and capture the output to a log file. For some commands, use the `tree` command to view all available variables and subcommands.

Command abbreviation

You can abbreviate words in the command line to their smallest number of non-ambiguous characters.

For example, the command `get system status` could be abbreviated to `g sy stat`.

Adding and removing options from lists

When configuring a list, the `set` command will remove the previous configuration.

For example, if a user group currently includes members A, B, and C, the command `set member D` will remove members A, B, and C. To avoid removing the existing members from the group, the command `set members A B C D` must be used.

To avoid this issue, the following commands are available:

append	Add an option to an existing list. For example, `append member D` adds user D to the user group without removing any of the existing members.
select	Clear all of the options except for those specified. For example, `select member B` removes all member from the group except for member B.
unselect	Remove an option from an existing list. For example, `unselect member C` removes only member C from the group, without affecting the other members.

Environment variables

The following environment variables are support by the CLI. Variable names are case-sensitive.

$USERFROM	The management access type (`ssh`, `jsconsole`, and so on) and the IPv4 address of the administrator that configured the item.
$USERNAME	The account name of the administrator that configured the item.
$SerialNum	The serial number of the FortiGate.

For example, to set a FortiGate device's host name to its serial number, use the following CLI command:

```
config system global
    set hostname $SerialNum
end
```

Special characters

The following characters cannot be used in most CLI commands: <, >, (,), #, ', and "

If one of those characters, or a space, needs to be entered as part of a string, it can be entered by using a special command, enclosing the entire string in quotes, or preceding it with an escape character (backslash, \).

To enter a question mark (?) or a tab, *Ctrl + V* or *Ctrl + Shift + -* (depending on the method being used to access the CLI) must be entered first.

Question marks and tabs cannot be copied into the CLI Console or some SSH clients. They must be typed in.

Character	Keys
?	Ctrl + V or Ctrl + Shift + - then ?
Tab	Ctrl + V then Tab
Space (as part of a string value, not to end the string)	Enclose the string in single or double quotation marks: `"Security Administrator"` or `'Security Administrator'`. Precede the space with a backslash: `Security\ Administrator`.
' (as part of a string value, not to begin or end the string)	\'
" (as part of a string value, not to begin or end the string)	\"
\	\\

Using grep to filter command output

The `get`, `show`, and `diagnose` commands can produce large amounts of output. The `grep` command can be used to filter the output so that it only shows the required information.

The grep command is based on the standard UNIX grep, used for searching text output based on regular expressions.

For example, the following command displays the MAC address of the internal interface:

```
get hardware nic internal | grep Current_HWaddr
    Current_HWaddr        00:09:0f:cb:c2:75
```

The following command will display all TCP sessions that are in the session list, including the session list line number in the output:

```
get system session list | grep -n tcp
```

The following command will display all of the lines in the HTTP replacement message that contain `URL` or `url`:

```
show system replacemsg http | grep -i url
```

The following options can also be used:

```
-A <num> After
```

```
-B <num> Before
```

```
-C <num> Context
```

The `-f` option is available to support contextual output, in order to show the complete configuration. The following example shows the difference in the output when `-f` is used versus when it is not used:

Without `-f`:

```
show | grep ldap-group1
    edit "ldap-group1"
        set groups "ldap-group1"
```

With `-f`:

```
show | grep -f ldap-group1
    config user group
        edit "ldap-group1"
            set member "pc40-LDAP"
        next
    end
    config firewall policy
        edit 2
            set srcintf "port31"
            set dstintf "port32"
            set srcaddr "all"
            set action accept
            set identity-based enable
            set nat enable
            config identity-based-policy
                edit 1
                    set schedule "always"
```

```
            set groups "ldap-group1"
            set dstaddr "all"
            set service "ALL"
        next
    end
  next
end
```

Language support and regular expressions

Characters such as ñ and é, symbols, and ideographs are sometimes acceptable input. Support varies depending on the type of item that is being configured. CLI commands, objects, field names, and options must use their exact ASCII characters, but some items with arbitrary names or values can be input using your language of choice. To use other languages in those cases, the correct encoding must be used.

Input is stored using Unicode UTF-8 encoding, but is not normalized from other encodings into UTF-8 before it is stored. If your input method encodes some characters differently than in UTF-8, configured items may not display or operate as expected.

Regular expressions are especially impacted. Matching uses the UTF-8 character values. If you enter a regular expression using a different encoding, or if an HTTP client sends a request in a different encoding, matches may not be what is expected.

For example, with Shift-JIS, backslashes could be inadvertently interpreted as the symbol for the Japanese yen (¥), and vice versa. A regular expression intended to match HTTP requests containing monetary values with a yen symbol may not work it if the symbol is entered using the wrong encoding.

For best results:

- use UTF-8 encoding, or
- use only characters whose numerically encoded values are the same in UTF-8, such as the US-ASCII characters that are encoded using the same values in ISO 8859-1, Windows code page 1252, Shift-JIS, and other encoding methods, or
- for regular expressions that must match HTTP requests, use the same encoding as your HTTP clients.

HTTP clients may send requests in encodings other than UTF-8. Encodings usually vary based on the client's operating system or input language. If the client's encoding method cannot be predicted, you might only be able to match the parts of the request that are in English, as the values for English characters tend to be encoded identically, regardless of the encoding method.

If the FortiGate is configured to use an encoding method other than UTF-8, the management computer's language may need to be changed, including the web browse and terminal emulator. If the FortiGate is configured using non-ASCII characters, all the systems that interact with the FortiGate must also support the same encoding method. If possible, the same encoding method should be used throughout the configuration to avoid needing to change the language settings on the management computer.

The GUI and CLI client normally interpret output as encoded using UTF-8. If they do not, configured items may not display correctly. Exceptions include items such as regular expression that may be configured using other encodings to match the encoding of HTTP requests that the FortiGate receives.

To enter non-ASCII characters in a terminal emulator:

1. On the management computer, start the terminal client.
2. Configure the client to send and receive characters using UTF-8 encoding.
   Support for sending and receiving international characters varies by terminal client.
3. Log in to the FortiGate.
4. At the command prompt, type your command and press *Enter*.
   Words that use encoded characters may need to be enclosed in single quotes (`'`).
   Depending on your terminal client's language support, you may need to interpret the characters into character codes before pressing *Enter*. For example, you might need to enter: `edit '\743\601\613\743\601\652'`
5. The CLI displays the command and its output.

Screen paging

By default, the CLI will pause after displaying each page worth of text when a command has multiple pages of output. this can be useful when viewing lengthy outputs that might exceed the buffer of terminal emulator.

When the display pauses and shows `--More--`, you can:

- Press *Enter* to show the next line,
- Press *Q* to stop showing results and return to the command prompt,
- Press an arrow key, *Insert*, *Home*, *Delete*, *End*, *Page Up*, or *Page Down* to show the next few pages,
- Press any other key to show the next page, or
- Wait for about 30 seconds for the console to truncate the output and return to the command prompt.

When pausing the screen is disabled, press *Ctrl + C* to stop the output and log out of the FortiGate.

To disable pausing the CLI output:

```
config system console
    set output standard
end
```

To enable pausing the CLI output:

```
config system console
    set output more
end
```

Editing the configuration file

The FortiGate configuration file can be edited on an external host by backing up the configuration, editing the configuration file, and then restoring the configuration to the FortiGate.

Editing the configuration file can save time is many changes need to be made, particularly if the plain text editor that you are using provides features such as batch changes.

To edit the configuration file:

1. Backup the configuration. See Configuration backups and reset on page 3686 for details.
2. Open the configuration file in a plain text editor that supports UNIX-style line endings.
3. Edit the file as needed.

Do not edit the first line of the configuration file.

This line contains information about the firmware version and FortiGate model. If you change the model number, the FortiGate will reject the configuration when you attempt to restore it.

4. Restore the modified configuration to the FortiGate. See Configuration backups and reset on page 3686 for details.
   The FortiGate downloads the configuration file and checks that the model information is correct. If it is correct, the configuration file is loaded and each line is checked for errors. If a command is invalid, that command is ignored. If the configuration file is valid, the FortiGate restarts and loads the downloaded configuration.

Command syntax

When entering a command, the CLI console requires that you use valid syntax and conform to expected input constraints. It rejects invalid commands. Indentation is used to indicate the levels of nested commands.

Each command line consists of a command word, usually followed by configuration data or a specific item that the command uses or affects.

Notation

Brackets, vertical bars, and spaces are used to denote valid syntax. Constraint notations, such as `<address_ipv4>`, indicate which data types or string patterns are acceptable value input.

All syntax uses the following conventions:

Angle brackets < >	Indicate a variable of the specified data type.
Curly brackets { }	Indicate that a variable or variables are mandatory.
Square brackets [ ]	Indicate that the variable or variables are optional. For example: `show system interface [<name_str>]` To show the settings for all interfaces, you can enter `show system interface` To show the settings for the Port1 interface, you can enter `show system interface port1`.
Vertical bar |	A vertical bar separates alternative, mutually exclusive options. For example: `set protocol {ftp | sftp}` You can enter either `set protocol ftp` or `set protocol sftp`.

Space	A space separates non-mutually exclusive options.
	For example:
	`set allowaccess {ping https ssh snmp http fgfm radius-acct probe-response capwap ftm}`
	You can enter any of the following:
	`set allowaccess ping`
	`set allowaccess https ping ssh`
	`set allowaccess http https snmp ssh ping`
	In most cases, to make changes to lists that contain options separated by spaces, you need to retype the entire list, including all the options that you want to apply and excluding all the options that you want to remove.

Optional values and ranges

Any field that is optional will use square-brackets. The overall config command will still be valid whether or not the option is configured.

Square-brackets can be used is to show that multiple options can be set, even intermixed with ranges. The following example shows a field that can be set to either a specific value or range, or multiple instances:

```
config firewall service custom
    set iprange <range1> [<range2> <range3> ...]
end
```

next

The `next` command is used to maintain a hierarchy and flow to CLI commands. It is at the same indentation level as the preceding `edit` command, to mark where a table entry finishes.

The following example shows the next command used in the subcommand `entries`:

```
config dlp filepattern
    edit <1>
        set name <name>
        set comment [comment]
        config entries
            edit <2>
                set filter-type {pattern | type}
            next
```

After configuring table entry `<2>` then entering `next`, the `<2>` table entry is saved and the console returns to the `entries` prompt:

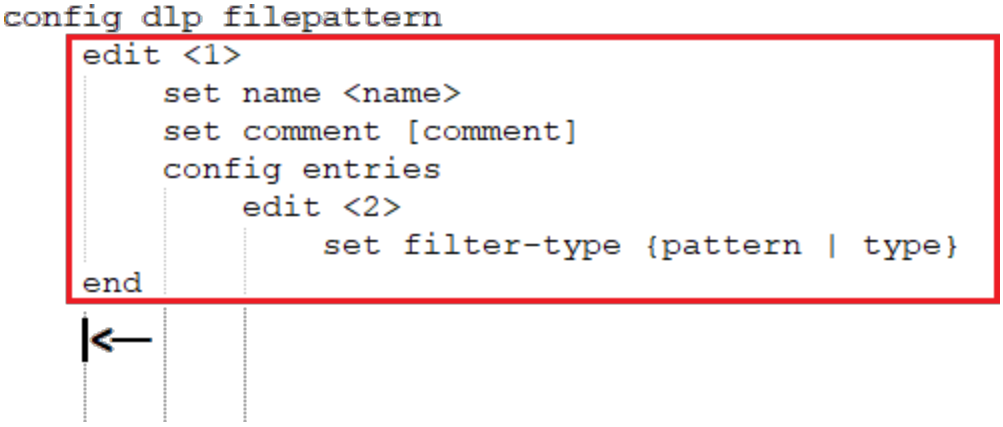
```
FGT60E1Q23456789 (entries) #
```

You can now create more table entries as needed, or enter `end` to save the table and return to the `filepattern` table element prompt.

end

The `end` command is used to maintain a hierarchy and flow to CLI commands.

The following example shows the same command and subcommand as the `next` command example, except `end` has been entered instead of `next` after the subcommand:



Entering `end` will save the `<2>` table entry and the table, and exit the `entries` subcommand entirely. The console returns to the filepattern table element prompt:

Subcommands

Subcommands are available from within the scope of some commands. When you enter a subcommand level, the command prompt changes to indicate the name of the current command scope. For example, after entering:

```
config system admin
```

the command prompt becomes:

```
(admin)#
```

Applicable subcommands are available until you exit the command, or descend an additional level into another subcommand. Subcommand scope is indicated by indentation.

For example, the `edit` subcommand is only available in commands that affects tables, and the `next` subcommand is available only in the `edit` subcommand:

```
config system interface
    edit port1
        set status up
    next
end
```

The available subcommands vary by command. From a command prompt under the `config` command, subcommands that affect tables and fields could be available.

Table subcommands

edit <table_row>	Create or edit a table value.
	In objects such as security policies, `<table_row>` is a sequence number. To create a new table entry without accidentally editing an existing entry, enter `edit 0`. The CLI will confirm that creation of entry 0, but will assign the next unused number when the entry is saved after entering `end` or `next`.
	For example, to create a new firewall policy, enter the following commands:
	`config firewall policy`
	`edit 0`
	`...`
	`next`
	`end`
	To edit an existing policy, enter the following commands:
	`config firewall policy`
	`edit 27`
	`...`
	`next`
	`end`
	The `edit` subcommand changes the command prompt to the name of the table value that is being edited, such as `(27) #`.

delete <table_row>	Delete a table value.
	For example, to delete firewall policy 27, enter the following commands:
	`config firewall policy`
	`delete 27`
	`end`

purge	Clear all table values. The `purge` command cannot be undone. To restore purged table values, the configuration must be restored from a backup.

move	Move an ordered table value.
	In the firewall policy table, this is equivalent to dragging a policy into a new position. It does not change the policy's ID number.
	For example, to move policy 27 to policy 30, enter the following commands:
	`config firewall policy`
	`move 27 to 30`
	`end`

	The `move` subcommand is only available in tables where the order of the table entries matters.

clone <table_row> to <table_row>	Make a clone of a table entry.
	For example, to create firewall policy 30 as a clone of policy 27, enter the following commands:
	`config firewall policy`
	`clone 27 to 30`
	`end`
	The `clone` subcommand may not be available for all tables.

rename <table_row> to <table_row>	Rename a table entry.
	For example to rename an administrator from Fry to Leela, enter the following commands:
	`config system admin`
	`rename Fry to Leela`
	`end`
	The `rename` subcommand is only available in tables where the entries can be renamed.

get	List the current table entries.
	For example, to view the existing firewall policy table entries, enter the following commands:
	`config firewall policy`
	`get`

show	Show the configuration. Only table entries that are not set to default values are shown.
end	Save the configuration and exit the current `config` command.

Purging the `system interface` or `system admin` tables does not reset default table values. This can result in being unable to connect to or log in to the FortiGate, requiring the FortiGate to be formatted and restored.

Field subcommands

set <field> <value>	Modify the value of a field. For example, the command `set fsso enable` sets the `fsso` field to the value `enable`.
unset	Set the field to its default value.
select	Clear all of the options except for those specified.

	For example, if a group contains members A, B, C, and D, to remove all members except for B, use the command `select member B`.
unselect	Remove an option from an existing list. For example, if a group contains members A, B, C, and D, to remove only member B, use the command `unselect member B`.
append	Add an option to an existing multi-option table value.
clear	Clear all the options from a multi-option table value.
get	List the configuration of the current table entry, including default and customized values.
show	Show the configuration. Only values that are not set to default values are shown.
next	Save changes to the table entry and exit the `edit` command so that you can configure the next table entry.
abort	Exit the command without saving.
end	Save the configuration and exit the current `config` command.

Permissions

Administrator (or access) profiles control what CLI commands an administrator can access by assigning read, write, or no access to each area of FortiOS. For information, see Administrator profiles on page 3218.

Read access is required to view configurations. Write access is required to make configuration changes. Depending on your account's profile, you may not have access to all CLI commands. To have access to all CLI commands, an administrator account with the *super_admin* profile must be used, such as the *admin* account.

Accounts assigned the *super_admin* profile are similar to the root administrator account. They have full permission to view and change all FortiGate configuration options, including viewing and changing other administrator accounts.

To increase account security, set strong passwords for all administrator accounts and change the passwords regularly. See Default administrator password on page 3269 and Password policy on page 3204 for more information.

Configuration and management

FortiOS can be managed through the graphical user interface (GUI) or the Command Line Interface (CLI) as well as other tools.

For	Use
Direct or individual configuration	FortiOS GUI and CLI: see Using the GUI on page 42 and Using the CLI on page 58. FortiExplorer Go: see FortiExplorer Go on page 74.
Mass provisioning, management, and orchestration	FortiManager and FortiGate Cloud: see the FortiManager page and the FortiGate Cloud page on the Fortinet Document Library.
Automation	REST API accessible through Fortinet Developer Network (FNDN): see Accessing Fortinet Developer Network on page 80 and REST API administrator. Automation tools, such as Terraform and Ansible: see Terraform: FortiOS as a provider on page 83.
Other tools and FortiConverter	The FortiConverter service helps you migrate a configuration from one FortiGate to another FortiGate, or from a third-party firewall to a FortiGate: see Migrating a configuration with FortiConverter on page 74.

FortiExplorer Go

FortiExplorer Go is a free mobile application that provisions and deploys BLE capable FortiGates with the BLE Autodiscovery feature. You can also use FortiExplorer Go to remotely manage FortiGates registered to your FortiCare account and deployed in FortiGate Cloud.

FortiExplorer Go is available on both iOS and Android devices. For more information, refer to the FortiExplorer Go User Guide for your respective device OS.

Migrating a configuration with FortiConverter

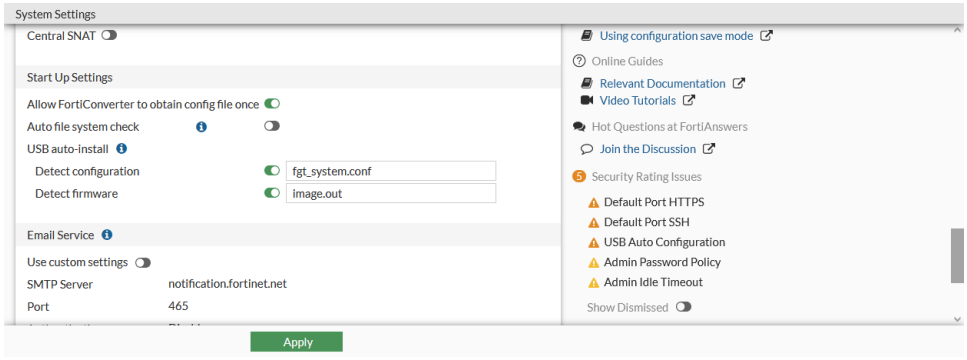
A configuration can be migrated from an older FortiGate device to a new FortiGate device directly from the FortiGate GUI, without having to access the FortiConverter portal.

Both the source and target FortiGates must be registered under the same FortiCare account and have internet connectivity to reach the FortiConverter server. The target FortiGate must also have a valid FortiConverter license.

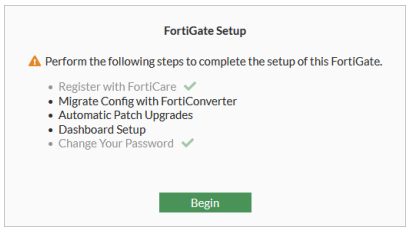
In this example, FortiGate A (FGTA) is replacing FortiGate B (FGTB). The configuration is migrated using FortiConverter, but without accessing the FortiConverter portal.

To migrate the configuration from FGTB to FGTA in the GUI:

1. On FGTB, go to *System* > *Settings*, enable *Allow FortiConverter to obtain config file once*, then click *Apply*.



2. Log in to FGTA and on the GUI startup menu click *Begin* to start *Migrate Config with FortiConverter*.

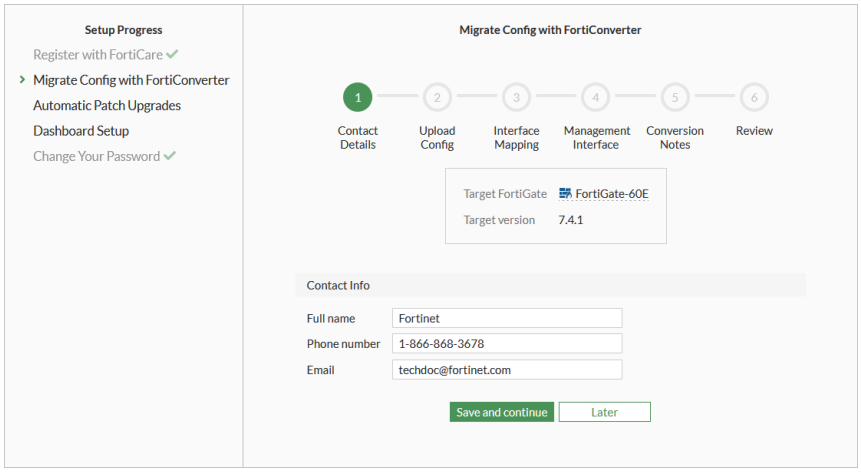


3. Click *Convert* to start the conversion process.

   If the device does not have a FortiConverter license, a warning will be shown and the *Convert* button will be unclickable. The license status is shown in the GUI on the *System* > *FortiGuard* page in the *License Information* table.

   You can toggle the *Don't show again* option and click *Later* to turn off reminders about the migration process.

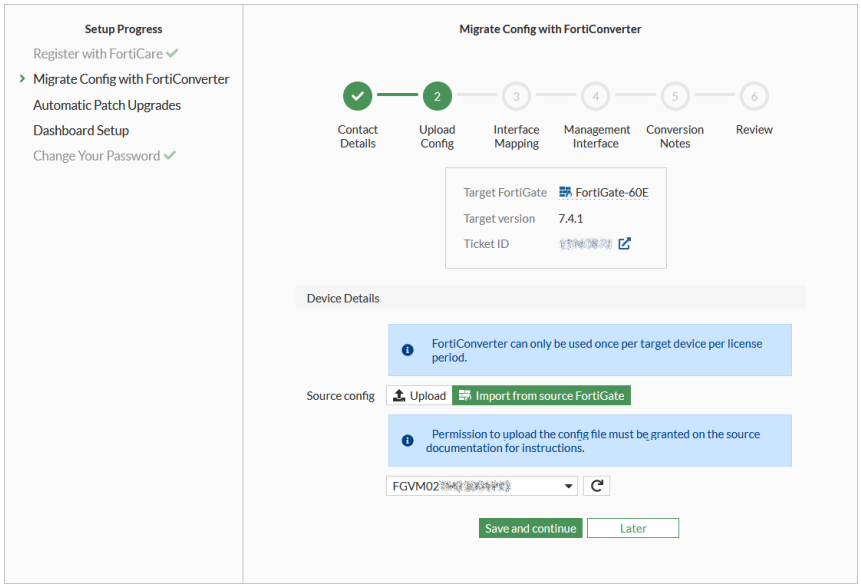
4. Enter the user contact information, then click *Save and continue*.



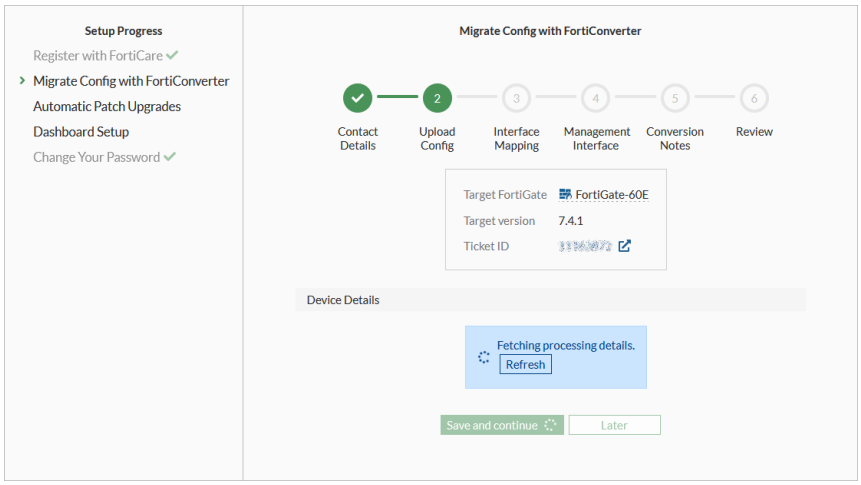
The FortiConverter ticket is created.

5. The source configuration can be uploaded from a file, or from another FortiGate. In this example, the configuration is uploaded from FGTB.
   - To upload from a file, set *Source config* to *Upload* then click *Browse* to locate the file.

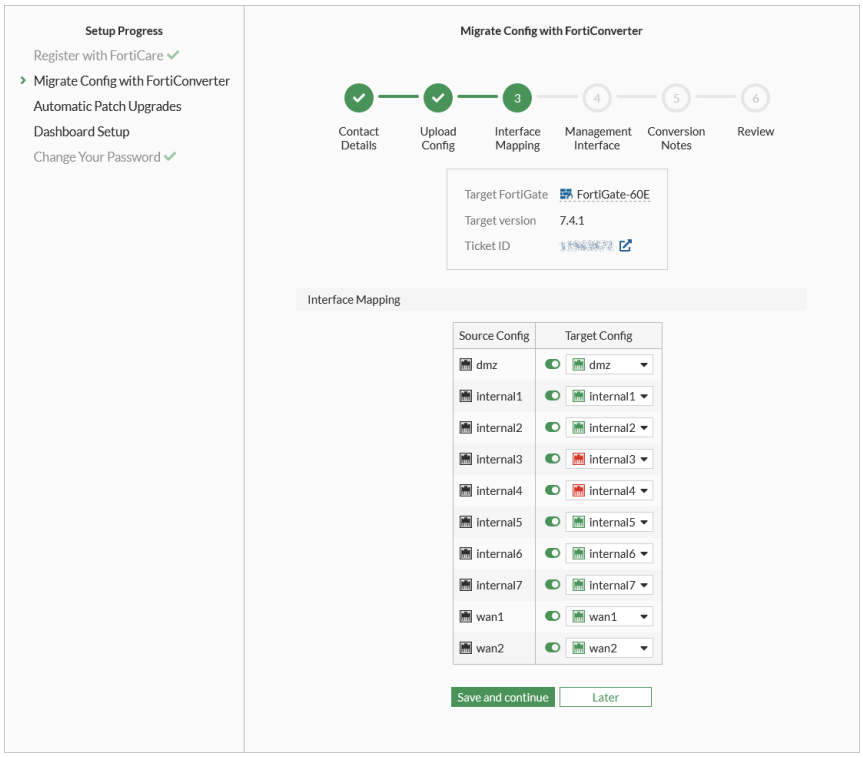
   - To import from FGTB, set *Source config* to *Import from source FortiGate* then select the FGTB. *Allow FortiConverter to obtain config file once* must be enabled in *System > Settings* on FGTB.



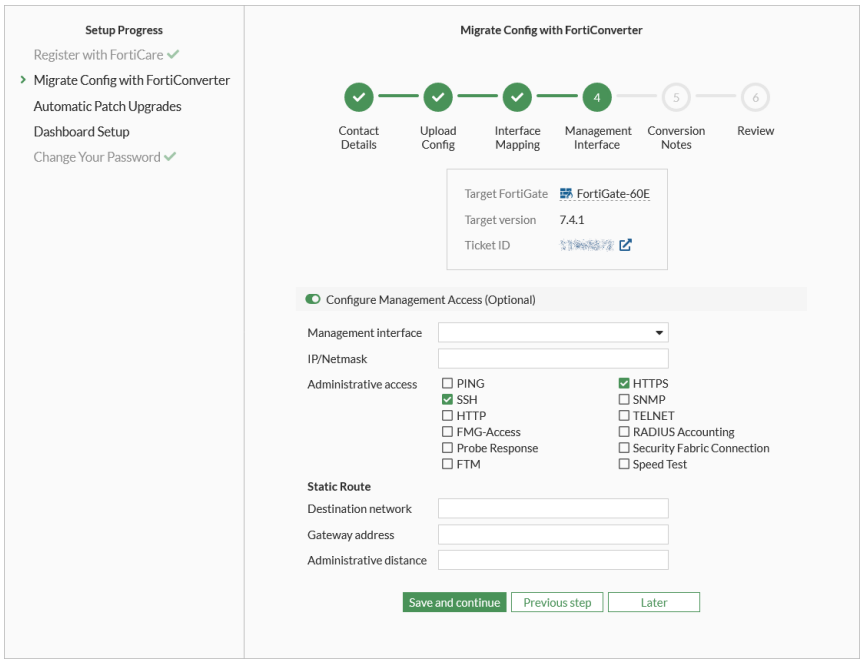
6. Click *Save and continue*, then wait for the FGTB configuration file to be uploaded to FortiConverter and processed. After the configuration is uploaded, the *Allow FortiConverter to obtain config file once* is automatically disabled on FGTB.



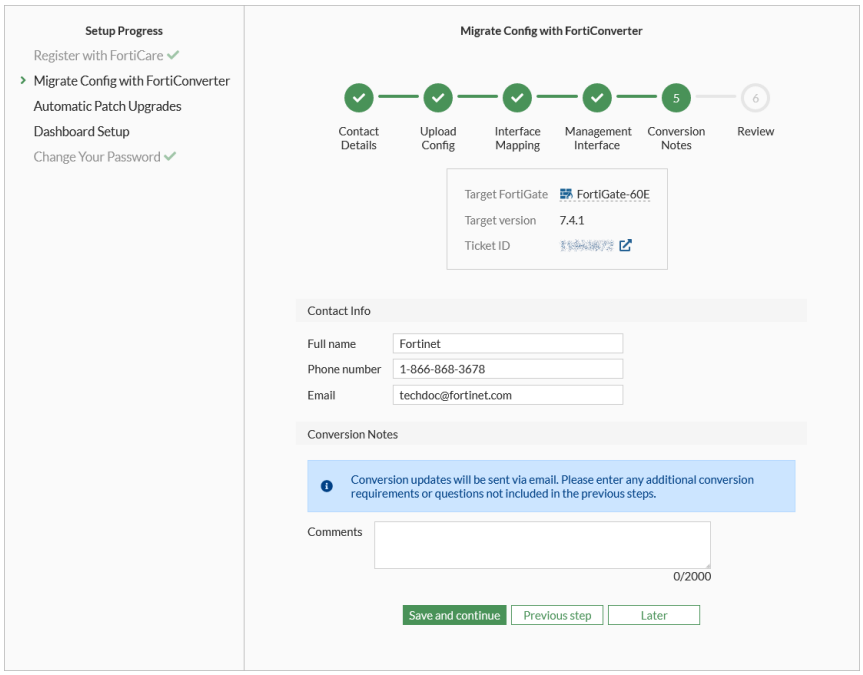
7. Define the interface mapping between the source and target configuration, then click *Save and continue*. The target interfaces are prepopulated.



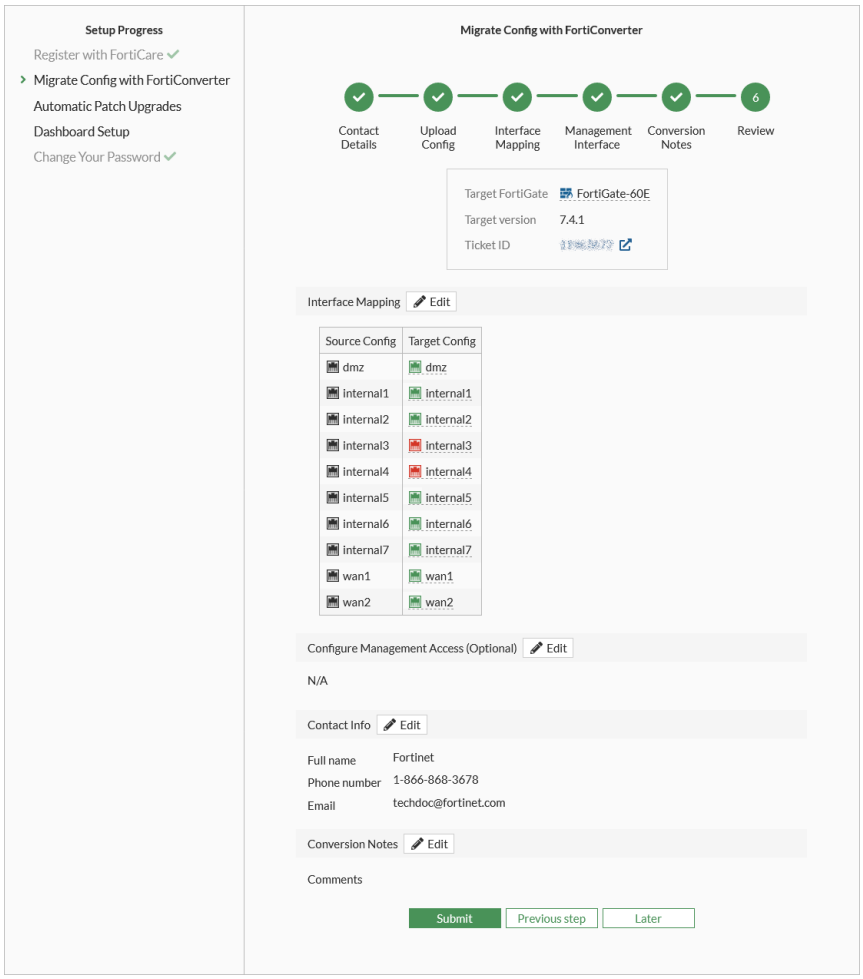
8. Optionally, configure management access on the target FortiGate (FGTA), then click *Save and continue*.



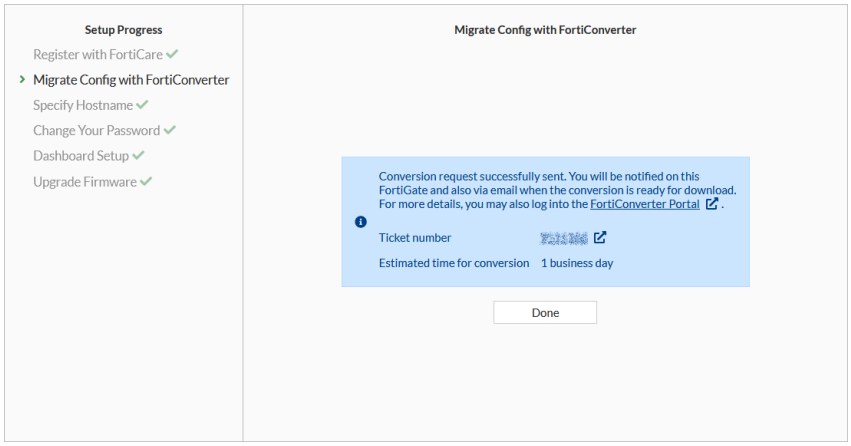
9. Enter conversion notes in the *Comments* field, then click *Save and continue*.



10. Review the content, then click *Submit*.

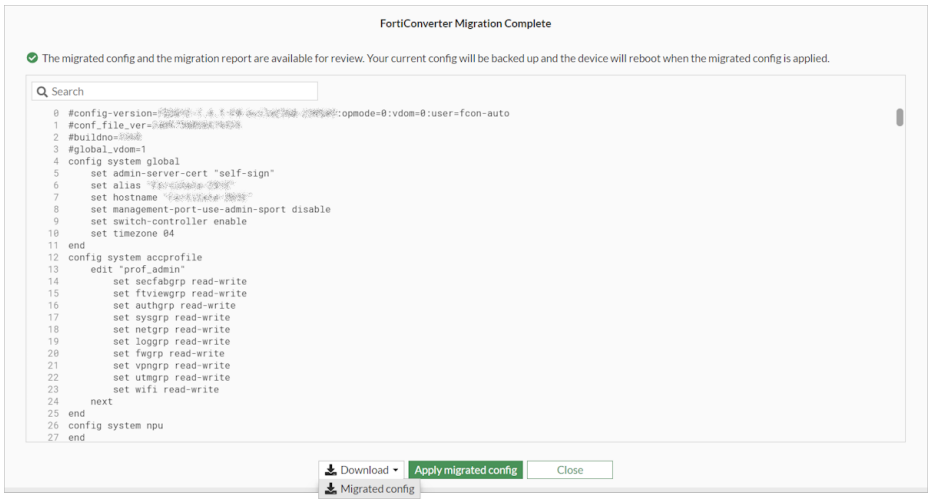


The conversion request is sent, an email is sent to confirm that the conversion process has started in FortiConverter, and the ticket status is shown. The estimated conversion time is one business day.



11. Click *Done*.

    When the conversion process completes, you will receive an email and a notifications in the FortiGate GUI.
12. In the GUI, click your administrator name and select *Configurations> FortiConverter*. The migrated configuration is shown for review, and can be downloaded.



13. Click *Apply migrated config* to apply the converted configuration to the FortiGate. This will cause the FortiGate to reboot. The existing configuration will be backed up before the converted configuration is applied.
14. To manually load to configuration file:
    a. Click your administrator name and select *Configuration* > *Restore*.

    b. Upload the converted configuration file, then click *OK*. This will cause the FortiGate to reboot.

To see the visibility status of the FortiConverter wizard:

```
diagnose sys forticonverter get-prompt-visibility
```

To set the visibility status of the FortiConverter wizard:

```
diagnose sys forticonverter set-prompt-visibility {visible | hidden}
```

Accessing Fortinet Developer Network

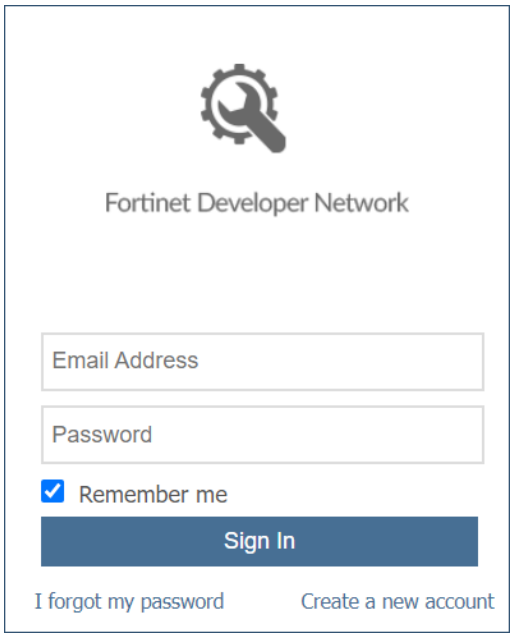
The Fortinet Developer Network (FNDN) is a subscription-based community that helps administrators enhance and increase the effectiveness of Fortinet products. Administrators can access the FortiAPI forum in FNDN to help create applications that interact with Fortinet products, such as custom web portals, automated deployment and provisioning systems, and scripted tasks. FNDN makes it easy for administrators and Fortinet professionals to interact, share sample code, and upload their own tools. The FortiOS REST API documentation is available within the FortiAPI forum.

All FNDN users must be sponsored by two Fortinet employees. The sponsors must be able to confirm the user's identity and need for access. Approvals from both sponsors are required before access is granted to new users. The sponsors' email addresses are required to create a new FNDN account.

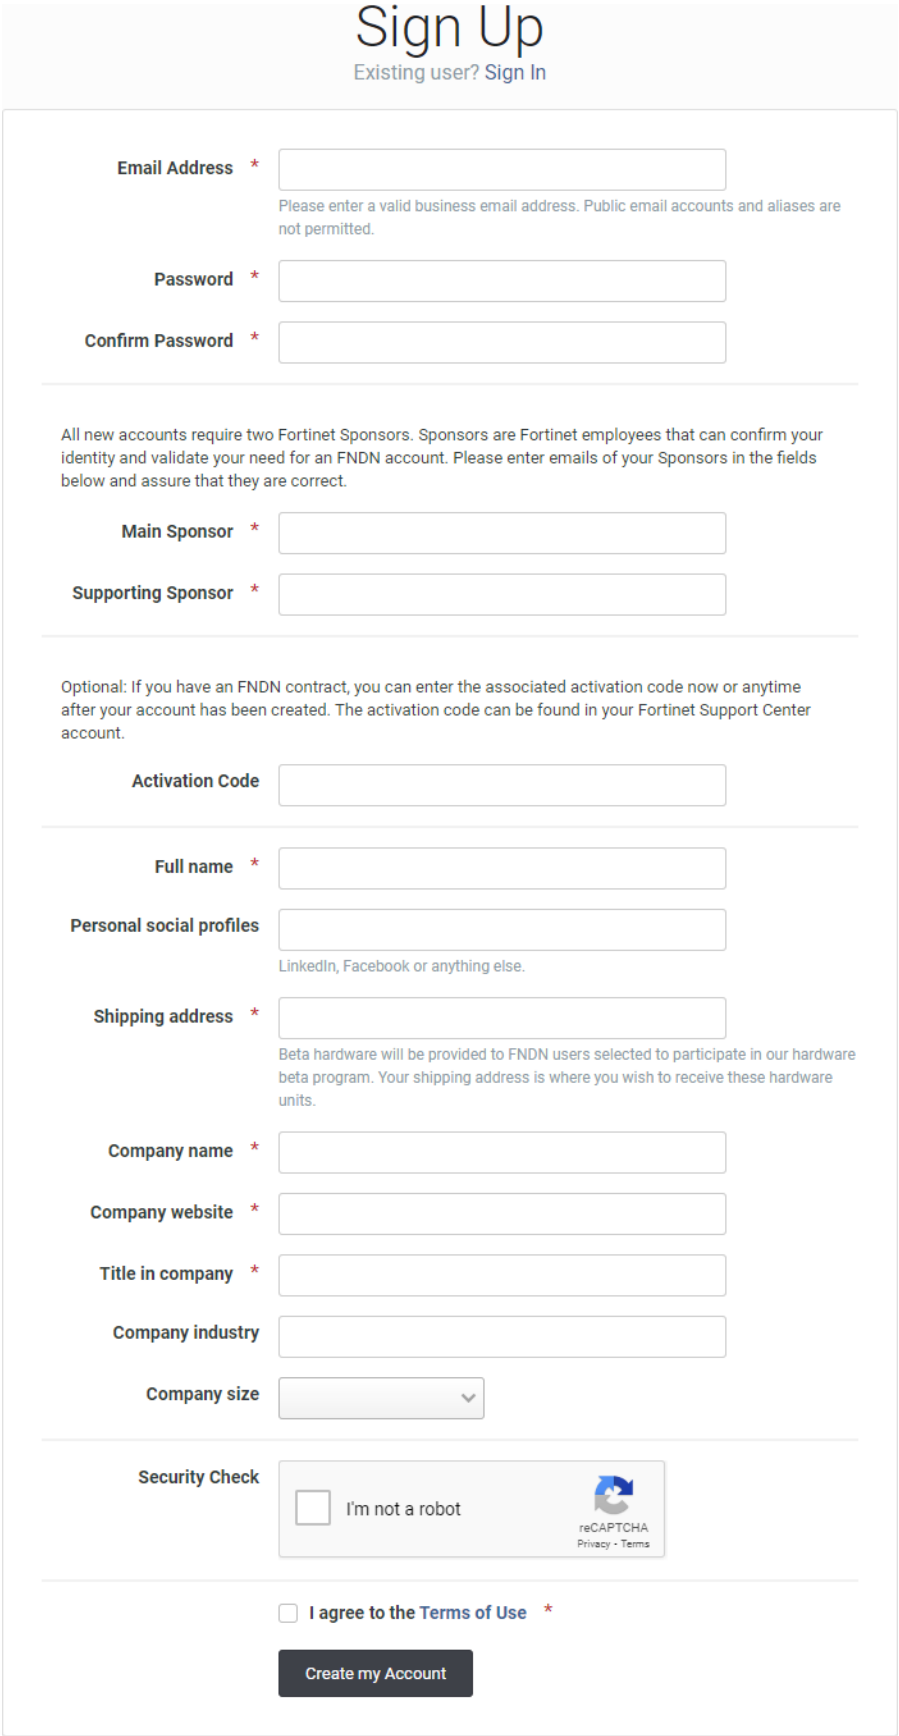
Basic and licensed access options are available. Refer to the Fortinet Developer Network data sheet for more information.

To create an FNDN account:

1. Obtain sponsorship from two Fortinet employees.
2. Go to the FNDN website, https://fndn.fortinet.net/. The log in page appears.



3. Click *Create a new account*. The *Sign Up* page appears.
4. Enter the information in the form fields and agree to the *Terms of Use*.



Sign Up
Existing user? Sign In
Email Address *
Please enter a valid business email address. Public email accounts and aliases are not permitted.
Password *
Confirm Password *
All new accounts require two Fortinet Sponsors. Sponsors are Fortinet employees that can confirm your identity and validate your need for an FNDN account. Please enter emails of your Sponsors in the fields below and assure that they are correct.
Main Sponsor *
Supporting Sponsor *
Optional: If you have an FNDN contract, you can enter the associated activation code now or anytime after your account has been created. The activation code can be found in your Fortinet Support Center account.
Activation Code
Full name *
Personal social profiles
LinkedIn, Facebook or anything else.
Shipping address *
Beta hardware will be provided to FNDN users selected to participate in our hardware beta program. Your shipping address is where you wish to receive these hardware units.
Company name *
Company website *
Title in company *
Company industry
Company size
Security Check
I'm not a robot
reCAPTCHA
Privacy - Terms
I agree to the Terms of Use *
Create my Account

5. Click *Create my Account*.
   New accounts are reviewed and approved by an FNDN administrator. After both sponsors approve the request, an FNDN administrator reviews the request and approves account access in around one business day if all requirements are met.

Terraform: FortiOS as a provider

Fortinet's Terraform support provides customers with more ways to efficiently deploy, manage, and automate security across physical FortiGate appliances and virtual environments. You can use Terraform to automate various IT infrastructure needs, thereby diminishing mistakes from repetitive manual configurations.

For example, if Fortinet is releasing a new FortiOS version, your organization may require you to test a new functionality to determine how it may impact the environment before globally deploying the new version. In this case, the ability to rapidly stand up environments and test these functions prior to production environment integration provides a resource-efficient and fault-tolerant approach.

The following example demonstrates how to use the Terraform FortiOS provider to perform simple configuration changes on a FortiGate unit. It requires the following:

- FortiOS 6.0 or later
- FortiOS Provider: This example uses terraform-provider-fortios 1.0.0.
- Terraform: This example uses Terraform 0.11.14.
- REST API administrator created on the FortiGate with the API key

For more information, see the Terraform FortiOS Provider at https://www.terraform.io/docs/providers/fortios/index.html.

To create a REST API administrator:

1. On the FortiGate, go to *System > Administrators* and click *Create New > REST API Admin*.
2. Enter the *Username* and, optionally, enter *Comments*.
3. Select an *Administrator Profile*.
4. We recommend that you create a new profile with minimal privileges for this terraform script:
   a. In the *Administrator Profile* drop down click *Create New*.
   b. Enter a name for the profile.
   c. Configure the *Access Permissions*:
      - *None*: The REST API is not permitted access to the resource.
      - *Read*: The REST API can send read requests (`HTTP GET`) to the resource.
      - *Read/Write*: The REST API can send read and write requests (`HTTP GET/POST/PUT/DELETE`) to the resource.
   d. Click *OK*.
5. Enter *Trusted Hosts* to specify the devices that are allowed to access this FortiGate.
6. Click *OK*.
   An API key is displayed. This key is only shown once, so you must copy and store it securely.

To configure FortiGate with Terraform Provider module support:

1. Download the terraform-provider-fortios file to a directory on the management computer.
2. Create a new file with the .tf extension for configuring your FortiGate:
   ```
   root@mail:/home/terraform# ls
   terraform-provider-fortios_v1.0.0_x4 test.tf
   ```
3. Edit the test.tf Terraform configuration file:
   In this example, the FortiGate's IP address is 10.6.30.5, and the API user token is 17b**********63ck. Your provider information must also be changed.

   ```
   # Configure the FortiOS Provider
   provider "fortios" {
   hostname = "10.6.30.5"
   token = "17b**********63ck"
   }
   ```

4. Create the resources for configuring your DNS object and adding a static route:

   ```
   resource "fortios_system_setting_dns" "test1" {
   primary = "172.16.95.16"
   secondary = "8.8.8.8"
   }
   resource "fortios_networking_route_static" "test1" {
   dst = "110.2.2.122/32"
   gateway = "2.2.2.2"
   blackhole = "disable"
   distance = "22"
   weight = "3"
   priority = "3"
   device = "port2"
   comment = "Terraform test"
   }
   ```

5. Save your Terraform configuration file.
6. In the terminal, enter `terraform init` to initialize the working directory.
   It reads the provider if the name follows the convention `terraform-provider-[name]`:

   ```
   root@mail:/home/terraform# terraform init
   Initializing the backend...
   Terraform has been successfully initialized!
   You may now begin working with Terraform. Try running "terraform plan" to see
   any changes that are required for your infrastructure. All Terraform commands
   should now work.
   If you ever set or change modules or backend configuration for Terraform,
   rerun this command to reinitialize your working directory. If you forget, other
   commands will detect it and remind you to do so if necessary.
   ```

7. Run `terraform -v` to verify the version of loaded provider module:

   ```
   root@mail:/home/terraform# terraform -v
   Terraform v0. 11.14
   + provider.fortios v1.0.0
   ```

8. Enter `terraform plan` to parse the configuration file and read from the FortiGate configuration to see what Terraform changes:

   This example create a static route and updates the DNS address. You can see that Terraform reads the DNS addresses from the FortiGate and then lists them.

```
root@mail:/home/terraform# terraform plan
Refreshing Terraform state in-memory prior to plan...
The refreshed state will be used to calculate this plan, but will not be
persisted to local or remote state storage.
fortios_networking_route_static.test1: Refreshing state... (ID: 2)
fortios_system_setting_dns.test1: Refreshing state... (ID: 96.45.45.45)
------------------------------------------------------------------------
An execution plan has been generated and is shown below.
Resource actions are indicated with the following symbols:
+ create
~ update in-place
Terraform will perform the following actions:
+ fortios_networking_route_static.test1
id: <computed>
blackhole: "disable"
comment: "Terraform test"
device: "port2"
distance: "22"
dst: "110.2.2.122/32"
gateway: "2.2.2.2"
priority: "3"
weight: "3"
~ fortios_system_setting_dns.test1
primary: "96.45.45.45" => "172.16.95.16"
secondary: "208.91.112.22" => "8.8.8.8"
Plan: 1 to add, 1 to change, 0 to destroy.
------------------------------------------------------------------------
Note: You didn't specify an "-out" parameter to save this plan, so Terraform
can't guarantee that exactly these actions will be performed if
"terraform apply" is subsequently run.
```

If you are running terraform-provider-fortios 1.1.0, you may see the following error:

```
Error: Error getting CA Bundle, CA Bundle should be set when insecure is
      false.
```

In this case, add the following line to the FortiOS provider configuration in the test.tf file:

```
insecure = "true"
```

9. Enter `terraform apply` to continue the configuration:

```
root@mail:/home/terraform# terraform apply
fortios_system_setting_dns.test1: Refreshing state... (ID: 96.45.45.45)
fortios_networking_route_static.test1: Refreshing state... (ID: 2)
An execution plan has been generated and is shown below.
Resource actions are indicated with the following symbols:
+ create
```

```
~ update in-place
Terraform will perform the following actions:
+ fortios_networking_route_static.test1
id: <computed>
blackhole: "disable"
comment: "Terraform test"
device: "port2"
distance: "22"
dst: "110.2.2.122/32"
gateway: "2.2.2.2"
priority: "3"
weight: "3"
~ fortios_system_setting_dns.test1
primary: "96.45.45.45" => "172.16.95.16"
secondary: "208.91.112.22" => "8.8.8.8"
Plan: 1 to add, 1 to change, 0 to destroy.
Do you want to perform these actions?
Terraform will perform the actions described above.
Only 'yes' will be accepted to approve.
Enter a value: yes
fortios_networking_route_static.test1: Creating...
blackhole: "" => "disable"
comment: "" => "Terraform test"
device: "" => "port2"
distance: "" => "22"
dst: "" => "110.2.2.122/32"
gateway: "" => "2.2.2.2"
priority: "" => "3"
weight: "" => "3"
fortios_system_setting_dns.test1: Modifying... (ID: 96.45.45.45)
primary: "96.45.45.45" => "172.16.95.16"
secondary: "208.91.112.22" => "8.8.8.8"
fortios_networking_route_static.test1: Creation complete after 0s (ID: 2)
fortios_system_setting_dns.test1: Modifications complete after 0s (ID: 172.16.95.16)
Apply complete! Resources: 1 added, 1 changed, 0 destroyed.
```

The FortiGate is now configured according to the configuration file.

10. To change or delete something in the future, edit the configuration file and then apply it again. In supported cases, it deletes, adds, or updates new entries as configured. For instance, in this example you can remove the static route and revert the DNS address to its original configuration by changing the .tf file:

    a. Edit the configuration file:

```
# Configure the FortiOS Provider
provider "fortios" {
hostname = "10.6.30.5"
token = "17b********************63ck"
}
resource "fortios_system_setting_dns" "test1" {
primary = "96.45.45.45"
secondary = "208.91.112.22"
}
```

```
#resource "fortios_networking_route_static" "test1" {
# dst = "110.2.2.122/32"
# gateway = "2.2.2.2"
# blackhole = "disable"
# distance = "22"
# weight = "3"
# priority = "3"
# device = "port2"
# comment = "Terraform test"
#}
```

b. Entering `terraform apply` deletes the static route that is commented out of the configuration file, and reverts the DNS address to the old address:

```
root@mail:/home/terraform# terraform apply
fortios_system_setting_dns.test1: Refreshing state... (ID: 172.16.95.16)
fortios_networking_route_static.test1: Refreshing state... (ID: 2)
An execution plan has been generated and is shown below.
Resource actions are indicated with the following symbols:
~ update in-place
- destroy
Terraform will perform the following actions:
- fortios_networking_route_static.test1
~ fortios_system_setting_dns.test1
primary: "172.16.95.16" => "96.45.45.45"
secondary: "8.8.8.8" => "208.91.112.22"
Plan: 0 to add, 1 to change, 1 to destroy.
Do you want to perform these actions?
Terraform will perform the actions described above.
Only 'yes' will be accepted to approve.
Enter a value: yes
fortios_networking_route_static.test1: Destroying... (ID: 2)
fortios_system_setting_dns.test1: Modifying... (ID: 172.16.95.16)
primary: "172.16.95.16" => "96.45.45.45"
secondary: "8.8.8.8" => "208.91.112.22"
fortios_networking_route_static.test1: Destruction complete after 0s
fortios_system_setting_dns.test1: Modifications complete after 0s (ID: 96.45.45.45)
Apply complete! Resources: 0 added, 1 changed, 1 destroyed.
```

Troubleshooting

Use the HTTPS daemon debug to begin troubleshooting why a configuration was not accepted:

```
# diagnose debug enable
# diagnose debug application httpsd -1
```

The REST API 403 error means that your administrator profile does not have sufficient permissions.

The REST API 401 error means that you do not have the correct token or trusted host.

Product registration with FortiCare

It is recommended to register your product with Fortinet. A FortiCare/FortiCloud account with Fortinet Technical Support (https://support.fortinet.com) is required to register products. This section describes how to register the product and includes information about other tasks performed with a FortiCare/FortiCloud account.

- FortiCare and FortiGate Cloud login on page 88
- FortiCare Register button on page 90
- Transfer a device to another FortiCloud account on page 92
- Deregistering a FortiGate on page 93

FortiCare and FortiGate Cloud login

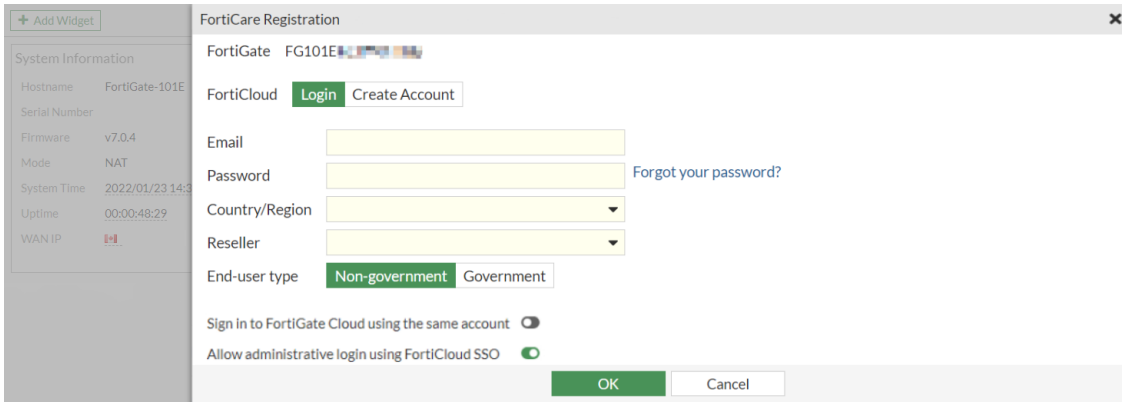
With FortiCloud, FortiOS supports a unified login to FortiCare and FortiGate Cloud. The FortiGate Cloud setup is a subset of the FortiCare setup.

- If the FortiGate is not registered, activating FortiGate Cloud will force you to register with FortiCare.
- If a FortiGate is registered in FortiCare using a FortiCloud account, then only that FortiCloud account can be used to activate FortiGate Cloud.
- If a different FortiCloud account was already used to activate FortiGate Cloud, then a notification asking you to migrate to FortiCloud is shown in the GUI after upgrading FortiOS.

The CLI can be used to activate FortiGate Cloud without registration, or with a different FortiCloud account.

To activate FortiGate Cloud and register with FortiCare at the same time:

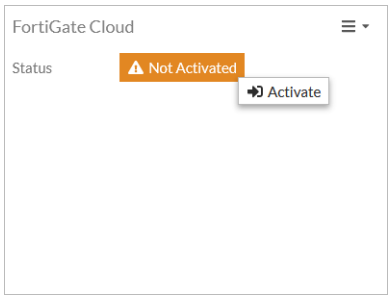
1. Go to *Dashboard* > *Status*.
2. In the FortiGate Cloud widget, click *Not Activated* > *Activate*.
   You must register with FortiCare before activating FortiGate Cloud.



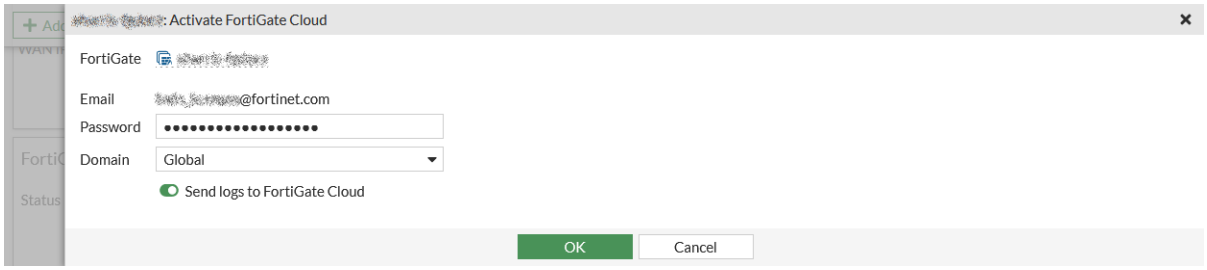
3. Enter your FortiCare *Email* address and *Password*.
4. Select your *Country/Region*, *Reseller*, and *End-user type*.
5. Enable *Sign in to FortiGate Cloud using the same account*.
6. Click *OK*.

To activate FortiGate Cloud on an already registered FortiGate:

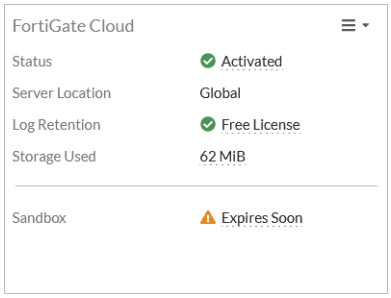
1. Go to *Dashboard* > *Status*.
2. In the *FortiGate Cloud* widget, click *Not Activated* > *Activate*.



3. Enter the password for the account that was used to register the FortiGate.

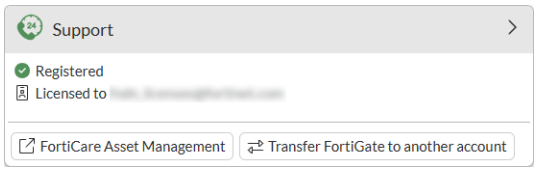


4. Click *OK*.
   The *FortiGate Cloud* widget now shows the activated FortiCloud account.

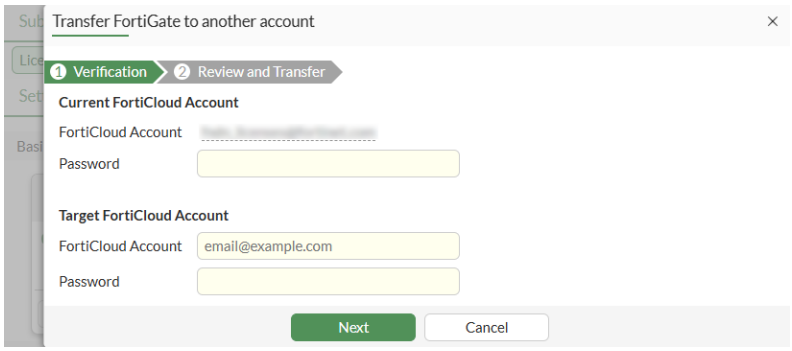


To migrate from the activated FortiGate Cloud account to the registered FortiCloud account:

1. Go to *System* > *FortiGuard*.
2. Go to the *Subscriptions* > *Licensed* tab.
3. In the *Support* widget, click *Transfer FortiGate to another account*.



4. Enter the *Password* of the current FortiCloud account.



5. Enter the target *FortiCloud Account* name and *Password*, then click *Next*.
6. Review the information in the *From* and *To* fields, then click *Transfer*.

To activate FortiGate Cloud using an account that is not used for registration:

1. Enter the following with the credentials for the account being used to activate FortiGate Cloud:

```
# execute fortiguard-log login <account_id> <password>
```

2. Check the account type:

```
# diagnose fdsm contract-controller-update
Protocol=2.0|Response=202|Firmware=FAZ-4K-FW-2.50-
100|SerialNumber=FAMS000000000000|Persistent=false|ResponseItem=HomeServer:172.16.95.151:443*A
lterServer:172.16.95.151:443*Contract:20200408*NextRequest:86400*UploadConfig:False*Management
Mode:Local*ManagementID:737941253*AccountType:multitenancy

Result=Success
```

A FortiCloud account that is not used for the support portal account cannot be used to register FortiGate. Attempting to activate FortiGate Cloud with this type of account will fail.

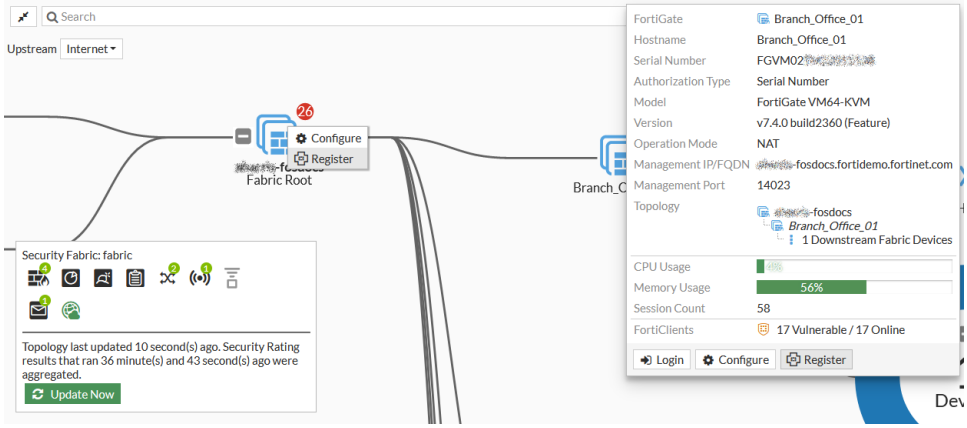
For FortiGates managed by FortiGate Cloud, automatic firmware patch may be enabled depending on the FortiGate Cloud version and portal in use. See the Administration Guide for the applicable FortiGate Cloud version and portal:

- Standard Portal Administration Guide
- 25.1.a Portal (Beta) Administration Guide
- Premium Portal Administration Guide

FortiCare Register button

The FortiCare *Register* button is displayed in the GUI on various Fabric and device related pages and widgets.

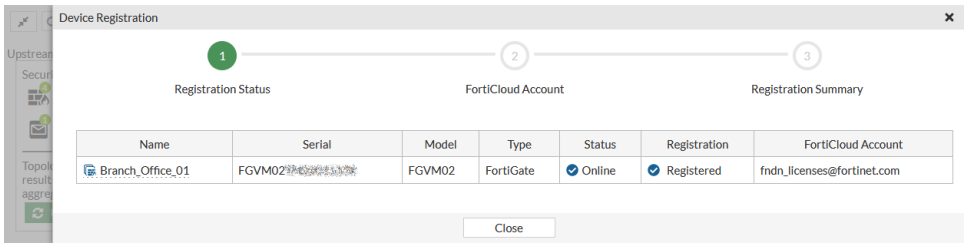
- To access the *Register* button on a topology page, click on or hover over the FortiGate device:



- To access the button from the *System* > *Firmware & Registration* or *System* > *HA* page, right-click on the device name.

The *Register* button is also accessible from tooltips for devices on the *Managed FortiAPs* and *Managed FortiSwitches pages*.

Clicking *Register* opens the *Device Registration* pane. If a device is already registered, the pane still opens and displays the device information.



Primary and secondary HA members can be registered to FortiCare at the same time from the primary unit by using the *Register* button. The secondary unit will register through the HA proxy.

In this example, a HA member is registered from the *Physical Topology* page.

To register a HA member to FortiCare:

1. On the primary unit, go to *Security Fabric* > *Physical Topology*, or expand the *Security Fabric* widget on the *Status* dashboard.
2. Hover over the HA member and click *Register*. The *Device Registration* pane opens.
3. Select the device and click *Register*.
4. Enter the required FortiCloud account information (password, country or region, reseller) and click *Submit*.
5. Once the registration is complete, click *Close*.

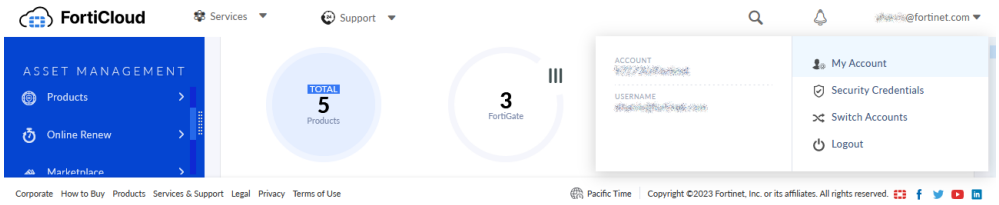
Transfer a device to another FortiCloud account

Master account users can transfer a device from one FortiCloud/FortiCare account to another. Users can transfer a device up to three times within a twelve-month time period. If more transfers are required within the twelve-month time period, contact Technical Support to request the transfer.

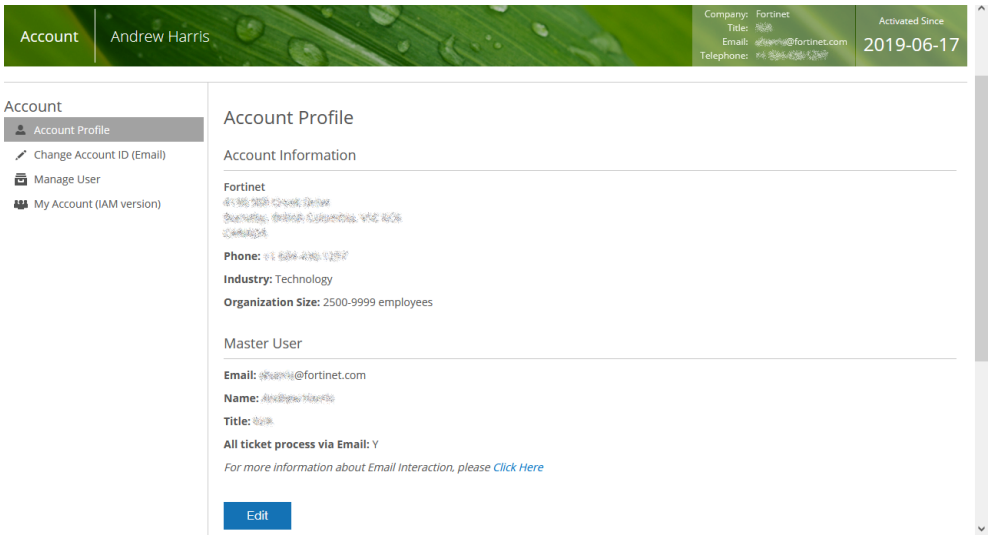
Requirements:

To transfer an account, you must:

- Have access to the FortiGate, as well as both the FortiCloud and FortiCare accounts.
- Be a master account user.
  To verify if you are the master account user, log in to support.fortinet.com. Click the username, then select *My Account*.



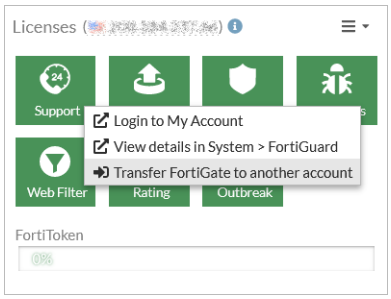
The *Account Profile* page opens.



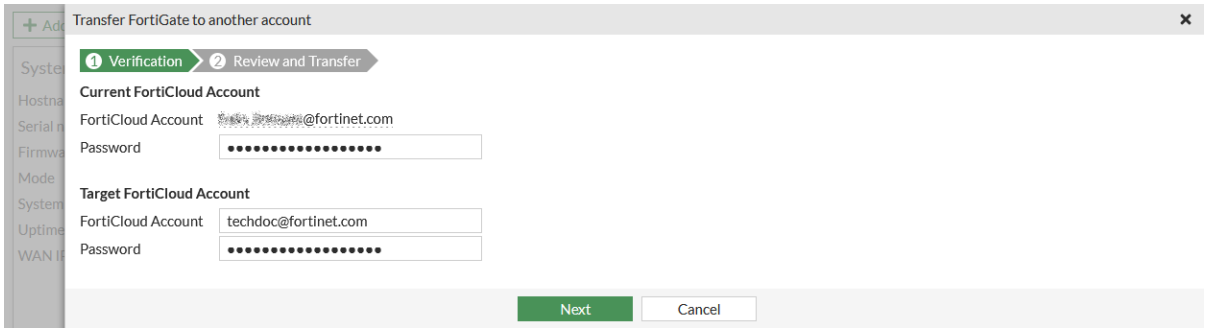
To transfer an account in the GUI:

1. Go to *Dashboard* > *Status*.
2. In the *Licenses* widget, click the *Support* link, then click *Transfer FortiGate to Another Account*.

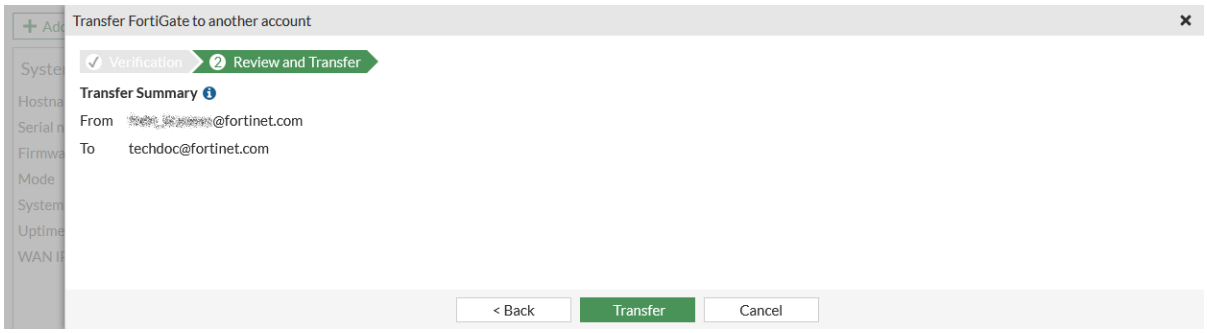
You can also transfer an account from *System* > *FortiGuard*.



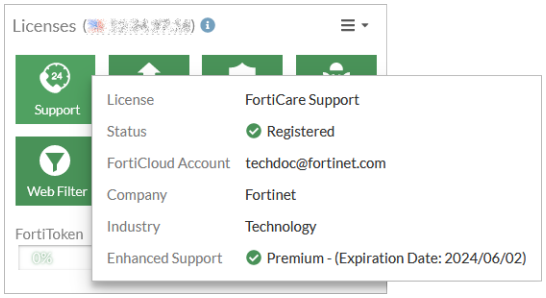
3. In the *Current FortiCloud Account* fields, enter the username and password for the current account. In the *Target FortiCloud Account* fields, enter the new username and password.
4. Click *Next*.



5. Review the information, then click *Transfer*.



After the transfer is complete, the new the FortiCloud account is displayed in the *Licenses* widget.



Deregistering a FortiGate

An administrator can deregister a FortiGate if the device has been registered for three or more years, using the GUI or CLI, without having to contact FortiCare administration. After the device is deregistered, all associated

contracts are also deregistered, and all of the administrator's information is wiped.

To deregister the FortiGate in the GUI:

1. Go to *System* > *FortiGuard* and in the *FortiCare Support* row select *Actions* > *Deregister FortiGate*.
   The FortiCare Deregistration pane opens.
2. Enter your password then click *Next*.
3. Confirm the FortiGate deregistration then click *Submit*.
   If the FortiGate has been registered for less then three years, the deregistration will fail.

To deregister the FortiGate in the CLI:

```
# diagnose forticare direct-registration product-deregister <accountID> <password>
```

If the FortiGate has been registered for less then three years, the deregistration will fail:

```
forticare_product_deregister:1335: Failed to get response (rc = 0, http_code = 403)
Unit deregistration unsuccessful.
```

FortiGate models

Not all FortiGates have the same features, and some models support low encryption. This section also describes typical LEDs found on FortiGate models.

- Differences between models on page 94
- Low encryption models on page 95
- LEDs on page 95
- Proxy-related features not supported on FortiGate 2 GB RAM models on page 98
- FGR-70F/FGR-70F-3G4G GPIO/DIO module on page 99

Differences between models

Not all FortiGates have the same features, particularly entry-level models (models 30 to 90). A number of features on these models are only available in the CLI.

Consult your model's QuickStart Guide, hardware manual, or the Feature / Platform Matrix for further information about features that vary by model.

FortiGate models differ principally by the names used and the features available:

- Naming conventions may vary between FortiGate models. For example, on some models the hardware switch interface used for the local area network is called *lan*, while on other units it is called *internal*.

- Certain features are not available on all models. Additionally, a particular feature may be available only through the CLI on some models, while that same feature may be viewed in the GUI on other models. If you believe your FortiGate model supports a feature that does not appear in the GUI, go to *System > Feature Visibility* and confirm that the feature is enabled. For more information, see Feature visibility on page 3595.

Low encryption models

Some FortiGate models support a low encryption (LENC) license. With an LENC license, FortiGate devices are considered low encryption models and are identified by *LENC*, for example FG-100E-LENC.

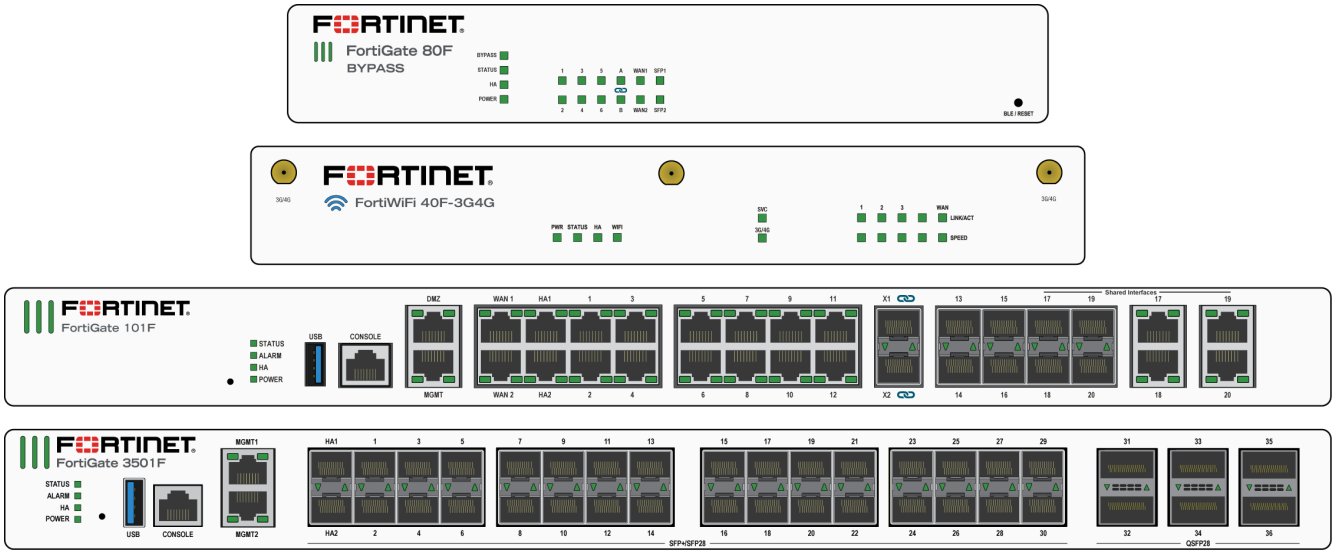
LENC models cannot use or inspect high encryption protocols, such as 3DES and AES. LENC models only use 56-bit DES encryption to work with SSL VPN and IPsec VPN, and they are unable to perform SSL inspection.

For a list of FortiGate models that support an LENC license, see FortiGate LENC Models.

LEDs

Check your device's QuickStart guide for specific LED information: FortiGate QuickStart Guides.

The following faceplates show examples of where the LEDs are typically found on FortiGate models:



The following tables list the possible LED states and their meanings. Not all devices include every LED or support every state.

LED	State	Description
Logo	Green or Blue	The unit is on
	Off	The unit is off
Power (PWR)	Green	The unit is on and/or both power supplies are functioning
	Amber or Red	Only one power supply is functional
	Flashing Amber or Red	Power failure
	Off	The unit is off
Status (STA)	Green	Normal
	Flashing Green	Booting up
	Amber	Major or minor alarm
	Red	Major alarm
	Flashing Amber or Red	BLE is on
	Off	The unit is off
Bypass (BYP)	Amber	Bypass Port Pair is active
	Off	Bypass Port Pair is off
Alarm	Red	Major alarm
	Amber	Minor alarm
	Off	No alarms
HA	Green	Operating in an HA cluster
	Amber or Red	HA failover
	Off	HA disabled
Max PoE	Green, Amber, or Red	Maximum PoE power allocated
	Off	PoE power available or normal
PoE	Green	Power delivered
	Flashing Green	Error or PoE device requesting power
	Off	No PoE device connected or no power delivered
SVC	Green	SVC is on
	Flashing Green	SVC activity
	Off	SVC is off

LED	State	Description
3G / 4G	Green	3G / 4G service is on
	Flashing Green	3G / 4G activity
	Off	3G / 4G service is off
WiFi	Green	WiFi connected
	Flashing Green	WiFi activity
	Off	WiFi is off
BLE	Blue	BLE on
	Flashing Blue	BLE in discovery
	Off	BLE off
Signed Firmware	Green	High: Unsigned firmware blocked (default)
	Red	Low: Unsigned firmware allowed with a warning
Power supplies and fans	See your device's QuickStart guide for power supply and fan LED information: FortiGate QuickStart Guides.	

Port LEDs

LED	State	Description
Ethernet and SFP	Solid color	Connected
	Flashing color	Transmitting and receiving data
	Off	No link established
PoE	Green	PoE power on or PoE device receiving power
	Amber	Providing power
	Red	Connected but not powered
	Off	PoE power off or no device receiving power

Alarm levels

Minor alarm

Also called an IPMI non-critical (NC) alarm, it indicates a temperature or power level outside of the normal operating range that is not considered a problem. For a minor temperature alarm, the system could respond by increasing the fan speed. A non-critical threshold can be an upper non-critical (UNC) threshold (for example, a high temperature or a high power level) or a lower non-critical (LNC) threshold (for example, a low power level).

Major alarm

Also called an IPMI critical or critical recoverable (CR) alarm, it indicates that the system is unable to correct the cause of the alarm, and that intervention is required. For example, the cooling system cannot provide enough cooling to reduce the temperature. It can also mean that the conditions are approaching the outside limit of the allowed operating range. A critical threshold can also be an upper critical (UC) threshold (such as a high temperature or high power level) or a lower critical (LC) threshold (such as a low power level).

Critical alarm

Also called an IPMI non-recoverable (NR) alarm, it indicates that the system has detected a temperature or power level that is outside of the allowed operating range and physical damage is possible.

Proxy-related features not supported on FortiGate 2 GB RAM models

As part of improvements to enhance performance and optimize memory usage on FortiGate models with 2 GB RAM or less, starting from version 7.4.4, FortiOS no longer supports proxy-related features. For a list of affected models, see the *FortiOS 7.6.2 Release Notes*.

FortiGate VMs are not affected by the size of the memory and will continue to support proxy-related features after upgrading to FortiOS 7.4.4 or later. However, it is recommended to have at least 4 GB of RAM for proper operation.

After upgrade to FortiOS 7.4.4 or later, the following proxy features are no longer supported on impacted devices:

- Zero Trust Network Access (ZTNA)
  This includes all ZTNA objects and functionalities, including applying ZTNA tags in IP/MAC based access control. For example, `ztna-status` can no longer be enabled, and `ztna-ems-tag` and `ztna-geo-tag` can no longer be used.
- UTM profile with proxy-based inspection mode
- Firewall policy with proxy-based inspection mode
- Explicit and transparent proxies
- Layer 7 Virtual server load balance protocols (HTTP, HTTPS, IMAPS, POP3S, SMTPS and SSL)
- Proxy-only UTM profiles:
  - Video Filter
  - Inline CASB
  - ICAP
  - Web application firewall (WAF)
  - SSH Filter
- WAN optimization

To confirm whether your FortiGate model has 2 GB RAM or less, enter `diagnose hardware sysinfo conserve` in the CLI. If the total RAM value is below 2000 MB (1000 MB = 1 GB), then your device has 2 GB RAM or less.

Upgrading from previous firmware versions

Before starting the upgrade from a firmware version that supports proxy-related features to FortiOS 7.4.4 or later that no longer supports proxy-related features on FortiGate 2 GB RAM models, it is crucial that you carefully review the following upgrade scenarios. The scenarios provide important information about the upgrade process and its potential impacts. Please proceed with the upgrade only after you fully understand and are comfortable with the conditions and potential outcomes outlined in these upgrade scenarios.

Previous version	Upon upgrade to FortiOS 7.4.4 or later
Proxy-based inspection mode is enabled on a firewall policy.	Inspection mode is converted to flow mode.
Proxy-based inspection mode is enabled on a firewall policy with proxy-only UTM profiles, such as WAF applied.	Inspection mode is converted to flow mode, and the proxy-only UTM profiles are removed. Proxy-only UTM profiles are no longer supported.
Proxy-related settings are configured on a security profile, such as Content Disarm on an AntiVirus Profile.	The security profile is converted to flow-based, and the proxy-related setting is no longer available.
A proxy-only feature, such as ZTNA, explicit proxy or WAN optimization, is enabled.	The proxy-only configuration is removed.

Before initiating the firmware upgrade process, it is crucial to create a backup of the current working configuration. This step ensures that you have a fallback option in case of any unforeseen issues during the upgrade.

Once you have secured a backup, you can proceed with the upgrade process. After the upgrade has been successfully completed, it is highly recommended to thoroughly review all your policies.

This review process lets you confirm that all the policies that you expect to be in place are present and will function as intended. Ensure any settings that are removed do not impact the security of your firewall policy. See the Best Practices guide for more information.

FGR-70F/FGR-70F-3G4G GPIO/DIO module

FortiGate Rugged 70F and FortiGate Rugged 70F-3G4G include a general purpose input output (GPIO) module, also known as a digital I/O (DIO) module. This module activates a digital output when triggered by a change in any digital input. For example, the digital input can be connected to a cabinet door to monitor the open/close status or low/high voltage status, and the output can be connected to a buzzer. When the DIO module detects a change from open to closed or a voltage change from low to high, it triggers the buzzer.

CLI for configuring DIO module alarms is available only on FortiGate Rugged 70F and FortiGate Rugged 70F-3G4G devices.

Use the `config system digital-io` command to configure the input status for the DIO module to monitor:

```
config system digital-io
    set input1-detection-mode {default | voltage}
    set input2-detection-mode {default | voltage}
    set output-keep-last-state {enable | disable}
end
```

`set input1-detection-mode {default | voltage}`	Configure the input mode: • `default`: Detect change from open to closed or closed to open. • `voltage`: Detect change from low to high voltage or high to low voltage.
`set output-keep-last-state {enable | disable}`	Enable/disable FortiGate to keep the alarm status after a reboot.

Use the `execute digital-io set-output` command to configure the output mode when an alarm is triggered, namely, the state of the normally closed to common (`NC_COM`) output and the normally open to common (`NO_COM`) output:

```
# execute digital-io set-output
alternating     Alternates between default and opposite.
default         NC_COM=closed and NO_COM=open.
opposite        NC_COM=open and NO_COM=closed.
```

Use the `diagnose sys digital-io state` command to check the input and output status reported by the DIO module:

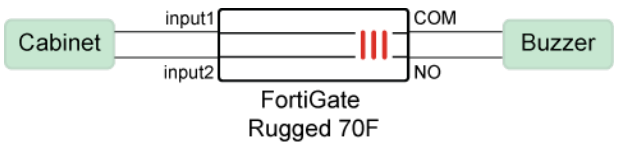
```
# diagnose sys digital-io state
Input1:    mode=default(open/closed) and state=open.
Input2:    mode=voltage(low/high) and state=low.
Output:    state=default, NO_COM=open, and NC_COM=closed.
output-keep-last-state: enable
```

Commands are also available to trigger SNMP traps and automation stitches for the DIO module. See SNMP traps and automation-stitch notifications for DIO module on page 3543 for more information.

For more information about the DIO module, see the FortiGate Rugged 70F Series QuickStart Guide and the Technical Tip: Overview of the Digital Input/Output (DIO) Module in FortiGate Rugged 70F Series community article.

Example

In this example, a FortiGate Rugged 70F is configured to monitor the open/close and low/high voltage status of a cabinet door, and the output is connected to a buzzer. When the status of the cabinet door changes, FortiGate triggers the buzzer



To configure the DIO module alarm:

1. Configure the input-detection mode:

   In this example, the input-detection mode for input1 is set to `default` and input2 is set to `voltage`, and the last output state is retained if FortiGate reboots.

   ```
   config system digital-io
       set input1-detection-mode default
       set input2-detection-mode voltage
       set output-keep-last-state enable
   end
   ```

2. Configure the output mode:

   In this example, the output is set to `default`. When triggered, the output is in a default state with the normally open to common (`NO_COM`) output being open, and the normally closed to common (`NC_COM`) output being closed. The output is triggered when the DIO module detects a change in the status of the inputs or detects an alarm event.

   ```
   # execute digital-io set-output default
   ```

3. View the input/output status being reported by the DIO module:

   In this example, the default state of `Input1` is `open`, and the default state of `Input2` is `low` voltage, which means the cabinet door is open, and the voltage is low.

   ```
   # diagnose sys digital-io state
   Input1: mode=default(open/closed), state=open
   Input2: mode=voltage(low/high), state=low
   Output: state=default, NO_COM=open, NC_COM=closed
   output-keep-last-state: enable
   ```

4. Close the cabinet door.
5. View the input/output status being reported by the DIO module:

   The state of `Input1` has changed to `closed`, and the state of `Input2` has changed to `high` voltage.

   ```
   # diagnose sys digital-io state
   Input1: mode=default(open/closed), state=closed
   Input2: mode=voltage(low/high), state=high
   Output: state=default, NO_COM=open, NC_COM=closed
   output-keep-last-state: enable
   ```

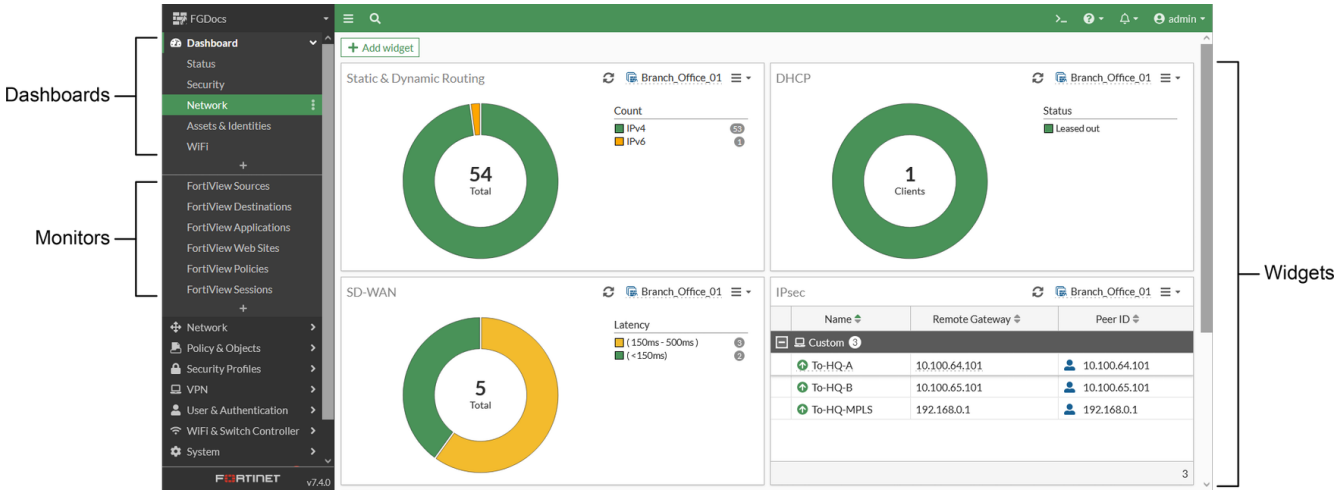
   The change in state triggers the buzzer.

Dashboards and Monitors

FortiOS includes predefined dashboards so administrators can easily monitor device inventory, security threats, traffic, and network health. You can customize the appearance of a default dashboard to display data pertinent to your Security Fabric or combine widgets to create custom dashboards. Many dashboards also allow you to switch views between Fabric devices.

Each dashboard contains a set of widgets that allow you to view drilldown data and take actions to prevent threats. Use widgets to perform tasks such as viewing device inventory, creating and deleting DHCP reservations, and disconnecting dial-up users. You can add or remove widgets in a dashboard or save a widget as a standalone monitor.

Monitors display information in both text and visual format. Use monitors to change views, search for items, view drilldown information, or perform actions such as quarantining an IP address. FortiView monitors for the top categories are located below the dashboards. All of the available widgets can be added to the tree menu as a monitor.

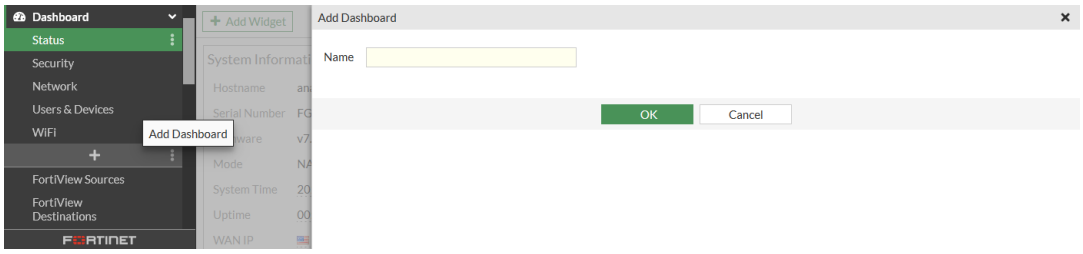


Using dashboards

You can combine widgets to create custom dashboards. You can also use the dropdown in the tree menu to switch to another device in the Security Fabric.

To create a new dashboard:

1. Under *Dashboard*, click the *Add Dashboard* button. The *Add Dashboard* window opens.



2. Enter a name in the *Name* field and click *OK*. The new dashboard opens.

To add a widget to a dashboard:

1. In the tree menu, select a dashboard.
2. In the banner, click *Add Widget*. The *Add Dashboard Widget* pane opens.
3. Click the *Add* button next to the widget. You can use the *Search* field to search for a widget. Enable *Show More* to view more widgets in a category.
4. Configure the widget settings, then click *Add Widget*.
5. Click *Close*.
6. (Optional) Click and drag the widget to the desired location in the dashboard.

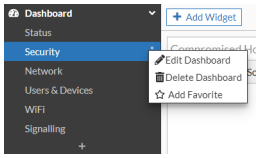
To edit a dashboard:

1. Click the *Actions* menu next to the dashboard and select*Edit Dashboard*.

2. Edit the dashboard and click *OK*.

To delete a dashboard:

1. Click the *Actions* menu next to the dashboard and select *Delete Dashboard*.

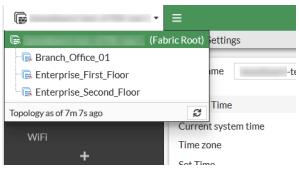


2. Click *Delete Dashboard* . The *Confirm* dialog opens.
3. *Click OK*.

You cannot delete the *Status* dashboard.

To switch to another device in the Security Fabric:

1. In the tree menu, click the device name and select a Fabric device from dropdown.

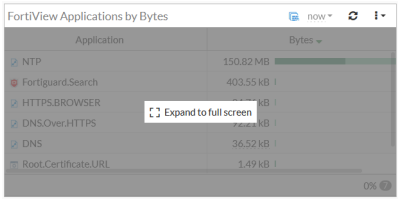


Using widgets

You can convert a widget to a standalone monitor, change the view type, configure tables, and filter data.

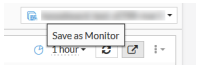
To save a dashboard widget as a monitor:

1. Hover over the widget and click *Expand to full screen*.



Full screen mode is not supported in all widgets.

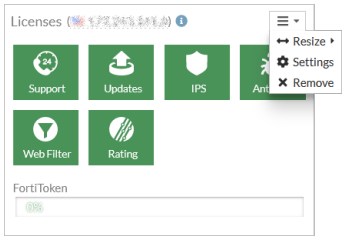
2. In the widget, click *Save as Monitor*. The *Add Monitor* window opens.



3. (Optional) Enter a new name for the monitor in the *Name* field.
4. Click *OK*.

To view the widget settings:

1. Click the menu dropdown at the right side of the widget and select *Settings*.



2. Configure the widget settings and click *OK*.

The settings will vary depending on the widget.

To configure a table in the widget:

1. Hover over the left side of the table header and click *Configure Table*.

2. Configure the table options:

Option	Description
Best Fit All Columns	Resizes all of the columns in a table to fit their content.
Reset Table	Resets the table to the default view.
Select Columns	Adds or removes columns from the view.

3. Click *Apply*.

To filter or configure a column in a table:

1. Hover over a column heading, and click *Filter/Configure Column*.

2. Configure the column options.

Option	Description
Resize to Contents	Resizes the column to fit the content.
Group by this Column	Groups the table rows by the contents in the selected column.

3. Click *Apply*.
4. To filter a column, enter a value in the *Filter* field, and click *Apply*.

Filtering is not supported in all widgets.

Widgets

Dashboards are created per VDOM when VDOM mode is enabled. For information about VDOM mode, see Virtual Domains on page 3298.

Some dashboards and widgets are not available in Multi-VDOM mode.

The following table lists the available widgets in VDOM mode:

Category	Widgets
FortiView	• FortiView Application Bandwidth • FortiView Applications • FortiView Cloud Applications • FortiView Destination Interfaces • FortiView Destination Owners • FortiView Destinations • FortiView Policies • FortiView Proxy Destinations • FortiView Proxy Policies • FortiView Proxy Sessions • FortiView Proxy Sources • FortiView Sessions • FortiView Source Interfaces • FortiView Sources • FortiView VPN • FortiView Web Categories • FortiView Web Sites • FortiView ZTNA Servers • FortiView Countries/Regions • FortiView Destination Firewall Objects • FortiView Interface Pairs • FortiView Search Phrases • FortiView Servers • FortiView Source Firewall Objects • FortiView Sources - WAN • FortiView Traffic Shaping
Security Fabric	• FortiGate Cloud • Security Fabric Status
Network	• DHCP

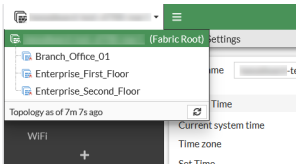
Category	Widgets
	• DNS • Interface Bandwidth • IP Pool Utilization • IPsec • Load Balance • Routing • SD-WAN • SSL-VPN • Top IP Pools by Assigned IPs The *Interface Bandwidth* widget can monitor a maximum of 25 interfaces.
System	• Administrators • Botnet Activity • HA Status • License Status • System Information • Top System Events • Virtual Machine
Resource Usage	• CPU Usage • Disk Usage • Log Rate • Logs Sent • Memory Usage • Session Rate • Sessions
Security	• Advanced Threat Protection Statistics • Assets - Vulnerabilities • Compromised Hosts • FortiSandbox Files • Quarantine • Top Endpoint Vulnerabilities • Top Failed Authentication • Top Threats • Top Threats - WAN
User & Authentication	• Assets • Assets - FortiClient

Category	Widgets
	• Firewall Users • FortiGuard Quota • Identities • Matched NAC Devices • Top Admin Logins • Top Cloud Users
WiFi	• Channel Utilization • Clients By FortiAP • FortiAP Status • Historical Clients • Interfering SSIDs • Login Failures • Rogue APs • Signal Strength • Top WiFi Clients

Viewing device dashboards in the Security Fabric

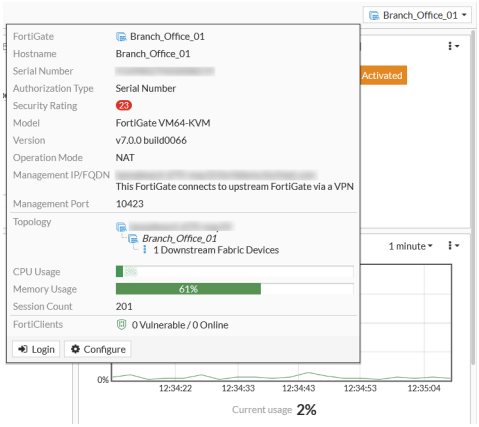
Use the device dropdown to view the dashboards in downstream Fabric devices. You can also create dedicated device dashboards or log in and configure Fabric devices.

To view the dashboards in Fabric devices, click the device dropdown at the left side of the page, and select a device from the list.



The device dropdown is available in the *Status*, *Security*, *Network*, *Assets & Identities*, and *WiFi* dashboards. You can also enable the dropdown when you create a dashboard.

To log in to or configure a Fabric device, hover over the device name until the device dialog opens and then select *Login* or *Configure*.

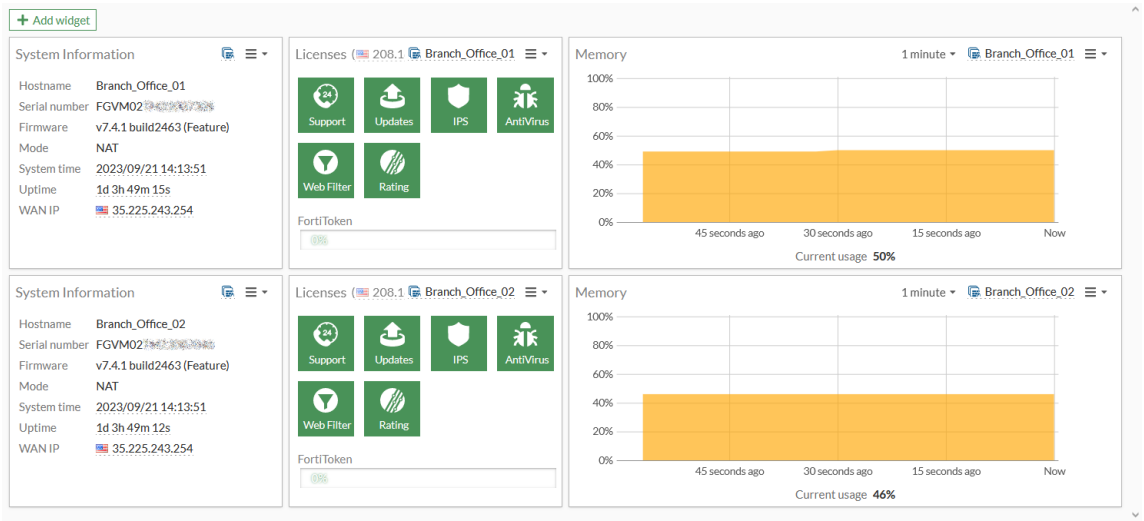


Creating a fabric system and license dashboard

Create a dashboard summary page to monitor all the Fabric devices in a single view. You can use this dashboard to monitor aspects of the devices such as system information, VPN and routing.

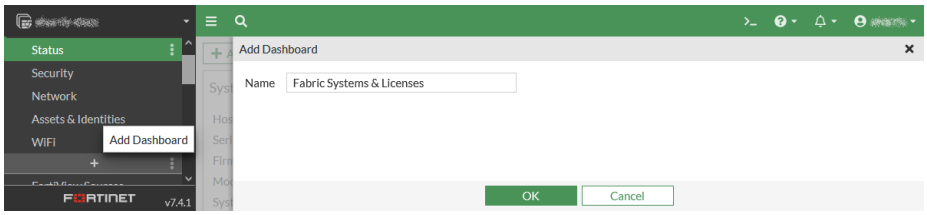
Example

The following image is an example of a *Fabric System & License* dashboard to monitor the *System Information*, *Licenses*, and *Memory* usage for *Branch_Office_01* and *Branch_Office_02*.

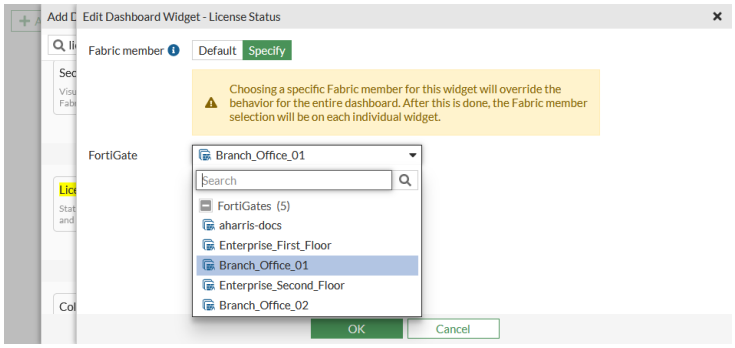


To create a system dashboard:

1. Click the *Add Dashboard* button. The *Add Dashboard* window opens.



2. In the *Name* field, enter a name such as *Fabric System & Licenses*, and click *OK*. The new dashboard appears.
3. In the banner, click *Add Widget*. The *Add Dashboard Widget* window opens. You can use the *Search* field to search for a specific widget (for example, *License Status*, *System Information*, and *Memory Usage*).
4. Click the *Add* button next to widget. The *Add Dashboard Widget* window opens.
5. In the *Fabric member* area, select *Specify* and select a device in the Security Fabric.



6. Click *Add Widget*. The widget is added to the dashboard.
   Repeat this step for all the devices you want to view in the dashboard.
7. (Optional) Arrange the widgets in the dashboard by Fabric device.

Dashboards

A dashboard is a collection of widgets that show the status of your devices, network, and Security Fabric at a glance. Widgets are condensed monitors that display a summary of the key details about your FortiGate pertaining to routing, VPN, DHCP, devices, users, quarantine, and wireless connections.

The following dashboards are included in the dashboard templates:

Dashboard	Default Template	Use these widgets to:
Status	• Comprehensive • Optimal	• View the device serial number, licenses, and administrators • View the status of devices in the security fabric • Monitor CPU and Memory usage • Monitor IPv4 and IPv6 sessions • View VMs and Cloud devices

Dashboard	Default Template	Use these widgets to:
Security	• Optimal	• View compromised hosts and host scan summary • View top threats and vulnerabilities
Network	• Optimal	• Monitor DHCP clients • Monitor IPsec VPN connections • Monitor current routing table • Monitor SD-WAN status • Monitor SSL-VPN connections
Assets & Identities	• Optimal	• View users and devices connected to the network • Identify threats from individual users and devices • View FortiGuard and FortiClient data • Monitor traffic bandwidth over time
WiFi	• Comprehensive • Optimal	• View FortiAP status, channel utilization, and clients • View login failures and signal strength • View the number of WiFi clients

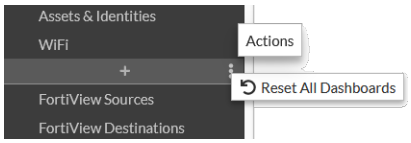
Resetting the default dashboard template

You can use the GUI to change the default dashboard template. The *Optimal* template contains a set of popular default dashboards and FortiView monitors. The *Comprehensive* template contains a set of default dashboards as well as all of the FortiView monitors.

Resetting the default template will delete any custom dashboards and monitors, and reset the widget settings.

To reset all dashboards:

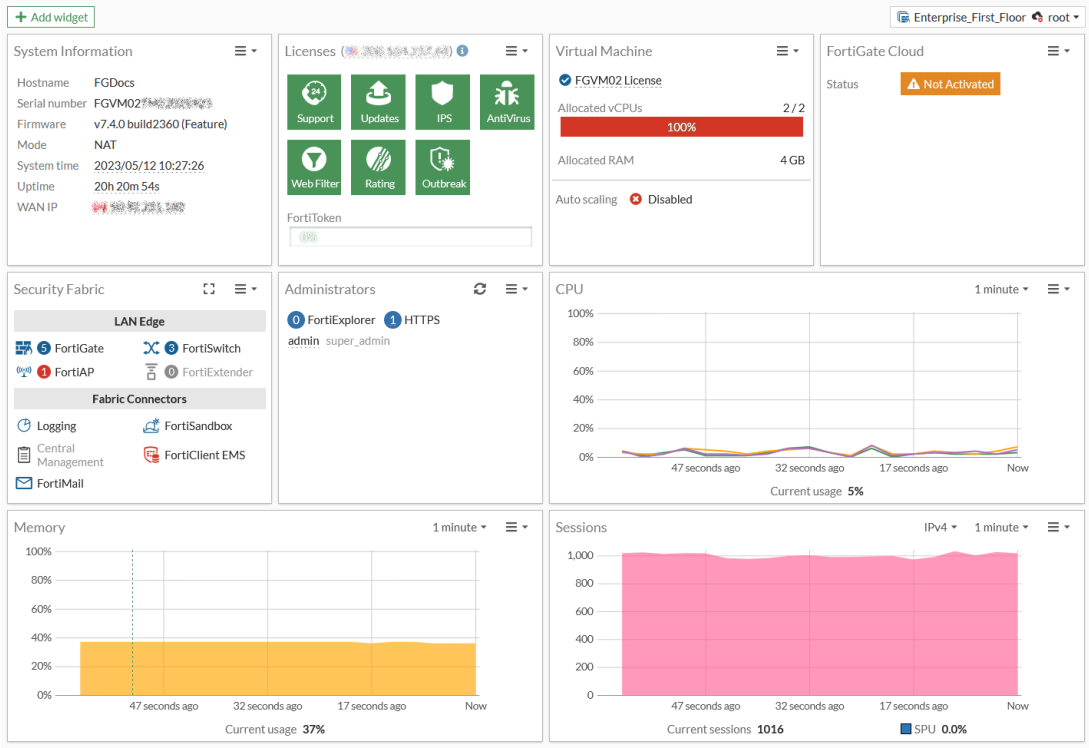
1. Click the *Actions* menu next to *Add Dashboard* or *Add Monitor* and click *Reset All Dashboards*. The *Dashboard Setup* window opens.



2. Select *Optimal* or *Comprehensive* and click *OK*.

Status dashboard

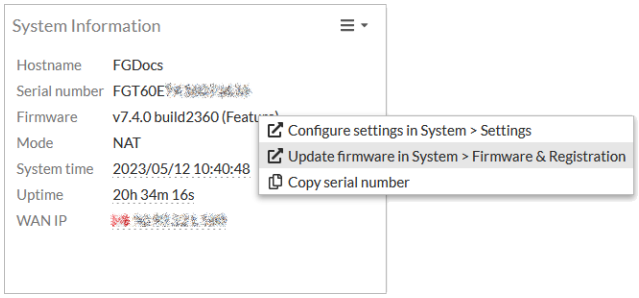
The *Status* dashboard provides an overview of your FortiGate device and the devices in your Security Fabric. If your FortiGate is a virtual machine, information about the virtual machine is also displayed in the dashboard.



Updating system information

The *System Information* widget contains links to the *Settings* module where you can update the *System Time*, *Uptime*, and *WAN IP*.

A notification will appear in the *Firmware* field when a new version of FortiOS is released. Click *Update firmware in System > Firmware & Registration* to view the available versions and update FortiOS.



Viewing Fabric devices

The *Security Fabric* widget provides a visual overview of the devices connected to the Fabric and their connection status. Hover of a device icon to view more information about the device.

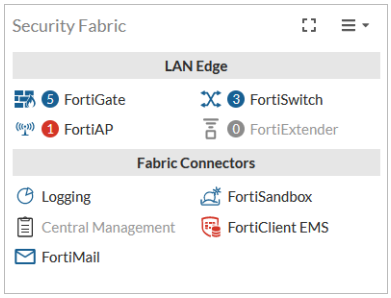
Click a device in the Fabric to:

- View the device in the physical or logical topology
- Register, configure, deauthorize, or log in to the device

- Open *Diagnostics and Tools*
- View the *FortiClient Monitor*

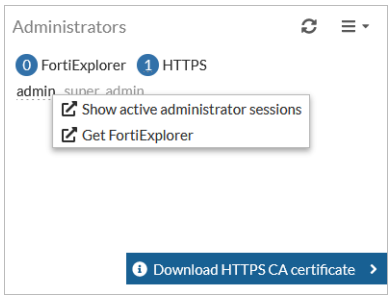
These options will vary depending on the device.

Click *Expand & Pin hidden content* to view all the devices in the Fabric at once.

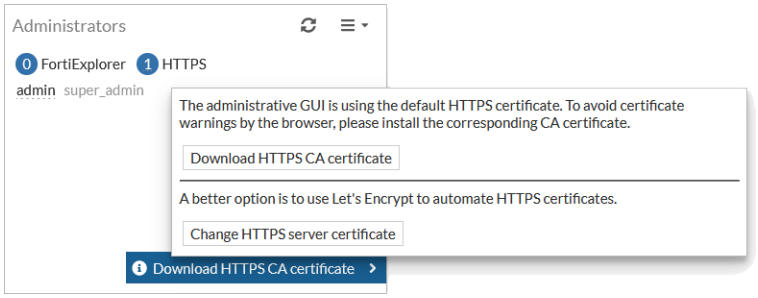


Viewing administrators

The *Administrators* widget displays the active administrators and their access interface. Click the username to view the *Active Administrator Sessions* monitor. You can use the monitor to end an administrator's session.

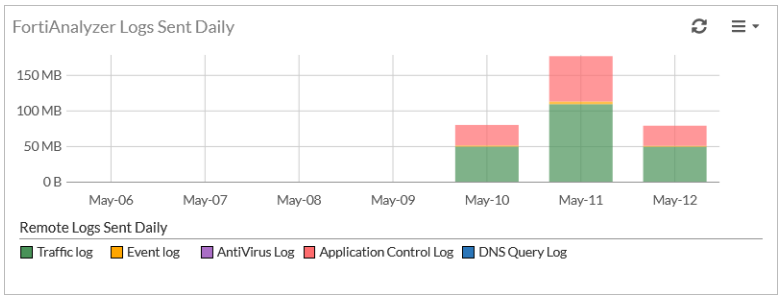


If the GUI is using the default HTTPS certificate, a warning is shown where you can download the HTTPS CA certificate or change the HTTPS server certificate.



Viewing logs sent for remote logging source

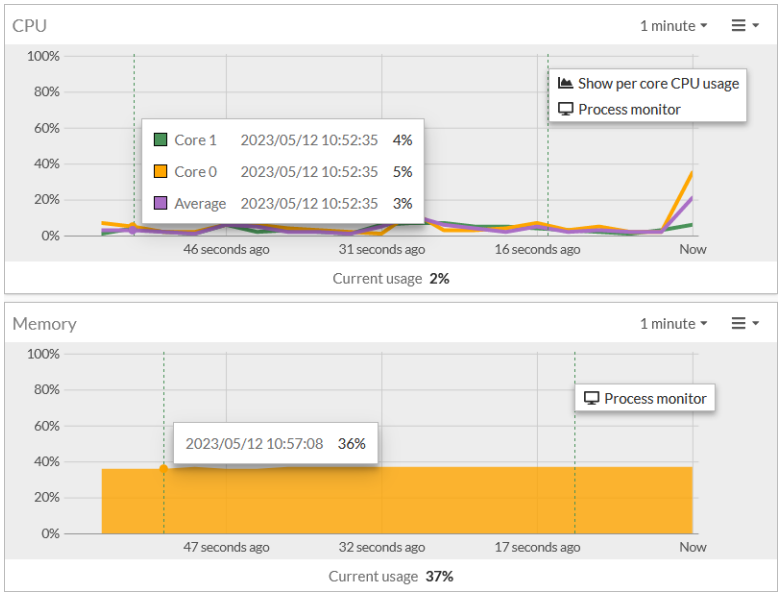
The *Logs Sent* widget displays chart for remote logging sources (FortiAnalyzer, FortiGate Cloud, and FortiAnalyzer Cloud) sent daily.



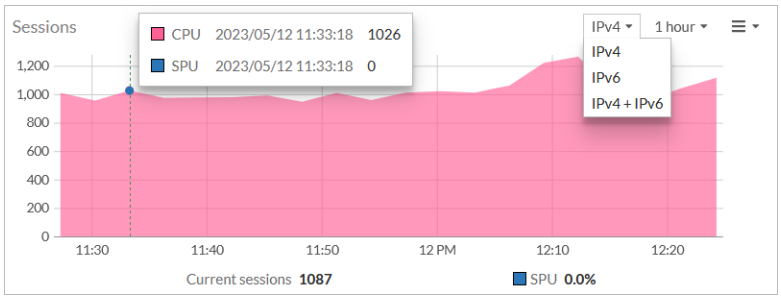
Resource widgets

The resource widgets show the current usage statistics for *CPU*, *Memory*, and *Sessions*.

Click the *CPU* monitor to show the per core CPU usage.



You can switch between *IPv4*, *IPv6*, or *IPv4+IPv6* in the *Sessions* monitor.



Security dashboard

The widgets in the *Security* dashboard provide a snapshot of the current threats and vulnerabilities targeting your Security Fabric.

The *Security* dashboard contains the following widgets:

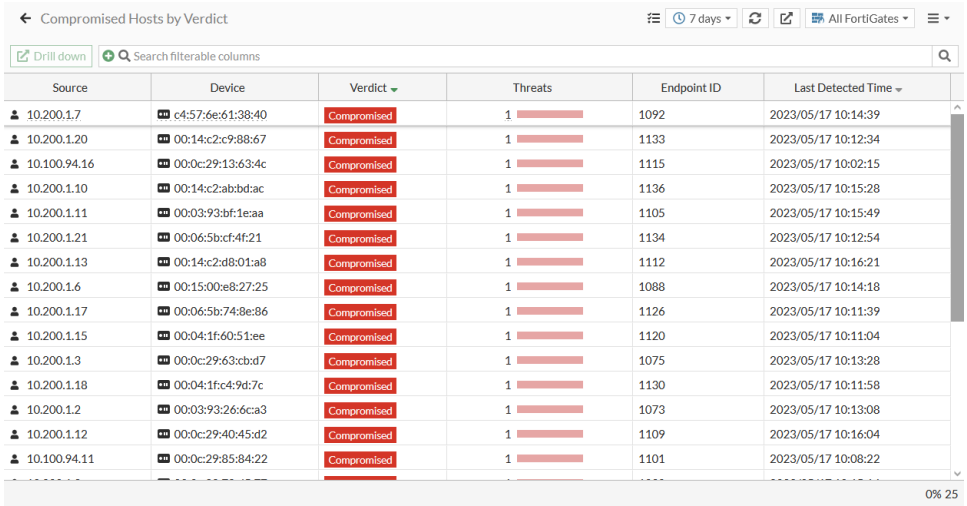
Widget	Description
Compromised Hosts by Verdict	Shows the session information for a compromised host. See Viewing session information for a compromised host on page 115.
Top Threats by Threat Level	Shows the top traffic sessions aggregated by threat. You can expand the widget to view drilldown information about the *Threat*, *Threat Category*, *Threat Level*, *Threat Score* and *Sessions*.
Assets - Vulnerabilities	Shows a summary of asset vulnerabilities.

Viewing session information for a compromised host

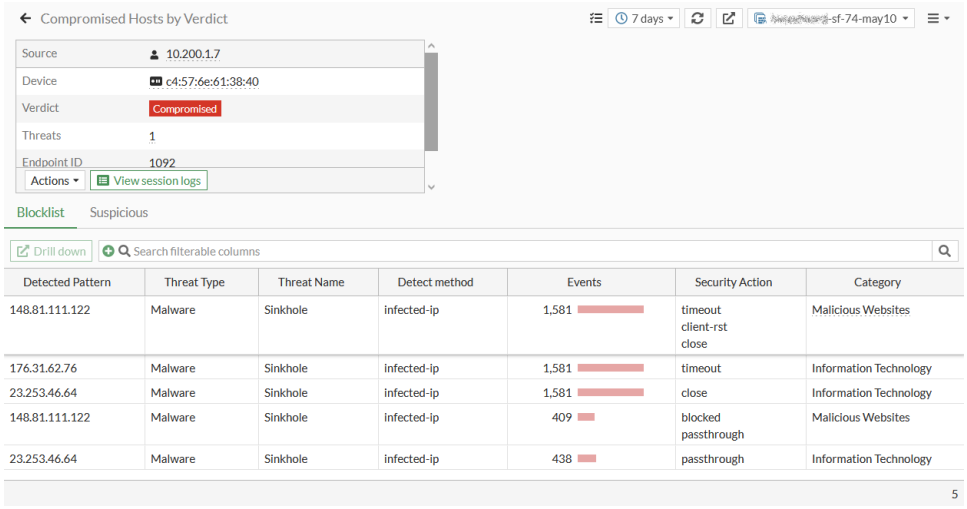
You can use the *Compromised Hosts by Verdict* widget to view the session information for a compromised host.

To view session information for a compromised host in the GUI:

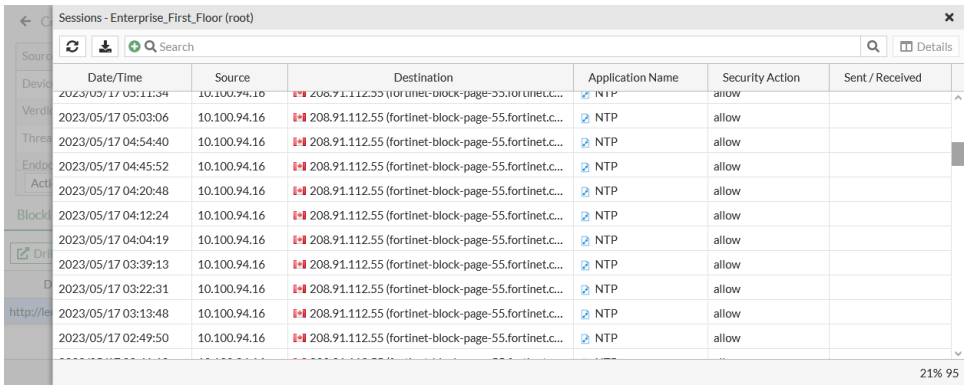
1. Go to *Dashboard* > *Security* and expand the *Compromised Hosts by Verdict* widget.



2. Double-click a compromised host to view the session information.



3. Select a session then click *View session logs* to view the session logs.



Network dashboard

The widgets in the Network dashboard show information related to networking for this FortiGate and other devices connected to your Security Fabric. Use this dashboard to monitor the status of Routing, DHCP, SD-WAN, IPsec and SSL VPN tunnels. All of the widgets in the *Network* dashboard can be expanded to full screen and saved as a monitor.

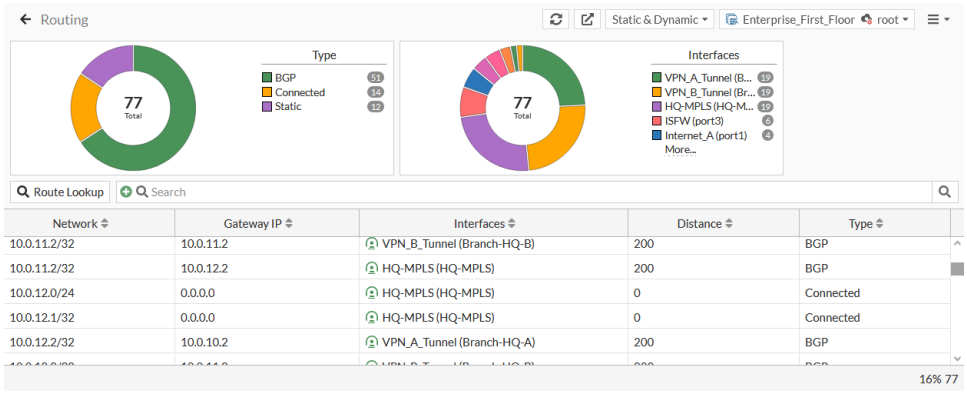
The *Network* dashboard contains the following widgets:

Widget	Description
Static & Dynamic Routing	Shows the static and dynamic routes currently active in your routing table. The widget also includes policy routes, BGP neighbors and paths, and OSPF neighbors. See Static & Dynamic Routing monitor on page 117.
DHCP	Shows the addresses leased out by FortiGate's DHCP servers. See DHCP monitor on page 120.
SD-WAN	Shows a summary of the SD-WAN status, including ADVPN shortcut

Widget	Description
	information.
IPsec	Shows the connection statuses of your IPsec VPN site to site and dial-up tunnels. See IPsec monitor on page 121.
SSL-VPN	Shows a summary of remote active users and the connection mode. See SSL-VPN monitor on page 126.
IP Pool Utilization	Shows IP pool utilization.

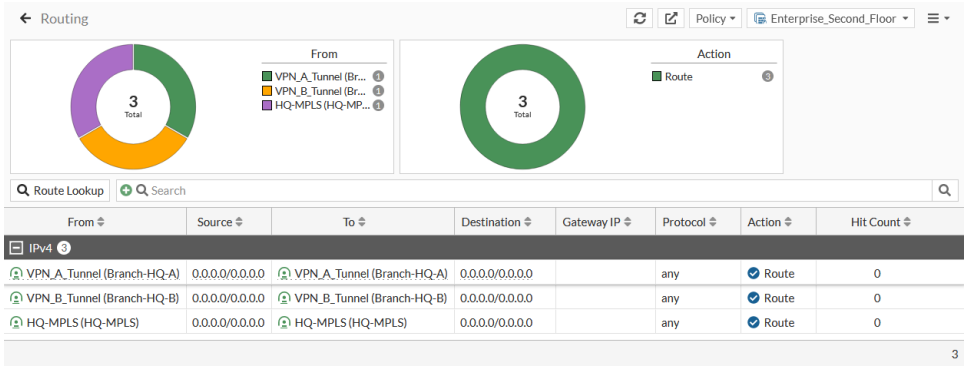
Static & Dynamic Routing monitor

The *Static & Dynamic Routing* monitor displays the routing table on the FortiGate, including all static and dynamic routing protocols in IPv4 and IPv6. You can also use this monitor to view policy routes, BGP neighbors and paths, and OSPF neighbors.



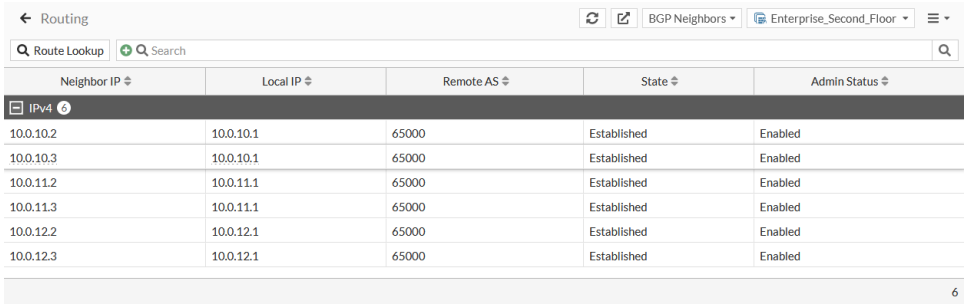
To view the routing monitor in the GUI:

1. Go to *Dashboard* > *Network*.
2. Hover over the *Routing* widget, and click *Expand to Full Screen*. The *Routing* monitor is displayed.
3. To view policy routes, click the monitors dropdown at the top of the page and select *Policy*.

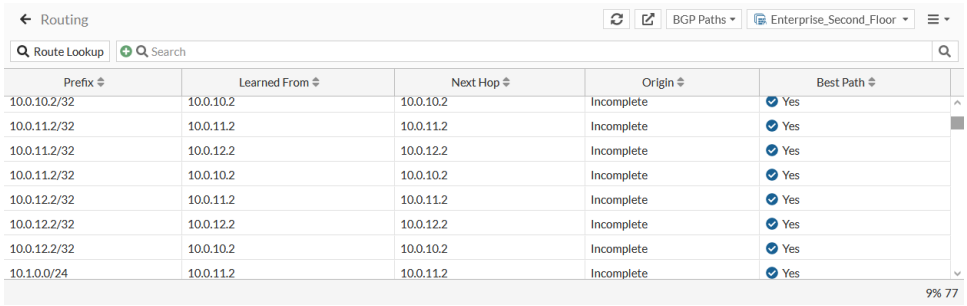


4. To view neighbors and paths, click the monitors dropdown and select the required neighbor or path type. For example:

- *BGP Neighbors*

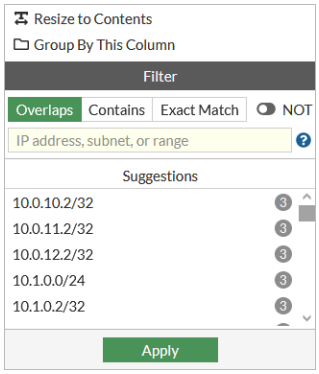


- *BGP Paths*



5. To filter a column:
   a. Hover over the column heading, and click the *Filter/Configure Column* icon.

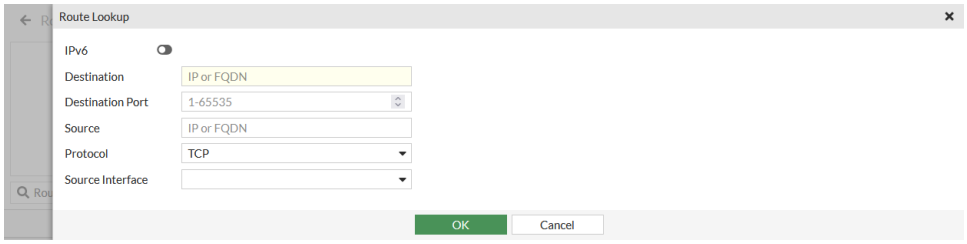
   b. Configure the filter, then click *Apply*.



6. (Optional) Click the *Save as Monitor* button to save the widget as monitor.

To look up a route in the GUI:

1. Click *Route Lookup*.



2. Enter an IP address in the *Destination* field.
3. Configure the remaining options as needed, then click *OK*.
   The matching route is highlighted on the *Routing* monitor.

To view the routing table in the CLI:

```
# get route info routing-table all
```

Sample output:

```
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default

Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 10.0.10.1, To-HQ-A
[1/0] via 10.0.12.1, To-HQ-MPLS
[1/0] via 10.10.11.1, To-HQ-B
[1/0] via 10.100.67.1, port1
[1/0] via 10.100.67.9, port2
C       10.0.10.0/24 is directly connected, To-HQ-A
C       10.0.10.2/32 is directly connected, To-HQ-A
C       10.0.11.0/24 is directly connected, To-HQ-B
C       10.0.11.2/32 is directly connected, To-HQ-B
C       10.0.12.0/24 is directly connected, To-HQ-MPLS
C       10.0.12.2/32 is directly connected, To-HQ-MPLS
C       10.1.0.0/24 is directly connected, port3
C       10.1.0.2/32 is directly connected, port3
C       10.1.0.3/32 is directly connected, port3
C       10.1.100.0/24 is directly connected, vsw.port6
```

To look up a firewall route in the CLI:

```
# diagnose firewall proute list
```

Sample output:

```
list route policy info(vf=root):

id=1(0x01) dscp_tag=0xfc 0xfc flags=0x0 tos=0x00 tos_mask=0x00 protocol=0 sport=0-0 iif=15(Branch-

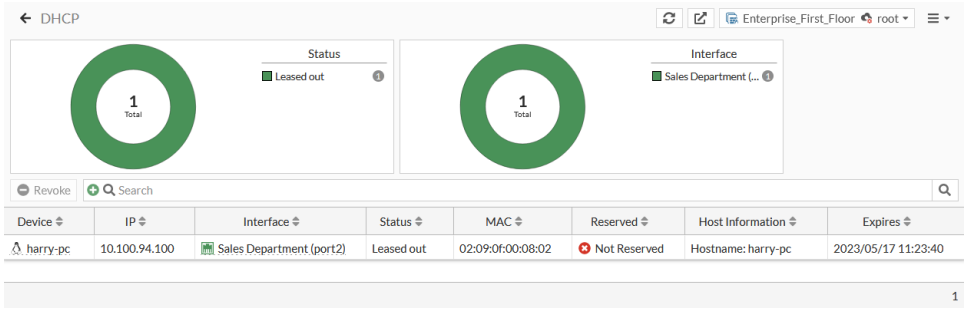
```

DHCP monitor

The DHCP monitor shows all the addresses leased out by FortiGate's DHCP servers. You can use the monitor to revoke an address for a device, or create, edit, and delete address reservations.



To view the DHCP monitor:

1. Go to *Dashboard* > *Network*.
2. Hover over the *DHCP* widget, and click *Expand to Full Screen*.

To filter or configure a column in the table, hover over the column heading and click the *Filter/Configure Column* button.

To revoke a lease:

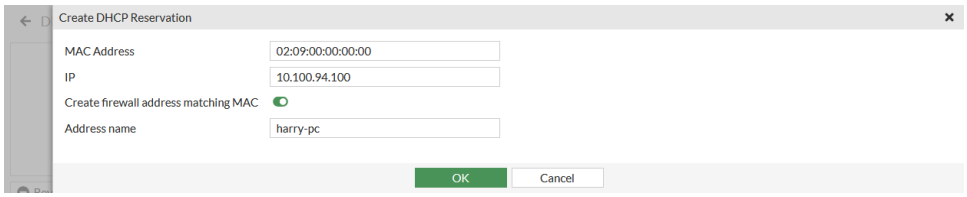
1. Select a device in the table.
2. In the toolbar, click *Revoke*, or right-click the device, and click *Revoke Lease(s)*. The *Confirm* page is displayed.

3. Click *OK*.

A confirmation window opens only if there is an associated address reservation. If there is no address, the lease will be removed immediately upon clicking *Revoke*.

To create a DHCP reservation:

1. Select a server in the table.
2. In the toolbar, click *Reservation* > *Create DHCP Reservation*, or right-click the device and click *Create DHCP Reservation*. The *Create New DHCP Reservation* page is displayed.
3. Configure the DHCP reservation settings.



4. Click *OK*.

To view top sources by bytes:

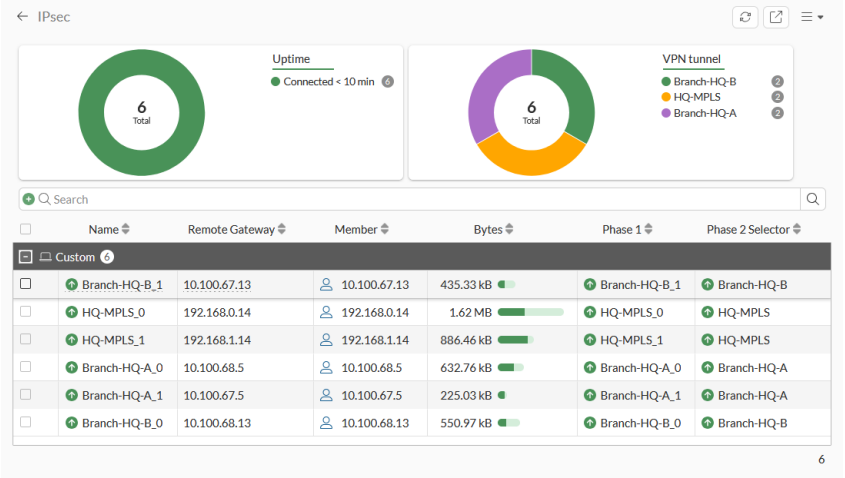
1. Right-click a device in the table and click *Show in FortiView*. The *FortiView Sources by Bytes* widget is displayed.

To view the DHCP lease list in the CLI:

```
# execute dhcp lease-list
```

IPsec monitor

The IPsec monitor displays all connected Site to Site VPN, Dial-up VPNs, and ADVPN shortcut tunnel information. It also includes pie charts for tunnel status and uptime, filters, and quick access to several tools. You can use the monitor to bring a phase 2 tunnel up or down or disconnect dial-up users. A notification appears in the monitor when users have not enabled two-factor authentication.

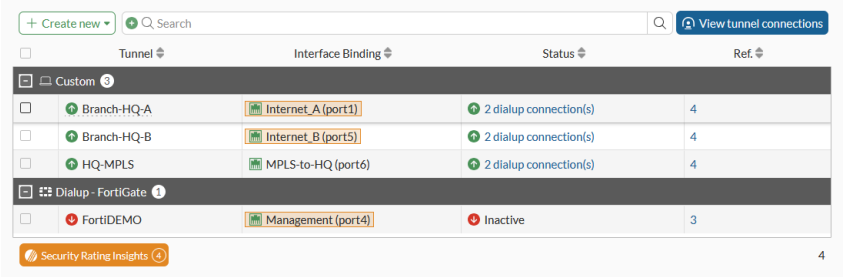


To access the IPsec monitor in the GUI:

1. Use one of the following methods:
   a. Go to *Dashboard* > *Network* and hover over the *IPsec* widget, and click *Expand to Full Screen*. A warning appears when an unauthenticated user is detected.

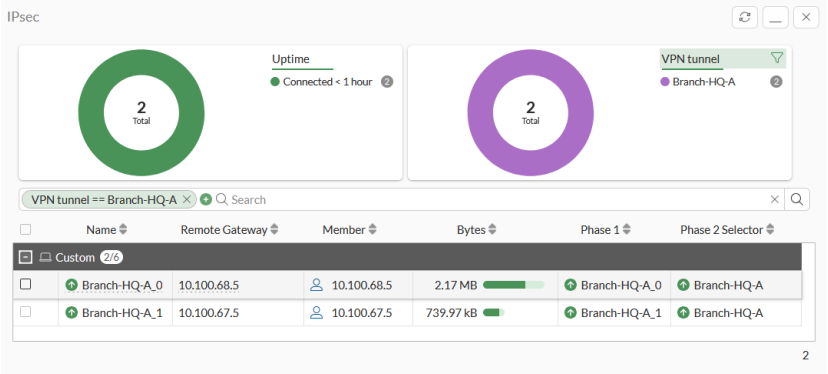
   To filter or configure a column in the table, hover over the column heading and click the *Filter/Configure Column* button.

   b. Go to *VPN* > *VPN Tunnels* and click *View tunnel connections*.



2. Hover over a record in the table. A tooltip displays the *Phase 1* and *Phase 2* interfaces. A warning appears next to a user who has not enabled two-factor authentication.
3. Click each pie chart to filter its information.

   For example, in the *VPN tunnel* pie chart, click the green pie or *Hub-1*. A filter icon displays beside *VPN tunnel*, the filter text displays in the *Search* bar, and the table displays the filtered results too.



Clear the filter by clicking the filter icon beside *VPN tunnel* or clicking an *X* in the *Search* bar.

4. Configure and filter the table as required, see Tables on page 43 for more information.

To reset statistics:

1. Select a tunnel in the table.
2. In the toolbar, click *Reset Statistics* or right-click the tunnel, and click *Reset Statistics*. The *Confirm* dialog is displayed.
3. Click *OK*.

To bring a tunnel up:

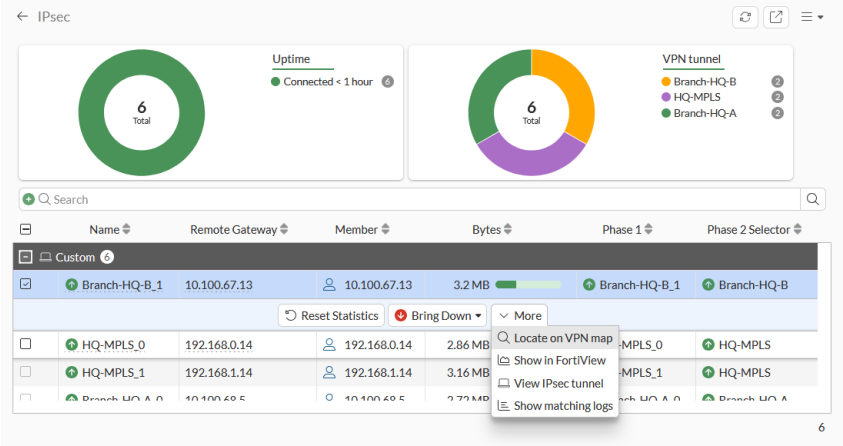
1. Select a tunnel in the table.
2. Click *Bring Up*, or right-click the tunnel, and click *Bring Up*. The *Confirm* dialog is displayed.
3. Click *OK*.

To bring a tunnel down:

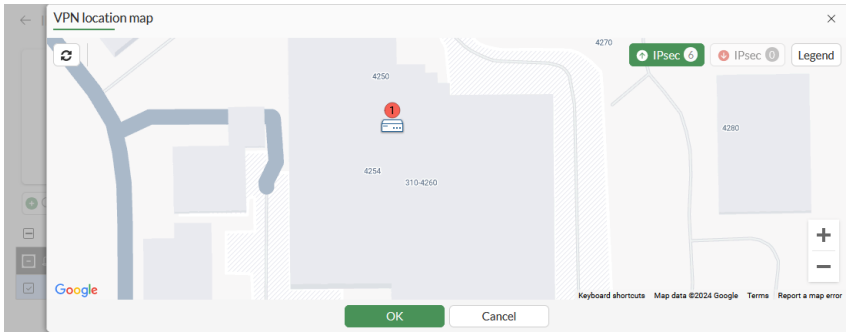
1. Select a tunnel in the table.
2. Click *Bring Down*, or right-click the tunnel, and click *Bring Down*.
   The entire tunnel, a phase 2 selector, or all phase 2 selectors can be brought down.
   The *Confirm* dialog is displayed.
3. Click *OK*.

To locate a tunnel on the VPN Map:

1. Select a tunnel in the table.
2. Click *More > Locate on VPN Map*, or right-click the tunnel, and click *Locate on VPN Map*.



The *VPN Location Map* is displayed.



3. Click *OK* to close the map.

To view tunnel connection in FortiView:

1. In the table, select a tunnel.
2. Click *More* > *Show in FortiView*, or right-click the tunnel and click *Show in FortiView*. The *FortiView VPN* pane is displayed.
3. Click *X* to close the pane.

To view the IPsec tunnel:

1. In the table, select a tunnel.
2. Click *More* > *View IPsec tunnel*, or right-click the tunnel and click *View IPsec tunnel*. The *VPN Tunnels* pane, filtered to the selected tunnel, is displayed.
3. Click *OK* or *Cancel* to close the pane.

To view matching logs for the tunnel:

1. In the table, select a tunnel.
2. Click *More* > *Show matching Logs*, or right-click the tunnel and click *Show matching logs*. The *Logs* pane is displayed.
3. Click *OK* to close the pane.

To view the IPsec monitor in the CLI:

```
# diagnose vpn tunnel list
```

Sample output:

```
list all ipsec tunnel in vd 0

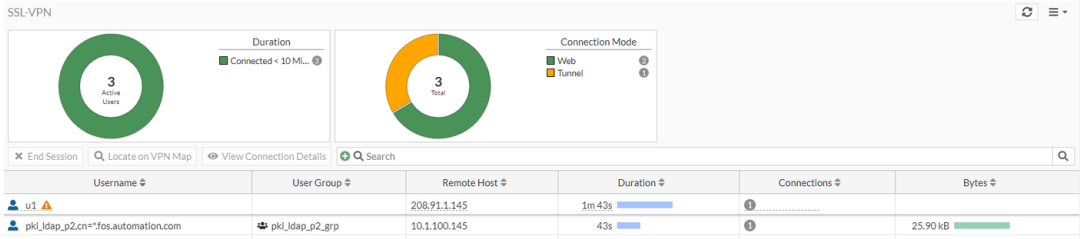
SSL-VPN monitor

The SSL-VPN monitor displays remote user logins and active connections. You can use the monitor to disconnect a specific connection. The monitor will notify you when VPN users have not enabled two-factor authentication.



To view the SSL-VPN monitor in the GUI:

1. Go *Dashboard* > *Network*.
2. Hover over the *SSL-VPN* widget, and click *Expand to Full Screen*.The *Duration* and *Connection Summary* charts are displayed at the top of the monitor.

To filter or configure a column in the table, hover over the column heading and click the *Filter/Configure Column* button.

To disconnect a user:

1. Select a user in the table.
2. In the table, right-click the user, and click *End Session*. The Confirm window opens.
3. Click *OK*.

To monitor SSL-VPN users in the CLI:

```
# get vpn ssl monitor
```

Sample output

```
SSL VPN Login Users:
Index User Group Auth Type Timeout From HTTP in/out HTTPS in/out
0 amitchell TAC 1(1) 296 10.100.64.101 3838502/11077721 0/0
1 mmiles Dev 1(1) 292 10.100.64.101 4302506/11167442 0/0

SSL VPN sessions:
Index User Group Source IP Duration I/O Bytes Tunnel/Dest IP
```

Assets & Identities

The *Assets & Identities* dashboard shows the current status of users and devices connected to your network. All of the widgets can be expanded to view as monitor. In monitor view, you can view asset details, create firewall

addresses, deauthenticate users, add IP addresses, ban IP addresses, quarantine hosts, and other such tasks.

The *Assets & Identities* dashboard includes the following widgets:

Widget	Description
Assets	Shows information from detected addresses, devices, and users on a single page. Information is grouped by device. For more information see Assets on page 127 and Asset details on page 129.
Identities	Shows information from detected addresses, devices, and users on a single page. Information is grouped by user.
Firewall Users	Monitor users that are logged into the network.
Quarantine	Monitor quarantined devices.
Matched NAC Devices	Monitor VLANs assigned to devices by FortiSwitch NAC policies.

See also Asset Identity Center page on page 3792.

Assets

You can enable device detection to allow FortiOS to monitor your networks and gather information about devices operating on those networks, including:

- MAC address
- IP address
- Operating system
- Hostname
- Username
- Endpoint tags
- When FortiOS detected the device and on which interface

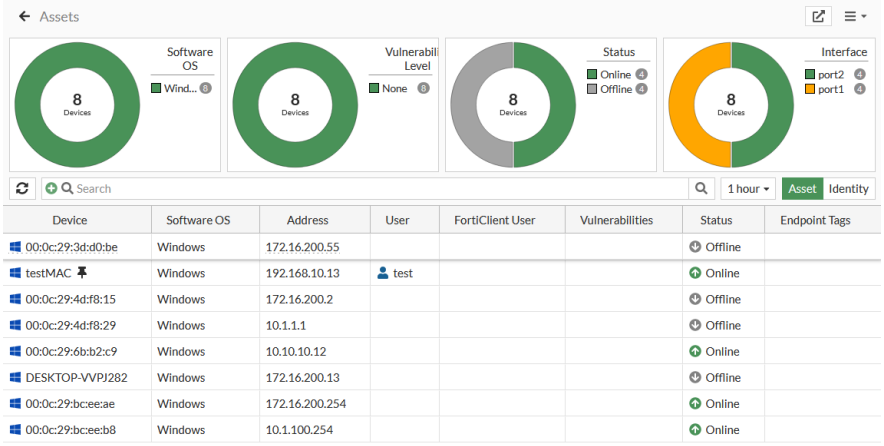
You can enable device detection separately on each interface in *Network > Interfaces*.

Device detection is intended for devices directly connected to your LAN and DMZ ports. The widget is only available when your *Interface Role* is *LAN*, *DMZ* or *Undefined*. It is not available when the role is WAN.

To view the assets monitor:

1. Go to *Dashboard > Assets & Identities*.
2. Hover over the *Assets* widget, and click *Click to expand*. The *Assets* monitor opens.
   If you are using the Comprehensive dashboard template, go to *Device Inventory Monitor*.
3. Hover over a device to display a tooltip with information and buttons.
4. Click the *Asset Details* button to view the details. See Asset details on page 129.

To filter or configure a column in the table, hover over the column heading, and click *Filter/Configure Column*. See Assets and filtering on page 128.



Assets and filtering

The *Assets* widget contains a series of summary charts that provide an overview of the operating system, vulnerability level, status, and interfaces. You can use these clickable charts to simplify filtering among your devices.

To view the device inventory and apply a filter:

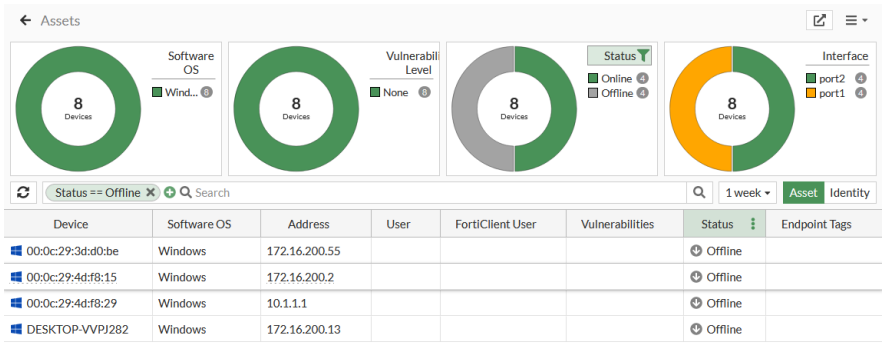
1. Go to *Dashboard* > *Assets & Identities*.
2. Hover over the *Assets* widget, and click *Click to expand*. The *Assets* monitor opens.
   If you are using the Comprehensive dashboard template, go to *Device Inventory Monitor*.
3. To filter a chart, click an item in the legend or chart area. The table displays the filter results.
4. To combine filters, hover over a column heading and click *Filter/Configure Column*.

5. Click the filter icon in the top-right corner of the chart to remove the filter.

Filter examples

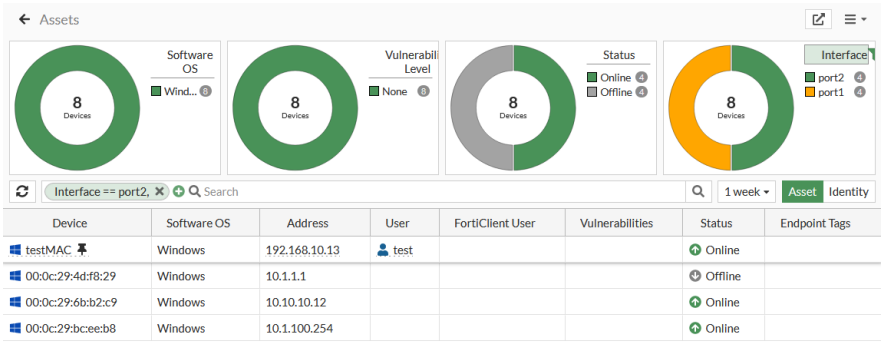
To filter all offline devices:

1. In the *Status* chart, click *Offline* in the legend or on the chart itself.



To filter all devices discovered on port2:

1. In the *Interfaces* chart, click *port2*.

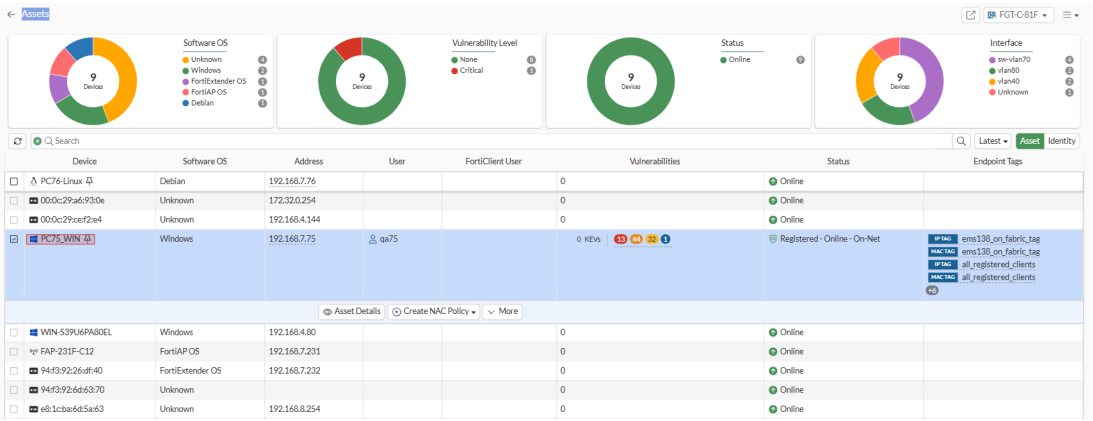


Asset details

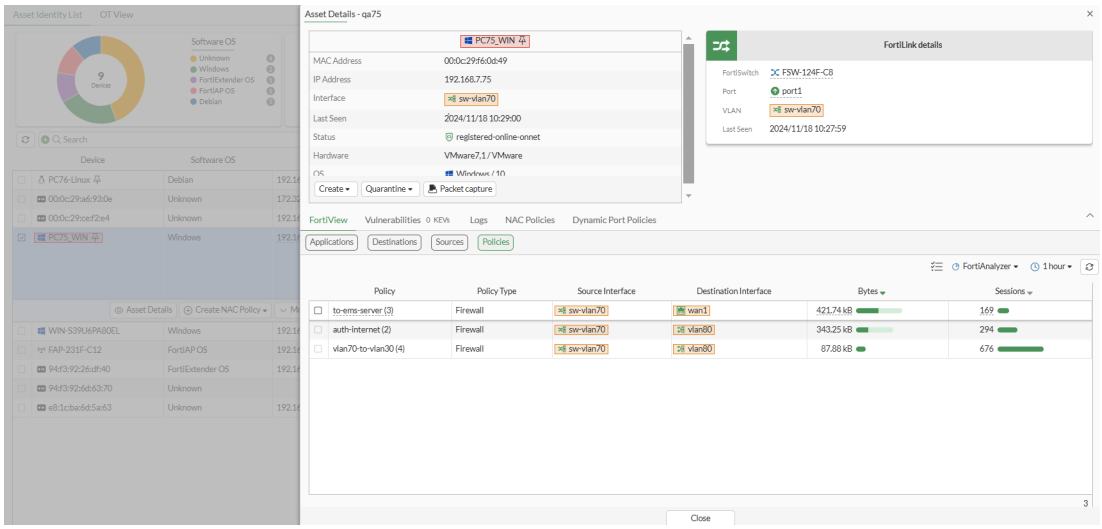
The *Asset Details* pane provides comprehensive endpoint information to streamline the diagnostic process and reduce reliance on CLI commands.

To view the Asset Details pane:

1. Go to *Dashboard* > *Assets & Identities*.
2. Hover over the *Assets* widget, and click *Click to Expand*. The *Assets* monitor opens.
   If you are using the Comprehensive dashboard template, go to *Device Inventory Monitor*.
3. Select a row to display a toolbar that includes the *Asset Details* button:
   You can also hover over the device to display a tooltip with the *Asset Details* button.



4. Click *Asset Details* to display the details.



On the top-left of the *Asset Details* pane is information about the endpoint, such as MAC address, IP address, interface, and so on. The following buttons are also available for the endpoint:

- *Create > Firewall Address*
- *Create > Firewall Policy*
- *Quarantine > Quarantine Host*
- *Quarantine > Ban IP*
- *Disassociate* is available for endpoints using a WiFi interface
- *Packet capture*

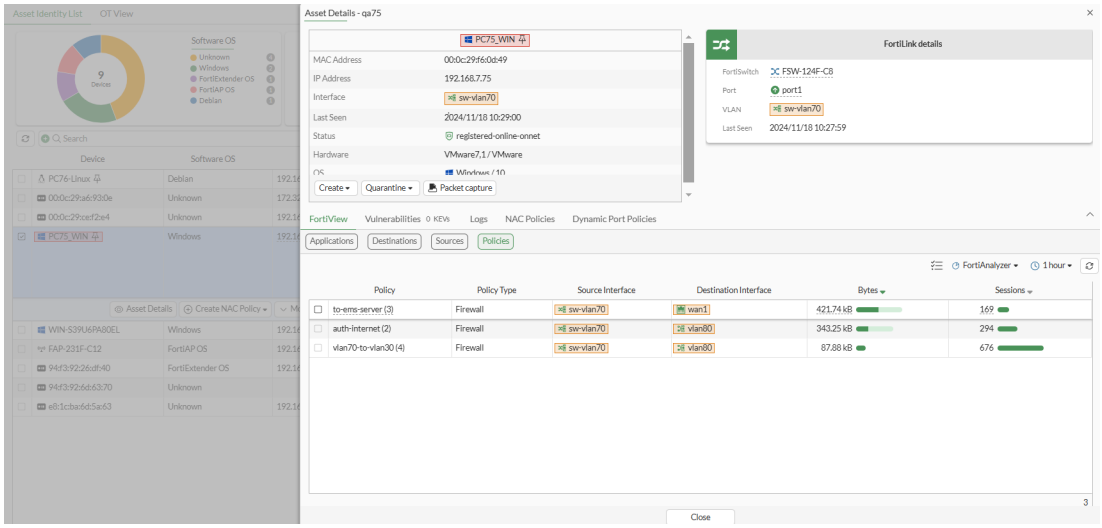
On the top-right are details about the WiFi or FortiLink interface when used by the endpoint.

Along the bottom are tabs of information, depending on the endpoint and interface used:

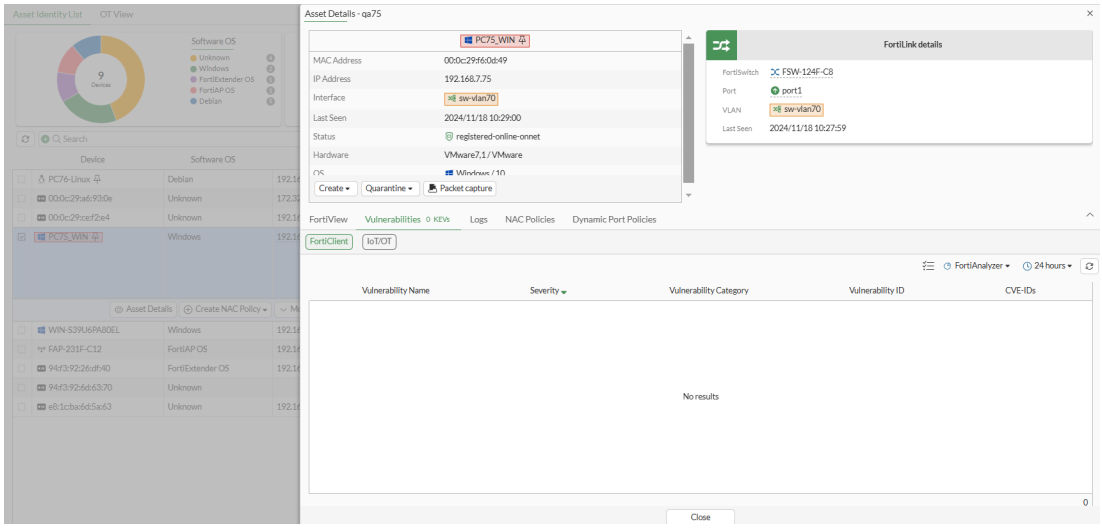
Tab	Subtabs
FortiView	Applications Destinations Sources Policies
Vulnerabilities/Vulnerabilities <number> KEVs	FortiClient IoT/OT
Logs	Forward Traffic ZTNA Traffic WiFi Events
WiFi Performance	N/A
NAC Policies	N/A
Dynamic Port Policies	N/A

Following are examples of the *Asset Details* pane for an endpoint named *PC75_WIN* using a VLAN interface:

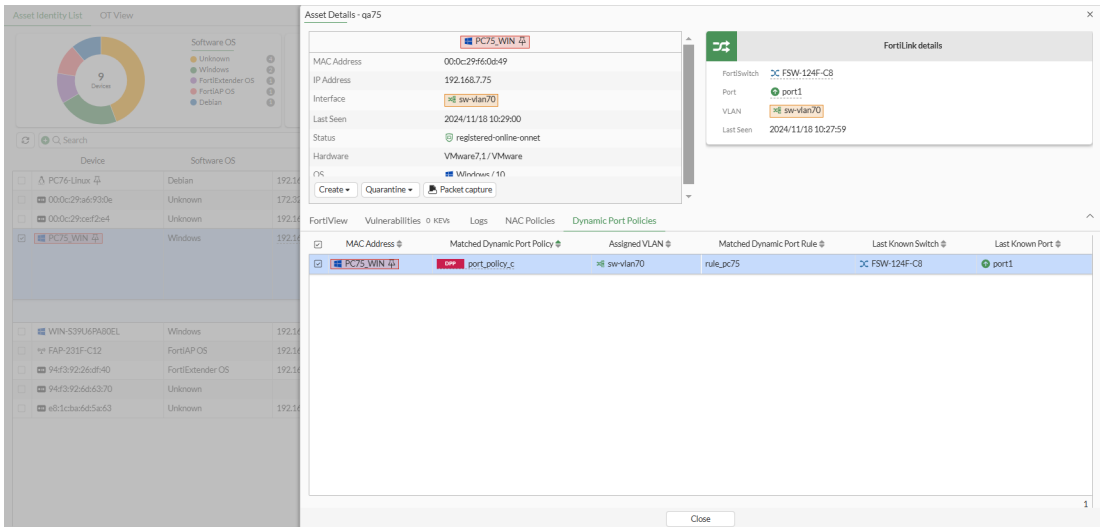
- The *FortiView > Policies* tab:



- The *Vulnerabilities > FortiClient* tab:



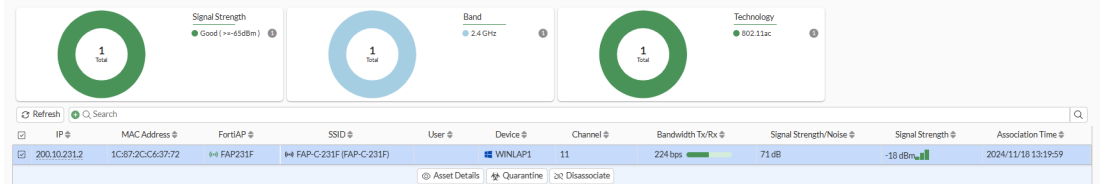
- The *Dynamic Port Policies* tab:



You can also access the *Asset Details* pane by clicking the *Asset Details* button from the following GUI locations:

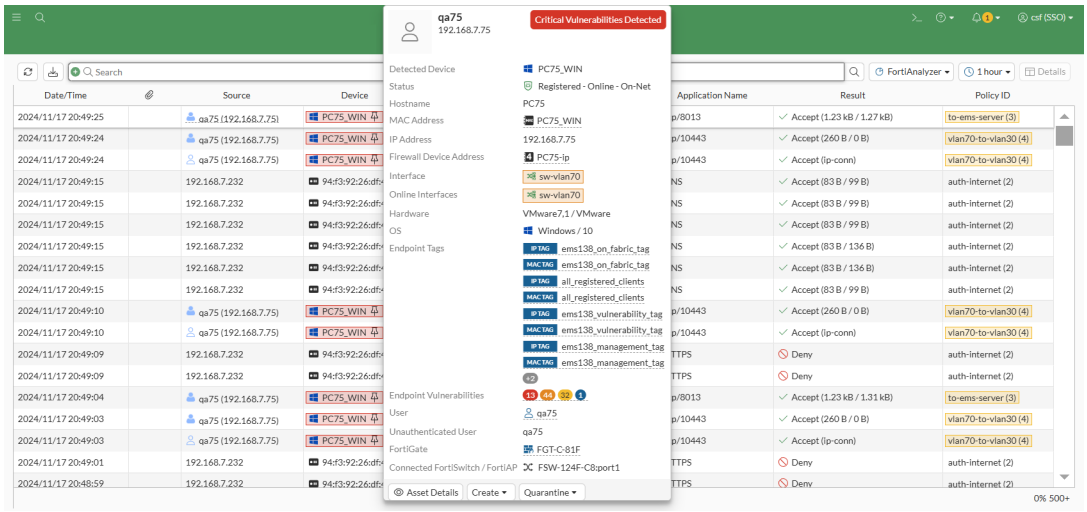
- On the *Dashboard* > *Assets & Identities* page:
  - *Assets - Vulnerabilities*
  - *Assets - FortiClient*
- On the *Security Fabric* page:
  - Go to *Physical Topology*, and hover over an endpoint to display a tooltip that includes the *Asset Details* button.

  - Go to *Asset Identity Center* page. Hover over a device to display a tooltip that includes the *Asset Details* button, or select a row in the table to display a toolbar that includes the *Asset Details* button.
- In the *WiFi & Switch Controller* menu:
  - Go to *WiFi Clients*. Hover over a device to display a tooltip that includes the *Asset Details* button, or select a row in the table to display a toolbar that includes the *Asset Details* button.



- Go to *FortiSwitch Clients*. Hover over a device to display a tooltip that includes the *Asset Details* button, or select a row in the table to display a toolbar that includes the *Asset Details* button.

- On the *Log & Report > Forward Traffic* page, hover over a device to display a tooltip that includes the *Asset Details* button:

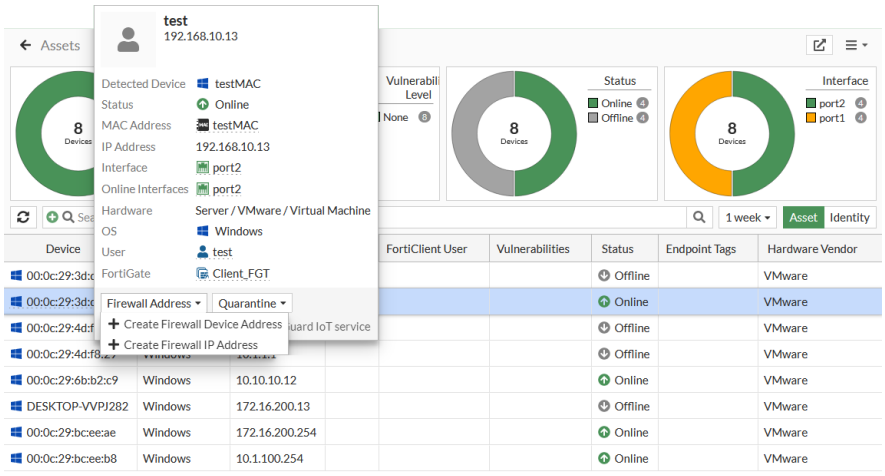


Adding MAC-based addresses to devices

Assets detected by device detection appear in the *Assets* widget. You can manage policies around devices by adding a new device object (MAC-based address) to a device. Once you add the MAC-based address, the device can be used in address groups or directly in policies.

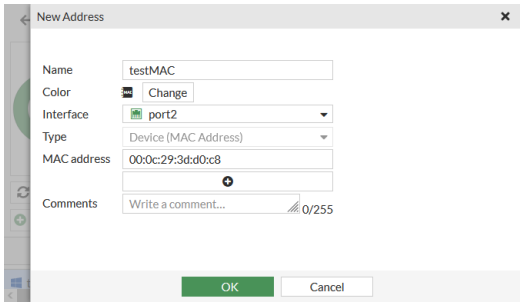
To add a MAC-based address to a device:

1. Go to *Dashboard > Assets & Identities*.
2. Hover over the *Assets* widget, and click *Click to expand*. The *Assets* monitor opens.
   If you are using the Comprehensive dashboard template, go to *Device Inventory Monitor*.
3. Click a device, then click *Firewall Address > Create Firewall IP Address*. The *New Address* pane opens.

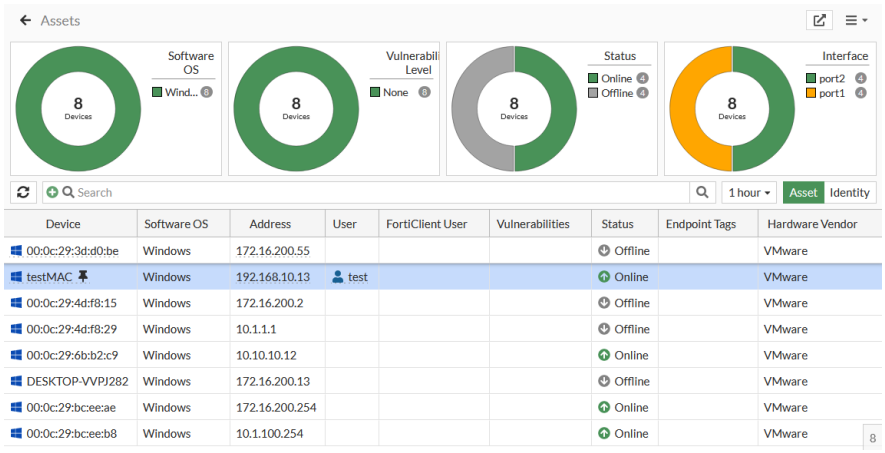


4. In the *Name* field, give the device a descriptive name so that it is easy to find it in the *Device* column.

5. Configure the *MAC Address*.

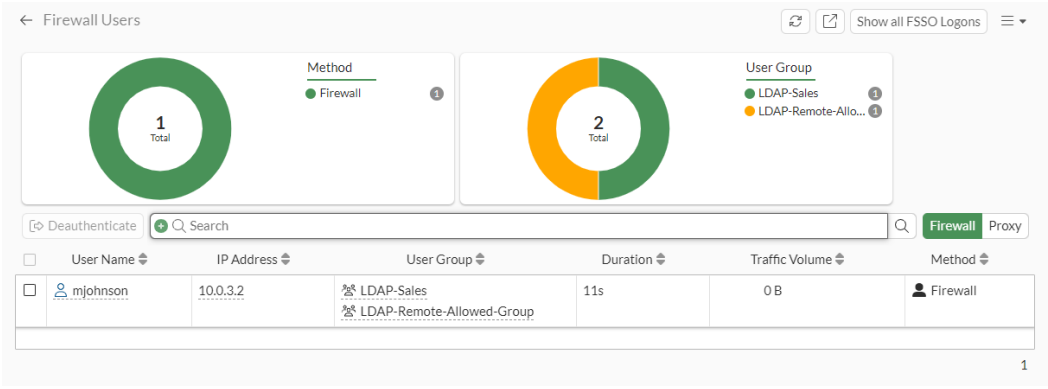


6. Click *OK*, then refresh the page. The MAC address icon appears in the *Address* column next to the device name.



Firewall Users monitor

The Firewall Users monitor displays all currently logged in firewall and proxy users. You can use the monitor to diagnose user-related logons or to highlight and deauthenticate a user.



To view the firewall monitor:

1. Go to *Dashboard* > *Assets & Identities*.
2. Hover over the *Firewall Users* widget, and click *Click to expand*.
   If you are using the Comprehensive dashboard template, go to *Firewall User Monitor*.

3. To show FSSO logons, click *Show all FSSO Logons* at the top right of the page.
4. To switch to the proxy user view, click *Proxy* (next to the search bar). Proxy user view shows used that authenticated over ZTNA and explicit proxy.

To filter or configure a column in the table, hover over the column heading and click the *Filter/Configure Column* button.

When the number of users exceeds 2000, the page no longer displays the search bar, filter columns, or graphs because lazily-loaded results do not support these GUI features.

To deauthenticate a user in the GUI:

1. Go to *Dashboard > Assets & Identities*.
2. Hover over the *Firewall Users* widget, and click *Click to expand*.
3. (Optional) Use the *Search* field to search for a specific user.
4. In the toolbar, click *Deauthenticate*, or right-click the user, and click *Deauthenticate*. The *Confirm* dialog is displayed.
5. Click *OK*.

To view and deauthenticate firewall users in the CLI:

```
# diagnose firewall auth list
# diagnose firewall auth filter <parameters>
# diagnose firewall auth clear
```

To view and deauthenticate proxy users in the CLI:

```
# diagnose wad user list
# diagnose wad user clear <ID> <IP|IPv6> <VDOM>
```

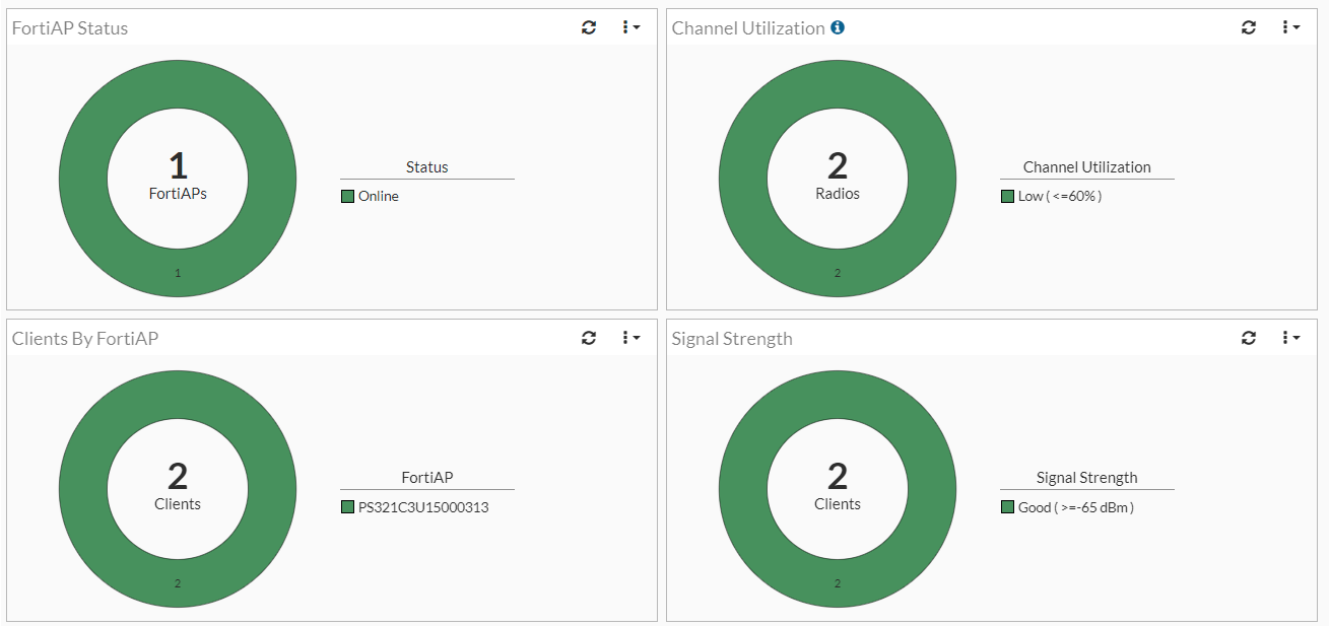
or

```
# diagnose wad user clear
```

WiFi dashboard

The *WiFi* dashboard provides an overview of your WiFi network's performance, including FortiAP status, channel utilization, WiFi clients and associated information, login failures, and signal strength.

To access the WiFi dashboard, go to *Dashboard > WiFi*.



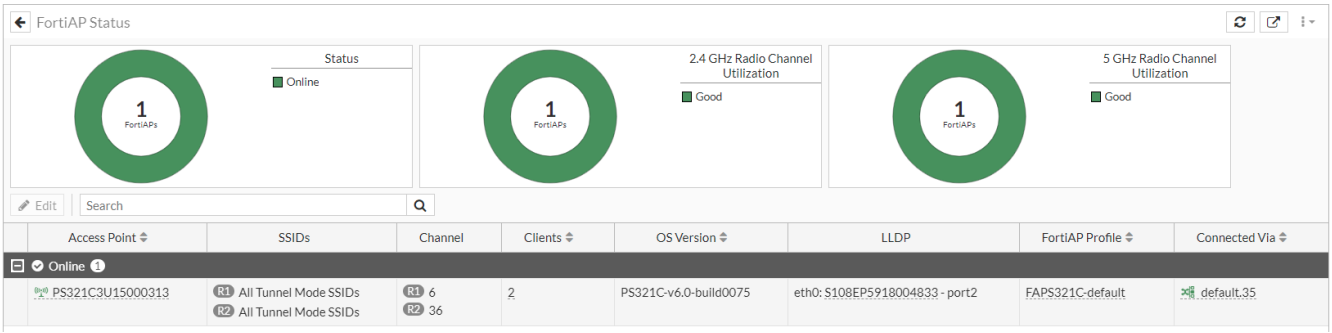
The WiFi dashboard can be customized per your requirements. To learn more about using and modifying dashboards and widgets, see Dashboards and Monitors on page 102.

This section describes the following monitors available for the WiFi Dashboard:

- FortiAP Status monitor on page 136
- Clients by FortiAP monitor on page 138

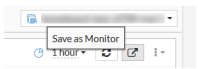
FortiAP Status monitor

The *FortiAP Status* monitor displays the status and the channel utilization of the radios of FortiAP devices connected to a FortiGate. It also provides access to tools to diagnose and analyze connected APs.



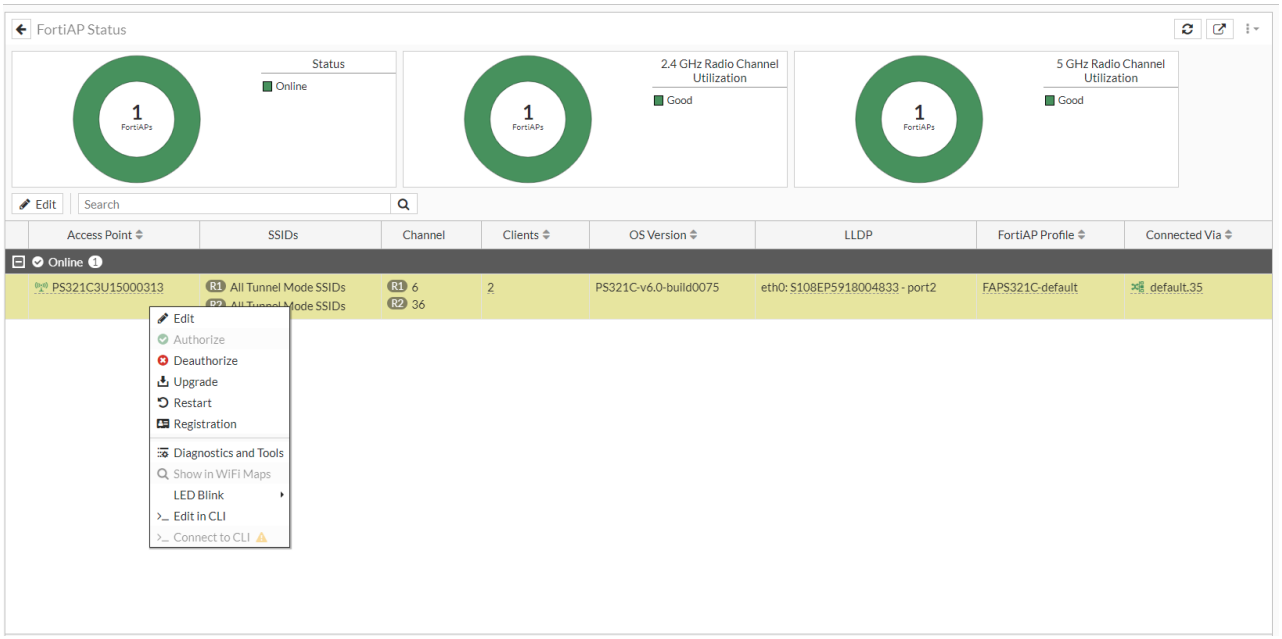
To view the *FortiAP Status* monitor:

1. Go to *Dashboard* > *WiFi*.
2. Hover over the *FortiAP Status* widget, and click *Expand to Full Screen*. The *FortiAP Status* monitor opens.
3. (Optional) Click *Save as Monitor* to save the widget as monitor.

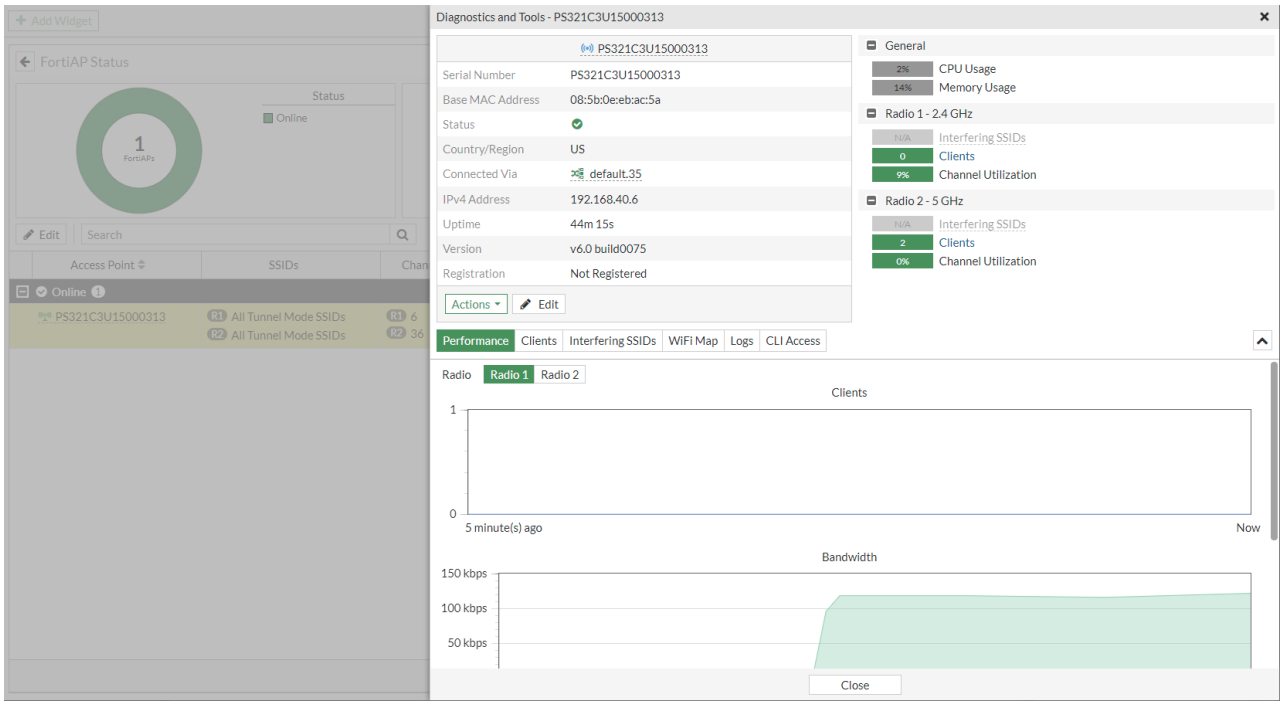


To view the Diagnostics and Tools menu:

1. Right-click an *Access Point* in the table, and click *Diagnostics and Tools*. The *Diagnostics and Tools* dialog opens.



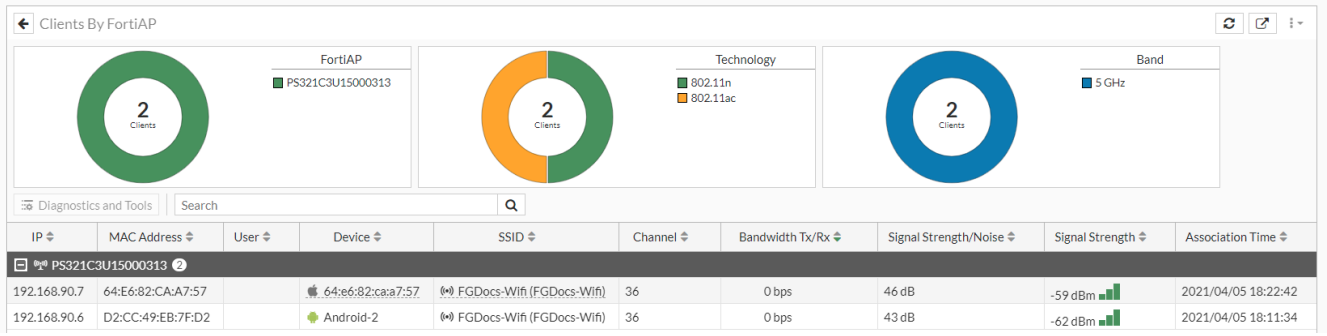
2. To monitor and analyze the FortiAP device, click on the tabs in the *Diagnostics and Tools* dialog, such as *Clients*, *Spectrum Analysis*, *VLAN Probe*, and so on.



The *Diagnostics and Tools* dialog is similar to the device dialog from *WiFi & Switch Controller* > *Managed FortiAPs*. To learn more about the various tabs and their functions, see Spectrum analysis of FortiAP E models, VLAN probe report, and Standardize wireless health metrics.

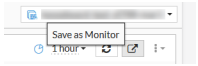
Clients by FortiAP monitor

The *Clients by FortiAP* monitor allows you to view detailed information about the health of individual WiFi connections in the network. It also provides access to tools to diagnose and analyze connected wireless devices.



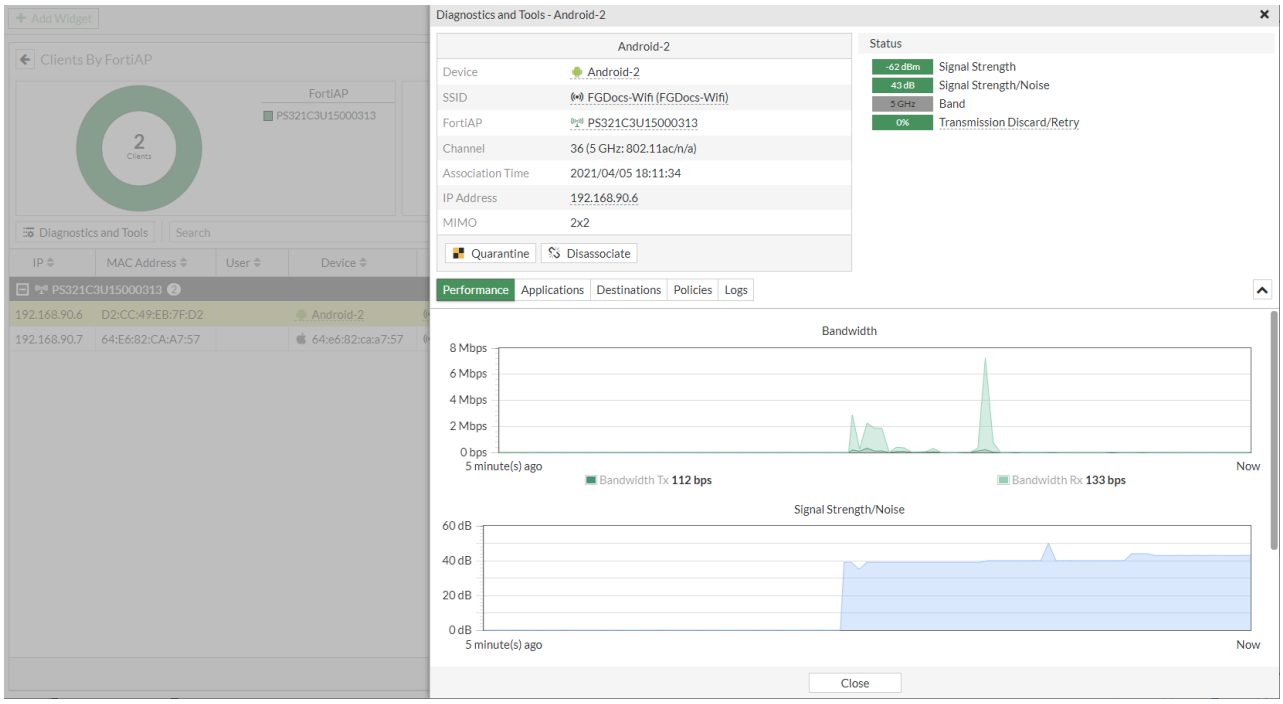
To view the *Clients by FortiAP* monitor:

1. Go to *Dashboard* > *WiFi*.
2. Hover over the *Clients by FortiAP* widget, and click *Expand to Full Screen*. The *Clients by FortiAP* monitor opens.
3. (Optional) Click *Save as Monitor* to save the widget as monitor.



To view the summary page for a wireless client:

1. Right-click a client in the table and select *Diagnostics and Tools*. The *Diagnostics and Tools - <device>* page is displayed.



2. (Optional) Click *Quarantine* to quarantine the client,
3. (Optional) Click *Disassociate* to disassociate the client.

Health status

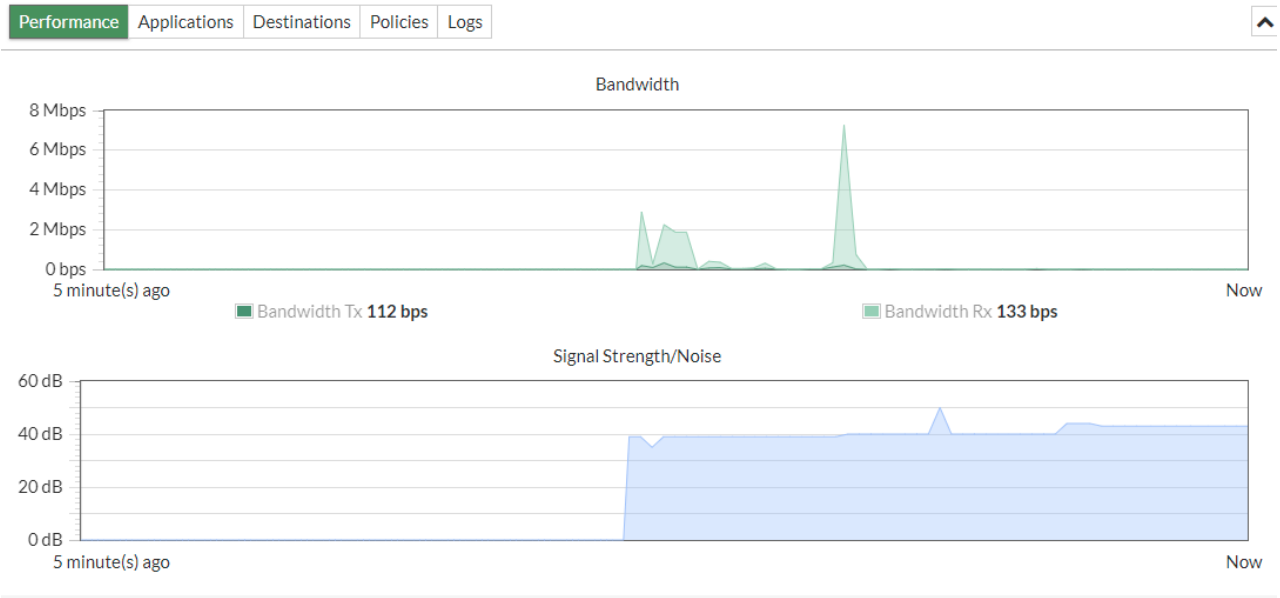
The *Status* section displays the overall health for the wireless connection. The overall health of the connection is:

- Good if the value range for all three conditions are *Good*
- Fair or poor if one of the three conditions is *Fair* or *Poor* respectively.

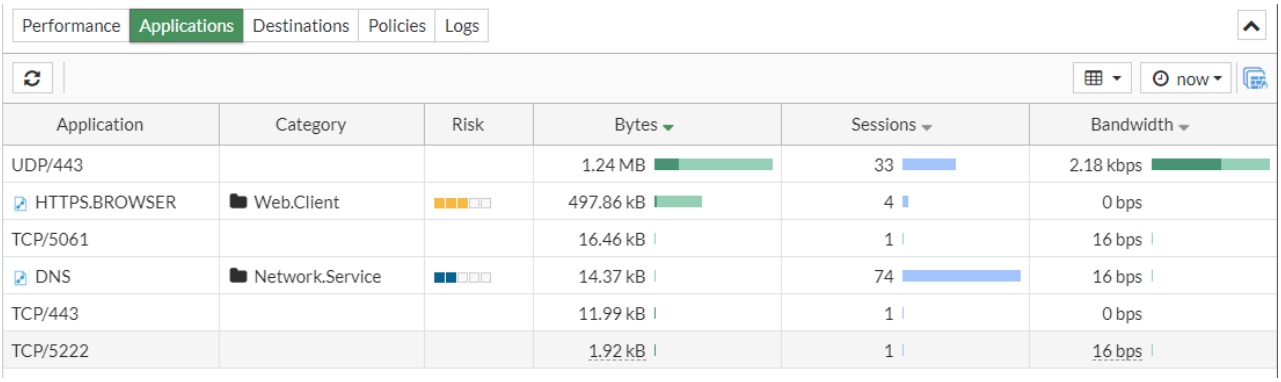
Condition	Value Range
Signal Strength	• *Good > -56dBm* • *-56dBm > Fair > -75dBm* • *Poor < -75dBm*
Signal Strength/Noise	• *Good > 39dBm* • *20dBm < Fair < 39dBm* • *Poor < 20dBm*
Band	• *Good = 5G band* • *Fair = 2.4G band*

The summary page also has the following FortiView tabs:

- *Performance*



- *Applications*



Application	Category	Risk	Bytes	Sessions	Bandwidth

Monitors

FortiGate supports both FortiView and Non-FortiView monitors. FortiView monitors are driven by traffic information captured from logs and real-time data. Non-FortiView monitors capture information from various real-time state tables on the FortiGate.

Non-FortiView monitors

Non-FortiView monitors capture information on various state tables, such as the routes in the routing table, devices in the device inventory, DHCP leases in the DHCP lease table, connected VPNs, clients logged into the wireless network, and much more. These monitors are useful when troubleshooting the current state of the FortiGate, and to identify whether certain objects are in the state table or not. For more information, see Dashboards on page 110.

FortiView monitors

FortiView is the FortiOS log view tool and comprehensive monitoring system for your network. FortiView integrates real-time and historical data into a single view on your FortiGate. It can log and monitor network threats, keep track of administration activities, and more.

Use FortiView monitors to investigate traffic activity such as user uploads and downloads, or videos watched on YouTube. You can view the traffic on the whole network by user group or by individual. FortiView displays the information in both text and visual format, giving you an overall picture of your network traffic activity so that you can quickly decide on actionable items.

FortiView is integrated with many UTM functions. For example, you can quarantine an IP address directly in FortiView or create custom devices and addresses from a FortiView entry.

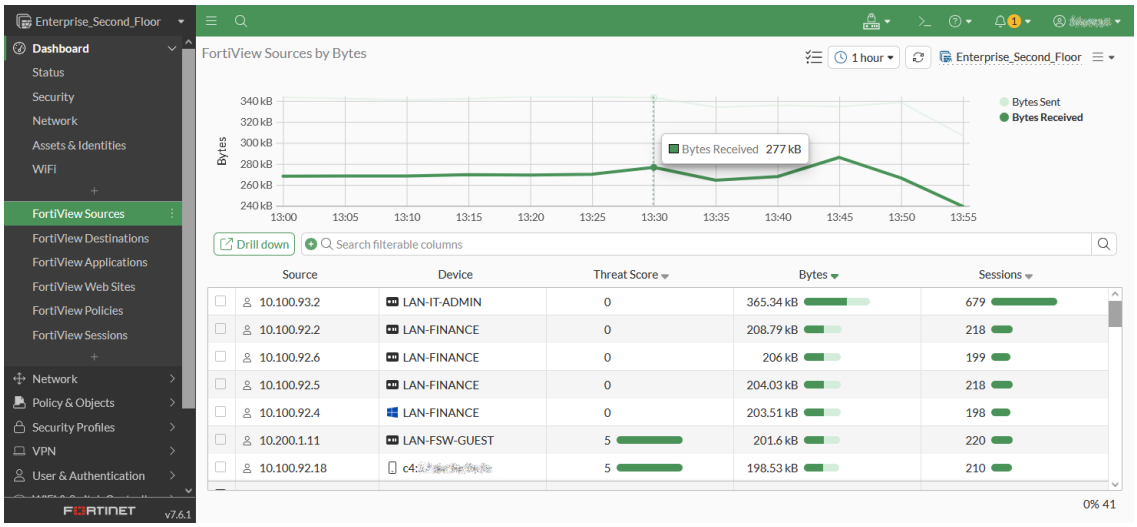
The logging range and depth will depend on the FortiGate model.

The *Optimal* template contains a set of popular default dashboards and FortiView monitors. The *Comprehensive* template contains a set of default dashboards as well as all of the FortiView monitors. See Dashboards on page 110.

Template	Monitors
Optimal	• FortiView Sources • FortiView Destinations • FortiView Applications • FortiView Web Sites • FortiView Policies • FortiView Sessions
Comprehensive	• FortiView Sources • FortiView Destinations • FortiView Applications • FortiView Web Sites • FortiView Threats • FortiView Compromised Hosts • FortiView Policies • FortiView Sessions • Device Inventory Monitor • Routing Monitor • DHCP Monitor • SD-WAN Monitor • FortiGuard Quota Monitor • IPsec Monitor • SSL-VPN Monitor • Firewall User Monitor • Quarantine Monitor • FortiClient Monitor • FortiAP Clients Monitor • Rogue APs Monitor

FortiView monitors

FortiView monitors are available in the tree menu under *Dashboards*. The menu contains several default monitors for the top categories. Additional FortiView monitors are available as widgets that can be added to the dashboards. You can also add FortiView monitors directly to the tree menu with the Add (**+**) button.



Core FortiView monitors

The following default monitors are available in the tree menu:

Dashboard	Usage
FortiView Sources	Displays Top Sources by traffic volume and drilldown by Source.
FortiView Destinations	Displays Top Destinations by traffic volume and drilldown by Destination.
FortiView Applications	Displays Top Applications by traffic volume and drilldown by Application.
FortiView Web Sites	Displays Top Websites by session count and drilldown by Domain.
FortiView Policies	Displays Top Policies by traffic volume and drilldown by Policy number
FortiView Sessions	Displays Top Sessions by traffic source and can be used to end sessions.

Usage is based on default settings. The pages may be customized further and sorted by other fields.

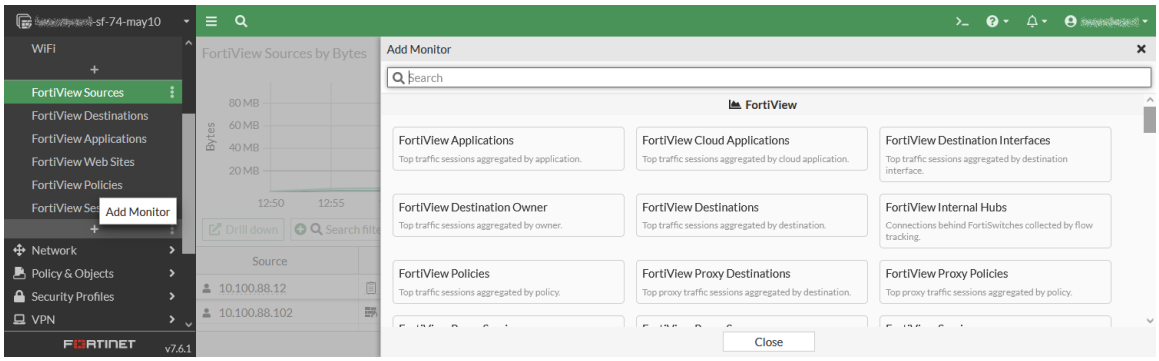
You can quarantine a host and ban an IP from all of the core FortiView monitors.

Adding FortiView monitors

Non-core FortiView monitors are available in the *Add monitor* pane. You can add a FortiView widget to a dashboard or the tree menu as a monitor.

To add a monitor to the tree menu:

1. In the tree menu, under the monitors section, click *Add Monitor* (+).



2. Click *Add* next to a monitor. You can use the *Search* field to search for a specific monitor.
3. In the *FortiGate* area, select *All FortiGates* or *Specify* to select a FortiGate device in the security fabric.
4. (Optional) In the *Data Source* area, select *Specify* and select a source device.
5. From the *Time Period* dropdown, select the time period. This option is not available in all monitors.
6. From the *Sort By* dropdown, select the sorting method.
7. Click *Add Monitor*. The monitor is added to the tree menu.

Monitors by category

Usage is based on the default settings. The monitors may be customized further and sorted by other fields.

LANDMARK

Widget	Sort by	Usage
Applications	Bytes/Sessions/Bandwidth/Packets	Displays top applications and drilldown by application.
Application Bandwidth	Bytes/Bandwidth	Displays bandwidth for top applications and drilldown by application.
Cloud Applications	Bytes/Sessions/Files(Up/Down)	Displays top cloud applications and drilldown by application.
Cloud Users	Bytes/Sessions/Files(Up/Down)	Displays top cloud users and drilldown by cloud user.
Compromised Hosts	Verdict	Displays compromised hosts and drilldown by source.
Countries/Regions	Bytes/Sessions/Bandwidth/Packets	Displays top countries/regions and drilldown by countries/regions.

Widget	Sort by	Usage
Destination Firewall Objects	Bytes/Sessions/Bandwidth/Packets	Displays top destination firewall objects and drilldown by destination objects.
Destination Owners	Bytes/Sessions/Bandwidth/Packets	Displays top destination owners and drilldown by destination.
Destinations	Bytes/Sessions/Bandwidth/Packets	Displays top destinations and drilldown by destination.
Search Phrases	Count	Displays top search phrases and drilldown by search phrase.
Source Firewall Objects	Bytes/Sessions/Bandwidth/Packets	Displays top search phrases and drilldown by source object.
Sources	Bytes/Sessions/Bandwidth/Packets	Displays top sources and drilldown by source.
Threats	Threat level/Threat Score/Sessions	Displays top threats and drilldown by threat.
Traffic Shaping	Dropped Bytes/Bytes/Sessions/Bandwidth/Packets	Displays top traffic shaping and drilldown by shaper.
Web Categories	Bytes/Sessions/Bandwidth/Packets	Displays top web categories and drilldown by category.
Web Sites	Bytes/Sessions/Bandwidth/Packets	Displays top web sites and drilldown by domain.
WiFi Clients	Bytes/Sessions	Displays top WiFi clients and drilldown by source.

WAN

Widget	Sort by	Usage
Servers	Bytes/Sessions/Bandwidth/Packets	Displays top servers and drilldown by server address.
Sources	Bytes/Sessions/Bandwidth/Packets	Displays top sources and drilldown by device.
Threats	Threat Level/Threat Score/Sessions	Displays top threats and drilldown by threat.

All Segments

Widget	Sort by	Usage
Admin Logins	Configuration Changes/Logins/Failed Logins	Displays top admin logins by username.

Widget	Sort by	Usage
Destination Interfaces	Bytes/Sessions/Bandwidth/Packets	Displays top destination interfaces by destination interface.
Endpoint Vulnerabilities	Severity	Displays top endpoint vulnerabilities by vulnerability name.
Failed Authentication	Failed Attempts	Displays top failed authentications by failed authentication source.
FortiSandbox Files	Submitted	Displays top FortiSandbox files by file name.
Interface Pairs	Bytes/Sessions/Bandwidth/Packets	Displays top interface pairs by source interface.
Policies	Bytes/Sessions/Bandwidth/Packets	Displays top policies by policy.
Source Interfaces	Bytes/Sessions/Bandwidth/Packets	Displays top source interfaces by source interface.
System Events	Level/Events	Displays top system events by event name.
VPN	Connections/Bytes	Displays top VPN connections by user.
Vulnerable Endpoint Devices	Detected Vulnerabilities	Displays top vulnerable endpoint devices by device.

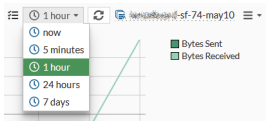
A maximum of 25 interfaces can be monitored at one time on a device.

Using the FortiView interface

Use the FortiView interface to customize the view and visualizations within a monitor to find the information you are looking for. The tools in the top menu bar allow you to change the time display, refresh or customize the data source, and filter the results. You can also right-click a table in the monitor to view drilldown information for an item.

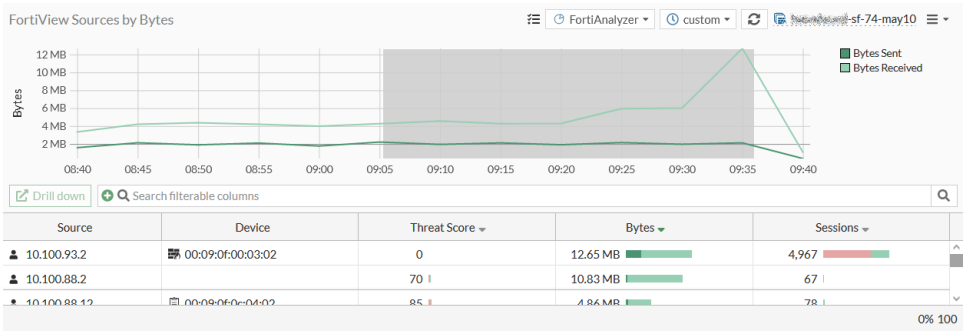
Real-time and historical charts

Use the *Time Display* dropdown to select the time period to display on the current monitor. Time display options vary depending on the monitor and can include real-time information (*now*) and historical information (*1 hour*, *24 hours*, and *7 days*).

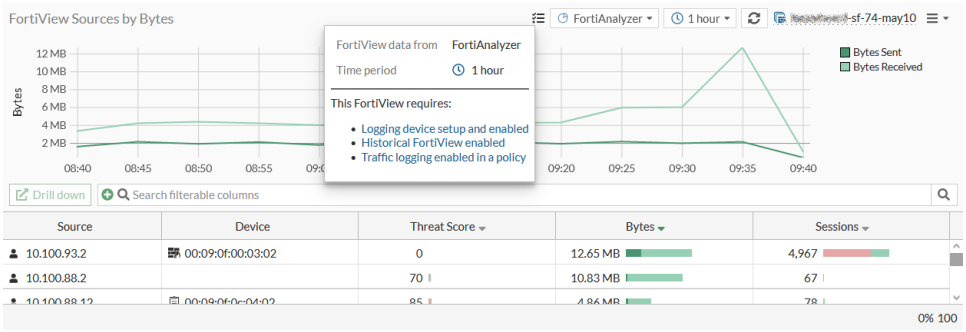


Disk logging or remote logging must be enabled to view historical information.

You can create a custom time range by selecting an area in table with your cursor.

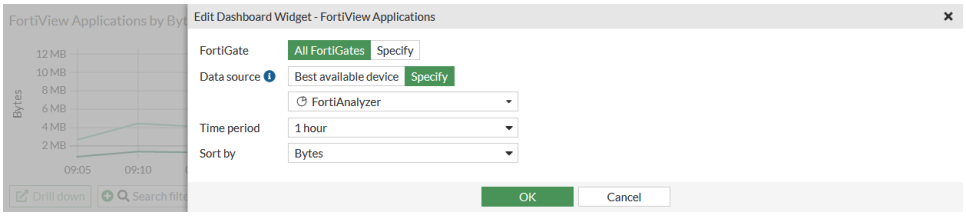


The icon next to the time period identifies the data source (FortiGate, FortiAnalyzer, or FortiGate Cloud). Hover over its icon to see a description of the chart, as well as links to the requirements.



Data source

FortiView gathers information from a variety of data sources. If there are no log disk or remote logging configured, the data will be drawn from the FortiGate's session table, and the *Time Period* is set to *Now*.



Other data sources that can be configured are:

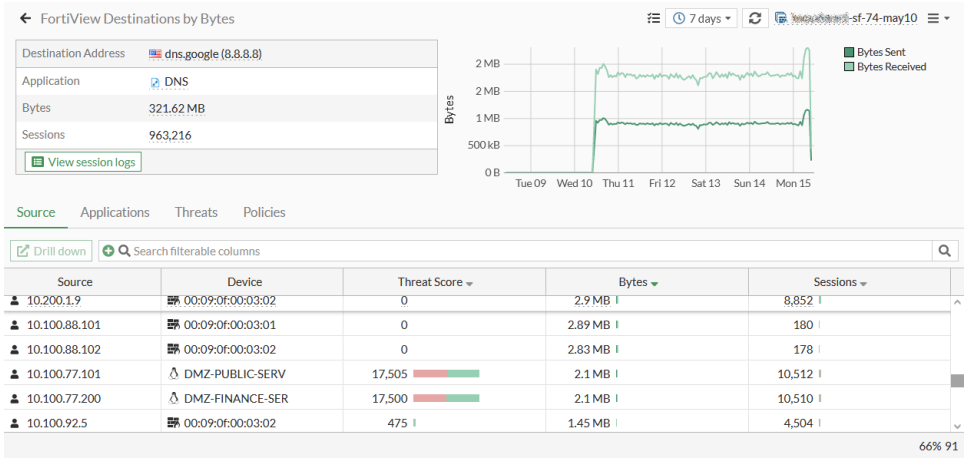
- FortiGate
- FortiAnalyzer
- FortiGate Cloud

When *Data Source* is set to *Best Available Device*, FortiAnalyzer is selected when available, then FortiGate Cloud, and then FortiGate.

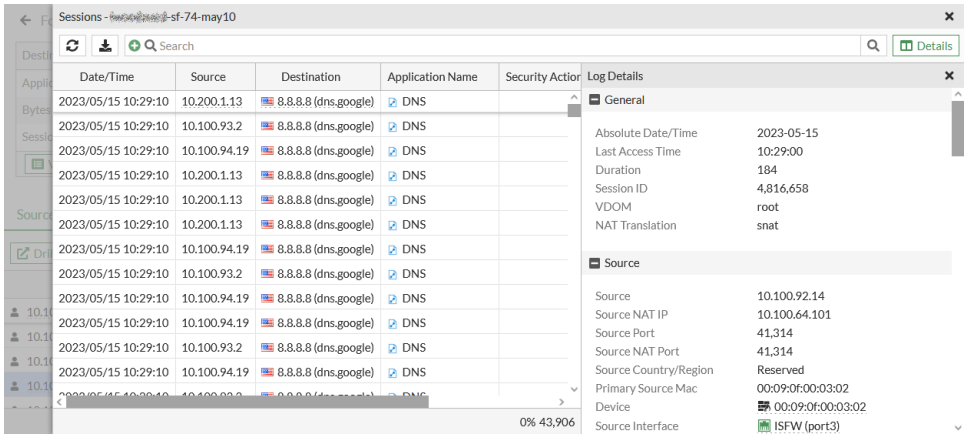
Drilldown information

Double-click or right-click an entry in a FortiView monitor and select *Drill Down to Details* to view additional details about the selected traffic activity. Click the *Back* icon in the toolbar to return to the previous view.

You can group drilldown information into different drilldown views. For example, you can group the drilldown information in the *FortiView Destinations* monitor by *Sources*, *Applications*, *Threats*, and *Policies*.



Select an entry, then click *View session logs* to view the session logs.

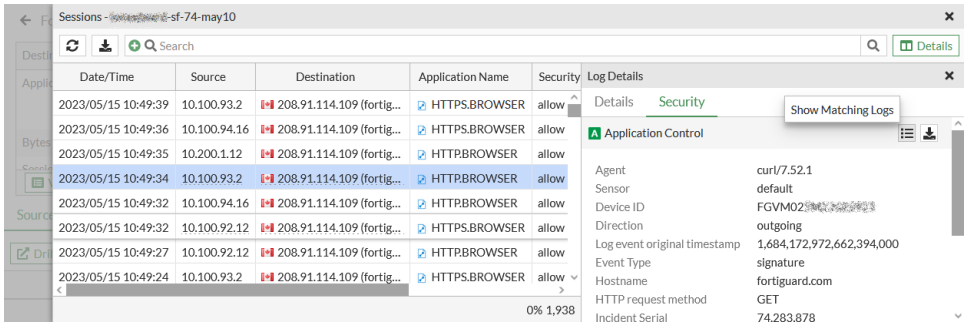


Graph	• The graph shows the bytes sent/received in the time frame. real time does not include a chart. • Users can customize the time frame by selecting a time period within the graph.
Summary of	• Shows information such as the user/avatar, avatar/source IP, bytes, and sessions total for the time period. • Can quarantine host (access layer quarantine) if they are behind a FortiSwitch or

	FortiAP. • Can ban IP addresses, adds the source IP address into the quarantine list.

Tabs	• Drilling down entries in any of these tabs (except sessions tab) will take you to the underlying traffic log in the sessions tab.
	• *Applications* shows a list of the applications attributed to the source IP. This can include scanned applications using Application Control in a firewall policy or unscanned applications.
	`config log gui-display`
	`set fortiview-unscanned-apps enable`
	`end`
	• *Destinations* shows destinations grouped by IP address/FQDN.
	• *Threats* lists the threats caught by UTM profiles. This can be from antivirus, IPS, Web Filter, Application Control, etc.
	• *Web Sites* contains the websites which were detected either with webfilter, or through FQDN in traffic logs.
	• *Web Categories* groups entries into their categories as dictated by the Web Filter Database.
	• *Policies* groups the entries into which polices they passed through or were blocked by.
	• *View session logs* shows the underlying logs (historical) or sessions (real time). Drilldowns from other tabs end up showing the underlying log located in this tab.
	• *Search Phrases* shows entries of search phrases on search engines captured by a Web Filter UTM profile, with deep inspection enabled in firewall policy.
	• More information can be shown in a tooltip while hovering over these entries.

To view matching logs or download a log, click the *Security* tab in the *Log Details* .



Enabling FortiView from devices

You can enable FortiView from SSD disk, FortiAnalyzer and FortiGate Cloud.

FortiView from disk

FortiView from disk is available on all FortiGates with an SSD disk.

Restrictions

Model	Supported view
Entry-level models with SSD	Five minutes and one hour
Mid-range models with SSD	Up to 24 hours

High-end models with SSD	Up to seven days
	To enable seven days view:
	`config log setting`
	`set fortiview-weekly-data enable`
	`end`

Configuration

A firewall policy needs to be in place with traffic logging enabled. For optimal operation with FortiView, internal interface roles should be clearly defined as LAN. DMZ and internet facing or external interface roles should be defined as WAN.

To configure logging to disk:

```
config log disk setting
   set status enable
end
```

To include sniffer traffic and local-deny traffic when FortiView from Disk:

```
config report setting
   set report-source forward-traffic sniffer-traffic local-deny-traffic
end
```

This feature is only supported through the CLI.

Troubleshooting

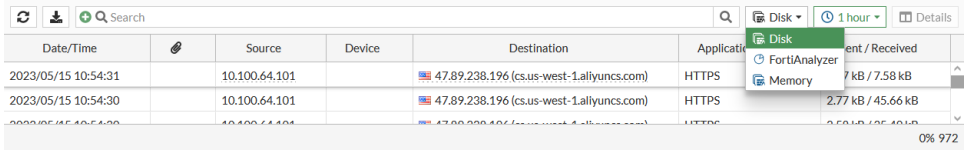
Use `execute report flush-cache` and `execute report recreate-db` to clear up any irregularities that may be caused by upgrading or cache issues.

Traffic logs

To view traffic logs from disk:

1. Go to *Log & Report*, and select either the *Forward Traffic*, *Local Traffic*, *Sniffer Traffic*, or *ZTNA Traffic* views.

2. In the toolbar, select *Disk* for the log location dropdown.



FortiView from FortiAnalyzer

Connect FortiGate to a FortiAnalyzer to increase the functionality of FortiView. Adding a FortiAnalyzer is useful when adding monitors such as the *Compromised Hosts*. FortiAnalyzer also allows you to view historical information for up to seven days.

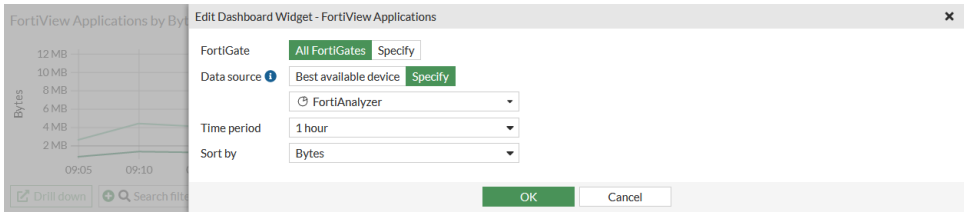
Requirements

- A FortiGate or FortiOS
- A compatible FortiAnalyzer (see Compatibility with FortiOS)

To configure logging to the FortiAnalyzer, see Configuring FortiAnalyzer on page 3711

To enable FortiView from FortiAnalyzer:

1. Go to *Dashboard* > *FortiView Sources*.
2. Select a time range other than *Now* from the dropdown list to view historical data.
3. In top menu, click the dropdown, and select *Settings*. The *Edit Dashboard Widget* dialog is displayed.
   a. In the *Data Source* area, click *Specify*.
   b. From the dropdown, select *FortiAnalyzer*, and click *OK*.



All the historical information now comes from the FortiAnalyzer.

When *Data Source* is set to *Best Available Device*, FortiAnalyzer is selected when available, then FortiGate Cloud, and then FortiGate.

FortiView from FortiGate Cloud

This function requires a FortiGate that is registered and logged into a compatible FortiGate Cloud. When using FortiGate Cloud, the *Time Period* can be set to up to 24 hours.

To configure logging to FortiGate Cloud, see Configuring cloud logging on page 3714.

To enable FortiView with log source as FortiGate Cloud:

1. Go to *Dashboard* > *FortiView Sources*.
2. In the top menu, click the dropdown, and select *Settings*. The *Edit Dashboard Widget* window opens.
   a. In the *Data Source* area, click *Specify*.
   b. From the dropdown, select *FortiGate Cloud*, then click *OK*.

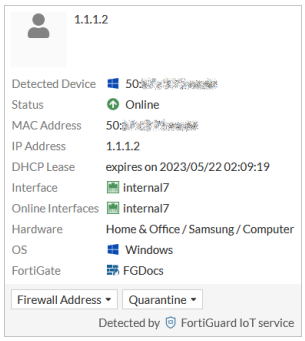
You can select FortiGate Cloud as the data source for all available FortiView pages and widgets.

FortiView sources

The *FortiView Sources* monitor displays top sources sorted by Bytes, Sessions or Threat Score. The information can be displayed in real time or historical views. You can use the monitor to create or edit a firewall device address or IP address definitions, quarantine hosts, and temporarily or permanently ban IPs.

To add a firewall device or IP address:

1. In the table, hover over the source or device MAC address. An information window opens.

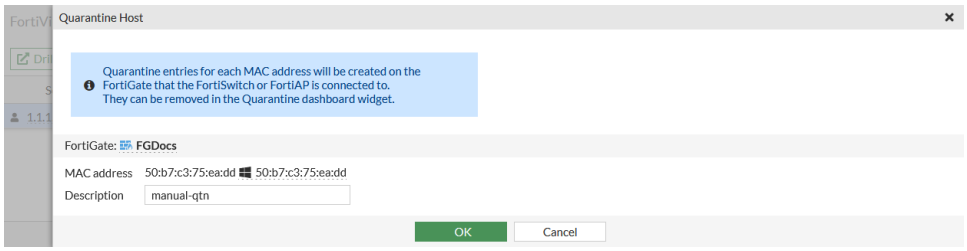


2. Click *Firewall Address* > *Create Firewall Device Address* or *Firewall Address* > *Create Firewall IP Address*. The *New Address* pane opens.
3. Configure the address settings as needed, then click *OK*.

Use the *Name* field to assign a descriptive name to a device so it is easier to find it in the *Device* column. After you finish configuring the device, refresh the page to see the new name in the monitor.

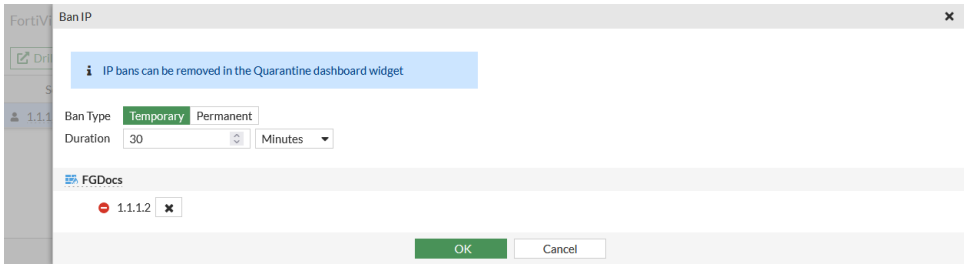
To quarantine a host:

1. In the table, hover over the source or device MAC address. An information window opens.
2. Click *Quarantine* > *Quarantine Host*. The *Quarantine Host* dialog is displayed.
3. Configure the quarantine settings, then click *OK*.



To ban an IP address:

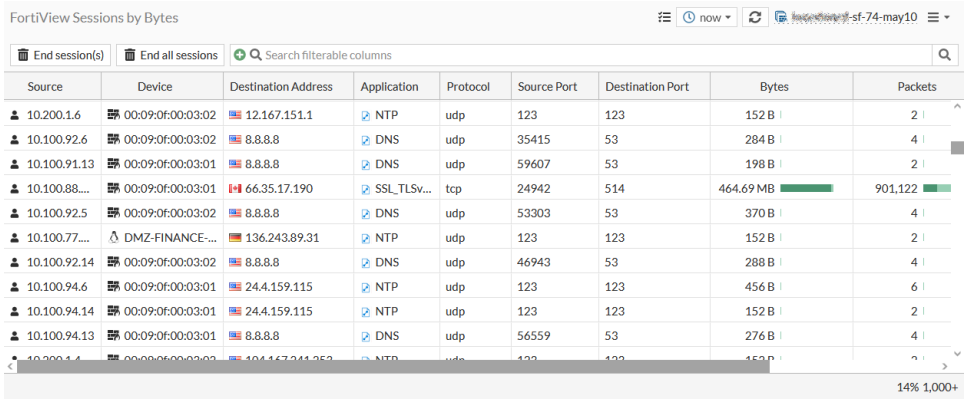
1. In the table, hover over the source or device MAC address. An information window opens.
2. Click *Quarantine* > *Ban IP* . The *Ban IP* dialog is displayed.
3. Configure the ban IP settings, then click *OK*.



FortiView Sessions

The *FortiView Sessions* monitor displays *Top Sessions* by traffic source and can be used to end sessions.

To view the *FortiView Sessions* dashboard, go to *Dashboard* > *FortiView Sessions*.

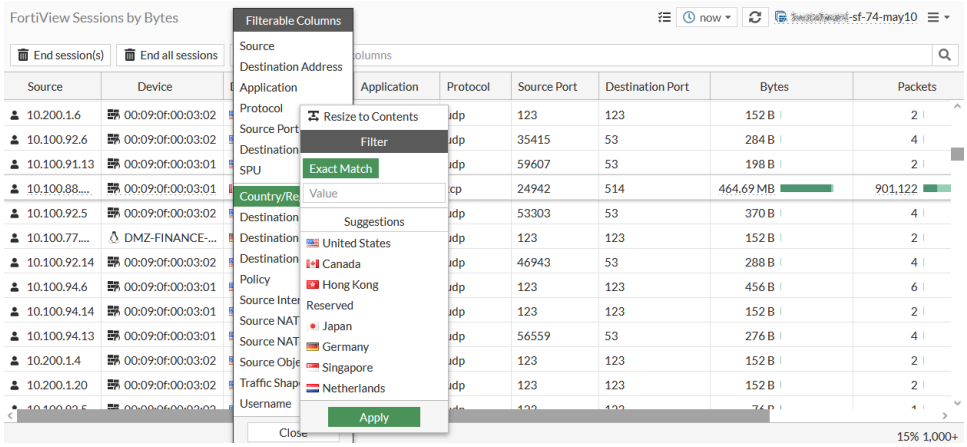


The session table displayed on the *FortiView Sessions* monitor is useful when verifying open connections. For example, if you have a web browser open to browse the Fortinet website, you would expect a session entry from your computer on port 80 to the IP address for the Fortinet website. You can also use a session table to investigate why there are too many sessions for FortiOS to process.

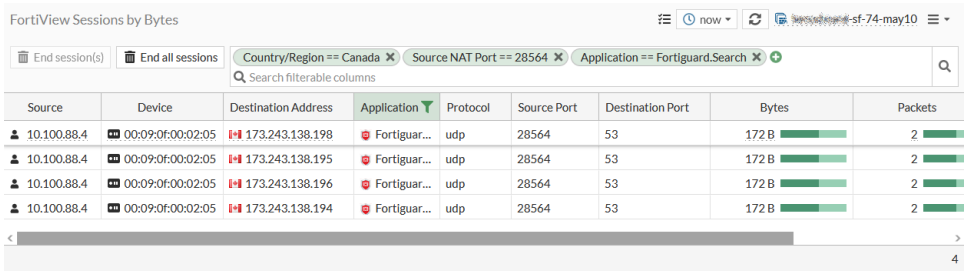
You can filter the sessions displayed in the session table by setting up the available filtering options.

To filter sessions in the session table:

1. Click on the *Add Filter* button at the top of the session table.
2. Select the required filtering option. The session table updates to the filter selection.



3. You may add one or more filters depending upon your requirements. To add more filters, repeat the above steps for a different set of filters.



You can be very specific with how you use filters and target sessions based on different filter combinations. For example, you may want to view all sessions from a device with a particular IP by adding the *Source IP* filter. Similarly, you may need to target all the sessions having a particular *Destination IP* and *Destination Port*, and so on.

You may also view the session data in the CLI.

To view session data using the CLI:

```
# diagnose sys session list
```

The session table output in the CLI is very large. You can use the supported filters in the CLI to show only the data you need.

To view session data with filters using the CLI:

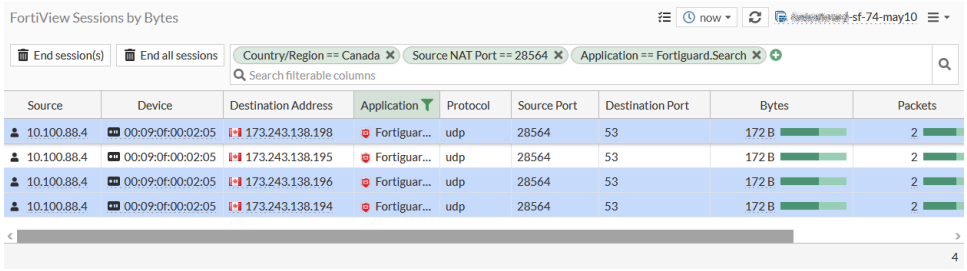
```
# diagnose sys session filter <option>
```

See to learn more about using the supported filters in the CLI.

You may also decide to end a particular session or all sessions for administrative purposes.

To end sessions from the GUI:

1. Select the session you want to end. To select multiple sessions, hold the *Ctrl* or *Shift* key on your keyboard while clicking the sessions.



2. Click on *End Session(s)* to end the selected sessions, or *End All Sessions* to end all active sessions.
3. Click *OK* in the confirmation dialog.

FortiView Top Source and Top Destination Firewall Objects monitors

The *FortiView Source Firewall Objects* and *FortiView Destination Firewall Objects* monitors leverage UUID to resolve firewall object address names for improved usability.

Requirements

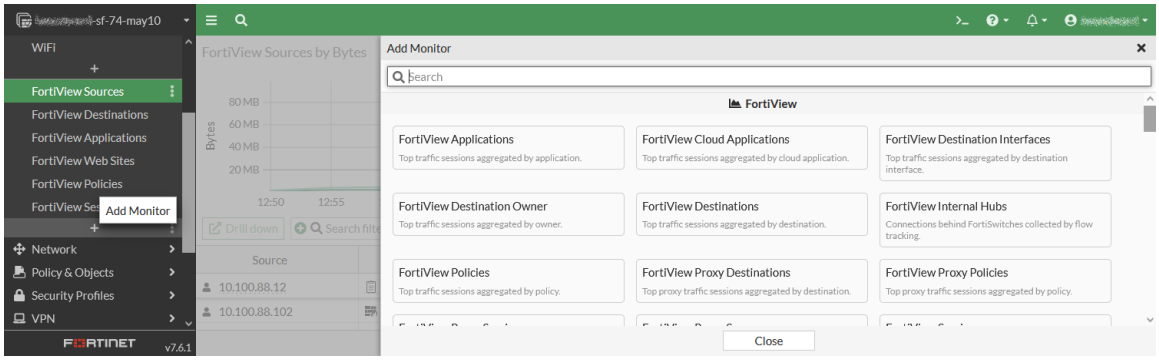
To have a historical *Firewall Objects*-based view, address objects' UUIDs need to be logged.

To enable address object UUID logging in the CLI:

```
config system global
   set log-uuid-address enable
end
```

To add a firewall object monitor in the GUI:

1. Click *Add Monitor*. The *Add Monitor* window opens.

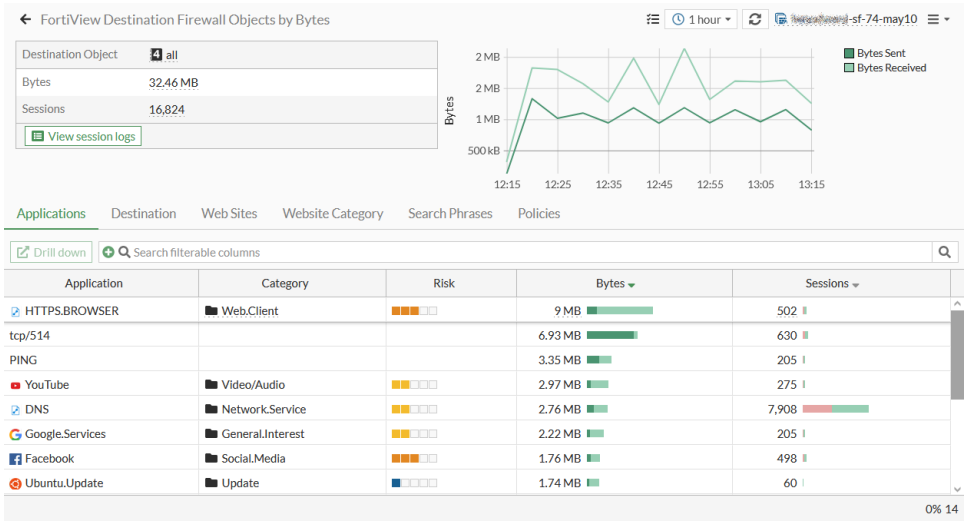


2. In the *Search* field, type *Destination Firewall Objects* and click the *Add* button next to the dashboard name.

3. In the *FortiGate* area, select the FortiGate(s) from the dropdown.
4. In the *Data Source* area, select *Best Available Device* or *Specify*. For information, see Using the FortiView interface on page 146.
5. From the *Time Period* dropdown, select the time period. Select *now* for real-time information, or (*1 hour*, *24 hours*, and *7 days*) for historical information.
6. From the *Sort By* dropdown, select *Bytes*, *Sessions*, *Bandwidth*, or *Packets*.
7. Click *OK*. The monitor is added to the tree menu.

To drill down Firewall Objects:

1. Open the *FortiView Source Firewall Objects* or *FortiView Destination Firewall Objects* monitor.
2. Select any source or destination object and click *Drill down*.
3. Click the tabs to sort the sessions.



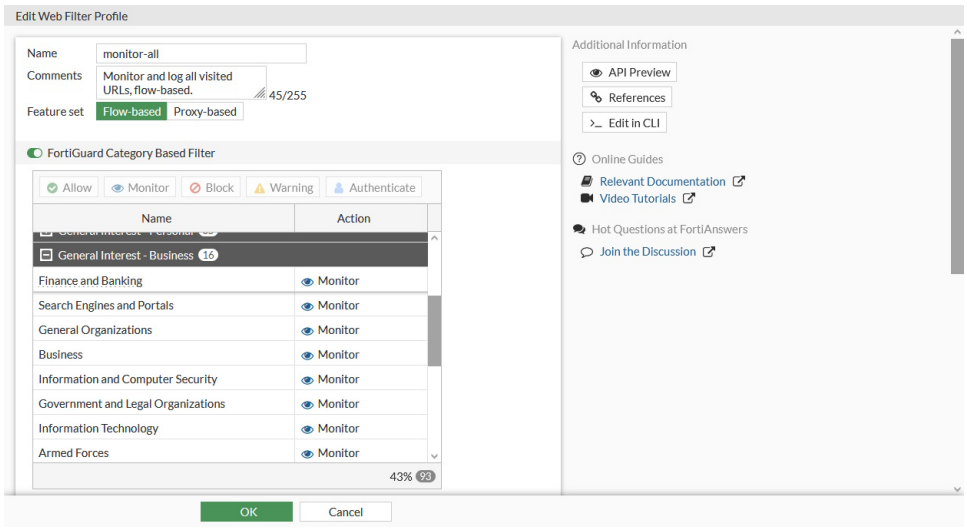
4. Select an entry, then click *View session logs* to view the session logs.

Viewing top websites and sources by category

You can use FortiGuard web categories to populate the category fields in various FortiView monitors such as *FortiView Web Categories*, *FortiView Websites* or *FortiView Sources*. To view the categories in a monitor, the web filter profile must be configured to at least monitor for a FortiGuard category based on a web filter and applied to a firewall policy for outbound traffic.

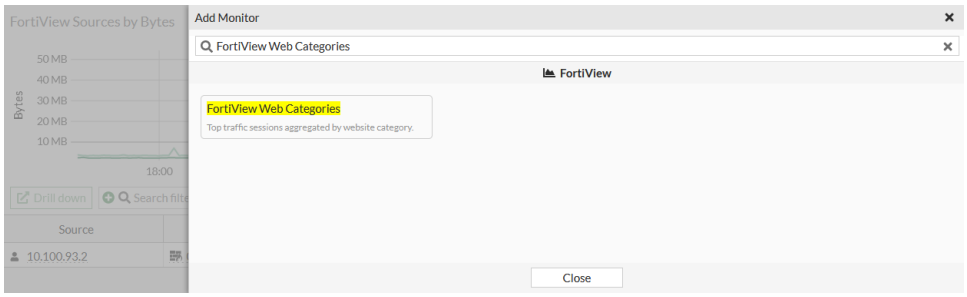
To verify the web filter profile is monitor-only:

1. Go to *Security Profiles* > *Web Filter*.
2. Double-click a web filter that is applied to an outbound traffic firewall policy. The *Edit Web Filter Profile* window opens.
3. Ensure *FortiGuard Category Based Filter* is enabled.
   In this example, the *General Interest - Business* categories are monitor-only.



To create a Web categories monitor:

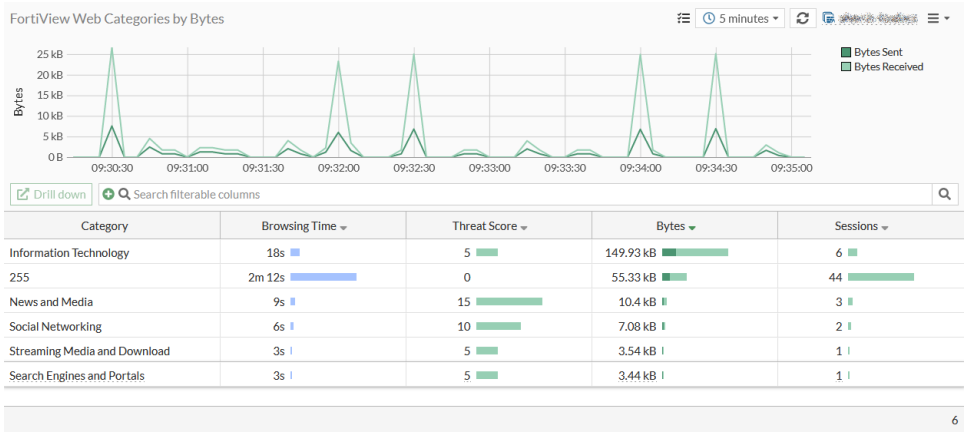
1. Click *Add Monitor*. The *Add Monitor* window opens.
2. In the *Search* field, type *FortiView Web Categories* and click the *Add* button next to the monitor name.



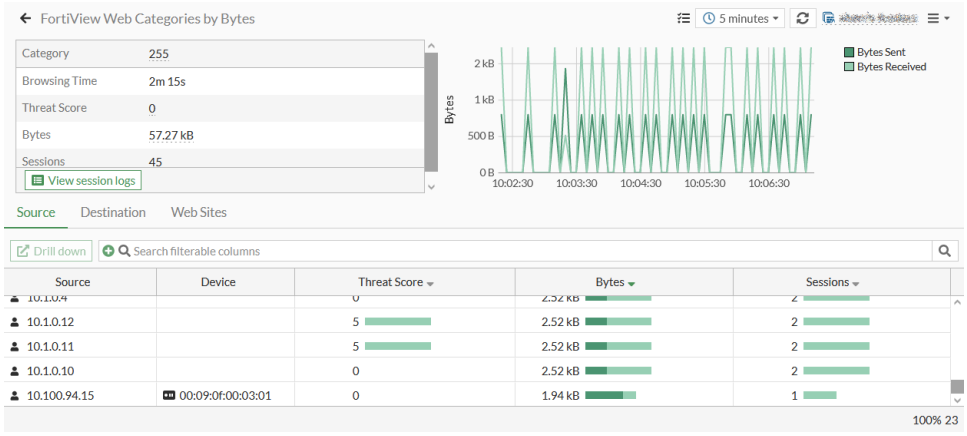
3. In the *FortiGate* area, select the FortiGate(s) from the dropdown.
4. In the *Data Source* area, click *Best Available Device* or *Specify* to select a device in the security fabric.
5. From the *Time Period* dropdown, select a time period greater than *Now*.
6. From the *Sort By* dropdown, select *Browsing Time*, *Threat Score*, *Bytes*, or *Sessions*.
7. Click *OK*. The widget is added to the tree menu.

Viewing the web filter category

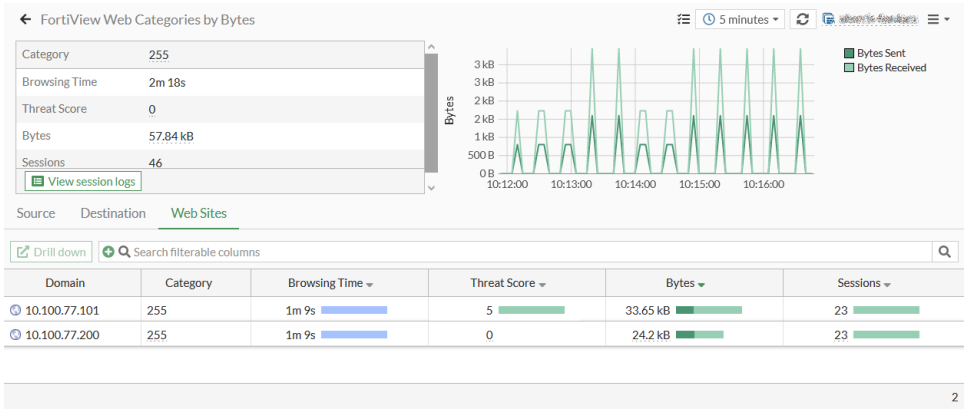
The web filter category name appears in the *Category* column of the dashboard.



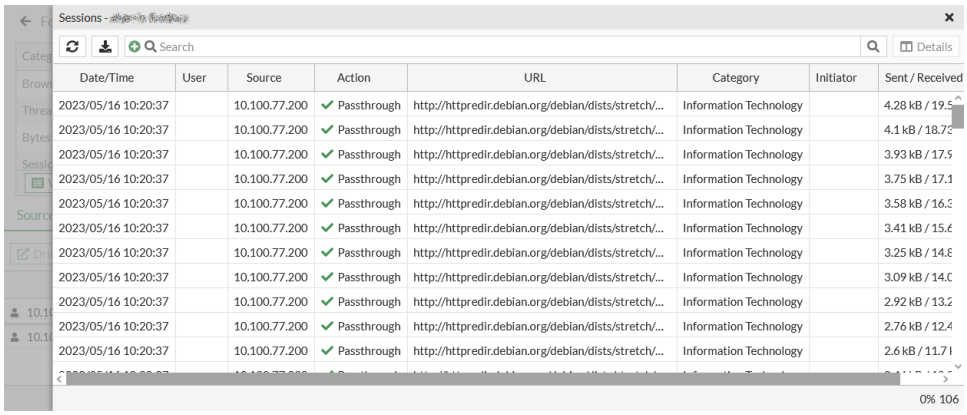
Drill down an entry in the table.



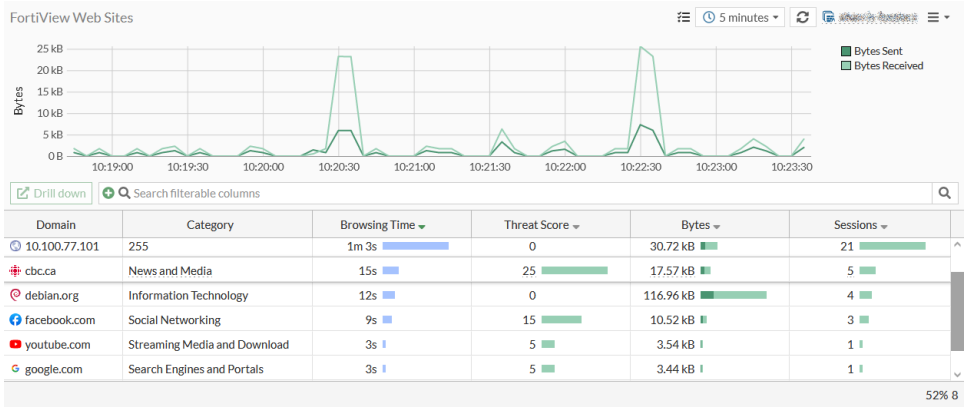
Click the *Web Sites* tab. The category name appears in the *Category* column.



Click *View session logs* to a view a list of the session logs. The category name appears in the *Category* column.



The category name also appears in the *Category* column in the *FortiView Websites* monitor and when drilling down in the *FortiView Sources* monitor.



Cloud application view

To see different cloud application views, set up the following:

- A FortiGate with a firewall policy that uses the *Application Control* security profile.
- A FortiGate with log data from the local disk or FortiAnalyzer.
- Optional but highly recommended: *SSL Inspection* set to *deep-inspection* in the related firewall policies.

Viewing cloud applications

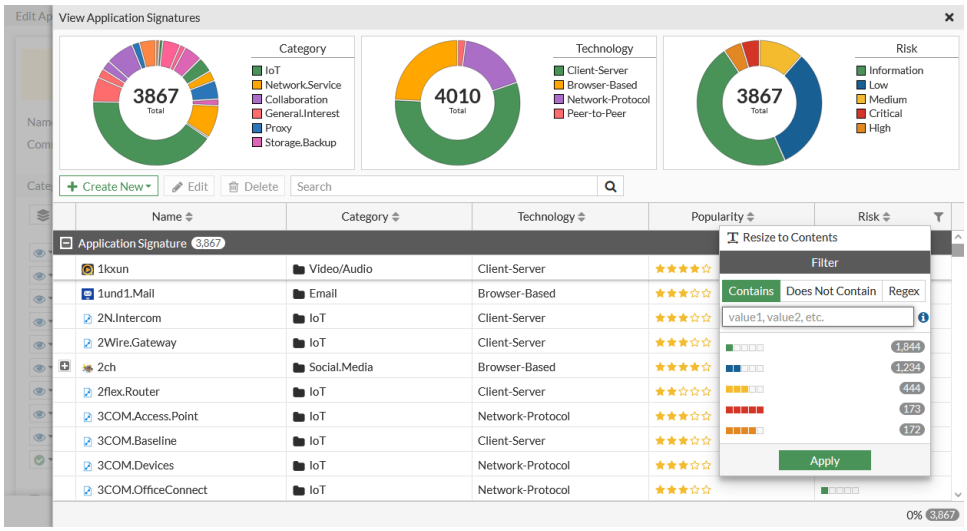
All cloud applications require *SSL Inspection* set to *deep-inspection* on the firewall policy. For example, `Facebook_File.Download` can monitor Facebook download behavior which requires *SSL deep-inspection* to parse the deep information in the network packets.

To view cloud applications:

1. Go to *Security Profiles* > *Application Control*.
2. Select an Application Control profile that is used by the firewall policy and click *Edit*.
3. On the *Edit Application Sensor* page, click *View Application Signatures*.

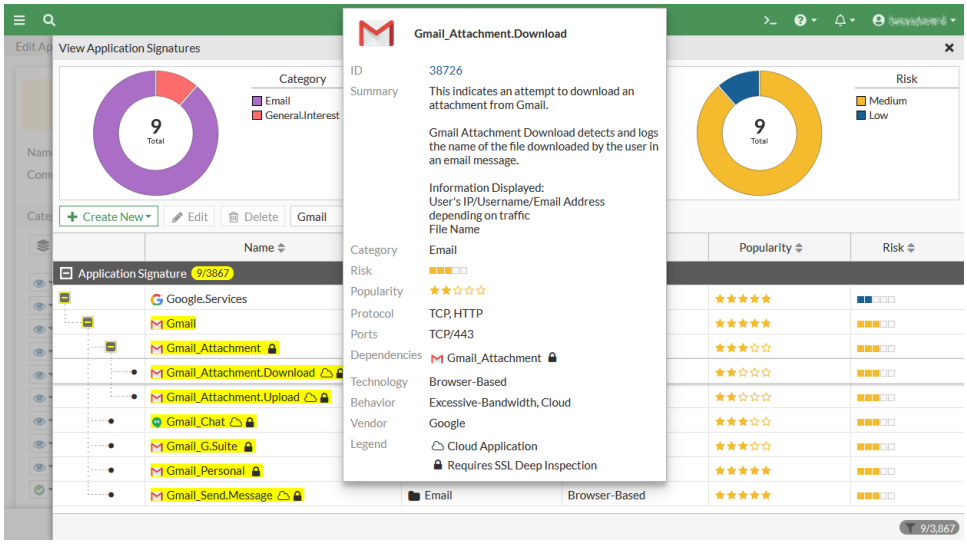
4. Hover over a column heading or the *Application Signature* bar. On the right, click the filter icon to filter the applications.

   Cloud applications have a cloud icon next to them. The lock icon indicates that the application requires SSL deep inspection.



5. Hover over an item to see its details.

   This example shows *Gmail_Attachment.Download*, a cloud application signature based sensor which requires SSL deep inspection. If any local network user behind the firewall logs into Gmail and downloads a Gmail attachment, that activity is logged.



Applications with cloud behavior

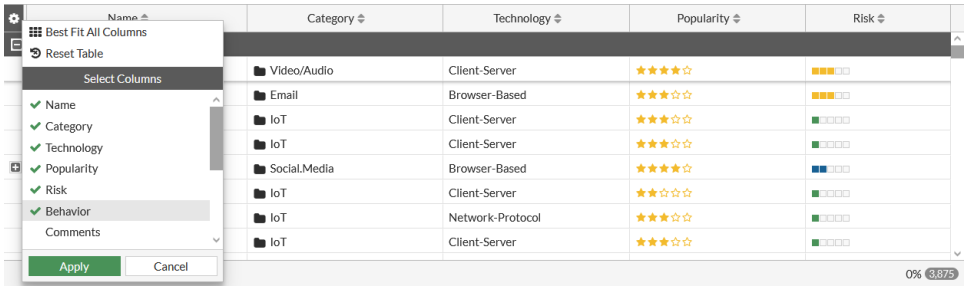
Applications with cloud behavior is a superset of cloud applications.

Some applications do not require SSL deep inspection, such as Facebook, Gmail, and YouTube. This means that if any traffic trigger application sensors for these applications, there is a FortiView cloud application view for that traffic.

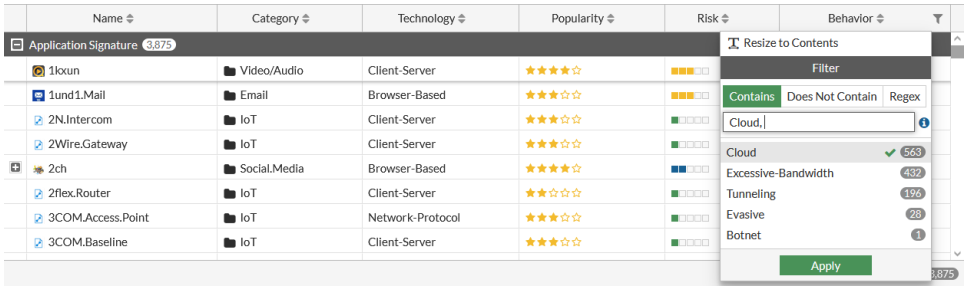
Other applications require SSL deep inspection, such as Gmail attachment, Facebook_Workplace, and so on.

To view applications with cloud behavior:

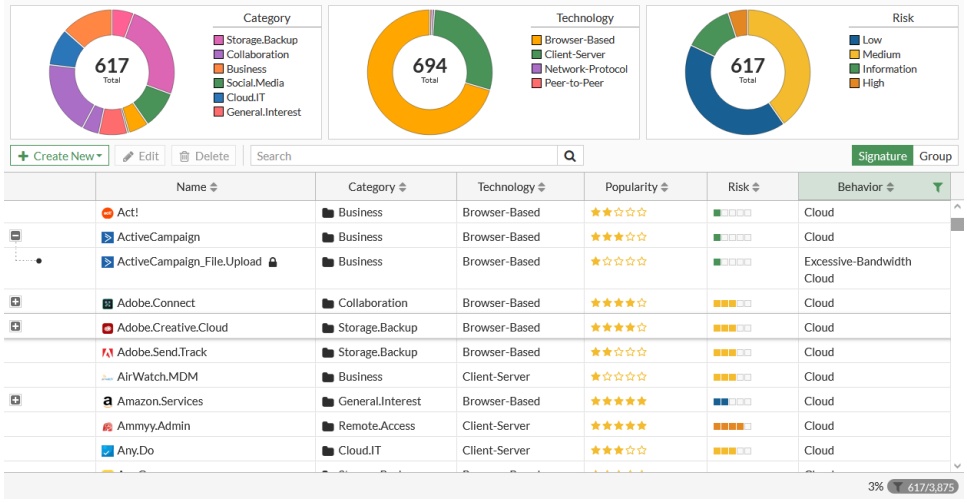
1. In the *Application Signature* page, ensure the *Behavior* column is displayed. If necessary, add the *Behavior* column.
   a. Hover over the left side of the table column headings to display the *Configure Table* icon.
   b. Click *Configure Table* and select *Behavior*.
   c. Click *Apply*.



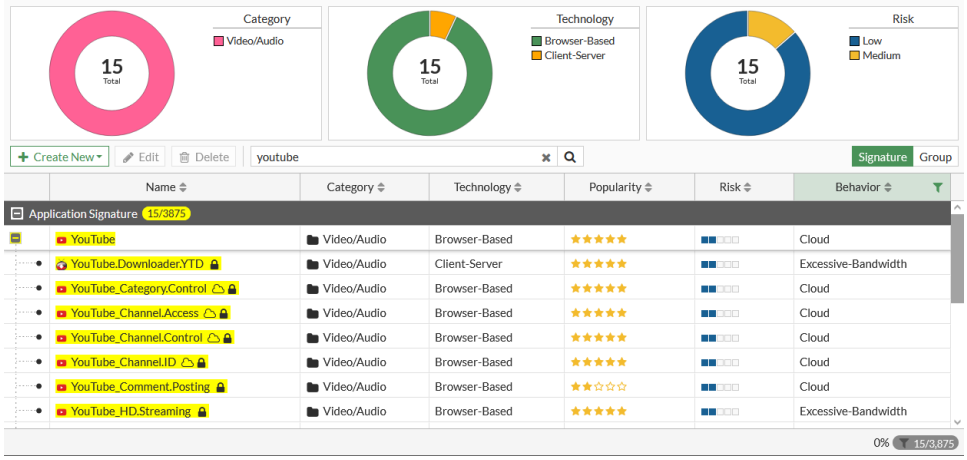
2. Click the filter icon in the *Behavior* column and select *Cloud* to filter by Cloud. Then click *Apply*.



3. The *Application Signature* page displays all applications with cloud behavior.

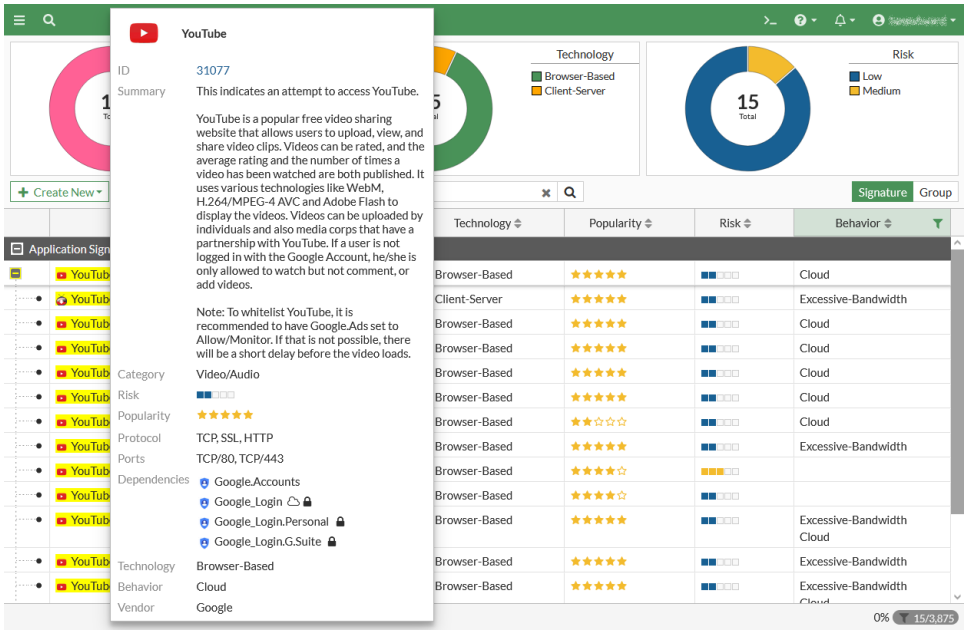


4. Use the *Search* box to search for applications. For example, you can search for *youtube*.



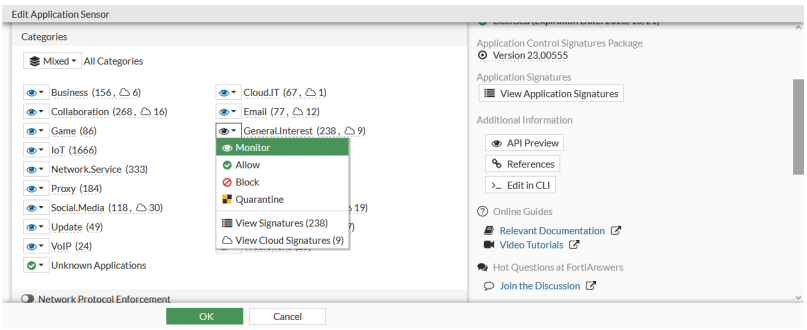
5. Hover over an item to see its details.

   This example shows an application sensor with no lock icon which means that this application sensor does not require SSL deep inspection. If any local network user behind the firewall tries to navigate to the YouTube website, that activity is logged.



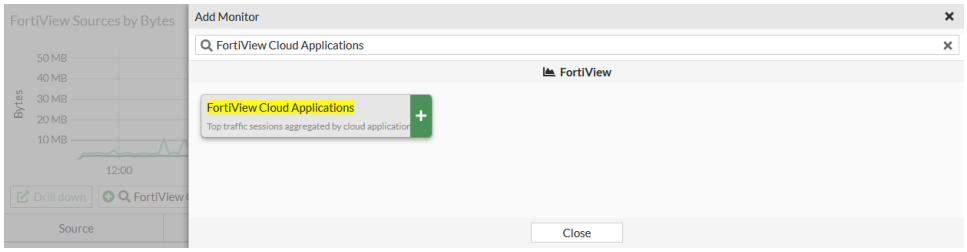
Configuring the Cloud Applications monitor

Go to *Security Profiles* > *Application Control* and edit a profile. On the *Edit Application Sensor* page in the *Categories* section, the eye icon next to a category means that category is monitored and logged.

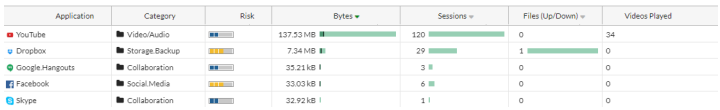


To add the Cloud Applications monitor in the GUI:

1. Click *Add Monitor*. The *Add monitor* window opens.
2. In the *Search* field, enter *FortiView Cloud Applications* and click the *Add* button next to the monitor.



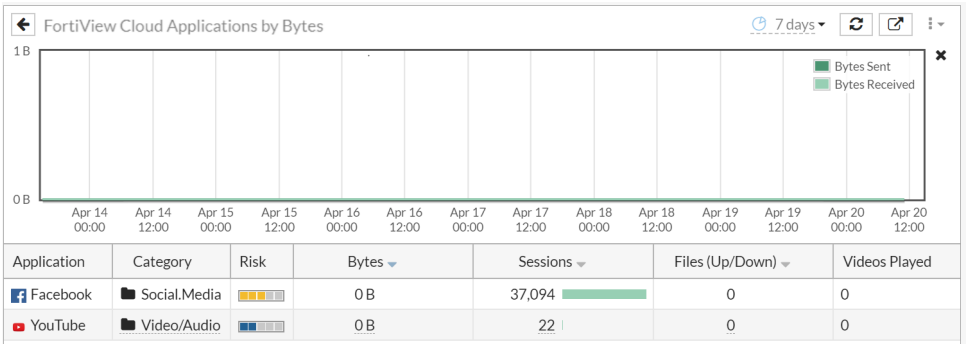
3. In the *FortiGate* area, select the FortiGate(s) from the dropdown.
4. In the *Data Source* area, click *Best Available Device* or *Specify* to select a device in the security fabric.
5. From the *Time Period* dropdown, select a time period greater than *Now*.
6. From the *Sort By* dropdown, select *Bytes*, *Sessions*, *Files (Up/Down)*, or *Videos Played*.
7. Click *OK*. The monitor is added to the tree menu.
8. Open the monitor. If SSL deep inspection is enabled in the related firewall policy, then the monitor shows the additional details that are logged, such as *Files (Up/Down)* and *Videos Played*.
   - For YouTube, the *Videos Played* column is triggered by the *YouTube_Video.Play* cloud application sensor. This shows the number of local network users who logged into YouTube and played YouTube videos.
   - For Dropbox, the *Files (Up/Down)* column is triggered by *Dropbox_File.Download* and *Dropbox_File.Upload* cloud application sensors. This shows the number of local network users who logged into Dropbox and uploaded or downloaded files.



Using the Cloud Applications monitor

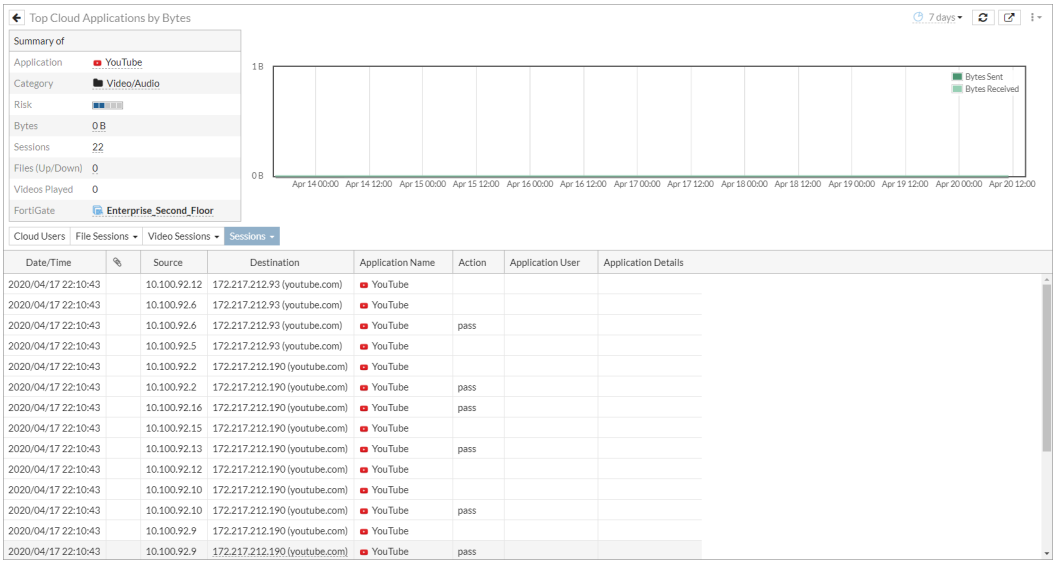
To see additional information in the Cloud Applications monitor:

1. In the tree menu, click the *FortiView Cloud Applications* monitor to open it.



2. For details about a specific entry, double-click the entry or right-click the entry and select *Drill Down to Details*.
3. To see all the sessions for an application, click *Sessions*.

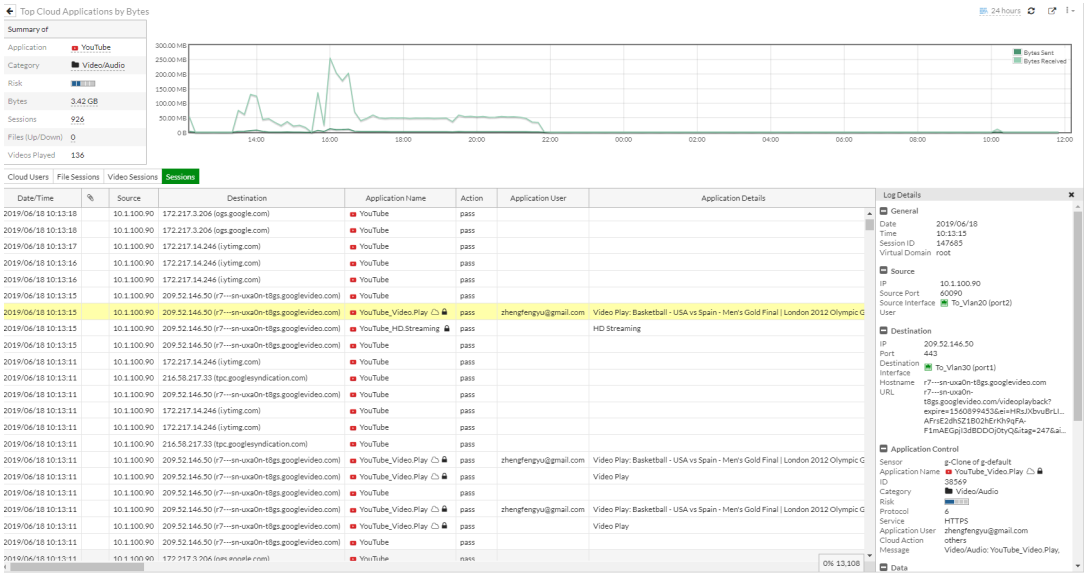
   In this example, the *Application Name* column shows all applications related to YouTube.



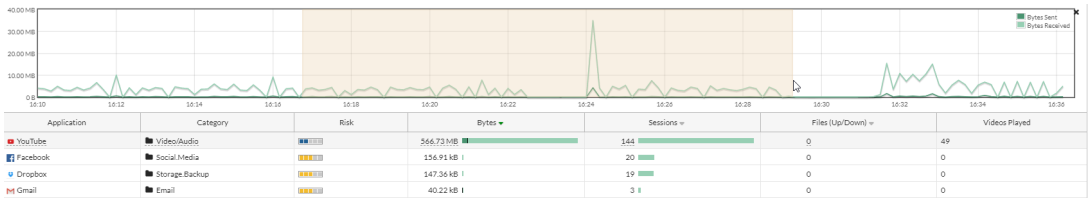
4. To view log details, double-click a session to display the *Log Details* pane.

Sessions monitored by SSL deep inspection (in this example, Youtube_Video.Play) captured deep information such as *Application User*, *Application Details*, and so on. The *Log Details* pane also shows additional deep information such as application *ID*, *Message*, and so on.

Sessions not monitored by SSL deep inspection (YouTube) did not capture the deep information.



5. To display a specific time period, select and drag in the timeline graph to display only the data for that time period.



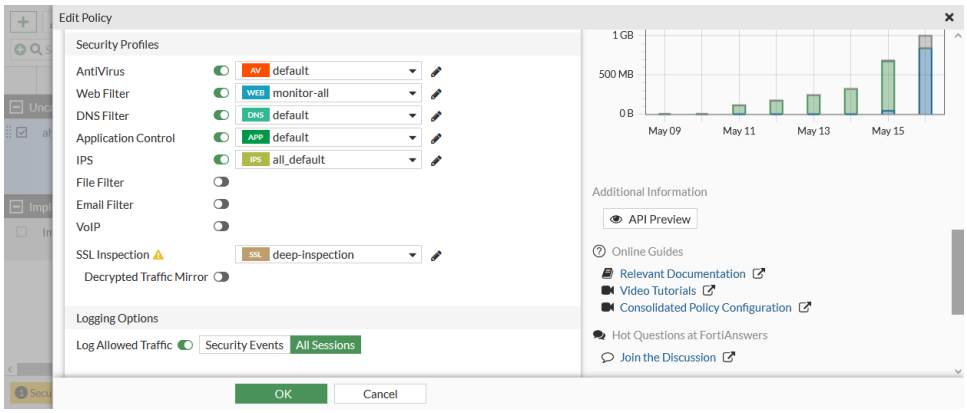
Top application: YouTube example

Monitoring network traffic with SSL deep inspection

This example describes how to monitor network traffic for YouTube using *FortiView Applications* view with SSL deep inspection.

To monitor network traffic with SSL deep inspection:

1. Create a firewall policy with the following settings:
   - *Application Control* is enabled.
   - *SSL Inspection* is set to *deep-inspection*.
   - *Log Allowed Traffic* is set to *All Sessions*.



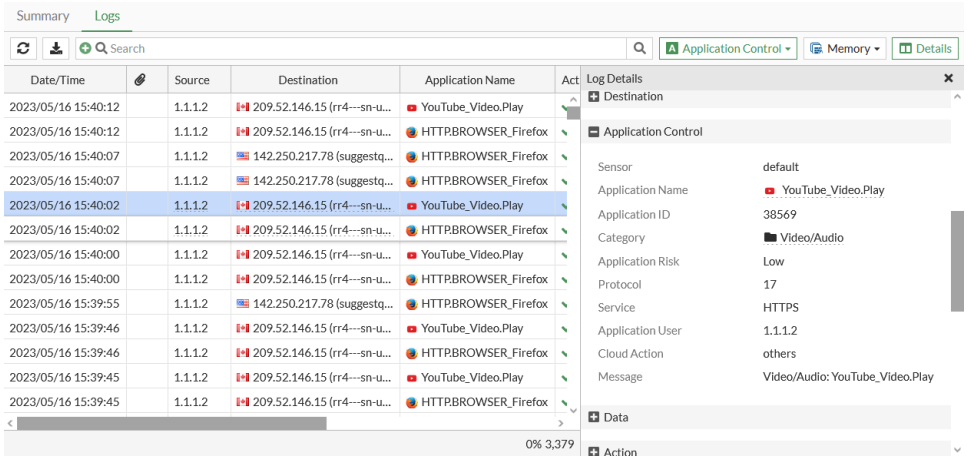
2. Go to *Security Profiles* > *Application Control*.
3. Select a related Application Control profile used by the firewall policy and click *Edit*.
4. Because YouTube cloud applications are categorized into *Video/Audio*, ensure the *Video/Audio* category is monitored. Monitored categories are indicate by an eye icon.
5. Click *View Application Signatures* and hover over YouTube cloud applications to view detailed information about YouTube application sensors.
6. Expand *YouTube* to view the Application Signatures associated with the application.

Application Signature	Description	Application ID
YouTube_Video.Access	An attempt to access a video on YouTube.	16420
YouTube_Channel.ID	An attempt to access a video on a specific channel on YouTube.	44956
YouTube_Comment.Posting	An attempt to post comments on YouTube.	31076
YouTube_HD.Streaming	An attempt to watch HD videos on YouTube.	33104
YouTube_Messenger	An attempt to access messenger on YouTube.	47858
YouTube_Video.Play	An attempt to download and play a video from YouTube.	38569
YouTube_Video.Upload	An attempt to upload a video to YouTube.	22564
YouTube	An attempt to access YouTube. This application sensor does not depend on SSL deep inspection so it does not have a cloud or lock icon.	31077
YouTube_Channel.Access	An attempt to access a video on a specific channel on YouTube.	41598

To view the application signature description, click the ID link in the information window.

7. On the test PC, log into YouTube and play some videos.
8. On the FortiGate, go to *Log & Report* > *Security Events*, select *Application Control*, and look for log entries for browsing and playing YouTube videos.

In this example, note the *Application User* and *Application Details*. Also note that the *Application Control ID* is *38569* showing that this entry was triggered by the application sensor *YouTube_Video.Play*.



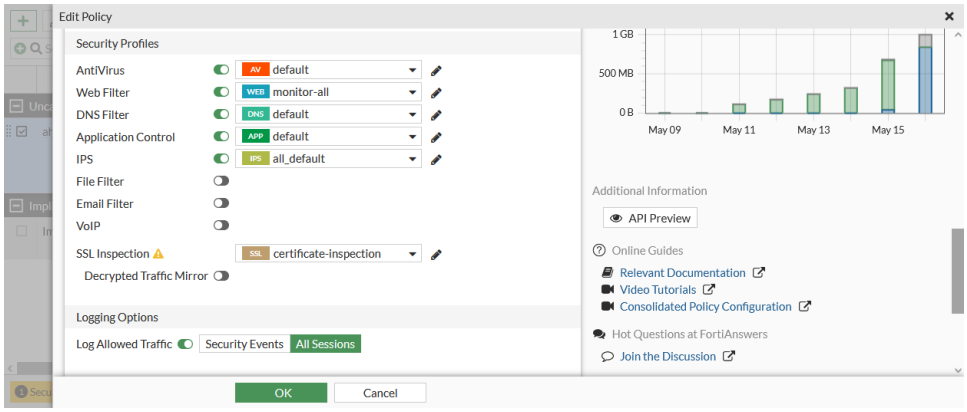
9. Go to *Dashboard* > *FortiView Applications*.
10. In the *FortiView Applications* monitor, double-click *YouTube* to view the drilldown information.
11. Click *View session logs* to see all the entries for the videos played. Check the sessions for *YouTube_Video.Play* with the ID *38569*.

Monitoring network traffic without SSL deep inspection

This example describes how to monitor network traffic for YouTube using FortiView cloud application view without SSL deep inspection.

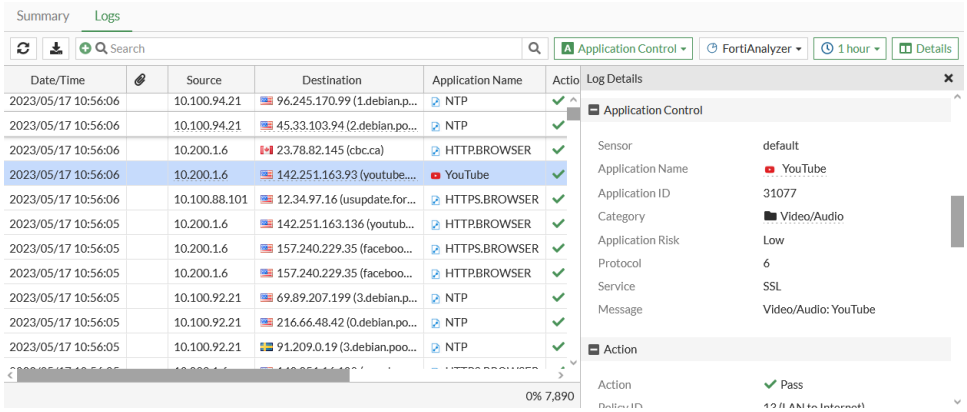
To monitor network traffic without SSL deep inspection:

1. Create a firewall policy with the following settings.
   - *Application Control* is enabled.
   - *SSL Inspection* is set to *certificate-inspection*.
   - *Log Allowed Traffic* is set to *All Sessions*.



2. On the test PC, log into YouTube and play some videos.
3. On the FortiGate, go to *Log & Report* > *Security Events* and look for log entries for browsing and playing YouTube videos in the *Application Control* card.

In this example, the log shows only applications with the name YouTube. The log cannot show YouTube application sensors which rely on SSL deep inspection.

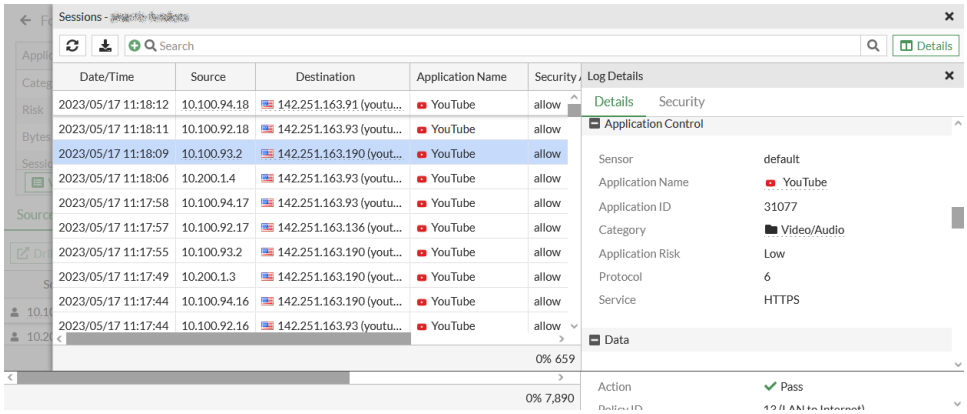


4. Go to *Dashboard* > *FortiView Applications*.

   The *FortiView Application by Bytes* monitor shows the YouTube cloud application without the video played information that requires SSL deep inspection.

5. Double-click *YouTube* and click *View session logs*.

   These sessions were triggered by the application sensor *YouTube* with the ID *31077*. This is the application sensor with cloud behavior which does not rely on SSL deep inspection.



Application risk levels

Application pose different levels of risk to the network, represented by a color code. The application risk levels are shown on various FortiView monitors, such as FortiView Applications, and related GUI pages. See Cloud application view on page 159 for example.

Applications within the same category can have different levels defined by FortiGuard analysts. Considerations may include whether an application is known to be malicious, has known vulnerabilities, or is a trusted enterprise application.

Application risk levels

Indicator	Risk	Description
	Risk Level 1 *Low*	These applications have little to no risk level. This is the default value when no risk is specified. Example categories: Update, Business
	Risk Level 2 *Elevated*	These applications have an elevated risk level. Example categories: Game, Collaboration, Social Media, Video/Audio, VoIP, Industrial, General Interest, Network Service, Web Client, Mobile
	Risk Level 3 *Medium*	These applications have a medium risk level. Example categories: Email, Storage Backup, Cloud-IT
	Risk Level 4 *High*	These applications have a high risk level. Example categories: P2P, Remote Access
	Risk Level 5 *Critical*	These applications have the highest risk level and are most prone to malware or vulnerabilities. Example categories: Botnet, Proxy

Network

The following topics provide information about network settings:

- FortiGate LAN extension on page 854
- SCTP packets with zero checksum on the NP7 platform on page 879
- Diagnostics on page 884

Interfaces

Physical and virtual interfaces allow traffic to flow between internal networks, and between the internet and internal networks. FortiOS has options for configuring interfaces and groups of sub-networks that can scale as your organization grows. The following table lists commonly used interface types.

Interface type	Description
Physical	A physical interface can be connected to with either Ethernet or optical cables. Depending on the FortiGate model, there is a varying number of Ethernet or optical physical interfaces. Some FortiGates have a grouping of interfaces labeled as *lan* that have a built-in switch functionality. See Physical interface on page 203 for more information.

Interface type	Description
VLAN	A virtual local area network (VLAN) logically divides a local area network (LAN) into distinct broadcast domains using IEEE 802.1Q VLAN tags. A VLAN interface supports VLAN tagging and is associated with a physical interface that can be connected to a device, such as a switch or a router that supports these tags. VLANs can be used on a FortiGate in NAT or transparent mode, and the FortiGate functions differently depending on the operation mode See VLAN on page 204 for more information.
Aggregate	An aggregate interface uses a link aggregation method to combine multiple physical interfaces to increase throughput and to provide redundancy. FortiOS supports a link aggregation (LAG) interface using the Link Aggregation Control Protocol (LACP) based on IEEE 802.3ad/802.1ax. See Aggregation and redundancy on page 219 for more information.
Redundant	A redundant interface combines multiple physical interfaces where traffic only uses one of the interfaces at a time. Its primary purpose is to provide redundancy. This interface is typically used with a fully-meshed HA configuration. See Aggregation and redundancy on page 219 for more information.
Loopback	A loopback interface is a logical interface that is always up because it has no physical link dependency, and the attached subnet is always present in the routing table. It can be accessed through several physical or VLAN interfaces. See Loopback interface on page 229 for more information.
Software switch	A software switch is a virtual switch interface implemented in firmware that allows member interfaces to be added to it. Devices connected to member interfaces communicate on the same subnet, and packets are processed by the FortiGate's CPU. A software switch supports adding a wireless SSID as a member interface. See Software switch on page 230 for more information.
Hardware switch	A hardware switch is a virtual switch interface implemented at the hardware level that allows member interfaces to be added to it. Devices connected to member interfaces communicate on the same subnet. A hardware switch relies on specific hardware to optimize processing and supports the Spanning Tree Protocol (STP). See Hardware switch on page 232 for more information.
Zone	A zone is a logical group containing one or more physical or virtual interfaces. Grouping interfaces in zones can simplify firewall policy configurations. See Zone on page 238 for more information.

Interface type	Description
Virtual wire pair	A virtual wire pair (VWP) is an interface that acts like a virtual wire consisting of two interfaces, with an interface at each of the wire. No IP addressing is configured on a VWP, and communication is restricted between the two interfaces using firewall policies. See Virtual wire pair on page 240 for more information.
FortiExtender WAN extension	A FortiExtender WAN extension is a managed interface that allows a connected FortiExtender to provide WAN connectivity to the FortiGate. See FortiExtender on page 631 for more information.
FortiExtender LAN extension	A FortiExtender LAN extension is a managed interface that allows a connected FortiExtender to provide LAN connectivity to the FortiGate. See FortiExtender on page 631 for more information.
Enhanced MAC VLAN	An enhanced media access control (MAC) VLAN, or EMAC VLAN, interface allows a physical interface to be virtually subdivided into multiple virtual interfaces with different MAC addresses. In FortiOS, the EMAC VLAN functionality acts like a bridge. See Enhanced MAC VLAN on page 247 for more information.
VXLAN	A Virtual Extensible LAN (VXLAN) interface encapsulates layer 2 Ethernet frames within layer 3 IP packets and is used for cloud and data center networks. See VXLAN on page 250 for more information.
Tunnel	A tunnel virtual interface is used for IPsec interface-based or GRE tunnels and are created when configuring IPsec VPN and GRE tunnels, respectively. The tunnel interface can be configured with IP addresses on both sides of the tunnel since this is a requirement when using a tunnel interface with a dynamic routing protocol. See OSPF with IPsec VPN for network redundancy on page 2582, GRE over IPsec on page 2446, and Cisco GRE-over-IPsec VPN on page 2486 for more information.
WiFi SSID	A WiFi SSID interface is used to control wireless network user access to a wireless local radio on a FortiWiFi or to a wireless access point using a FortiAP. The SSID is created using the *WiFi & Switch Controller > SSIDs page*, and it appears in the *Network > Interfaces* page once it is created. See Defining a wireless network interface (SSID) in the FortiWiFi and FortiAP Configuration Guide for more information.
VDOM link	A VDOM link allows VDOMs to communicate internally without using additional physical interfaces. See Inter-VDOM routing for more information.

Interface settings

Administrators can configure both physical and virtual FortiGate interfaces in *Network* > *Interfaces*. There are different options for configuring interfaces when FortiGate is in NAT mode or transparent mode.

The available options will vary depending on feature visibility, licensing, device model, and other factors. The following list is not comprehensive.

To configure an interface in the GUI:

1. Go to *Network* > *Interfaces*.
2. Click *Create New* > *Interface*.
3. Configure the interface fields:

Interface Name	Physical interface names cannot be changed.
Alias	Enter an alternate name for a physical interface on the FortiGate unit. This field appears when you edit an existing physical interface. The alias does not appear in logs. The maximum length of the alias is 25 characters.
Type	The configuration type for the interface, such as VLAN, Software Switch, 802.3ad Aggregate, and others.
Interface	This field is available when *Type* is set to *VLAN*. Select the name of the physical interface that you want to add a VLAN interface to. Once created, the VLAN interface is listed below its physical interface in the *Interface* list. You cannot change the physical interface of a VLAN interface.
VLAN ID	This field is available when *Type* is set to *VLAN*. Enter the VLAN ID. The VLAN ID can be any number between 1 and 4094 and must match the VLAN ID added by the IEEE 802.1Q-compliant router or switch that is connected to the VLAN subinterface. The VLAN ID can be edited after the interface is added.
VRF ID	Virtual Routing and Forwarding (VRF) allows multiple routing table instances to coexist on the same router. One or more interface can have a VRF, and packets are only forwarded between interfaces with the same VRF.
Virtual Domain	Select the virtual domain to add the interface to. Only administrator accounts with the *super_admin* profile can change the *Virtual Domain*.
Interface Members	This section can have different formats depending on the *Type*. Members can be selected for some interface types: • *Software Switch* or *Hardware Switch*: Specify the physical and wireless interfaces joined into the switch. • *802.3ad Aggregate* or *Redundant Interface*: This field includes the

	available and selected interface lists.
Role	Set the role setting for the interface. Different settings will be shown or hidden when editing an interface depending on the role: • *LAN*: Used to connected to a local network of endpoints. It is default role for new interfaces. • *WAN*: Used to connected to the internet. When WAN is selected, the *Estimated bandwidth* setting is available, and the following settings are not: *DHCP server*, *Create address object matching subnet*, *Device detection*, *Security mode*, *One-arm sniffer*, *Dedicate to extension/fortiap modes*, and *Admission Control*.and will show Estimated Bandwidth settings. • *DMZ*: Used to connected to the DMZ. When selected, *DHCP server* and *Security mode* are not available. • *Undefined*: The interface has no specific role. When selected, *Create address object matching subnet* is not available.
Estimated bandwidth	The estimated WAN bandwidth. The values can be entered manually, or saved from a speed test executed on the interface. The values can be used in SD-WAN rules that use the Maximize Bandwidth or Best Quality strategy.
Traffic mode	This option is only available when *Type* is *WiFi SSID*. • *Tunnel*: Tunnel to wireless controller • *Bridge*: Local bridge with FortiAP's interface • *Mesh*: Mesh downlink
Address	
Addressing mode	Select the addressing mode for the interface. • *Manual*: Add an IP address and netmask for the interface. If IPv6 configuration is enabled, you can add both an IPv4 and an IPv6 address. • *DHCP*: Get the interface IP address and other network settings from a DHCP server. • *Auto-managed by IPAM*: Assign subnets to prevent duplicate IP addresses from overlapping within the same Security Fabric. See Configure IPAM locally on the FortiGate on page 179. • *PPPoE*: Get the interface IP address and other network settings from a PPPoE server. This option is only available on entry-level FortiGate models. • *One-Arm Sniffer*: Set the interface as a sniffer port so it can be used to detect attacks. See One-arm sniffer on page 190.
IP/Netmask	If *Addressing Mode* is set to *Manual*, enter an IPv4 address and subnet mask for the interface. FortiGate interfaces cannot have multiple IP addresses on the same subnet.
IPv6 addressing mode	Select the addressing mode for the interface: • *Manual*: Add an IP address and netmask for the interface.

	• *DHCP*: Get the interface IP address and other network settings from a DHCP server. • *Delegated*: Select an *IPv6 upstream interface* that has DHCPv6 prefix delegation enabled, and enter an *IPv6 subnet* if needed. The interface will get the IPv6 prefix from the upstream DHCPv6 server that is connected to the IPv6 upstream interface, and form the IPv6 address with the subnet configured on the interface.
IPv6 Address/Prefix	If *Addressing Mode* is set to *Manual* and IPv6 support is enabled, enter an IPv6 address and subnet mask for the interface. A single interface can have an IPv4 address, IPv6 address, or both.
Auto configure IPv6 address	Automatically configure an IPv6 address using Stateless Address Auto-configuration (SLAAC). This option is available when *IPv6 addressing mode* is set to *Manual*.
DHCPv6 prefix delegation	Enable/disable DHCPv6 prefix delegation, which can be used to delegate IPv6 prefixes from an upstream DHCPv6 server to another interface or downstream device. When enabled, there is an option to enable a *DHCPv6 prefix hint* that helps the DHCPv6 server provide the desired prefix.
Create address object matching subnet	This option is available and automatically enabled when *Role* is set to *LAN* or *DMZ*. This creates an address object that matches the interface subnet and dynamically updates the object when the IP/Netmask changes. See Interface subnet on page 1761 for more information.
Secondary IP Address	Add additional IPv4 addresses to this interface.
Administrative Access	
IPv4 Administrative Access	Select the types of administrative access permitted for IPv4 connections to this interface. See Configure administrative access to interfaces on page 177.
IPv6 Administrative Access	Select the types of administrative access permitted for IPv6 connections to this interface. See Configure administrative access to interfaces on page 177.
DHCP Server	Enable a DHCP server for the interface. See DHCP servers and relays on page 445.
Stateless Address Auto-configuration (SLAAC)	Enable to provide IPv6 addresses to connected devices using SLAAC.
DHCPv6 Server	Select to enable a DHCPv6 server for the interface. When enabled, you can configure *DNS service* settings: *Delegated* (delegate the DNS received from the upstream server), *Same as System DNS*, or *Specify* (up to four servers).

	You can also enable *Stateful server*to configure the DHCPv6 server to be stateful. Manually enter the IP range, or use Delegated mode to delegate IP prefixes from an upstream DHCPv6 server connected to the upstream interface.
Network	
Device Detection	Enable/disable passively gathering device identity information about the devices on the network that are connected to this interface.
Security Mode	Enable/disable captive portal authentication for this interface. After enabling captive portal authentication, you can configure the authentication portal, user and group access, custom portal messages, exempt sources and destinations/services, and redirect after captive portal.
DSL Settings	
Physical mode	Set to *ADSL* or *VDSL*.
Transfer mode	Set to *PTM* or *ATM*. If the *Transfer mode* is set to *ATM*, the *Virtual channel identification*, *Virtual path identification*, *ATM protocol*, and *MUX type* can be configured.
Traffic Shaping	
Outbound shaping profile	Enable/disable traffic shaping on the interface. This allows you to enforce bandwidth limits on individual interfaces. See Interface-based traffic shaping profile on page 1849 for more information.
Miscellaneous	
Comments	Enter a description of the interface of up to 255 characters.
Status	Enable/disable the interface. • *Enabled*: The interface is active and can accept network traffic. • *Disabled*: The interface is not active and cannot accept traffic.

4. Click *OK*.

To configure an interface in the CLI:

```
config system interface
    edit <name>
        set vdom <VDOM_name>
        set mode {static | dhcp | pppoe}
        set ip <IP_address/netmask>
        set security-mode {none | captive-portal | 802.1X}
        set egress-shaping-profile <profile>
        set device-identification {enable | disable}
        set allowaccess {ping https ssh http snmp telnet fgfm radius-acct probe-response fabric
ftm}
        set eap-supplicant {enable | disable}
        set eap-method {peap | tls}
```

```
        set eap-identity <identity>
        set eap-password <password>
        set eap-ca-cert <CA_cert>
        set eap-user-cert <user_cert>
        set secondary-IP enable
        config secondaryip
            edit 1
                set ip 9.1.1.2 255.255.255.0
                set allowaccess ping https ssh snmp http
            next
        end
    next
end
```

Configure administrative access to interfaces

You can configure the protocols that administrators can use to access interfaces on the FortiGate. This helps secure access to the FortiGate by restricting access to a limited number of protocols. It helps prevent users from accessing interfaces that you don't want them to access, such as public-facing ports.

As a best practice, you should configure administrative access when you're setting the IP address for a port.

To configure administrative access to interfaces in the GUI:

1. Go to *Network* > *Interfaces*.
2. Create or edit an interface.
3. In the *Administrative Access* section, select which protocols to enable for *IPv4* and *IPv6 Administrative Access*.

Industrial Connectivity	Allow Industrial Connectivity service access to proxy traffic between serial port and TCP/IP. Available with FortiGate Rugged models equipped with a serial RS-232 (DB9/RJ45) interface and when *Role* is set to *Undefined* or *WAN*. See Industrial Connectivity on page 880.

Speed Test	Allow this interface to listen to speed test sender requests.
	To allow the FortiGate to be configured as speed test server, configure the following:
	`config system global`
	`  set speedtest-server {enable | disable}`
	`end`
	For more detail, see Running speed tests from the hub to the spokes in dial-up IPsec tunnels on page 1363.

HTTPS	Allow secure HTTPS connections to the FortiGate GUI through this interface. If configured, this option is enabled automatically.

HTTP	Allow HTTP connections to the FortiGate GUI through this interface. This option can only be enabled if HTTPS is already enabled.
PING	The interface responds to pings. Use this setting to verify your installation and for testing.
FMG-Access	Allow FortiManager authorization automatically during the communication exchanges between FortiManager and FortiGate devices.
SSH	Allow SSH connections to the CLI through this interface.
SNMP	Allow a remote SNMP manager to request SNMP information by connecting to this interface.
FTM	Allow FortiToken Mobile Push (FTM) access.
RADIUS Accounting	Allow RADIUS accounting information on this interface.
Security Fabric Connection	Allow Security Fabric access. This enables FortiTelemetry and CAPWAP.

FEC implementations on 10G, 25G, 40G, and 100G interfaces

Only supported FEC (forward error correction) implementations are allowed to be configured on 10G, 25G, 40G, and 100G interfaces based on the speed that is selected.

- For 1000M, 10G, or 40G interfaces, FEC is not supported and the option is disabled.
- For 25G and 100G interfaces, FEC is automatically set to `cl91-rs-fec` by default.

To configure an interface for FEC:

```
config system interface
    edit <name>
        set speed {10000full | 1000full | 100Gauto | 100Gfull | 25000auto | 25000full | 40000full}
        set mediatype {sr4 | lr4 | cr4}
        set forward-error-correction {disable | cl91-rs-fec | cl74-fc-fec}
    next
end
```

`speed {10000full | 1000full | 100Gauto | 100Gfull | 25000auto | 25000full | 40000full}`	Set the interface speed: • 10000full: 10G full-duplex • 1000full: 1000M full-duplex • 100Gauto: 100G auto-negotiation • 100Gfull: 100G full-duplex • 25000auto: 25G auto-negotiation • 25000full: 25G full-duplex • 40000full: 40G full-duplex
`mediatype {sr4 | lr4 | cr4}`	Set the media type to use: • sr4: short-range transceiver (4-lane)

	• lr4: long-range transceiver (4-lane) • cr4: copper transceiver (4-lane)
`forward-error-correction {disable | cl91-rs-fec | cl74-fc-fec}`	Set the forward error correction type: • disable: disable forward error correction • cl91-rs-fec: Reed-Solomon (FEC CL91) • cl74-fc-fec: Firecode (FEC CL74)

To change the interface speed from 40G to 100G:

```
config system interface
    edit port26
        set speed 100Gfull
    next
end

The speed/mediatype/FEC of port26 will be changed from 40000full/sr4/disable to 100Gfull/sr4/cl91-
rs-fec.
Do you want to continue? (y/n) y
```

Since the speed changed to 100G, the `mediatype` setting automatically changes to `sr4`, and the `forward-error-correction` setting automatically changes to `cl91-rs-fec`. When the speed was 40G, the `forward-error-correction` setting was disabled.

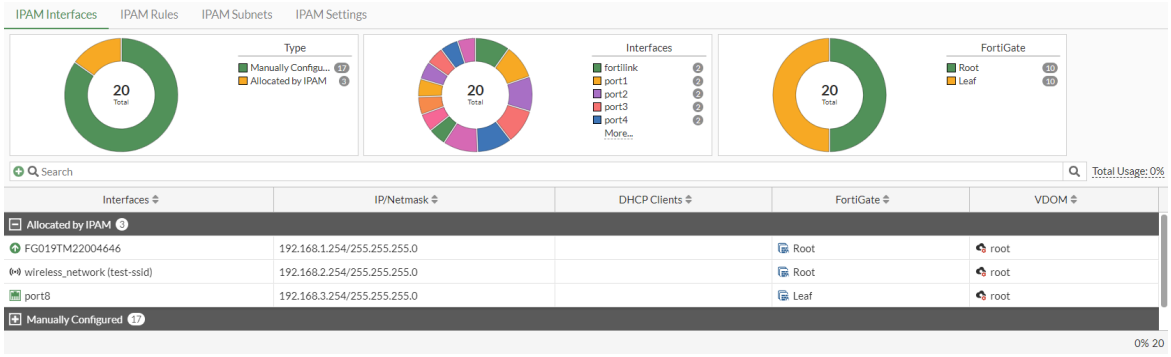
Configure IPAM locally on the FortiGate

IPAM (IP address management) is available locally on the FortiGate. A standalone FortiGate, or a Fabric root in the Security Fabric, can act as the IPAM server. Interfaces configured to be auto-managed by IPAM will receive an address from the IPAM server's address/subnet pool. *DHCP Server* is automatically enabled in the GUI, and the address range is populated by IPAM. Users can customize the address pool subnet and the size of a subnet that an interface can request.

Interfaces with a LAN role, wireless network interfaces (`vap-switch` type), and FortiExtender LAN extension interfaces (`lan-extension` type) can receive an IP address from an IPAM server without any additional configuration at the interface level (see Interfaces on page 170 for more information).

IPAM detects and resolves any IP conflicts that may occur on the interfaces that it manages. Users have the option to manually edit the interface or reallocate the IP.

IPAM can be configured on the *Network* > *IPAM* page using the *IPAM Settings*, *IPAM Rules*, *IPAM Interfaces*, and *IPAM Subnets* tabs.



To configure IPAM settings in the GUI:

1. Go to *Network* > *IPAM* and select the *IPAM Settings* tab.
2. Enable or disable the following settings:
   a. *Status*
   b. *Auto-resolve conflicts*
   c. *Interfaces with LAN role*
   d. *FortiAP SSIDs*
   e. *FortiExtender LAN extensions*
3. Click *OK*.

To configure IPAM settings in the CLI:

```
config system ipam
    set pool-subnet <class IP and netmask>
    set status {enable | disable}
    set automatic-conflict-resolution {enable | disable}
    set manage-lan-addresses {enable | disable}
    set manage-lan-extension-addresses {enable | disable}
    set manage-ssid-addresses {enable | disable}
    config pools
        edit <pool_name>
            set subnet <IP address/netmask>
        next
    end
    config rules
        edit <rule_name>
            set device <name1> <name2> ...
            set interface <name1> <name2> ...
            set pool <pool_name>
        next
    end
end
```

`pool-subnet <class IP and netmask>`	Set the IPAM pool subnet, class A or class B subnet.

`status {enable | disable}`	Enable/disable IP address management services.
`automatic-conflict-resolution {enable | disable}`	Enable/disable automatic conflict resolution. When `automatic-conflict-resolution` is enabled, IPAM will periodically check and validate the addresses of all interfaces. In case of any conflicts, IPAM will automatically attempt to obtain a new address for the affected interface managed by IPAM, ensuring no address duplication.
`manage-lan-addresses {enable | disable}`*	Enable/disable default management of LAN interface addresses.
`manage-lan-extension-addresses {enable | disable}`*	Enable/disable default management of FortiExtender LAN extension interface addresses.
`manage-ssid-addresses {enable | disable}`*	Enable/disable default management of FortiAP SSID addresses.
`config pools`	Set the subnet for the IP pool.
`config rules`	Set the device, interface, and IP pool for IPAM rules.

* When a `manage-` option is enabled, any interface that meets the specified criteria will automatically receive an IP address from IPAM. However, if this option is disabled, interfaces that meet the criteria will not be configured by IPAM. All `manage-` options are disabled by default. The central FortiIPAM configuration can be overridden at the interface level.

To override the central FortiIPAM configuration at the interface level:

```
config system interface
    edit <name>
        set ip-managed-by-fortiipam {enable | disable | inherit-global}
    next
end
```

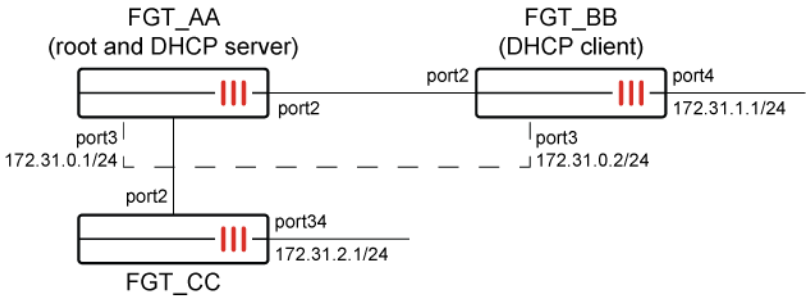
The default setting is to inherit from the global configuration (`inherit-global`) through the relevant `manage-` option under `config system ipam`.

The following options are available for allocating the subnet size:

```
config system interface
    set managed-subnetwork-size {32 | 64 | 128 | 256 |512 | 1024 | 2048 | 4096 | 8192 | 16384 |
32768 | 65536}
end
```

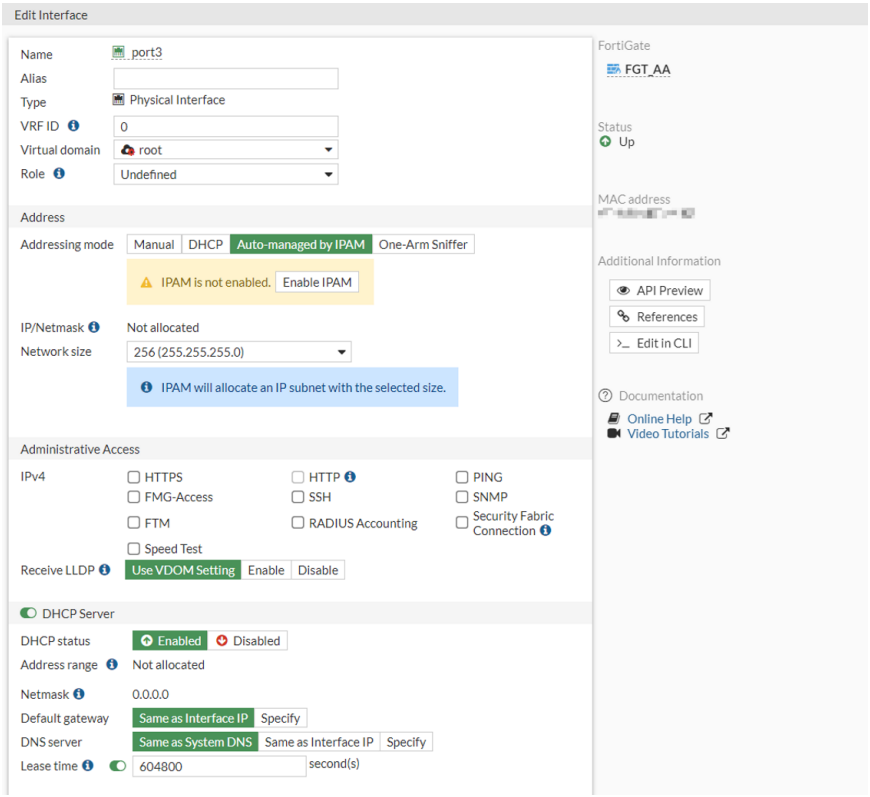
Example 1: physical interfaces

In this example, FGT_AA is the Security Fabric root with IPAM enabled. FGT_BB and FGT_CC are downstream Fabric devices and retrieve IPAM information from FGT_AA. The Fabric interface on all FortiGates is port2. FGT_AA acts as the DHCP server, and FGT_BB acts as the DHCP client.

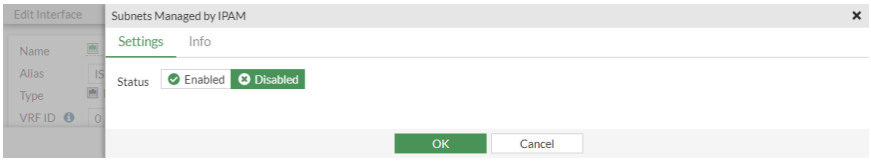


To configure IPAM locally in the Security Fabric:

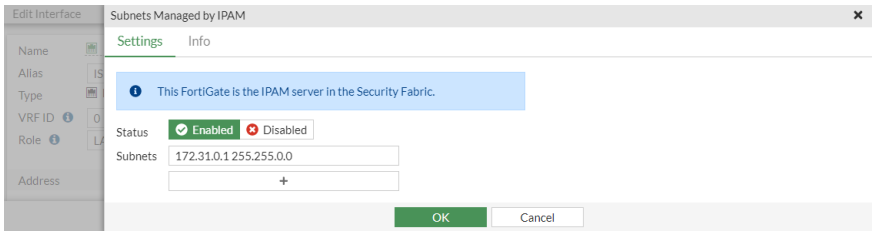
1. On the root FortiGate, go to *Network* > *Interfaces* and edit port3.
2. For *Addressing Mode*, select *Auto-Managed by IPAM*. *DHCP Server* is automatically enabled.



3. In this example, IPAM is not enabled yet. Click *Enable IPAM*. The *Subnets Managed by IPAM* pane opens.



4. Select *Enabled*, enter the *Pool subnet* (only class A and B are allowed) and click *OK*. The root FortiGate is now the IPAM server in the Security Fabric.



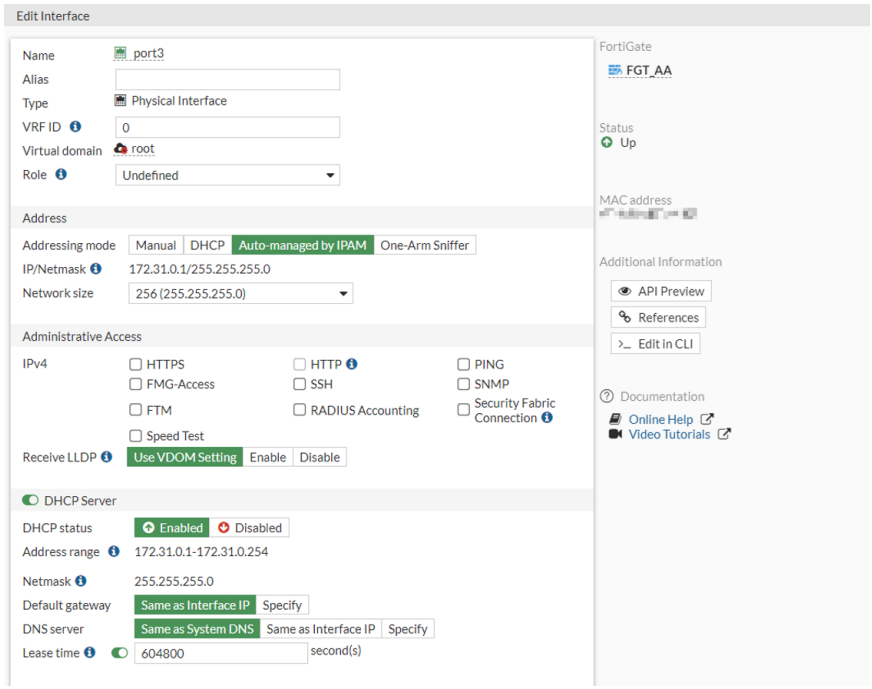
The following is configured in the backend:

```
config system interface
    edit "port3"
        set vdom "root"
        set ip 172.31.0.1 255.255.0.0
        set type physical
        set device-identification enable
        set snmp-index 5
        set ip-managed-by-fortiipam enable
        end
    next
end

config system ipam
    set status enable
end
```

IPAM is managing a 172.31.0.0/16 network and assigned port3 a /24 network by default.

The *IP/Netmask* field in the *Address* section has been automatically assigned a class C IP by IPAM. The *Address range* and *Netmask* fields in the *DHCP Server* section have also been automatically configured by IPAM.

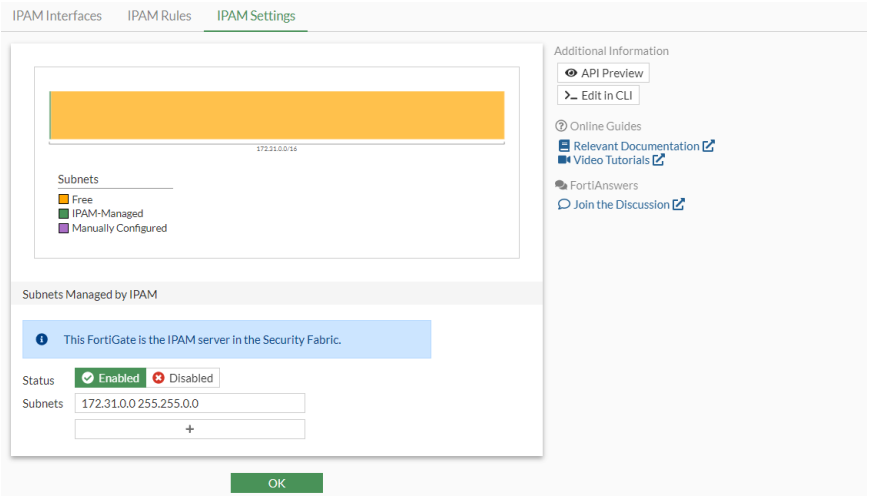


5. Click *OK*.
6. Log in to FGT-BB and set the *Addressing Mode* of port4 to *Auto-Managed by IPAM*. The subnet assigned from the pool on the root is 172.31.1.1/24.
7. Log in to FG_CC and set the *Addressing Mode* of port34 to *Auto-Managed by IPAM*. The subnet assigned from the pool on the root is 172.31.2.1/24.

Any interface on a downstream FortiGate can be managed by the IPAM server. The interface does not have to be directly connected to the Fabric root FortiGate.

To edit the IPAM subnet:

1. Go to *Network* > *IPAM* > *IPAM Settings*.
2. Edit the pool subnet if needed.



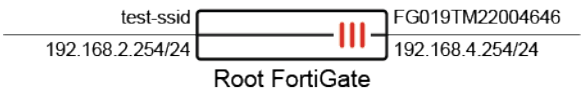
3. Click *OK*.

   On downstream FortiGates, the settings on the *Network* > *IPAM* > *IPAM Settings* tab cannot be changed if IPAM is enabled on the root FortiGate.

Go to *Network* > *IPAM* > *IPAM Interfaces* to view the subnet allocations (port34, port3, and port3) and DHCP lease information. On FGT_BB, port3 is a DHCP client and the DHCP server interface (FGT_AA port3) is managed by IPAM, so it is displayed in the *Manually Configured* section.

Example 2: wireless network and FortiExtender LAN extension interfaces

In this example, the FortiGate serves as the Security Fabric root and has two interfaces: test-ssid (`vap-switch` type) and FG019TM22004646 (`lan-extension` type). Currently, neither interface has an IP address assigned to it.



To configure IPAM on the root FortiGate:

1. Go to *Network* > *IPAM* and select the *IPAM Settings* tab.
2. Enable the *Status*, *Auto-resolve conflicts*, *Interfaces with LAN role*, *FortiAP SSIDs*, and *FortiExtender LAN extensions* settings.

   IPAM is disabled by default, so all these options are disabled by default. Each option must be activated individually to function, and they do not depend on one another.

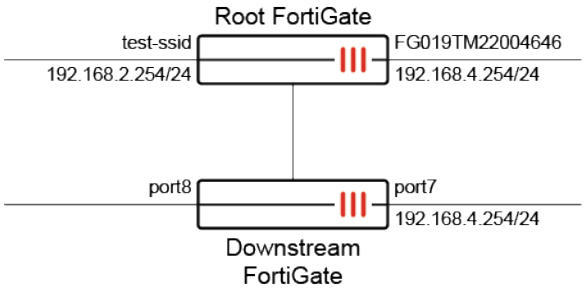
3. Click *OK*.

   After enabling IPAM on the root FortiGate with the specified settings, FortiGates that are part of the Security Fabric and have an interface set to either the LAN role, `vap-switch` type, or `lan-extension` type will automatically receive an IP assignment from the IPAM server without requiring any additional configuration at the interface level.
4. Verify the list of IPAM entries:

```
# diagnose sys ipam list entries
Entries: (sn, vdom, interface, subnet/mask, conflict)

IPAM Entries:
  FGVM08TM22004645 root FG019TM22004646 192.168.4.254/24
  FGVM08TM22004645 root test-ssid 192.168.2.254/24
```

When a downstream FortiGate joins the Security Fabric, the port7 interface is configured with a static IP (192.168.4.254/24), and port8 is set to a LAN role with no IP address assigned. The IPAM server assigns an IP to port8 of the downstream FortiGate since its role was set to LAN. It is observed that the FG019TM22004646 interface of the root FortiGate conflicts with port7 of the downstream FortiGate.



To verify the IP address conflict resolution:

1. On the root FortiGate, go to *Network* > *IPAM* and select the *IPAM Interfaces* tab.

   There is a conflict marker (warning icon) beside the IP address of *FG019TM22004646* due to a conflict between the IPAM-assigned interface FG019TM22004646 of the root FortiGate and the manually configured interface of the downstream FortiGate.

   a. Verify the list of IPAM entries in the CLI:

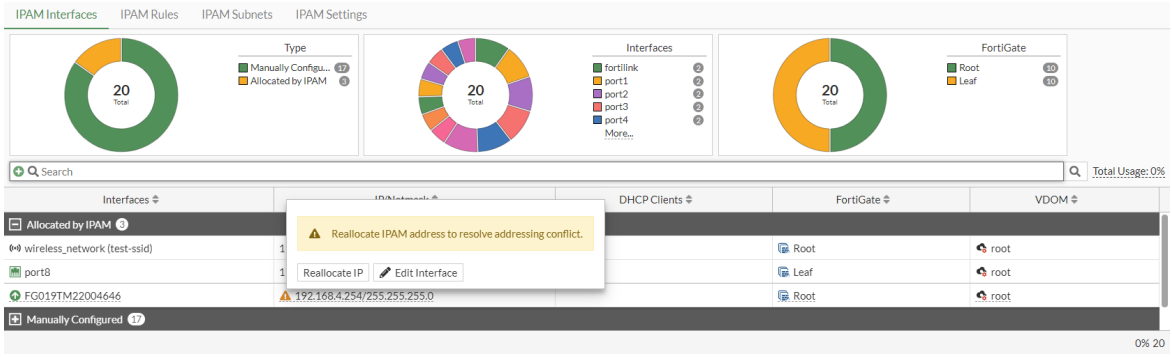
```
# diagnose sys ipam list entries
Entries: (sn, vdom, interface, subnet/mask, conflict)

  IPAM Entries:
  FGVM08TM22004645 root test-ssid 192.168.2.254/24
  FGVM08TM22004647 root port8 192.168.3.254/24
  FGVM08TM22004645 root FG019TM22004646 192.168.4.254/24 C
```

2. After some time, since *Auto-resolve conflicts* is enabled in the IPAM settings, the conflict is resolved automatically.

   FG019TM22004646 has been assigned a new IP address of 192.168.1.254/24.

   If *Auto-resolve conflicts* is disabled in the IPAM settings, mouse over the conflict marker and select *Reallocate IP* to manually reallocate the IP address.



a. Verify the list of IPAM entries in the CLI:

```
# diagnose sys ipam list entries
Entries: (sn, vdom, interface, subnet/mask, conflict)

  IPAM Entries:
  FGVM08TM22004645 root FG019TM22004646 192.168.1.254/24
  FGVM08TM22004645 root test-ssid 192.168.2.254/24
  FGVM08TM22004647 root port8 192.168.3.254/24
```

Diagnostics

Use the following commands to view IPAM related diagnostics.

To view the largest available subnet size:

```
# diagnose sys ipam largest-available-subnet
Largest available subnet is a /17.
```

To verify IPAM allocation information:

```
# diagnose sys ipam list entries
IPAM Entries: (sn, vdom, interface, subnet/mask, flag)
  F140EP4Q17000000 root port34 172.31.2.1/24 0
  FG5H1E5818900001 root port3 172.31.0.1/24 0
  FG5H1E5818900002 root port4 172.31.1.1/24 0
  FG5H1E5818900003 root port3 172.31.0.2/24 1
```

To verify the available subnets:

```
# diagnose sys ipam list subnets
IPAM free subnets: (subnet/mask)
  172.31.3.0/24
  172.31.4.0/22
  172.31.8.0/21
  172.31.16.0/20
  172.31.32.0/19
  172.31.64.0/18
  172.31.128.0/17
```

To remove a device from IPAM in the Security Fabric:

```
# diagnose sys ipam delete device F140EP4Q17000000
Successfully removed device F140EP4Q17000000 from ipam
```

Interface MTU packet size

Changing the maximum transmission unit (MTU) on FortiGate interfaces changes the size of transmitted packets. Most FortiGate device's physical interfaces support jumbo frames that are up to 9216 bytes, but some only support 9000 or 9204 bytes.

To avoid fragmentation, the MTU should be the same as the smallest MTU in all of the networks between the FortiGate and the destination. If the packets sent by the FortiGate are larger than the smallest MTU, then they are fragmented, slowing down the transmission. Packets with the DF flag set in the IPv4 header are dropped and not fragmented .

On many network and endpoint devices, the path MTU is used to determine the smallest MTU and to transmit packets within that size.

- ASIC accelerated FortiGate interfaces, such as NP6, NP7, and SOC4 (np6xlite), support MTU sizes up to 9216 bytes.
- FortiGate VMs can have varying maximum MTU sizes, depending on the underlying interface and driver.
- Virtual interfaces, such as VLAN interfaces, inherit their MTU size from their parent interface.

To verify the supported MTU size:

```
config system interface
    edit <interface>
        set mtu-override enable
        set mtu <integer>
    next
end
```

To change the MTU size:

```
config system interface
    edit <interface>
        set mtu-override enable
        set mtu <max bytes>
    next
end
```

Maximum MTU size on a path

To manually test the maximum MTU size on a path, you can use the ping command on a Windows computer.

For example, you can send ICMP packets of a specific size with a DF flag, and iterate through increasing sizes until the ping fails.

- The `-f` option specifies the Do not Fragment (DF) flag.
- The `-l` option specifies the length, in bytes, of the Data field in the echo Request messages. This does not include the 8 bytes for the ICMP header and 20 bytes for the IP header. Therefore, if the maximum MTU is 1500 bytes, then the maximum supported data size is: 1500 - 8 - 20 = 1472 bytes.

To determine the maximum MTU size on a path:

1. In Windows command prompt, try a likely MTU size:

```
>ping 4.2.2.1 -l 1472 -f
Pinging 4.2.2.1 with 1472 bytes of data:
Reply from 4.2.2.1: bytes=1472 time=41ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=42ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=103ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=38ms TTL=52

Ping statistics for 4.2.2.1:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 38ms, Maximum = 103ms, Average = 56ms
```

2. Increase the size and try the ping again:

```
>ping 4.2.2.1 -l 1473 -f
Pinging 4.2.2.1 with 1473 bytes of data:
Request timed out.

Ping statistics for 4.2.2.1:
    Packets: Sent = 1, Received = 0, Lost = 1 (100% loss),
```

The second test fails, so the maximum MTU size on the path is 1472 bytes + 8-byte ICMP header + 20-byte IP header = 1500 bytes

Maximum segment size

The TCP maximum segment size (MSS) is the maximum amount of data that can be sent in a TCP segment. The MSS is the MTU size of the interface minus the 20 byte IP header and 20 byte TCP header. By reducing the TCP MSS, you can effectively reduce the MTU size of the packet.

The TCP MSS can be configured in a firewall policy (see Configurations in the CLI on page 1573), or directly on an interface.

To configure the MSS on an interface:

```
config system interface
    edit "wan2"
        set vdom "root"
        set mode dhcp
        set allowaccess ping fgfm
        set type physical
        set tcp-mss 1448
        set role wan
```

```
    next
end
```

One-arm sniffer

You can use a one-arm sniffer to configure a physical interface as a one-arm intrusion detection system (IDS). Traffic sent to the interface is examined for matches to the configured security profile. The matches are logged, and then all received traffic is dropped. Sniffing only reports on attacks; it does not deny or influence traffic.

You can also use the one-arm sniffer to configure the FortiGate to operate as an IDS appliance to sniff network traffic for attacks without actually processing the packets. To configure a one-arm IDS, enable sniffer mode on a physical interface and connect the interface to the SPAN port of a switch or a dedicated network tab that can replicate the traffic to the FortiGate.

If the one-arm sniffer option is not available, this means the interface is in use. Ensure that the interface is not selected in any firewall policies, routes, virtual IPs, or other features where a physical interface is specified. The option also does not appear if the role is set to WAN. Ensure the role is set to LAN, DMZ, or undefined.

One-arm sniffer supports monitoring mirrored traffic that includes VLAN-tagged, VXLAN, and GRE encapsulated packets.

The following table lists some of the one-arm sniffer settings you can configure:

Field	Description
Security Profiles	The following profiles are configurable in the GUI and CLI: • Antivirus • Web filter • Application control • IPS • File filter The following profiles are only configurable in the CLI: • Email filter • DLP • IPS DoS

Each security profile has a predefined profile for *One-Arm Sniffer* called *sniffer-profile*. The *sniffer-profile* can be viewed or edited from the GUI through the *Edit Interface* page only. Please refer to the Example configuration on page 191 for a demonstration.

The sniffer traffic log is generated by the IPS engine. If no UTM profile is enabled in the sniffer policy, then the IPS engine is not running and no sniffer traffic log is generated. If a UTM profile is enabled in the sniffer policy:

- When *Log allowed traffic* is set to *Security events* (`utm` in the CLI), only security events are logged in the sniffer traffic log.
- When *Log allowed traffic* is set to *All sessions* (`all` in the CLI), clean traffic and security events are logged in sniffer traffic log.

CPU usage and packet loss

Traffic scanned on the one-arm sniffer interface is processed by the CPU, even if there is an SPU, such as NPU or CP, present. The one-arm sniffer may cause higher CPU usage and perform at a lower level than traditional inline scanning, which uses NTurbo or CP to accelerate traffic when present.

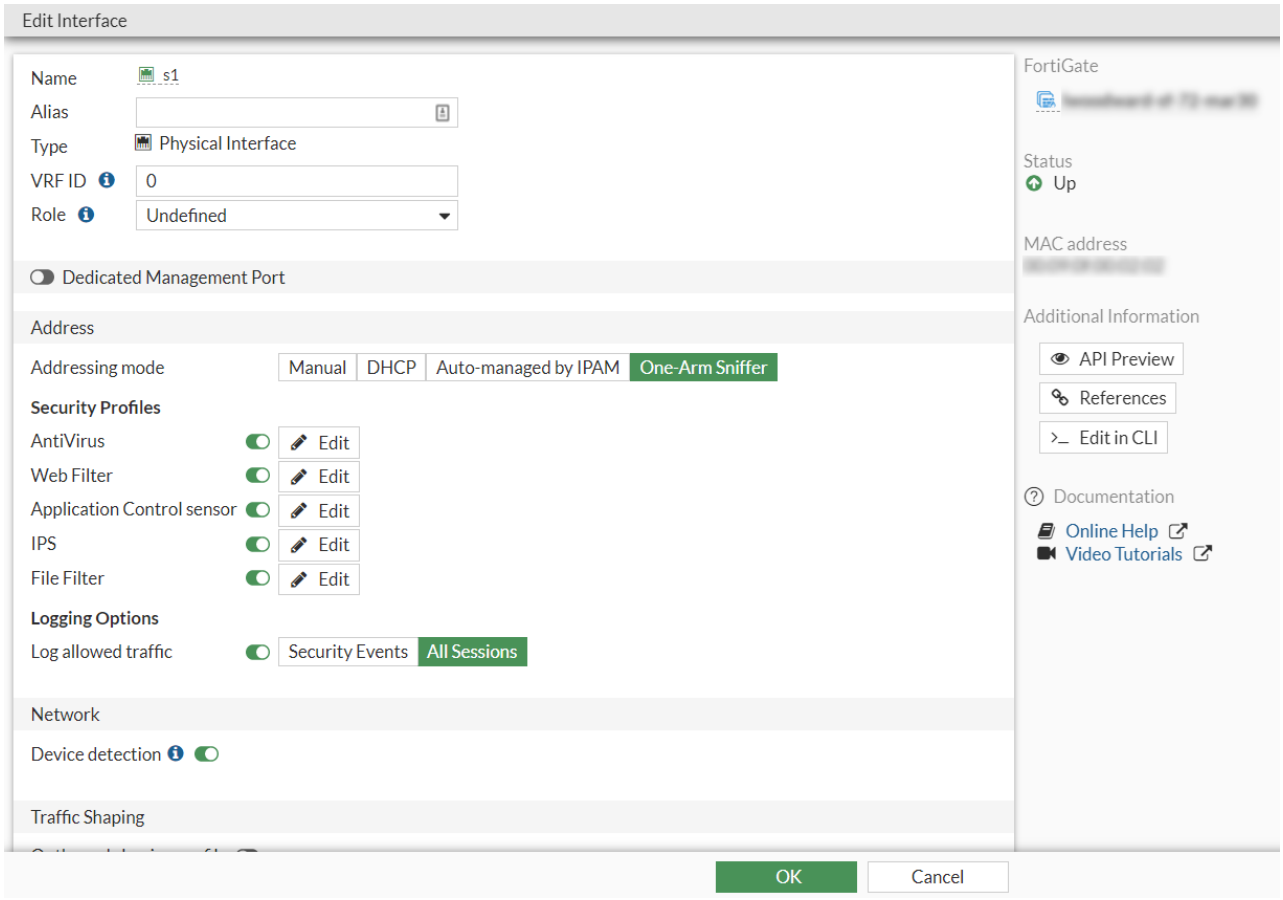
The absence of high CPU usage does not indicate the absence of packet loss. Packet loss may occur due to the capacity of the TAP devices hitting maximum traffic volume during mirroring, or on the FortiGate when the kernel buffer size is exceeded and it is unable to handle bursts of traffic.

Example configuration

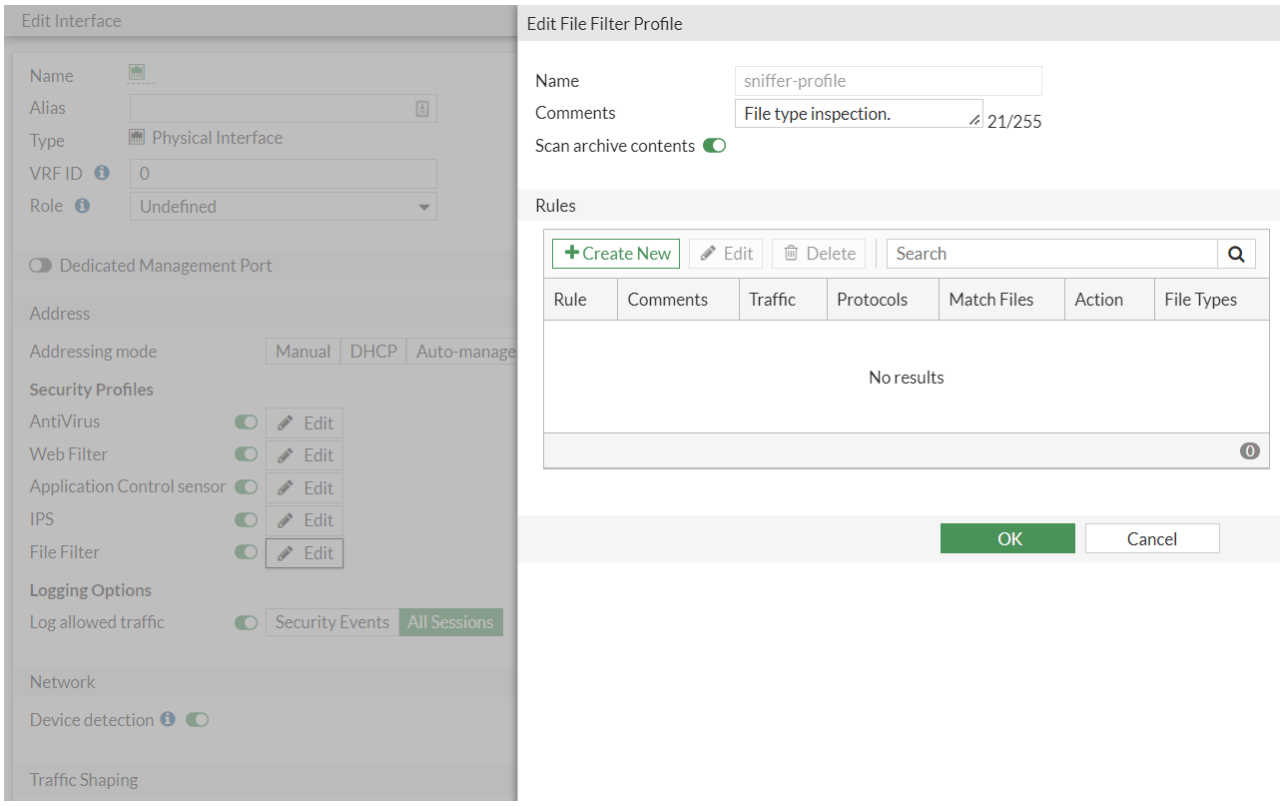
The following example shows how to configure a file filter profile that blocks PDF and RAR files used in a one-arm sniffer policy.

To configure a one-arm sniffer policy in the GUI:

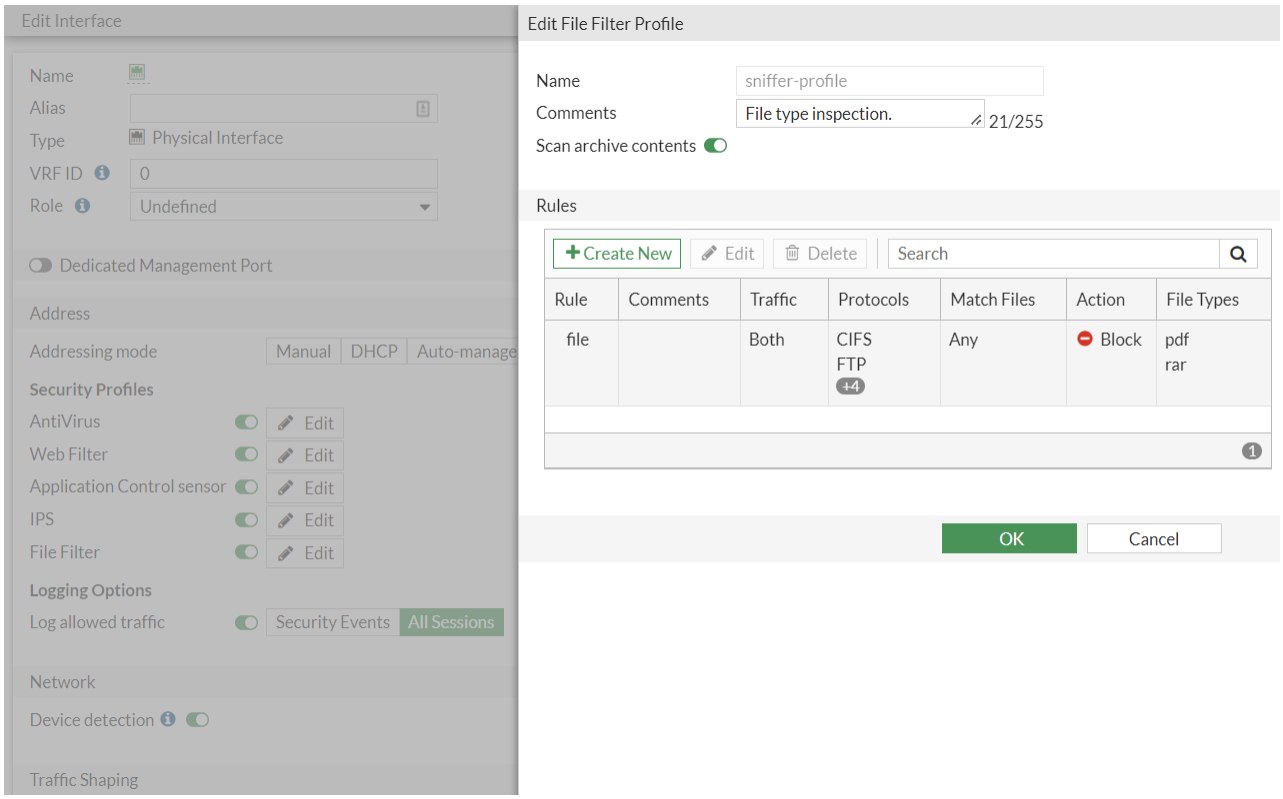
1. Go to *Network* > *Interfaces* and double-click a physical interface to edit it.
2. For *Role*, select either *LAN*, *DMZ*, or *Undefined*.
3. For *Addressing Mode*, select *One-Arm Sniffer*.



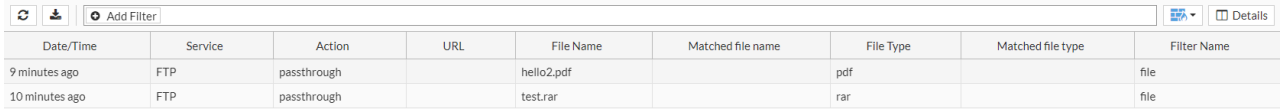
4. In the *Security Profiles* section, enable *File Filter* and click *Edit*. The *Edit File Filter Profile* pane opens.
5. In the *Rules* table, click *Create New*.



6. Configure the rule:
   a. For *File types*, click the + and select *pdf* and *rar*.
   b. For *Action*, select *Block*.
   c. Click *OK* to save the rule.
7. Click *OK* to save the file filter profile.



8. Click *OK* to save the interface settings.
9. Go to *Log & Report* > *Security Events* to view the *File Filter* logs.



To configure a one-arm sniffer policy in the CLI:

1. Configure the interface:

```
config system interface
    edit "s1"
        set vdom "root"
        set ips-sniffer-mode enable
        set type physical
        set role undefined
        set snmp-index 31
    next
end
```

2. Configure the file filter profile:

```
config file-filter profile
    edit "sniffer-profile"
        set comment "File type inspection."
        config rules
```

```
            edit "1"
                set protocol http ftp smtp imap pop3 cifs
                set action block
                set file-type "pdf" "rar"
            next
        end
    next
end
```

3. Configure the firewall sniffer policy:

```
config firewall sniffer
    edit 1
        set interface "s1"
        set file-filter-profile-status enable
        set file-filter-profile "sniffer-profile"
    next
end
```

4. View the log:

```
# execute log filter category  19
# execute log display
1 logs found.
1 logs returned.

1: date=2020-12-29 time=09:14:46 eventtime=1609262086871379250 tz="-0800" logid="1900064000"
type="utm" subtype="file-filter" eventtype="file-filter" level="warning" vd="root" policyid=1
sessionid=792 srcip=172.16.200.55 srcport=20 srcintf="s1" srcintfrole="undefined"
dstip=10.1.100.11 dstport=56745 dstintf="s1" dstintfrole="undefined" proto=6 service="FTP"

filename="hello.pdf" filesize=9539 filetype="pdf" msg="File was blocked by file filter."
```

Interface migration wizard

The *Integrate Interface* option on the *Network > Interfaces* page helps migrate a physical port into another interface or interface type such as aggregate, software switch, redundant, zone, or SD-WAN zone. The FortiGate will migrate object references either by replacing the existing instance with the new interface, or deleting the existing instance based on the user's choice. Users can also change the VLAN ID of existing VLAN sub-interface or FortiSwitch VLANs.

The interface migration wizard does not support turning an aggregate, software switch, redundant, zone, or SD-WAN zone interface back into a physical interface.

Integrating an interface

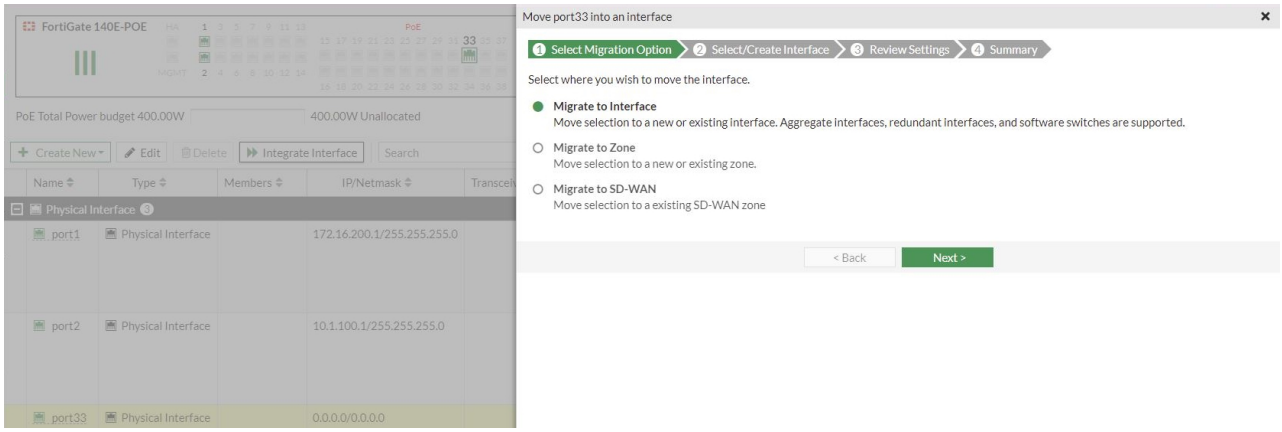
In this example, a DHCP server interface is integrated into a newly created redundant interface, which transfers the DHCP server to a redundant interface.

To integrate an interface:

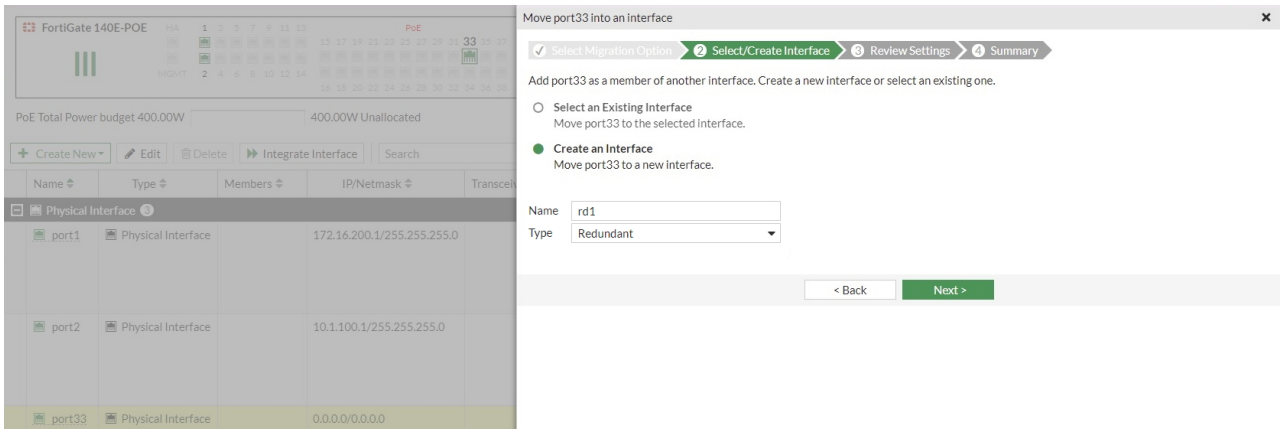
1. Go to *Network* > *Interfaces* and select an interface in the list.
2. Click *Integrate Interface*. The wizard opens.

Alternatively, select an interface in the list. Then right-click and select *Integrate Interface*.

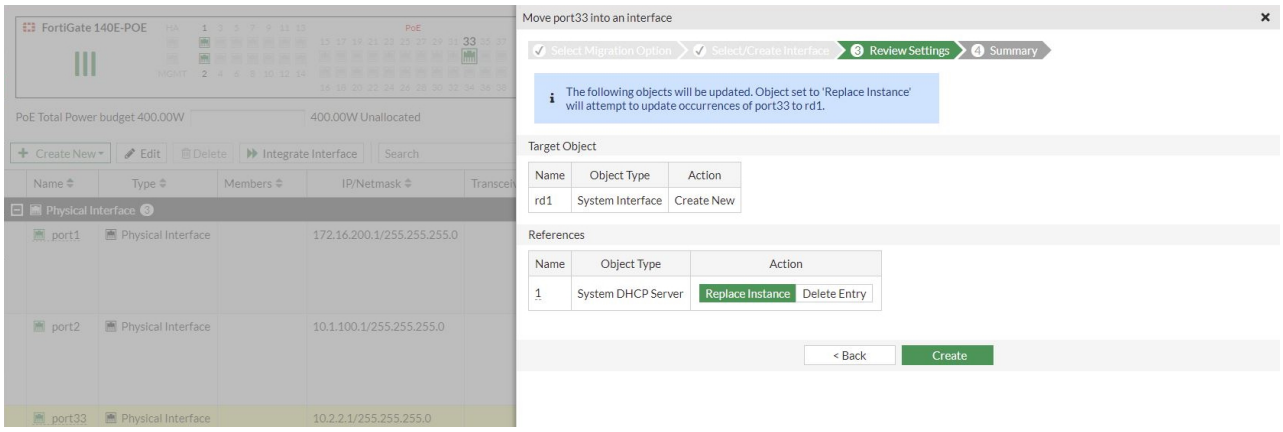
3. Select *Migrate to Interface* and click *Next*.



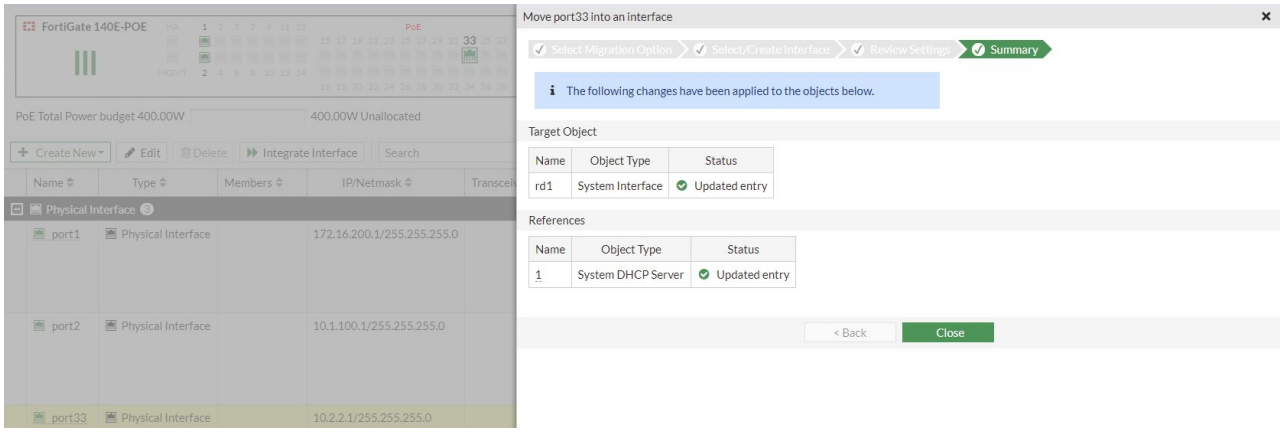
4. Select *Create an Interface*. Enter a name (*rd1*) and set the *Type* to *Redundant*.



5. Click *Next*. The *References* sections lists the associated services with options to *Replace Instance* or *Delete Entry*.
6. For the DHCP server *Action*, select *Replace Instance* and click *Create*.



7. The migration occurs automatically and the statuses for the object and reference change to *Updated entry*. Click *Close*.

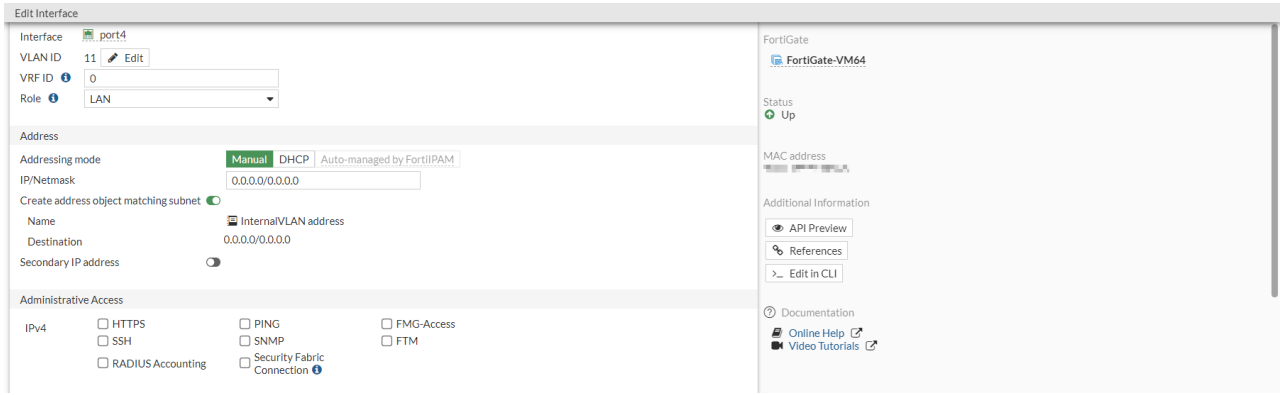


Changing the VLAN ID

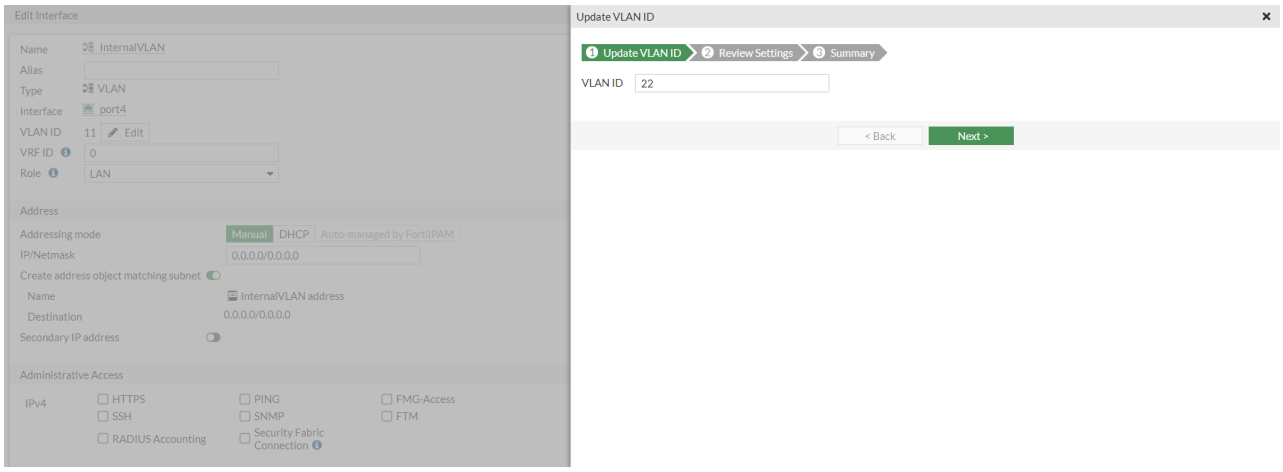
In this example, the VLAN ID of *InternalVLAN* is changed from 11 to 22.

To change the VLAN ID:

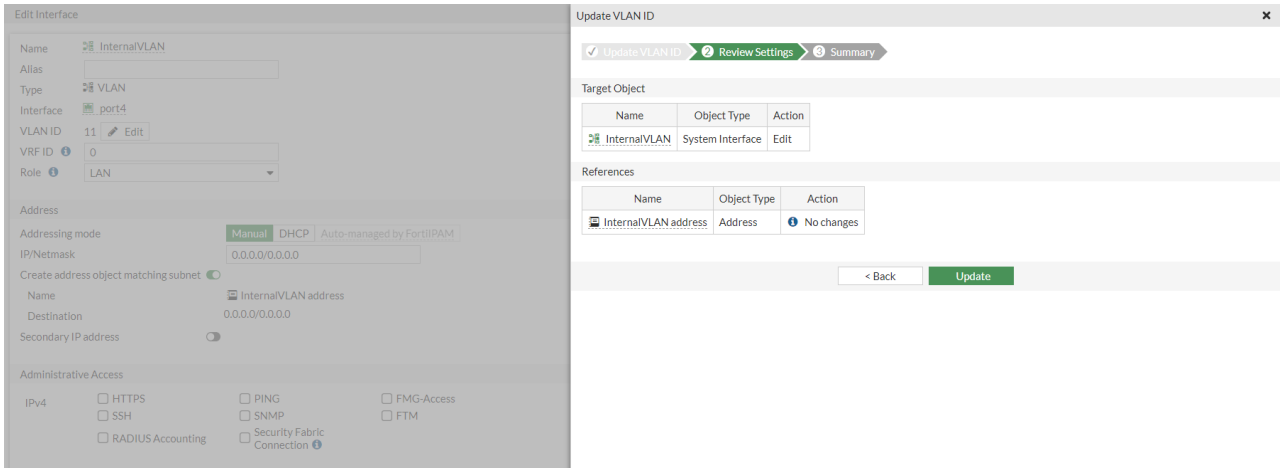
1. Go to *Network* > *Interfaces* and edit an existing interface.
2. Beside the *VLAN ID* field, click *Edit*. The *Update VLAN ID* window opens.



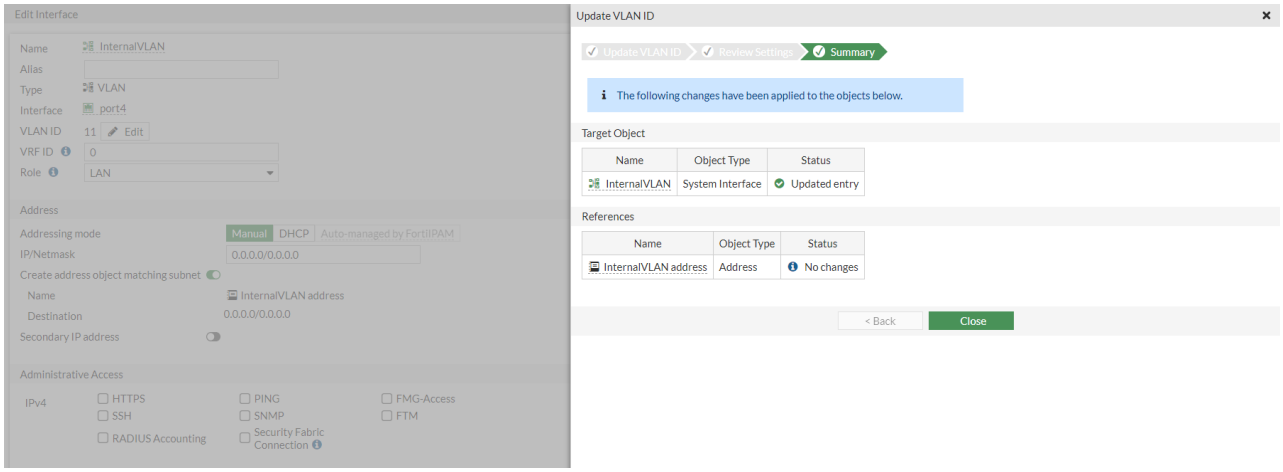
3. Enter the new ID (*22*) and click *Next*.



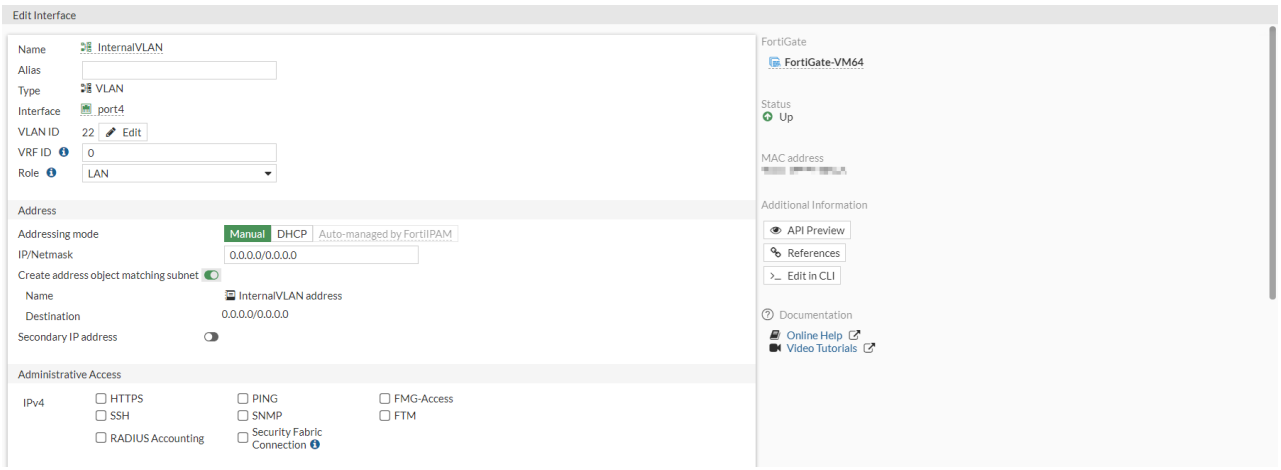
4. Verify the changes, then click *Update* and *OK*.



5. The target object status changes to *Updated entry*. Click *Close*.



In the interface settings, the ID displays as *22*.



Captive portals

A captive portal is used to enforce authentication before web resources can be accessed. Until a user authenticates successfully, any HTTP request returns the authentication page. After successfully authenticating, a user can access the requested URL and other web resources, as permitted by policies. The captive portal can also be configured to only allow access to members of specific user groups.

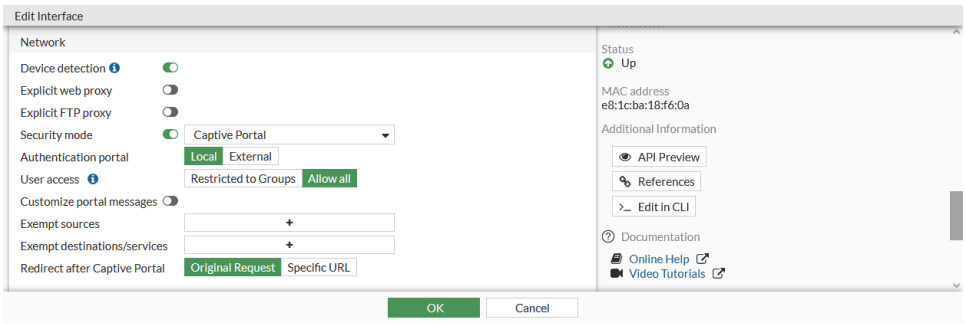
Captive portals can be hosted on the FortiGate or an external authentication server. They can be configured on any network interface, including VLAN and WiFi interfaces. On a WiFi interface, the access point appears open, and the client can connect to access point with no security credentials, but then sees the captive portal authentication page. See Captive Portal Security, in the FortiWiFi and FortiAP Configuration Guide for more information.

All users on the interface are required to authenticate. Exemption lists can be created for devices that are unable to authenticate, such as a printer that requires access to the internet for firmware upgrades.

When configuring a bridge mode SSID, you do not need to enable captive portal.

To configure a captive portal in the GUI:

1. Go to *Network* > *Interfaces* and edit the interface that the users connect to. The interface *Role* must be *LAN* or *Undefined*.
2. Enable *Security mode*.



3. Configure the following settings, then click *OK*.

Authentication Portal	Configure the location of the portal: • *Local*: the portal is hosted on the FortiGate unit. • *External*: enter the FQDN or IP address of external portal.
User access	Select if the portal applies to all users, or selected user groups: • *Restricted to Groups*: restrict access to the selected user groups. The *Login page* is shown when a user tries to log in to the captive portal. • *Allow all*: all users can log in, but access will be defined by relevant policies. The *Disclaimer page* is shown when a user tried to log in to the captive portal.
Customize portal messages	Enable to use custom portal pages, then select a replacement message group. See Custom captive portal pages on page 200.
Exempt sources	Select sources that are exempt from the captive portal. Each exemption is added as a rule in an automatically generated exemption list.
Exempt destinations/services	Select destinations and services that are exempt from the captive portal. Each exemption is added as a rule in an automatically generated exemption list.
Redirect after Captive Portal	Configure website redirection after successful captive portal authentication: • *Original Request*: redirect to the initially browsed to URL . • *Specific URL*: redirect to the specified URL.

To configure a captive portal in the CLI:

1. If required, create a security exemption list:

```
config user security-exempt-list
    edit <list>
        config rule
            edit 1
                set srcaddr <source(s)>
                set dstaddr <source(s)>
                set service <service(s)>
```

```
            next
            edit 2
                set srcaddr <source(s)>
                set dstaddr <source(s)>
                set service <service(s)>
            next
        end
    next
end
```

2. Configure captive portal authentication on the interface:

```
config system interface
    edit <interface>
        set security-mode {none | captive-portal}
        set security-external-web <string>
        set replacemsg-override-group <group>
        set security-redirect-url <string>
        set security-exempt-list <list>
        set security-groups <group(s)>
    next
end
```

Custom captive portal pages

Portal pages are HTML files that can be customized to meet user requirements.

Most of the text and some of the HTML in the message can be changed. Tags are enclosed by double percent signs (%%); most of them should not be changed because they might carry information that the FortiGate unit needs. For information about customizing replacement messages, see Modifying replacement messages on page 3555.

The images on the pages can be replaced. For example, your organization's logo can replace the Fortinet logo. For information about uploading and using new images in replacement messages, see Replacement message images on page 3557.

The following pages are used by captive portals:

Login Page	Requests user credentials. The *%%QUESTION%%* tag provides the *Please enter the required information to continue.* text. This page is shown to users that are trying to log in when *User access* is set to *Restricted to Groups*.
Login Failed Page	Reports that incorrect credentials were entered, and requests correct credentials. The *%%FAILED_MESSAGE%%* tag provides the *Firewall authentication failed. Please try again.* text.
Disclaimer Page	A statement of the legal responsibilities of the user and the host organization that the user must agree to before proceeding. This page is shown users that are trying to log in when *User access* is set to *Allow all*.

Declined Disclaimer Page	Shown if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

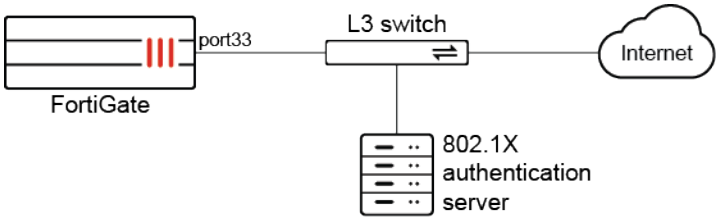
Configuring a FortiGate interface to act as an 802.1X supplicant

A FortiGate interface can be configured to act as a 802.1X supplicant. The settings can be enabled on the network interface in the CLI. The EAP authentication method can be either PEAP or TLS using a user certificate.

```
config system interface
    edit <interface>
        set eap-supplicant {enable | disable}
        set eap-method {peap | tls}
        set eap-identity <identity>
        set eap-password <password>
        set eap-ca-cert <CA_cert>
        set eap-user-cert <user_cert>
    next
end
```

Example

In this example, the FortiGate connects to an L3 switch that is not physically secured. All devices that connect to the internet through the L3 switch must be authenticated with 802.1X on the switch port by either a username and password (PEAP), or a user certificate (TLS). Configuration examples for both EAP authentication methods on port33 are shown.



To configure EAP authentication with PEAP:

1. Configure the interface:

```
config system interface
    edit "port33"
        set vdom "vdom1"
        set ip 7.7.7.2 255.255.255.0
        set allowaccess ping https ssh snmp http telnet fgfm radius-acct probe-response fabric
        set stpforward enable
        set type physical
        set snmp-index 42
        set eap-supplicant enable
        set eap-method peap
        set eap-identity "test1"
        set eap-password **********
```

```
    next
end
```

2. Verify the interface's PEAP authentication details:

```
# diagnose test app eap_supp 2
Interface: port33
status:Authorized
method: PEAP
identity: test1
ca_cert:
client_cert:
private_key:
last_eapol_src =70:4c:a5:3b:0b:c6
```

Traffic is able to pass because the status is authorized.

To configure EAP authentication with TLS:

1. Configure the interface:

```
config system interface
    edit "port33"
        set vdom "vdom1"
        set ip 7.7.7.2 255.255.255.0
        set allowaccess ping https ssh snmp http telnet fgfm radius-acct probe-response fabric
        set stpforward enable
        set type physical
        set snmp-index 42
        set eap-supplicant enable
        set eap-method tls
        set eap-identity "test2@fortiqa.net"
        set eap-ca-cert "root_G_CA_Cert_1.cer"
        set eap-user-cert "root_eap_client_global.cer"
    next
end
```

2. Verify the interface's TLS authentication details:

```
# diagnose test application eap_supp 2
Interface: port33
status:Authorized
method: TLS
identity: test2@fortiqa.net
ca_cert: /etc/cert/ca/root_G_CA_Cert_1.cer
client_cert: /etc/cert/local/root_eap_client_global.cer
private_key: /etc/cert/local/root_eap_client_global.key
last_eapol_src =70:4c:a5:3b:0b:c6
```

Traffic is able to pass because the status is authorized.

Physical interface

A FortiGate has several physical interfaces that can connect to Ethernet or optical cables. Depending on the FortiGate model, it can have a varying combination of Ethernet, small form-factor pluggable (SFP), and enhanced small form-factor pluggable (SFP+) interfaces.

The port names, as labeled on the FortiGate, appear in the interfaces list on the *Network > Interfaces* page. Hover the cursor over a port to view information, such as the name and the IP address.

Refer to Configuring an interface for basic GUI and CLI configuration steps.

Displaying transceiver status information for SFP and SFP+ interfaces

Transceiver status information for SFP and SFP+ interfaces installed on the FortiGate can be displayed in the GUI and CLI. For example, the type, vendor name, part number, serial number, and port name. The CLI output includes additional information that can be useful for diagnosing transmission problems, such as the temperature, voltage, and optical transmission power.

To view transceiver status information in the GUI:

1. Go to *Network > Interfaces*. The *Transceiver* column is visible in the table, which displays the transceiver vendor name and part number.
2. Hover the cursor over a transceiver to view more information.

To view transceiver status information in the CLI:

```
# get system interface transceiver
Interface port9 - SFP/SFP+
  Vendor Name  :            FINISAR CORP.
  Part No.     :            FCLF-8521-3
  Serial No.   :            PMS***
Interface port10 - Transceiver is not detected.
Interface port11 - SFP/SFP+
  Vendor Name  :            QNC
  Part No.     :            LCP-1250RJ3SRQN
  Serial No.   :            QNDT****
Interface port12 - SFP/SFP+
  Vendor Name  :            QNC
  Part No.     :            LCP-1250RJ3SRQN
  Serial No.   :            QNDT****
Interface s1 - SFP/SFP+
  Vendor Name  :            JDSU
  Part No.     :            PLRXPLSCS4322N
  Serial No.   :            CB26U****
Interface s2 - SFP/SFP+
  Vendor Name  :            JDSU
  Part No.     :            PLRXPLSCS4321N
  Serial No.   :            C825U****
```

```
Interface vw1 - Transceiver is not detected.
Interface vw2 - Transceiver is not detected.
Interface x1 - SFP/SFP+
  Vendor Name  :            Fortinet

VLAN

Virtual local area networks (VLANs) multiply the capabilities of your FortiGate and can also provide added network security. VLANs use ID tags to logically separate devices on a network into smaller broadcast domains. These smaller domains forward packets only to devices that are part of that VLAN domain. This reduces traffic and increases network security.

VLANs in NAT mode

In NAT mode, the FortiGate unit functions as a layer-3 device. In this mode, the FortiGate unit controls the flow of packets between VLANs and can also remove VLAN tags from incoming VLAN packets. The FortiGate unit can also forward untagged packets to other networks such as the Internet.

In NAT mode, the FortiGate unit supports VLAN trunk links with IEEE 802.1Q-compliant switches or routers. The trunk link transports VLAN-tagged packets between physical subnets or networks. When you add VLAN subinterfaces to the FortiGate's physical interfaces, the VLANs have IDs that match the VLAN IDs of packets on the trunk link. The FortiGate unit directs packets with VLAN IDs to subinterfaces with matching IDs.

You can define VLAN subinterfaces on all FortiGate physical interfaces. However, if multiple virtual domains are configured on the FortiGate unit, you only have access to the physical interfaces on your virtual domain. The FortiGate unit can tag packets leaving on a VLAN subinterface. It can also remove VLAN tags from incoming packets and add a different VLAN tag to outgoing packets.

Normally in VLAN configurations, the FortiGate unit's internal interface is connected to a VLAN trunk, and the external interface connects to an Internet router that is not configured for VLANs. In this configuration, the FortiGate unit can apply different policies for traffic on each VLAN interface connected to the internal interface, which results in less network traffic and better security.

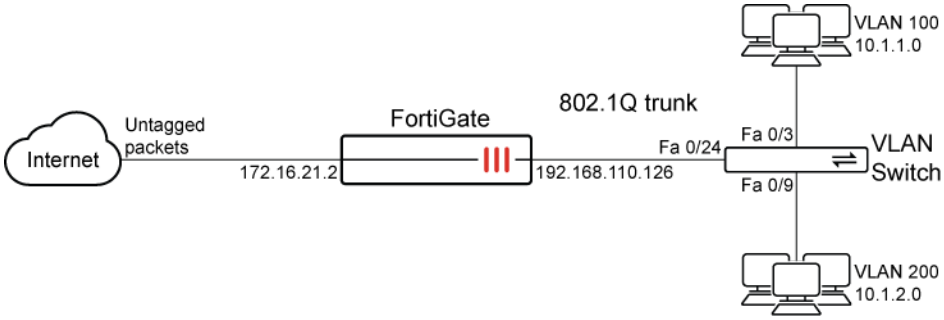
Sample topology

In this example, two different internal VLAN networks share one interface on the FortiGate unit and share the connection to the Internet. This example shows that two networks can have separate traffic streams while sharing a single interface. This configuration can apply to two departments in a single company or to different companies.

There are two different internal network VLANs in this example. VLAN_100 is on the 10.1.1.0/255.255.255.0 subnet, and VLAN_200 is on the 10.1.2.0/255.255.255.0 subnet. These VLANs are connected to the VLAN switch.

The FortiGate internal interface connects to the VLAN switch through an 802.1Q trunk. The internal interface has an IP address of 192.168.110.126 and is configured with two VLAN subinterfaces (VLAN_100 and VLAN_200). The external interface has an IP address of 172.16.21.2 and connects to the Internet. The external interface has no VLAN subinterfaces.

When the VLAN switch receives packets from VLAN_100 and VLAN_200, it applies VLAN ID tags and forwards the packets of each VLAN both to local ports and to the FortiGate unit across the trunk link. The FortiGate unit has policies that allow traffic to flow between the VLANs, and from the VLANs to the external network.



Sample configuration

In this example, both the FortiGate unit and the Cisco 2950 switch are installed and connected and basic configuration has been completed. On the switch, you need access to the CLI to enter commands. No VDOMs are enabled in this example.

General configuration steps include:

1. Configure the external interface.
2. Add two VLAN subinterfaces to the internal network interface.
3. Add firewall addresses and address ranges for the internal and external networks.
4. Add security policies to allow:
   - the VLAN networks to access each other.
   - the VLAN networks to access the external network.

To configure the external interface:

```
config system interface
    edit external
        set mode static
        set ip 172.16.21.2 255.255.255.0
```

```
    next
end
```

To add VLAN subinterfaces:

```
config system interface
    edit VLAN_100
        set vdom root
        set interface internal
        set type vlan
        set vlanid 100
        set mode static
        set ip 10.1.1.1 255.255.255.0
        set allowaccess https ping
    next
    edit VLAN_200
        set vdom root
        set interface internal
        set type vlan
        set vlanid 200
        set mode static
        set ip 10.1.2.1 255.255.255.0
        set allowaccess https ping
    next
end
```

To add the firewall addresses:

```
config firewall address
    edit VLAN_100_Net
        set type ipmask
        set subnet 10.1.1.0 255.255.255.0
    next
    edit VLAN_200_Net
        set type ipmask
        set subnet 10.1.2.0 255.255.255.0
    next
end
```

To add security policies:

Policies 1 and 2 do not need NAT enabled, but policies 3 and 4 do need NAT enabled.

```
config firewall policy
    edit 1
        set srcintf VLAN_100
        set srcaddr VLAN_100_Net
        set dstintf VLAN_200
        set dstaddr VLAN_200_Net
        set schedule always
```

```
        set service ALL
        set action accept
        set nat disable
        set status enable
    next
    edit 2
        set srcintf VLAN_200
        set srcaddr VLAN_200_Net
        set dstintf VLAN_100
        set dstaddr VLAN_100_Net
        set schedule always
        set service ALL
        set action accept
        set nat disable
        set status enable
    next
    edit 3
        set srcintf VLAN_100
        set srcaddr VLAN_100_Net
        set dstintf external
        set dstaddr all
        set schedule always
        set service ALL
        set action accept
        set nat enable
        set status enable
    next
    edit 4
        set srcintf VLAN_200
        set srcaddr VLAN_200_Net
        set dstintf external
        set dstaddr all
        set schedule always
        set service ALL
        set action accept
        set nat enable
        set status enable
    next
end
```

VLANs in transparent mode

In transparent mode, the FortiGate unit behaves like a layer-2 bridge but can still provide services such as antivirus scanning, web filtering, spam filtering, and intrusion protection to traffic. Some limitations of transparent mode is that you cannot use SSL VPN, PPTP/L2TP VPN, DHCP server, or easily perform NAT on traffic. The limits in transparent mode apply to IEEE 802.1Q VLAN trunks passing through the unit.

You can insert the FortiGate unit operating in transparent mode into the VLAN trunk without making changes to your network. In a typical configuration, the FortiGate unit internal interface accepts VLAN packets on a VLAN trunk from a VLAN switch or router connected to internal network VLANs. The FortiGate external interface forwards VLAN-tagged packets through another VLAN trunk to an external VLAN switch or router and on to

external networks such as the Internet. You can configure the unit to apply different policies for traffic on each VLAN in the trunk.

To pass VLAN traffic through the FortiGate unit, you add two VLAN subinterfaces with the same VLAN ID, one to the internal interface and the other to the external interface. You then create a security policy to permit packets to flow from the internal VLAN interface to the external VLAN interface. If required, create another security policy to permit packets to flow from the external VLAN interface to the internal VLAN interface. Typically in transparent mode, you do not permit packets to move between different VLANs. Network protection features such as spam filtering, web filtering, and anti-virus scanning, are applied through the UTM profiles specified in each security policy, enabling very detailed control over traffic.

When the FortiGate unit receives a VLAN-tagged packet on a physical interface, it directs the packet to the VLAN subinterface with the matching VLAN ID. The VLAN tag is removed from the packet and the FortiGate unit then applies security policies using the same method it uses for non-VLAN packets. If the packet exits the FortiGate unit through a VLAN subinterface, the VLAN ID for that subinterface is added to the packet and the packet is sent to the corresponding physical interface.

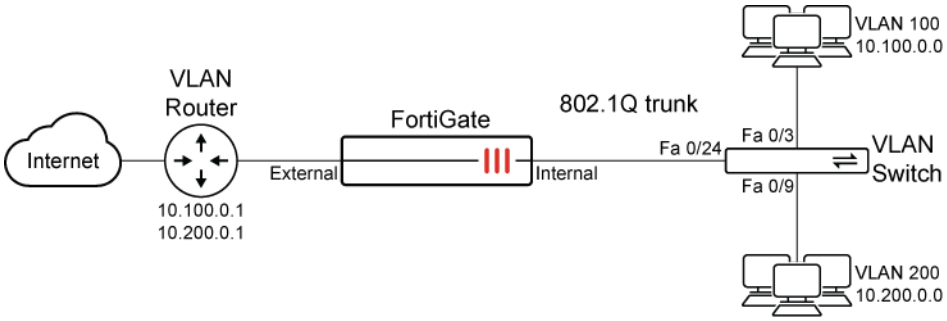
Sample topology

In this example, the FortiGate unit is operating in transparent mode and is configured with two VLANs: one with an ID of 100 and the other with ID 200. The internal and external physical interfaces each have two VLAN subinterfaces, one for VLAN_100 and one for VLAN_200.

The IP range for the internal VLAN_100 network is 10.100.0.0/255.255.0.0, and for the internal VLAN_200 network is 10.200.0.0/255.255.0.0.

The internal networks are connected to a Cisco 2950 VLAN switch which combines traffic from the two VLANs onto one in the FortiGate unit's internal interface. The VLAN traffic leaves the FortiGate unit on the external network interface, goes on to the VLAN switch, and on to the Internet. When the FortiGate units receives a tagged packet, it directs it from the incoming VLAN subinterface to the outgoing VLAN subinterface for that VLAN.

In this example, we create a VLAN subinterface on the internal interface and another one on the external interface, both with the same VLAN ID. Then we create security policies that allow packets to travel between the VLAN_100_int interface and the VLAN_100_ext interface. Two policies are required: one for each direction of traffic. The same is required between the VLAN_200_int interface and the VLAN_200_ext interface, for a total of four security policies.



Sample configuration

There are two main steps to configure your FortiGate unit to work with VLANs in transparent mode:

1. Add VLAN subinterfaces.
2. Add security policies.

You can also configure the protection profiles that manage antivirus scanning, web filtering, and spam filtering.

To add VLAN subinterfaces:

```
config system interface
    edit VLAN_100_int
        set type vlan
        set interface internal
        set vlanid 100
    next
    edit VLAN_100_ext
        set type vlan
        set interface external
        set vlanid 100
    next
    edit VLAN_200_int
        set type vlan
        set interface internal
        set vlanid 200
    next
    edit VLAN_200_ext
        set type vlan
        set interface external
        set vlanid 200
    next
end
```

To add security policies:

```
config firewall policy
    edit 1
        set srcintf VLAN_100_int
        set srcaddr all
        set dstintf VLAN_100_ext
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 2
        set srcintf VLAN_100_ext
        set srcaddr all
        set dstintf VLAN_100_int
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
```

```
    edit 3
        set srcintf VLAN_200_int
        set srcaddr all
        set dstintf VLAN_200_ext
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 4
        set srcintf VLAN_200_ext
        set srcaddr all
        set dstintf VLAN_200_int
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
end
```

Virtual VLAN switch

The hardware switch ports on FortiGate models that support virtual VLAN switches can be used as a layer 2 switch. Virtual VLAN switch mode allows 802.1Q VLANs to be assigned to ports, and the configuration of one interface as a trunk port.

The following FortiGate series are supported in FortiOS 7.6: 40F, 60F, 70F, 80F, 90G, 100F, 120G, 200F, 300E, 400E, 400F, 600F, 900G, 1100E, 1800F, 2600F, 3000F, 3200F, 3500F, 3700F, 4200F, 4400F, and 4800F. FortiWiFi 60F models are not supported.

The `virtual-switch-vlan` option must be enabled in the CLI to configure VLAN switch mode from the GUI or CLI.

To enable VLAN switches:

```
config system global
    set virtual-switch-vlan enable
end
```

After this setting is enabled, any previously configured hardware switches will appear in the *Network > Interfaces* page under *VLAN Switch*.

To enable VLAN switch mode in the GUI:

1. Go to *System > Settings*.
2. In the *View Settings* section, enable *VLAN switch mode*.
3. Click *Apply*.

Basic configurations

Hardware switch ports can be configured as either a VLAN switch port or a trunk port. The available interfaces and allowable VLAN IDs that can be used depend on the FortiGate model. It is recommended to remove ports from the default VLAN switch before you begin configurations.

To create a new VLAN and assign ports in the GUI:

1. Go to *Network* > *Interfaces* and click *Create New* > *Interface*.
2. Enter a name and configure the following:
   a. Set the *Type* to *VLAN Switch*.
   b. Enter a *VLAN ID*.
   c. Click the *+* and add the *Interface Members*.
   d. Configure the *Address* and *Administrative Access* settings as needed.
3. Click *OK*.

To create a new VLAN and assign ports in the CLI:

1. Configure the VLAN:

```
config system virtual-switch
    edit "VLAN10"
        set physical-switch "sw0"
        set vlan 10
        config port
            edit "internal1"
            next
            edit "internal2"
            next
        end
    next
end
```

2. Configure the VLAN switch interface addressing:

```
config system interface
    edit "VLAN10"
        set vdom "root"
        set ip 192.168.10.99 255.255.255.0
        set allowaccess ping https ssh snmp http fgfm
        set type hard-switch
    next
end
```

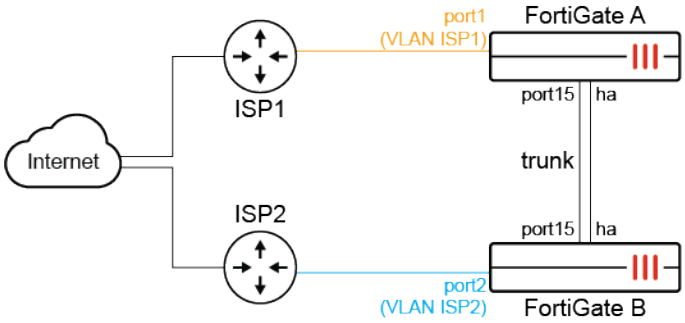
To designate an interface as a trunk port:

```
config system interface
    edit internal5
        set trunk enable
```

```
    next
end
```

Example 1: HA using a VLAN switch

In this example, two FortiGates in an HA cluster are connected to two ISP routers. Instead of connecting to external L2 switches, each FortiGate connects to each ISP router on the same hardware switch port on the same VLAN. A trunk port connects the two FortiGates to deliver the 802.1Q tagged traffic to the other. A full mesh between the FortiGate cluster and the ISP routers is achieved where no single point of failure will cause traffic disruptions.



This example assumes that the HA settings are already configured. The interface and VLAN switch settings are identical between cluster members and synchronized. See HA using a hardware switch to replace a physical switch on page 3399 for a similar example that does not use a VLAN switch.

To configure the VLAN switches:

1. Configure the ISP interfaces with the corresponding VLAN IDs:

```
config system virtual-switch
    edit "ISP1"
        set physical-switch "sw0"
        set vlan 2951
        config port
            edit "port1"
            next
        end
    next
    edit "ISP2"
        set physical-switch "sw0"
        set vlan 2952
        config port
            edit "port2"
            next
        end
    next
end
```

2. Configure the VLAN switch interface addressing:

```
config system interface
    edit "ISP1"
        set vdom "root"
        set ip 192.168.10.99 255.255.255.0
        set allowaccess ping
        set type hard-switch
    next
    edit "ISP2"
        set vdom "root"
        set ip 192.168.20.99 255.255.255.0
        set allowaccess ping
        set type hard-switch
    next
end
```

3. Designate port15 as the trunk port:

```
config system interface
    edit port15
        set trunk enable
    next
end
```

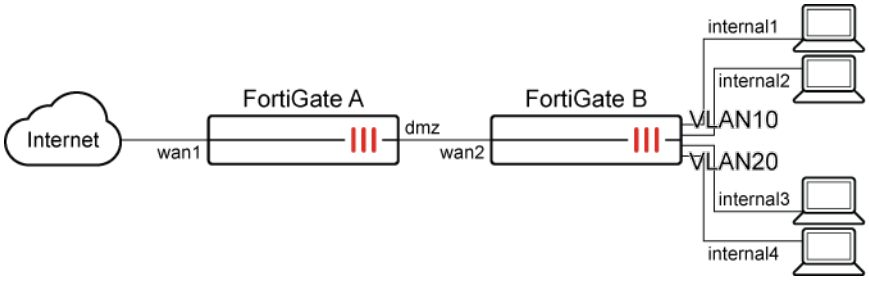
4. Configure firewall policies to allow outgoing traffic on the ISP1 and ISP2 interfaces:

```
config firewall policy
    edit 1
        set srcintf "port11"
        set dstintf "ISP1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
    edit 2
        set srcintf "port11"
        set dstintf "ISP2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Example 2: LAN extension

In this example, two hardware switch ports are assigned VLAN10, and two ports are assigned VLAN20 on FortiGate B. The wan2 interface is designated as the trunk port, and is connected to the upstream FortiGate A.

The corresponding VLAN subinterfaces VLAN10 and VLAN20 on the upstream FortiGate allow further access to other networks.



The available interfaces and VLAN IDs varies between FortiGate models. The FortiGate B in this example is a 60F model.

To configure FortiGate B:

1. Configure the VLAN interfaces:

```
config system virtual-switch
    edit "VLAN10"
        set physical-switch "sw0"
        set vlan 10
        config port
            edit "internal1"
            next
            edit "internal2"
            next
        end
    next
    edit "VLAN20"
        set physical-switch "sw0"
        set vlan 20
        config port
            edit "internal3"
            next
            edit "internal4"
            next
        end
    next
end
```

2. Configure the VLAN switch interface addressing:

```
config system interface
    edit "VLAN10"
        set vdom "root"
        set ip 192.168.10.99 255.255.255.0
        set allowaccess ping https ssh snmp http fgfm
        set type hard-switch
```

```
    next
    edit "VLAN20"
        set vdom "root"
        set ip 192.168.20.99 255.255.255.0
        set allowaccess ping https ssh snmp http fgfm
        set type hard-switch
    next
end
```

3. Designate wan2 as the trunk port:

```
config system interface
    edit wan2
        set trunk enable
    next
end
```

To configure FortiGate A:

1. Configure the VLAN subinterfaces:

```
config system interface
    edit "VLAN10"
        set ip 192.168.10.98 255.255.255.0
        set allowaccess ping https ssh
        set role lan
        set interface "dmz"
        set vlanid 10
    next
    edit "VLAN20"
        set ip 192.168.20.98 255.255.255.0
        set allowaccess ping https ssh
        set role lan
        set interface "dmz"
        set vlanid 20
    next
end
```

2. Configure the DHCP server on VLAN10:

```
config system dhcp server
    edit 0
        set dns-service default
        set default-gateway 192.168.10.98
        set netmask 255.255.255.0
        set interface "VLAN10 "
        config ip-range
            edit 1
                set start-ip 192.168.10.100
                set end-ip 192.168.10.254
            next
        end
```

```
        set timezone-option default
    next
end
```

3. Configure firewall policies that allow traffic from the VLAN10 and VLAN20 interfaces to the internet:

```
config firewall policy
    edit 0
        set name "VLAN10-out"
        set srcintf "VLAN10"
        set dstintf "wan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
    edit 0
        set name "VLAN20-out"
        set srcintf "VLAN20"
        set dstintf "wan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

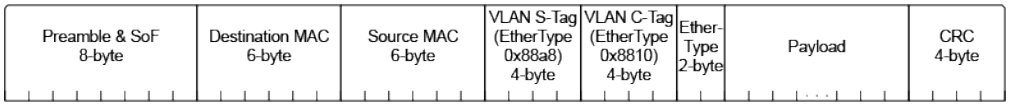
To test the connection:

1. Connect a PC to internal1 on FortiGate B.
2. Verify that it receives an IP address from FortiGate A's DHCP server.
3. From the PC, ping FortiGate B on 192.168.10.99.
4. Ping FortiGate A on 192.168.10.98.
5. Connect to the internet. Traffic is allowed by the VLAN10-out policy.

QinQ 802.1Q in 802.1ad

QinQ (802.1ad) allows multiple VLAN tags to be inserted into a single frame, and can be configured on supported FortiGate devices.

In this example, the customer connects to a provider that uses 802.1ad double-tagging to separate their customer VLANs. The FortiGate connecting to the provider double-tags its frames with an outer provider-tag (S-Tag) and an inner customer-tag (C-Tag).



The customer identifies itself with the provider-tag (S-Tag) 232 and uses the customer-tag (C-Tag) 444 for traffic to its VLAN.

QinQ is not supported on top of hardware switch interfaces.

To configure the interfaces:

1. Configure the interface to the provider that uses the outer tag (S-Tag):

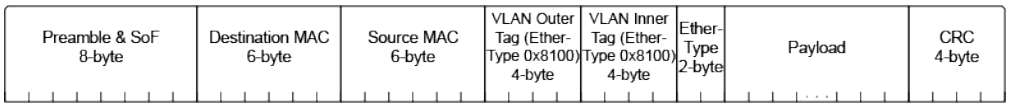
```
config system interface
    edit "vlan-8021ad"
        set vdom "root"
        set vlan-protocol 8021ad
        set device-identification enable
        set role lan
        set snmp-index 47
        set interface "PORT"
        set vlanid 232
    next
end
```

2. Configure a dynamic VLAN interface that uses the inner tag (C-Tag):

```
config system interface
    edit "DVLAN"
        set vdom "vdom1"
        set device-identification enable
        set role lan
        set snmp-index 48
        set interface "vlan-8021ad"
        set vlanid 444
    next
end
```

QinQ 802.1Q in 802.1Q

QinQ (802.1Q in 802.1Q) is supported for FortiGate VM models, where multiple VLAN tags can be inserted into a single frame.



In this example, the FortiGate VM is connected to a provider vSwitch and then a customer switch. The FortiGate encapsulates the frame with an outer 802.1Q tag of VLAN 100 and an inner 802.1Q tag of VLAN 200; port5 is used as the physical port. The provider vSwitch strips the outer tag and forwards traffic to the appropriate customer. Then the customer switch strips the inner tag and forwards the packet to the appropriate customer VLAN.

QinQ is not supported on top of hardware switch interfaces.

To configure the interfaces:

1. Configure the interface to the provider that uses the outer tag:

```
config system interface
    edit "vlan-8021q"
        set vdom "root"
        set device-identification enable
        set role lan
        set interface "port5"
        set vlan-protocol 8021q
        set vlanid 100
    next
end
```

2. Configure the interface to the provider that uses the inner tag:

```
config system interface
    edit "vlan-qinq8021q"
        set vdom "root"
        set ip 1.1.1.71 255.255.255.0
        set allowaccess ping https ssh snmp http
        set device-identification enable
        set role lan
        set interface "vlan-8021q"
        set vlanid 200
    next
end
```

To verify the traffic:

1. From the FortiGate, ping 1.1.1.72:

```
# execute ping 1.1.1.72
PING 1.1.1.72 (1.1.1.72): 56 data bytes
64 bytes from 1.1.1.72: icmp_seq=0 ttl=255 time=0.2 ms
64 bytes from 1.1.1.72: icmp_seq=1 ttl=255 time=0.1 ms
64 bytes from 1.1.1.72: icmp_seq=2 ttl=255 time=0.1 ms
64 bytes from 1.1.1.72: icmp_seq=3 ttl=255 time=0.1 ms
^C
--- 1.1.1.72 ping statistics ---
```

```
4 packets transmitted, 4 packets received, 0% packet loss
round-trip min/avg/max = 0.1/0.1/0.2 ms
```

2. Verify the packet capture frame header output captured from the FortiGate's port5:

```
Frame 2: 106 bytes on wire (848 bits), 106 bytes captured (848 bits)
Ethernet II, Src: VMware_93:ae:8f (00:50:56:93:ae:8f), Dst: VMware_93:e3:72
(00:50:56:93:e3:72)
    Destination: VMware_93:e3:72 (00:50:56:93:e3:72)
    Source: VMware_93:ae:8f (00:50:56:93:ae:8f)
    Type: 802.1Q Virtual LAN (0x8100)
802.1Q Virtual LAN, PRI: 0, DEI: 0, ID: 100
    000. .... .... .... = Priority: Best Effort (default) (0)
    ...0 .... .... .... = DEI: Ineligible
    .... 0000 0110 0100 = ID: 100
    Type: 802.1Q Virtual LAN (0x8100)
802.1Q Virtual LAN, PRI: 0, DEI: 0, ID: 200
    000. .... .... .... = Priority: Best Effort (default) (0)
    ...0 .... .... .... = DEI: Ineligible
    .... 0000 1100 1000 = ID: 200
    Type: IPv4 (0x0800)
Internet Protocol Version 4, Src: 1.1.1.71, Dst: 1.1.1.72
Internet Control Message Protocol
```

The outer tag (first tag) is an 802.1Q tag with VLAN ID 100. The inner tag (second tag) is also an 802.1Q tag with VLAN ID 200.

Aggregation and redundancy

Link aggregation (IEEE 802.3ad/802.1ax) enables you to bind two or more physical interfaces together to form an aggregated (combined) link. This new link has the bandwidth of all the links combined. If a link in the group fails, traffic is transferred automatically to the remaining interfaces. The only noticeable effect is reduced bandwidth.

This feature is similar to redundant interfaces. The major difference is a redundant interface group only uses one link at a time, where an aggregate link group uses the total bandwidth of the functioning links in the group, up to eight (or more).

An interface is available to be an aggregate interface if:

- It is a physical interface and not a VLAN interface or subinterface.
- It is not already part of an aggregate or redundant interface.
- It is in the same VDOM as the aggregated interface. Aggregate ports cannot span multiple VDOMs.
- It does not have an IP address and is not configured for DHCP or PPPoE.
- It is not referenced in any security policy, VIP, IP Pool, or multicast policy.
- It is not an HA heartbeat interface.
- It is not one of the FortiGate-5000 series backplane interfaces.

When an interface is included in an aggregate interface, it is not listed on the *Network > Interfaces* page. Interfaces still appear in the CLI although configuration for those interfaces do not take affect. You cannot

configure the interface individually and it is not available for inclusion in security policies, VIPs, IP pools, or routing.

Example configuration

This example creates an aggregate interface on a FortiGate-140D POE using ports 3-5 with an internal IP address of 10.1.1.123, as well as the administrative access to HTTPS and SSH.

To create an aggregate interface in the GUI:

1. Go to *Network* > *Interfaces* and select *Create New* > *Interface*.
2. Set *Name* to *aggregate*.
3. Set *Type* to *802.3ad Aggregate*.
4. Set *Interface members* to *port4*, *port5*, and *port6*.
5. Set *Addressing mode* to *Manual*.
6. Set *IP/Netmask* to *10.1.1.123/24*.
7. For *Administrative Access*, select *HTTPS* and *SSH*.
8. Click *OK*.

To create an aggregate interface in the CLI:

```
config system interface
    edit "aggregate"
        set vdom "root"
        set ip 10.1.1.123 255.255.255.0
        set allowaccess https ssh
        set type aggregate
        set member "port4" "port5" "port6"
        set snmp-index 45
    next
end
```

Redundancy

In a redundant interface, traffic only goes over one interface at any time. This differs from an aggregated interface where traffic goes over all interfaces for increased bandwidth. This difference means redundant interfaces can have more robust configurations with fewer possible points of failure. This is important in a fully-meshed HA configuration.

An interface is available to be in a redundant interface if:

- It is a physical interface and not a VLAN interface.
- It is not already part of an aggregated or redundant interface.
- It is in the same VDOM as the redundant interface.
- It does not have an IP address and is not configured for DHCP or PPPoE.
- It has no DHCP server or relay configured on it.
- It does not have any VLAN subinterfaces.
- It is not referenced in any security policy, VIP, or multicast policy.

- It is not monitored by HA.
- It is not one of the FortiGate-5000 series backplane interfaces.

When an interface is included in a redundant interface, it is not listed on the *Network > Interfaces* page. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, or routing.

Example configuration

To create a redundant interface in the GUI:

1. Go to *Network > Interfaces* and select *Create New > Interface*.
2. Set *Name* to *redundant*.
3. Set *Type* to *Redundant Interface*.
4. Set *Interface members* to *port4*, *port5*, and *port6*.
5. Set *Addressing mode* to *Manual*.
6. Set *IP/Netmask* to *10.13.101.100/24*.
7. For *Administrative Access*, select *HTTPS* and *SSH*.
8. Click *OK*.

To create a redundant interface in the CLI:

```
config system interface
    edit "redundant"
        set vdom "root"
        set ip 10.13.101.100 255.255.255.0
        set allowaccess https http
        set type redundant
        set member "port4" "port5" "port6"
        set snmp-index 9
    next
end
```

Enhanced hashing for LAG member selection

FortiGate models that have an internal switch that supports modifying the distribution algorithm can use enhanced hashing to help distribute traffic evenly, or load balance, across links on the Link Aggregation (LAG) interface.

The enhanced hashing algorithm is based on a 5-tuple of the IP protocol, source IP address, destination IP address, source port, and destination port.

Different computation methods allow for more variation in the load balancing distribution, in case one algorithm does not distribute traffic evenly between links across different XAUIs. The available methods are:

xor16	Use the XOR operator to make a 16 bit hash.
xor8	Use the XOR operator to make an 8 bit hash.

xor4	Use the XOR operator to make a 4 bit hash.
crc16	Use the CRC-16-CCITT polynomial to make a 16 bit hash.

The following NP6 non-service FortiGate models support this feature: 1500D, 1500DT, 3000D, 3100D, 3200D, 3700D, and 5001D.

To configure the enhanced hashing:

```
config system npu
    set lag-out-port-select {enable | disable}
    config sw-eh-hash
        set computation {xor4 | xor8 | xor16 | crc16}
        set ip-protocol {include | exclude}
        set source-ip-upper-16 {include | exclude}
        set source-ip-lower-16 {include | exclude}
        set destination-ip-upper-16 {include | exclude}
        set destination-ip-lower-16 {include | exclude}
        set source-port {include | exclude}
        set destination-port {include | exclude}
        set netmask-length {0 - 32}
    end
end
```

For example, to use XOR16 and include all of the fields in the 5-tuple to compute the link in the LAG interface that the packet is distributed to:

```
config system npu
    set lag-out-port-select enable
    config sw-eh-hash
        set computation xor16
        set ip-protocol include
        set source-ip-upper-16 include
        set source-ip-lower-16 include
        set destination-ip-upper-16 include
        set destination-ip-lower-16 include
        set source-port include
        set destination-port include
        set netmask-length 32
    end
end
```

LAG interface status signals to peer device

FortiGate can signal LAG (link aggregate group) interface status to the peer device. If the number of available links in the LAG on the FortiGate falls below the configured minimum number of links (`min-links`), the LAG interface goes down on both the FortiGate and the peer device.

When the minimum number of links is satisfied again, the LAG interface automatically resumes operation on both the FortiGate and the peer device. While the LAG interface is down, interface members are in the Link Aggregation Control Protocol (LACP) MUX state of *Waiting*.

Example

In this example, the LAG interface is configured on FGT_A and peered with FGT_B.

To verify the configuration:

1. On FGT_A, check the minimum number of links for the LAG interface named test_agg1.
   In the following example, `set min-links 1` indicates that a minimum of one alive interface member is required to keep the LAG interface up.

```
# show
config system interface
    edit "test_agg1"
        set vdom "vdom1"
        set ip 11.1.1.1 255.255.255.0
        set allowaccess ping https
        set type aggregate
        set member "port7" "port8" "port9"
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 41
        set min-links 1
    next
end
```

2. Change the status of port9 to down.

```
config system interface
    edit port9
        set status down
    next
end
```

3. On FGT_A, test the LAG interface named test_agg1.
   The status is up for test_agg1 interface because two interface members (port7 and port8) are up, and only one interface member (port9) is down.

```
# diagnose netlink aggregate name test_agg1
LACP flags: (A|P)(S|F)(A|I)(I|O)(E|D)(E|D)
(A|P) - LACP mode is Active or Passive
(S|F) - LACP speed is Slow or Fast
(A|I) - Aggregatable or Individual
(I|O) - Port In sync or Out of sync
(E|D) - Frame collection is Enabled or Disabled
(E|D) - Frame distribution is Enabled or Disabled

status: up
```

```

```

4. On FGT_A, change the minimum number of links to 3.

```
config system interface
    edit "test_agg1"
        set vdom "vdom1"
        set ip 11.1.1.1 255.255.255.0
        set allowaccess ping https
        set type aggregate
        set member "port7" "port8" "port9"
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 41
        set min-links 3
    next
end
```

5. On FGT_A, check the LAG interface named test_agg1:
   The status is down for test_agg1 interface because only two of the three required interface members are up. Interface members port7 and port8 are up, but interface member port9 is down.

```
# diagnose netlink aggregate name test_agg1

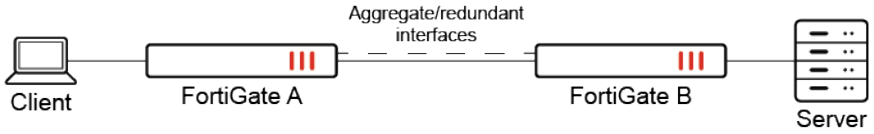
Failure detection for aggregate and redundant interfaces

When an aggregate or redundant interface goes down, the corresponding fail-alert interface changes to down. When an aggregate or redundant interface comes up, the corresponding fail-alert interface changes to up.



Fail-detect for aggregate and redundant interfaces can be configured using the CLI.

To configure an aggregate interface so that port3 goes down with it:

```
config system interface
   edit "agg1"
      set vdom "root"
      set fail-detect enable
      set fail-alert-method link-down
      set fail-alert-interfaces "port3"
      set type aggregate
      set member "port1" "port2"
   next
end
```

To configure a redundant interface so that port4 goes down with it:

```
config system interface
   edit "red1"
      set vdom "root"
      set fail-detect enable
      set fail-alert-method link-down
      set fail-alert-interfaces "port4"
      set type redundant
      set member "port1" "port2"
   next
end
```

Loopback interface

A loopback interface is a logical interface that is always up. Its IP address does not depend on one specific physical port, and the attached subnet is always present in the routing table. Therefore, it can be accessed through several physical or VLAN interfaces.

Typically, a loopback interface can be used with management access, BGP peering, PIM rendezvous points, and SD-WAN.

A loopback interface requires appropriate firewall policies to allow traffic to the interface. For example, see IPsec tunnel terminated on a loopback interface on page 229.

GRE tunnels and other IP/IPv6 tunnels, where tunnel traffic is handled before the route lookup, do not require firewall policies to allow traffic to the interface. The ingress interface is changed to the tunnel interface by the time the policy is checked.

Multiple loopback interfaces can be configured in either non-VDOM mode or in each VDOM.

Dynamic routing protocols can be enabled on loopback interfaces. For example, loopback interfaces are a good practice for OSPF. To make it easier to troubleshoot OSPF, set the OSPF router ID to the same value as the loopback IP address to access a specific FortiGate using that IP address and SSH.

A loopback interface is configured using similar steps as a physical interface (see Configuring an interface).

IPsec tunnel terminated on a loopback interface

As mentioned above, a loopback interface requires appropriate firewall policies to allow traffic to the interface. In other words, traffic ingressing on an interface that is destined for the IP address associated with a loopback interface requires an appropriate firewall policy from that interface to the loopback interface otherwise the traffic will be dropped.

For example, consider the following topology where an IPsec tunnel is terminated on a loopback interface, VPN_LO, on the FortiGate FGT-1 and on a WAN interface on the FortiGate FGT-2.

We will focus on the configuration required for FortiGate FGT-1.

IPsec tunnel terminates on a loopback interface, VPN_LO, which has an associated IP address that the remote peer will use as its IPsec remote gateway address.

The IPsec tunnel uses wan1 as its underlay interface.

In this scenario, the administrator of the FortiGate FGT-1 device must configure a firewall policy from the wan1 interface to the VPN_LO interface that allows incoming traffic from the remote peer to reach the VPN_LO interface for proper IPsec tunnel connectivity.

For example:

```
config firewall policy
    edit 4
        set name "Loopback-In"
        set srcintf "wan1"
        set dstintf "VPN_LO"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic disable
    next
end
```

Software switch

A software switch is a virtual switch that is implemented at the software or firmware level and not at the hardware level. A software switch can be used to simplify communication between devices connected to different FortiGate interfaces. For example, a software switch lets you place the FortiGate interface connected to an internal network on the same subnet as your wireless interfaces. Then devices on the internal network can communicate with devices on the wireless network without any additional configuration on the FortiGate unit, such as additional security policies.

A software switch can also be useful if you require more hardware ports for the switch on a FortiGate unit. For example, if your FortiGate unit has a 4-port switch, WAN1, WAN2, and DMZ interfaces, and you need one more port, you can create a soft switch that can include the four-port switch and the DMZ interface, all on the same subnet. These types of applications also apply to wireless interfaces, virtual wireless interfaces, and physical interfaces such as those in FortiWiFi and FortiAP units.

Similar to a hardware switch, a software switch functions like a single interface. It has one IP address, and all the interfaces in the software switch are on the same subnet. Traffic between devices connected to each interface is not regulated by security policies, and traffic passing in and out of the switch is controlled by the same policy.

When setting up a software switch, consider the following:

- Ensure that you have a back up of the configuration.
- Ensure that you have at least one port or connection, such as the console port, to connect to the FortiGate unit. If you accidentally combine too many ports, you need a way to undo errors.
- The ports that you include must not have any link or relation to any other aspect of the FortiGate unit, such as DHCP servers, security policies, and so on.
- Ensure the *Create address object matching subnet* option is disabled, if any port *Role* is set to either *LAN* or *DMZ*.
- For increased security, you can create a captive portal for the switch to allow only specific user groups access to the resources connected to the switch.

Some of the difference between software and hardware switches are:

Feature	Software switch	Hardware switch
Processing	Packets are processed in software by the CPU.	Packets are processed in hardware by the hardware switch controller, or SPU where applicable.
STP	Not Supported	Supported
Wireless SSIDs	Supported	Not Supported
Intra-switch traffic	Allowed by default. Can be explicitly set to require a policy.	Allowed by default.
Active-active HA load balancing	Not supported	Supported

To create a software switch in the GUI:

1. Go to *Network* > *Interfaces*.
2. Click *Create New* > *Interface*.
3. Set *Type* to *Software Switch*.
4. Configure the *Name*, *Interface members*, and other fields as required.
   To add an interface to a software switch, it cannot be referenced by an existing, configuration and its IP address must be set to 0.0.0.0/0.0.0.0.
5. Click *OK*.

To create a software switch in the CLI:

```
config system switch-interface
    edit <interface>
        set vdom <vdom>
        set member <interface_list>
        set type switch
    next
end
config system interface
    edit <interface>
        set vdom <vdom>
        set type switch
        set ip <ip_address>
        set allowaccess https ssh ping
    next
end
```

To add an interface to a software switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.

Example

For this example, the wireless interface (WiFi) needs to be on the same subnet as the DMZ1 interface to facilitate wireless synchronization between an iPhone and a local computer. Because synchronization between two subnets is problematic, putting both interfaces on the same subnet allows synchronization to work. The software switch will accomplish this.

1. Clear the interfaces and back up the configuration:
   a. Ensure the interfaces are not used for other security policy or for other use on the FortiGate unit.
   b. Check the WiFi and DMZ1 ports to ensure that DHCP is disabled and that there are no other dependencies on these interfaces.
   c. Save the current configuration so that it can be recovered if something goes wrong.
2. Merge the WiFi port and DMZ1 port to create a software switch named `synchro` with an IP address of 10.10.21.12 and administrative access for HTTPS, SSH and PING:

```
config system switch-interface
    edit synchro
        set vdom "root"
        set type switch
        set member dmz1 wifi
    next
end
config system interface
    edit synchro
        set ip 10.10.21.12 255.255.255.0
        set allowaccess https ssh ping
    next
end
```

After the switch is set up, add security policies, DHCP servers, and any other settings that are required.

Hardware switch

A hardware switch is a virtual switch interface that groups different ports together so that the FortiGate can use the group as a single interface. Supported FortiGate models have a default hardware switch called either *internal* or *lan*. The hardware switch is supported by the chipset at the hardware level.

Ports that are connected to the same hardware switch behave like they are on the same physical switch in the same broadcast domain. Ports can be removed from a hardware switch and assigned to another switch or used as standalone interfaces.

Some of the difference between hardware and software switches are:

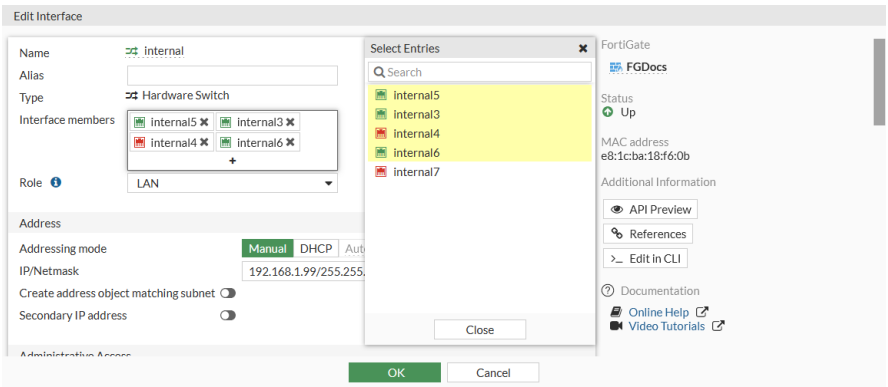
Feature	Hardware switch	Software switch
Processing	Packets are processed in hardware by the hardware switch controller, or SPU where applicable.	Packets are processed in software by the CPU.

Feature	Hardware switch	Software switch
STP	Supported	Not Supported
802.1x	Supported on the following NP6 platforms: FG-30xE, FG-40xE, and FG-110xE	Not Supported
Wireless SSIDs	Not Supported	Supported
Intra-switch traffic	Allowed by default.	Allowed by default. Can be explicitly set to require a policy.

After ports are added to a virtual switch with STP or 802.1x enabled, you can enable or disable STP or 802.1x for each member port.

To change the ports in a hardware switch in the GUI:

1. Go to *Network* > *Interface* and edit the hardware switch.
2. Click inside the *Interface members* field.



3. Select interfaces to add or remove them from the hardware switch, then click *Close*.
   To add an interface to a hardware switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.
4. Click *OK*.
   Removed interfaces will now be listed as standalone interfaces in the *Physical Interface* section.

To remove ports from a hardware switch in the CLI:

```
config system virtual-switch
    edit "internal"
        config port
            delete internal2
            delete internal7
            ...
        end
    next
end
```

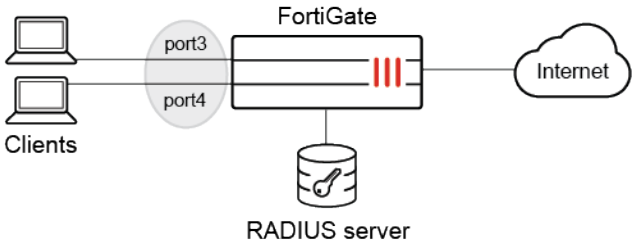
To add ports to a hardware switch in the CLI:

```
config system virtual-switch
    edit "internal"
        set physical-switch "sw0"
        config port
            edit "internal3"
            next
            edit "internal5"
            next
            edit "internal4"
            next
            edit "internal6"
            next
        end
    next
end
```

To add an interface to a hardware switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.

Example of using 802.1X on virtual switches

In this example, port3 and port4 are part of a hardware switch interface. The hardware switch acts as a virtual switch so that devices can connect directly to these ports and perform 802.1X authentication on the port.

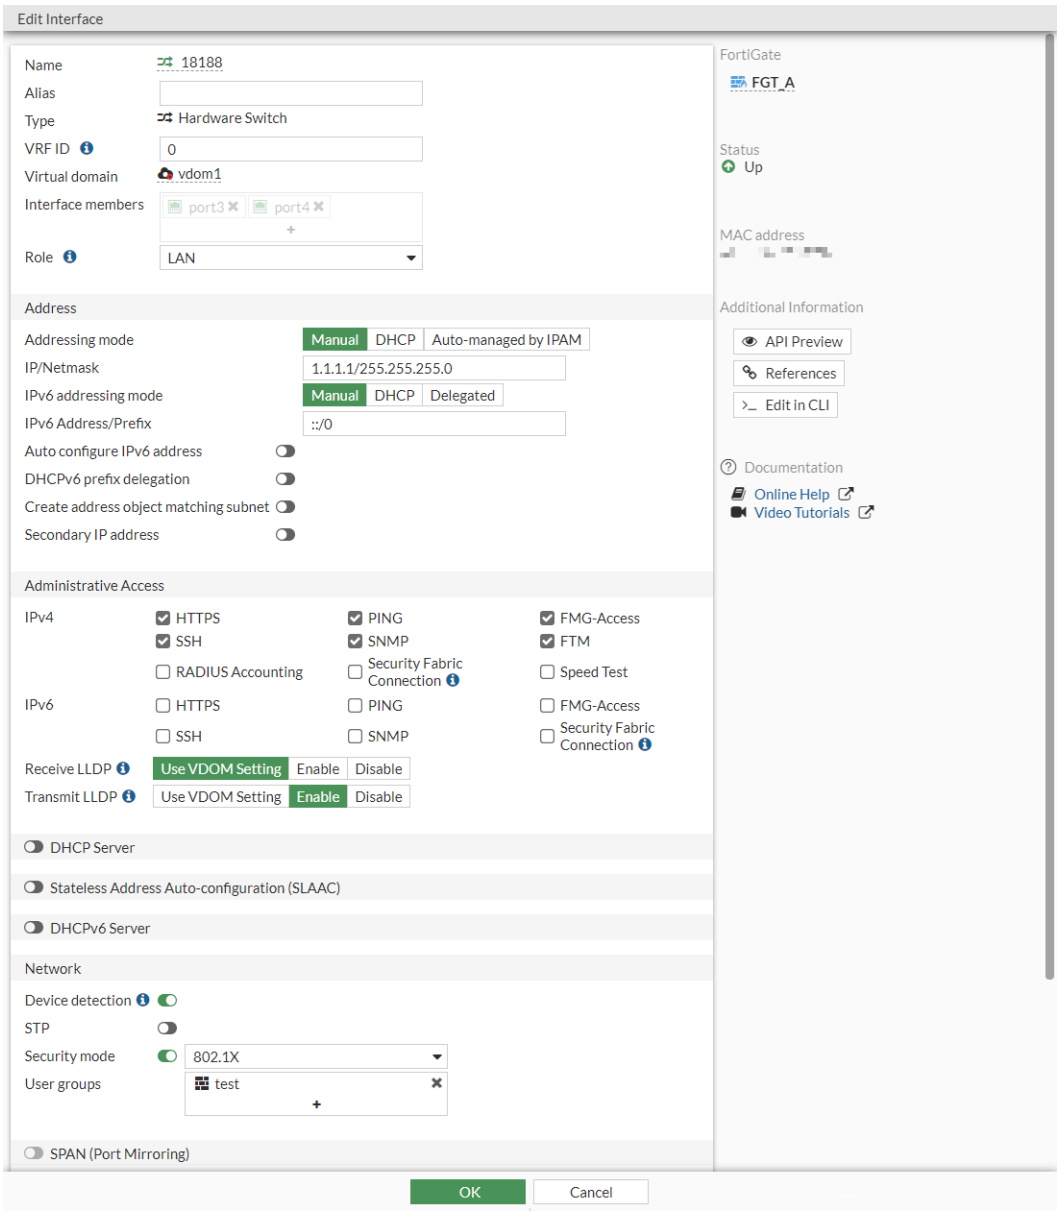


Prerequisites:

1. Configure a RADIUS server (see RADIUS servers on page 3032).
2. Define a user group named test to use the remote RADIUS server and for 802.1X authentication (see User definition, groups, and settings on page 2991).
3. Configure a hardware switch (named 18188) with port3 and port4 as the members.
4. Configure a firewall policy that allows traffic from the 18188 hardware switch to go to the internet.
5. Enable 802.1X authentication on the client devices.

To configure 802.1X authentication on a hardware switch in the GUI:

1. Go to *Network* > *Interfaces* and edit the hardware switch.
2. In the *Network* section, enable *Security mode* and select *802.1X*.
3. Click the + to add the *User group*.



4. Click *OK*.

To configure 802.1X authentication on a hardware switch in the CLI:

1. Configure the virtual hardware switch interfaces:

```
config system virtual-switch
    edit "18188"
        set physical-switch "sw0"
        config port
            edit "port3"
            next
            edit "port4"
            next
```

```
        end
    next
end
```

2. Configure 802.1X authentication:

```
config system interface
    edit "18188"
        set vdom "vdom1"
        set ip 1.1.1.1 255.255.255.0
        set allowaccess ping https ssh snmp fgfm ftm
        set type hard-switch
        set security-mode 802.1X
        set security-groups "test"
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 52
    next
end
```

To verify the that the 802.1X authentication was successful:

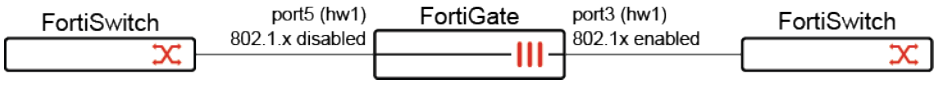
1. Get a client connected to port3 to authenticate to access the internet.
2. In FortiOS, verify the 802.1X authentication port status:

```
# diagnose sys 802-1x status

Virtual switch '18188' (default mode) 802.1x member status:
  port3: Link up, 802.1X state: authorized
  port4: Link up, 802.1X state: unauthorized
```

Example of disabling 802.1x on one port

In this example, FortiGate is connected to two switches, and a virtual switch named hw1 is configured with two port members: port3 and port5. 802.1x authentication is enabled for port3 and disabled for port5.



To configure 802.1x authentication for individual ports:

1. Configure a virtual switch to use port3 and port5:

```
config system virtual-switch
    edit "hw1"
        set physical-switch "sw0"
        config port
            edit "port3"
            next
```

```
            edit "port5"
            next
        end
    next
end
```

2. Enable 802.1x authentication for the virtual switch:

```
config system interface
   edit "hw1"
        set vdom "vdom1"
        set ip 6.6.6.1 255.255.255.0
        set allowaccess ping https ssh
        set type hard-switch
        set security-mode 802.1X
        set security-groups "group_radius"
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 55
        set ip-managed-by-fortiipam disable
    next
end
```

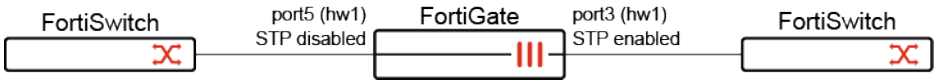
3. Disable 802.1x authentication on port5:

```
config system interface
    edit "port5"
        set vdom "vdom1"
        set type physical
        set security-8021x-member-mode disable
        set snmp-index 9
    next
end
```

802.1x authentication is disabled on port5 and remains enabled on port3.

Example of disabling STP on one port

In this example, FortiGate is connected to two switches, and a virtual switch named hw1 is configured with two port members: port3 and port5. STP is enabled for port3 and disabled for port5. Any STP sent to port5 is silently ignored. Port3 remains enabled for STP.



To configure STP for individual ports:

1. Configure a virtual switch to use port3 and port5:

```
config system virtual-switch
    edit "hw1"
        set physical-switch "sw0"
        config port
            edit "port3"
            next
            edit "port5"
            next
        end
    next
end
```

2. Enable STP for the virtual switch:

```
config system interface
    edit "hw1"
        set vdom "vdom1"
        set ip 6.6.6.1 255.255.255.0
        set allowaccess ping https ssh
        set type hard-switch
        set stp enable
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 55
        set ip-managed-by-fortiipam disable
    next
end
```

3. Disable STP on port5 by enabling it as an STP edge port:

```
config system interface
    edit "port5"
        set vdom "vdom1"
        set type physical
        set stp-edge enable
        set snmp-index 9
    next
end
```

Port5 is enabled as an edge port with STP disabled. Port3 remains enabled for STP.

Zone

Zones are a group of one or more physical or virtual FortiGate interfaces that you can apply firewall policies to for controlling inbound and outbound traffic. Grouping interfaces and VLAN subinterfaces into zones simplifies

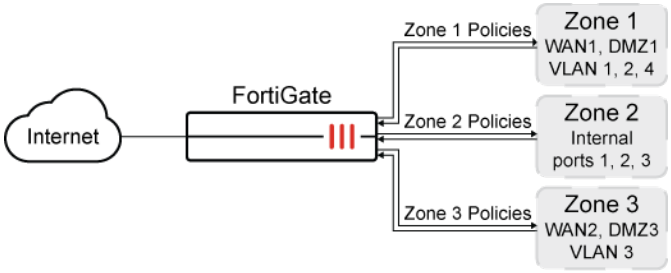
creating firewall policies where a number of network segments can use the same policy settings and protection profiles.

When you add a zone, you select the names of the interfaces and VLAN subinterfaces to add to the zone. Each interface still has its own address. Routing is still done between interfaces, that is, routing is not affected by zones. You can use firewall policies to control the flow of intra-zone traffic.

For example, in the sample configuration below, the network includes three separate groups of users representing different entities on the company network. While each group has its own set of ports and VLANs in each area, they can all use the same firewall policy and protection profiles to access the Internet. Rather than the administrator making nine separate firewall policies, he can make administration simpler by adding the required interfaces to a zone and creating three policies.

Example configuration

You can configure policies for connections to and from a zone but not between interfaces in a zone. For this example, you can create a firewall policy to go between zone 1 and zone 3, but not between WAN2 and WAN1, or WAN1 and DMZ1.



To create a zone in the GUI:

1. Go to *Network* > *Interfaces*.

   If VDOMs are enabled, go to the VDOM to create a zone.

2. Click *Create New* > *Zone*.
3. Configure the *Name* and add the *Interface Members*.
4. Enable or disable *Block intra-zone traffic* as required.
5. Click *OK*.

To configure a zone to include the interfaces WAN1, DMZ1, VLAN1, VLAN2 and VLAN4 using the CLI:

```
config system zone
    edit zone_1
        set interface WAN1 DMZ1 VLAN1 VLAN2 VLAN4
        set intrazone {deny | allow}
    next
end
```

Using zone in a firewall policy

To configure a firewall policy to allow any interface to access the Internet using the CLI:

```
config firewall policy
    edit 2
        set name "2"
        set srcintf "zone_1"
        set dstintf "port15"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Intra-zone traffic

In the zone configuration you can `set intrazone deny` to prohibit the different interfaces in the same zone to talk to each other.

For example, if you have ten interfaces in your zone and the `intrazone` setting is `deny`. You now want to allow traffic between a very small number of networks on different interfaces that are part of the zone but you do not want to disable the intra-zone blocking.

In this example, the zone VLANs are defined as: `192.168.1.0/24`, `192.168.2.0/24`, ... `192.168.10.0/24`.

This policy allows traffic from 192.168.1.x to 192.168.2.x even though they are in the same zone and intra-zone blocking is enabled. The intra-zone blocking acts as a default deny rule and you have to specifically override it by creating a policy within the zone.

To enable intra-zone traffic, create the following policy:

Source Interface	Zone-name, e.g., `Vlans`
Source Address	192.168.1.0/24
Destination	Zone-name (same as Source Interface, i.e., `Vlans`)
Destination Address	192.168.2.0/24

Virtual wire pair

A virtual wire pair consists of two interfaces that do not have IP addressing and are treated like a transparent mode VDOM. All traffic received by one interface in the virtual wire pair can only be forwarded to the other interface, provided a virtual wire pair firewall policy allows this traffic. Traffic from other interfaces cannot be routed to the interfaces in a virtual wire pair. Redundant and 802.3ad aggregate (LACP) interfaces can be included in a virtual wire pair.

Virtual wire pairs are useful for a typical topology where MAC addresses do not behave normally. For example, port pairing can be used in a Direct Server Return (DSR) topology where the response MAC address pair may not match the request's MAC address pair.

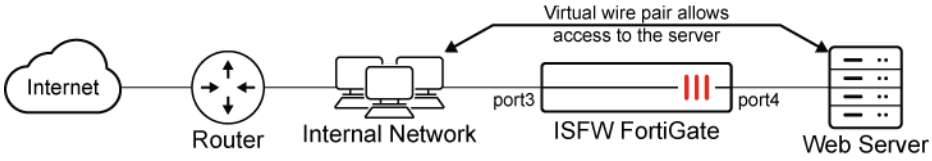
When creating a new virtual wire pair, the *Interface members* field displays interfaces without assigned addresses. Interfaces with assigned addresses are not displayed.

Therefore, you cannot add to a virtual wire pair an interface with *Addressing mode* set to *DHCP*. If you change the interface settings to *Manual* with *IP/Netmask* set to *0.0.0.0/0.0.0.0*, you can add the interface to a virtual wire pair.

Example

In this example, a virtual wire pair (port3 and port4) makes it easier to protect a web server that is behind a FortiGate operating as an Internal Segmentation Firewall (ISFW). Users on the internal network access the web server through the ISFW over the virtual wire pair.

Interfaces used in a virtual wire pair cannot be used to access the ISFW FortiGate. Before creating a virtual wire pair, make sure you have a different port configured to allow admin access using your preferred protocol.



To add a virtual wire pair using the GUI:

1. Go to *Network* > *Interfaces*.
2. Click *Create New* > *Virtual Wire Pair*.
3. Enter a name for the virtual wire pair.
4. Select the *Interface Members* to add to the virtual wire pair (*port3* and *port 4*).
   These interfaces cannot be part of a switch, such as the default LAN/internal interface.
5. If required, enable *Wildcard VLAN* and set the *VLAN Filter*.
6. Click *OK*.

To add a virtual wire pair using the CLI:

```
config system virtual-wire-pair
    edit "VWP-name"
        set member "port3" "port4"
        set wildcard-vlan disable
    next
end
```

To create a virtual wire pair policy using the GUI:

1. Go to *Policy & Objects* > *Firewall Virtual Wire Pair Policy*.
2. Click *Create New*.
3. In the *Virtual Wire Pair* field, click the + to add the virtual wire pair.
4. Select the direction (arrows) that traffic is allowed to flow.
5. Configure the other settings as needed.
6. Click *OK*.

To create a virtual wire pair policy using the CLI:

```
config firewall policy
    edit 1
        set name "VWP-Policy"
        set srcintf "port3" "port4"
        set dstintf "port3" "port4"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set fsso disable
    next
end
```

Configuring multiple virtual wire pairs in a virtual wire pair policy

You can create a virtual wire pair policy that includes different virtual wire pairs in NGFW profile and policy mode. This reduces overhead to create multiple similar policies for each VWP. In NGFW policy mode, multiple virtual wire pairs can be configured in a *Security Virtual Wire Pair Policy* and *Virtual Wire Pair SSL Inspection & Authentication* policy.

The virtual wire pair settings must have wildcard VLAN enabled. When configuring a policy in the CLI, the virtual wire pair members must be entered in `srcintf` and `dstintf` as pairs.

To configure multiple virtual wire pairs in a policy in the GUI:

1. Configure the virtual wire pairs:
   a. Go to *Network* > *Interfaces* and click *Create New* > *Virtual Wire Pair*.
   b. Create a pair with the following settings:

Name	test-vwp-1
Interface members	wan1, wan2
Wildcard VLAN	Enable

   c. Click *OK*.
   d. Click *Create New* > *Virtual Wire Pair* and create another pair with the following settings:

Name	test-vwp-2
Interface members	port19, port20
Wildcard VLAN	Enable

e. Click *OK*.

2. Configure the policy:
   a. Go to *Policy & Objects* > *Firewall Virtual Wire Pair Policy* and click *Create New*.
   b. In the *Virtual Wire Pair* field, click the *+* to add *test-vwp-1* and *test-vwp-2*. Select the direction for each of the selected virtual wire pairs.

   c. Configure the other settings as needed.
   d. Click *OK*.

To configure multiple virtual wire pairs in a policy in the CLI:

1. Configure the virtual wire pairs:

```
config system virtual-wire-pair
    edit "test-vwp-1"
        set member "wan1" "wan2"
        set wildcard-vlan enable
    next
    edit "test-vwp-2"
        set member "port19" "port20"
        set wildcard-vlan enable
    next
end
```

2. Configure the policy:

```
config firewall policy
    edit 1
        set name "vwp1&2-policy"
        set srcintf "port19" "wan1"
        set dstintf "port20" "wan2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
end
```

PRP handling in NAT mode with virtual wire pair

PRP (Parallel Redundancy Protocol) is supported in NAT mode for a virtual wire pair. This preserves the PRP RCT (redundancy control trailer) while the packet is processed by the FortiGate.

To configure PRP handling on a device in NAT mode:

1. Enable PRP in the VDOM settings:

```
(root) # config system settings
    set prp-trailer-action enable
end
```

2. Enable PRP in the NPU attributes:

```
(global) # config system npu
    set prp-port-in "port15"
    set prp-port-out "port16"
end
```

3. Configure the virtual wire pair:

```
(root) # config system virtual-wire-pair
    edit "test-vwp-1"
        set member "port15" "port16"
    next
end
```

Using VLAN sub-interfaces in virtual wire pairs

VLAN sub-interfaces, such as regular 802.1Q and 802.1ad (QinQ), are allowed to be members of a virtual wire pair.

Example

In this example, the FortiGate has two VLAN interfaces. The first interface is a QinQ (802.1ad) interface over the physical interface port3. The second interface is a basic 802.1Q VLAN interface over physical interface port5. These two interfaces are grouped in a virtual wire pair so that bi-directional traffic is allowed. This example demonstrates ICMP from the client (3.3.3.4) sent to the server (3.3.3.1).

To configure VLAN sub-interfaces in a virtual wire pair:

1. Configure the QinQ interfaces:

```
config system interface
    edit "8021ad-port3"
        set vdom "vdom1"
        set vlan-protocol 8021ad
        set device-identification enable
        set role lan
        set snmp-index 31
        set interface "port3"
        set vlanid 3
    next
    edit "8021Q"
        set vdom "vdom1"
        set device-identification enable
        set role lan
        set snmp-index 32
        set interface "8021ad-port3"
        set vlanid 33
    next
end
```

2. Configure the 802.1Q interface:

```
config system interface
    edit "8021q-port5"
        set vdom "vdom1"
        set device-identification enable
        set role lan
        set snmp-index 33
        set interface "port5"
        set vlanid 5
    next
end
```

3. Configure the virtual wire pair:

```
config system virtual-wire-pair
    edit "VWP1"
```

```
        set member "8021Q" "8021q-port5"
    next
end
```

4. Configure the firewall policy:

```
config firewall policy
    edit 1
        set name "1"
        set srcintf "8021Q" "8021q-port5"
        set dstintf "8021Q" "8021q-port5"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
    next
end
```

To verify that bi-directional traffic passes through the FortiGate:

```
# diagnose sys session filter policy  1
# diagnose sys session list

session info: proto=1 proto_state=00 duration=18 expire=42 timeout=0 flags=00000000 socktype=0
sockport=0 av_idx=0 use=3

DVLAN QinQ on NP7 platforms over virtual wire pairs

DVLAN 802.1ad and 802.1Q modes are supported on NP7 platforms over virtual wire pairs, which provides better performance and packet processing.

The default DVLAN mode is 802.1ad, but the DVLAN mode can be changed using `diagnose npu np7 dvlan-mode <dvlan_mode> {<npid> | all}`. The DVLAN mode can be applied to a specific NPID or all NPIDs. For example:

- `diagnose npu np7 dvlan-mode 802.1AD 0` will set NP0 to work in 802.1ad mode.
- `diagnose npu np7 dvlan-mode 802.1Q all` will set all NPUs to work in 802.1Q mode.

A reboot is required for custom DVLAN settings to take effect. To avoid any inconveniences or disruptions, changing the DVLAN settings should be done during a scheduled downtime or maintenance window.

The DVLAN mode should only be changed if you are solely using the virtual wire pair (VWP) and are seeking to enhance performance. Enabling this feature may impact VLAN interfaces within your network.

In the virtual wire pair settings, the `outer-vlan-id` can be set. This is the same value as the outer provider-tag (S-Tag).

To configure the outer VLAN ID:

```
config system virtual-wire-pair
    edit "dvlan-test"
        set member "port33" "port34"
        set wildcard-vlan enable
        set outer-vlan-id 1234
    next
end
```

Enhanced MAC VLAN

The Media Access Control (MAC) Virtual Local Area Network (VLAN) feature in Linux allows you to configure multiple virtual interfaces with different MAC addresses (and therefore different IP addresses) on a physical interface.

FortiGate implements an enhanced MAC VLAN consisting of a MAC VLAN with bridge functionality. Because each MAC VLAN has a unique MAC address, virtual IP addresses (VIPs) and IP pools are supported, and you can disable Source Network Address Translation (SNAT) in policies.

MAC VLAN cannot be used in a transparent mode virtual domain (VDOM). In a transparent mode VDOM, a packet leaves an interface with the MAC address of the original source instead of the interface's MAC address. FortiGate implements an enhanced version of MAC VLAN where it adds a MAC table in the MAC VLAN which learns the MAC addresses when traffic passes through.

If you configure a VLAN ID for an enhanced MAC VLAN, it won't join the switch of the underlying interface. When a packet is sent to this interface, a VLAN tag is inserted in the packet and the packet is sent to the driver of the underlying interface. When the underlying interface receives a packet, if the VLAN ID doesn't match, it won't deliver the packet to this enhanced MAC VLAN interface.

When using a VLAN ID, the ID and the underlying interface must be a unique pair, even if the belong to different VDOMs. This is because the underlying, physical interface uses the VLAN ID as the identifier to dispatch traffic among the VLAN and enhanced MAC VLAN interfaces.

If you use an interface in an enhanced MAC VLAN, do not use it for other purposes such as a management interface, HA heartbeat interface, or in Transparent VDOMs.

If a physical interface is used by an EMAC VLAN interface, you cannot use it in a Virtual Wire Pair.

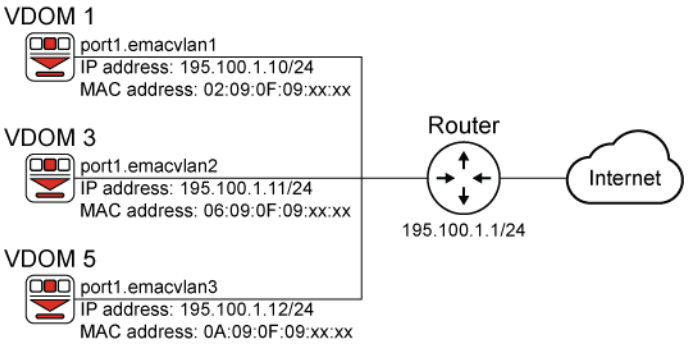
In high availability (HA) configurations, enhanced MAC VLAN is treated as a physical interface. It's assigned a unique physical interface ID and the MAC table is synchronized with the secondary devices in the same HA cluster.

In HA configurations, FortiGate assigns a virtual MAC to each interface. Virtual interfaces, such as EMAC VLAN interfaces with underlying NPU VLINK interface, are an exception and do not get assigned virtual MAC addresses.

Example 1: Enhanced MAC VLAN configuration for multiple VDOMs that use the same interface or VLAN

In this example, a FortiGate is connected, through port 1 to a router that's connected to the Internet. Three VDOMs share the same interface (port 1) which connects to the same router that's connected to the Internet. Three enhanced MAC VLAN interfaces are configured on port 1 for the three VDOMs. The enhanced MAC VLAN interfaces are in the same IP subnet segment and each have unique MAC addresses.

The underlying interface (port 1) can be a physical interface, an aggregate interface, or a VLAN interface on a physical or aggregate interface.



To configure enhanced MAC VLAN for this example in the CLI:

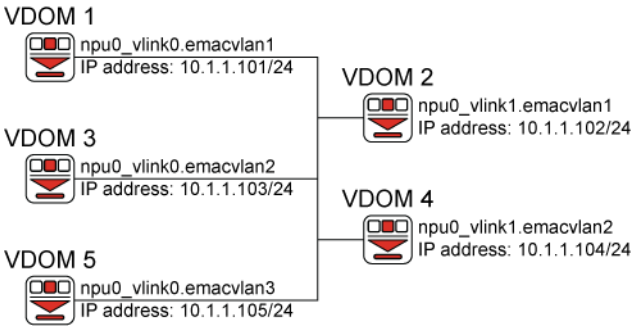
```
config system interface
    edit port1.emacvlan1
        set vdom VDOM1
        set type emac-vlan
        set interface port1
    next
```

```
    edit port 1.emacvlan2
        set vdom VDOM2
        set type emac-vlan
        set interface port1
    next
    edit port1.emacvlan3
        set vdom VDOM3
        set type emac-vlan
        set interface port1
    next
end
```

Example 2: Enhanced MAC VLAN configuration for shared VDOM links among multiple VDOMs

In this example, multiple VDOMs can connect to each other using enhanced MAC VLAN on network processing unit (NPU) virtual link (Vlink) interfaces.

FortiGate VDOM links (NPU-Vlink) are designed to be peer-to-peer connections and VLAN interfaces on NPU Vlink ports use the same MAC address. Connecting more than two VDOMs using NPU Vlinks and VLAN interfaces is not recommended as the VLAN interfaces share the same MAC address. To avoid overlapping MAC addresses on the same NPU Vlink, use EMAC VLANs instead.



To configure enhanced MAC VLAN for this example in the CLI:

```
config system interface
    edit npu0_vlink0.emacvlan1
        set vdom VDOM1
        set type emac-vlan
        set interface npu0_vlink0
    next
    edit npu0_vlink0.emacvlan2
        set vdom VDOM3
        set type emac-vlan
        set interface npu0_vlink0
    next
    edit npu0_vlink1.emacvlan1
        set vdom VDOM2
        set type emac-vlan
```

```
        set interface npu0_vlink1
    next
end
```

Example 3: Enhanced MAC VLAN configuration for unique MAC addresses for each VLAN interface on the same physical port

Some networks require a unique MAC address for each VLAN interface when the VLAN interfaces share the same physical port. In this case, the enhanced MAC VLAN interface is used the same way as normal VLAN interfaces.

To configure this, use the `set vlanid` command for the VLAN tag. The VLAN ID and interface must be a unique pair, even if they belong to different VDOMs.

To configure enhanced MAC VLAN:

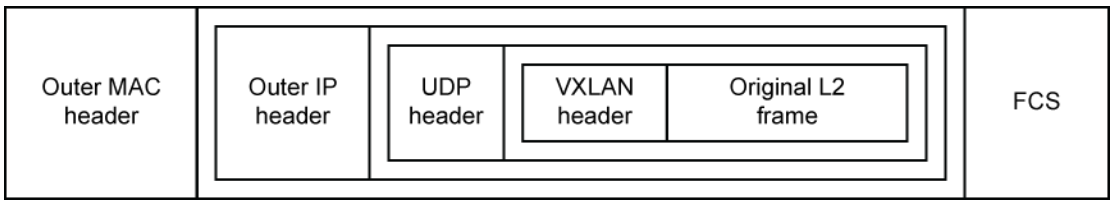
```
config system interface
    edit <interface-name>
        set type emac-vlan
        set vlanid <VLAN-ID>
        set interface <physical-interface>
    next
end
```

FortiGate supports a maximum of 512 EMAC VLAN interfaces per underlying interface, and a maximum of 600 MAC addresses including EMAC VLAN interfaces.

VXLAN

Virtual Extensible LAN (VXLAN) is a network virtualization technology used in large cloud computing deployments. It encapsulates layer 2 Ethernet frames within layer 3 IP packets using the UDP transport protocol on port 4789. VXLAN endpoints that terminate VXLAN tunnels can be virtual or physical switch ports, and are known as VXLAN tunnel endpoints (VTEPs).

Sample VXLAN packet



A VXLAN packet encapsulation occurs by first inserting a VXLAN header in front of the original layer 2 frame. This VXLAN header uses 3 B for the VNID that is used to identify the VXLAN segment, meaning that there are

16,777,215 different possible VNIDs. This allows for more unique LAN segments than possible VLANs. The original frame and the VXLAN header are then encapsulated into the UDP payload. The outer IP header allows it to be routed and transported over a layer 3 network, thus providing a layer 2 overlay scheme over a layer 3 network.

This equates to 50 B of overhead over the original frame: 14 B (Ethernet) + 20 B (IPv4) + 8 B (UDP) + 8 B (VXLAN headers). Since fragmenting a VXLAN packet is not recommended, it is advisable to increase the MTU size to 1550 B or above if possible, or to decrease the TCP MSS size inside a firewall policy.

For more information about VXLAN, see RFC 7348.

The following topics provide information about VXLAN:

- General VXLAN configuration and topologies on page 251
- VLAN inside VXLAN on page 255
- Virtual wire pair with VXLAN on page 257
- VXLAN over IPsec tunnel with virtual wire pair on page 259
- VXLAN over IPsec using a VXLAN tunnel endpoint on page 264
- VXLAN with MP-BGP EVPN on page 269
- VXLAN troubleshooting on page 282

General VXLAN configuration and topologies

This topic describes general VXLAN configurations and commonly used topologies. In the most basic configuration, a FortiGate is configured as a VXLAN tunnel endpoint (VTEP).

To configure a FortiGate as a VTEP:

1. Configure the local interface:

```
config system vxlan
    edit <name>
        set interface <string>
        set vni <integer>
        set ip-version {ipv4-unicast | ipv6-unicast | ipv4-multicast | ipv6-multicast}
        set dstport <integer>
        set remote-ip <IP_address>
        set remote-ip6 <IP_address>
    next
end
```

`interface <string>`	Set the local outgoing interface for the VXLAN encapsulated traffic.
`vni <integer>`	Set the VXLAN network ID.
`ip-version {ipv4-unicast | ipv6-unicast | ipv4-multicast | ipv6-multicast}`	Set the IP version to use for the VXLAN device and communication over VXLAN (default = ipv4-unicast).
`dstport <integer>`	Set the VXLAN destination port (default = 4789).

`remote-ip <IP_address>`	Set the IPv4 address of the remote VXLAN endpoint.
`remote-ip6 <IP_address>`	Set the IPv6 address of the remote VXLAN endpoint.

The VXLAN system interface is automatically created with a `vxlan` type.

2. Configure the VXLAN interface settings:

```
config system interface
    edit <name>
        set vdom <string>
        set type vxlan
        set ip <IP_address>
        set allowaccess {ping https ssh http telnet fgfm radius-acct probe-response fabric ftm
speed-test}
    next
end
```

3. Connect the internal interface and VXLAN interface to the same L2 network.
   - Connect using a software switch:

```
config system switch-interface
    edit <name>
        set vdom <string>
        set member <member_1> <member_2> ... <member_n>
        set intra-switch-policy {implicit | explicit}
    next
end
```

`member <member_1> <member_2> ... <member_n>`	Enter the VXLAN interface and other physical or virtual interfaces that will share the L2 network. When adding an interface member to a software switch, it cannot have an IP address or be referenced in any other settings. For newly created VLAN interfaces, it is advised to change the role from LAN to undefined so that an address is not automatically assigned.
`intra-switch-policy {implicit | explicit}`	Allow any traffic between switch interfaces or require firewall policies to allow traffic between switch interfaces: • `implicit`: traffic between switch members is implicitly allowed. • `explicit`: traffic between switch members must match firewall policies (explicit firewall policies are required to allow traffic between members). When in explicit mode, traffic can be offloaded to SOC4/SOC5/NP6/NP7 processors.

   - Connect using a virtual wire pair:

```
config system virtual-wire-pair
    edit <name>
        set member <member_1> <member_2>
        set wildcard-vlan {enable | disable}
        set vlan-filter <filter>
```

```
    next
end
```

`member <member_1> <member_2>`	Enter the VXLAN interface and other physical or virtual interface that will share the L2 network.
`wildcard-vlan {enable | disable}`	Enable/disable wildcard VLAN. Disable to prevent VLAN-tagged traffic between the members of the virtual wire pair (default). Enable for VLAN tags to be allowed between the members.
`vlan-filter <filter>`	When wildcard-vlan is enabled, set the VLAN filter to specify which VLANs are allowed. By default, an empty vlan-filter allows all VLANs.

4. If using a virtual wire pair, configure a firewall policy that allows bi-directional traffic between the members of the virtual wire pair and inspection between them:

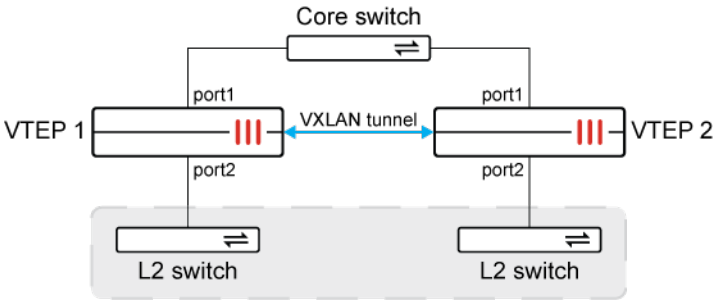
```
config firewall policy
    edit <id>
        set name <name>
        set srcintf <member_1> <member_2>
        set dstintf <member_1> <member_2>
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
    next
end
```

Topologies

Many topologies can be deployed with VXLAN. A FortiGate can connect to VXLAN endpoints that are Fortinet devices or devices from other vendors. In the following topologies, it is assumed that at least one of the VTEPs is a FortiGate. The second VTEP can be any vendor.

Basic VXLAN between two VTEPs

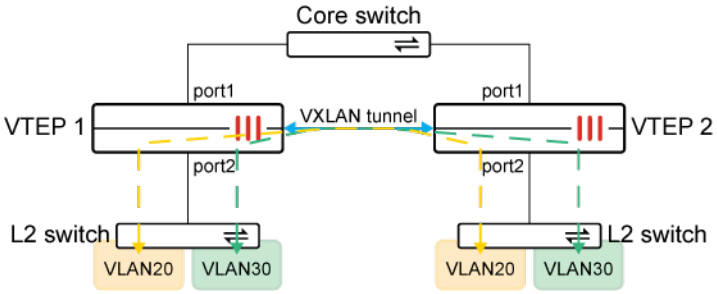
In this topology, a FortiGate (VTEP 1) is configured with a VXLAN interface over port1 where the `remote-ip` points to port1 of VTEP 2. The VXLAN interface and port2 can be associated with the same L2 network by making them members of either a software switch or a virtual wire pair. Devices under the L2 switches are part of the same L2 network.



See Virtual wire pair with VXLAN on page 257 for an example configuration.

VXLAN between two VTEPs with wildcard VLANs

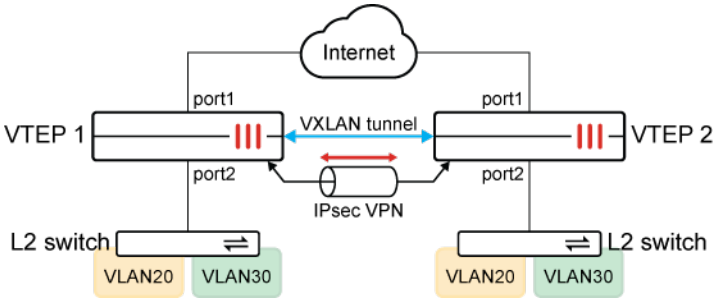
In this topology, a FortiGate (VTEP 1) is configured with a VXLAN interface over port1 where the `remote-ip` points to port1 of VTEP 2. The VXLAN interface is combined with port2 into the same L2 network using a virtual wire pair. The virtual wire pair allows wildcard VLANs to pass, which allows VLAN tags to be encapsulated over VXLAN. As a result, VLANs can span different switches over VXLAN.



Variations of these two scenarios can also be found in FortiGate to FortiSwitch FortiLink connections over VXLAN. See Deployment procedures in the FortiSwitch VXLAN Deployment Guide for example configurations.

VXLAN between two VTEPs over IPsec

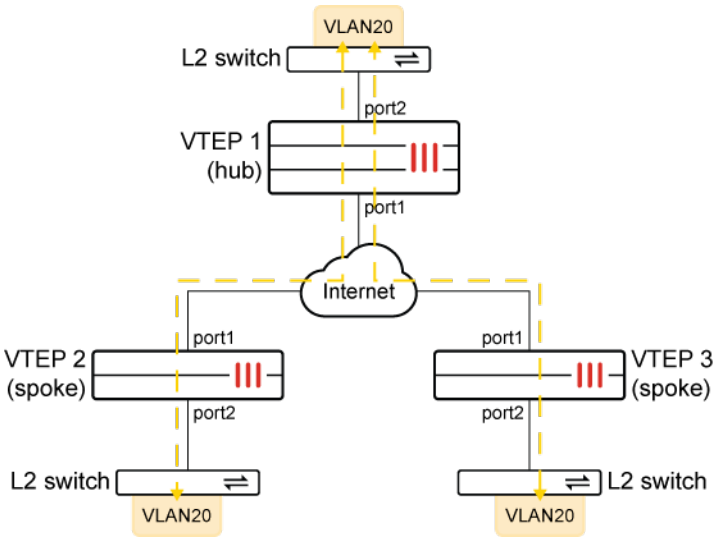
In scenarios where VTEPs are located in different sites and traffic must be secured between the sites, VXLAN will need to be encrypted over IPsec. The VXLAN interface must use the IPsec interface as its outgoing interface. The `remote-ip` must be configured as the IP of the remote IPsec gateway. The VXLAN interface can be combined with port2 into the same L2 network using a software switch or virtual wire pair. Devices under the L2 switches can communicate with each other.



See VXLAN over IPsec tunnel with virtual wire pair on page 259 for an example configuration. A variation of this scenario is explained in FortiGate LAN extension on page 854 and in FortiExtender as FortiGate LAN extension (FortiExtender FortiGate-Managed Administration Guide).

VXLAN between multiple VTEPs in an IPsec hub and spoke topology

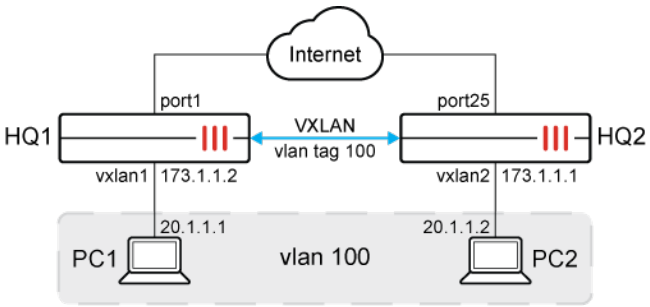
In this topology, an IPsec VPN hub and spoke overlay network is already configured between sites. To allow networks behind the hub and spokes to be connected together, each spoke has a VXLAN connection to the hub, and the hub allows interconnection between its private network and each of the VXLAN interfaces to the spokes. In this scenario, the private networks behind each spoke are actually on the same L2 network as the private network behind the hub.



See VXLAN over IPsec using a VXLAN tunnel endpoint on page 264 for an example configuration.

VLAN inside VXLAN

VLANs can be assigned to VXLAN interfaces. In a data center network where VXLAN is used to create an L2 overlay network and for multitenant environments, a customer VLAN tag can be assigned to VXLAN interface. This allows the VLAN tag from VLAN traffic to be encapsulated within the VXLAN packet.



To configure VLAN inside VXLAN on HQ1:

1. Configure VXLAN:

```
config system vxlan
   edit "vxlan1"
      set interface port1
      set vni 1000
      set remote-ip 173.1.1.1
```

```
   next
end
```

2. Configure system interface:

```
config system interface
   edit vlan100
     set vdom root
     set vlanid 100
     set interface dmz
   next
   edit vxlan100
     set type vlan
     set vlanid 100
     set vdom root
     set interface vxlan1
   next
end
```

3. Configure software-switch:

```
config system switch-interface
   edit sw1
      set vdom root
      set member vlan100 vxlan100
      set intra-switch-policy implicit
   next
end
```

The default `intra-switch-policy implicit` behavior allows traffic between member interfaces within the switch. Therefore, it is not necessary to create firewall policies to allow this traffic.

Instead of creating a software-switch, it is possible to use a virtual-wire-pair as well. See Virtual wire pair with VXLAN on page 257.

To configure VLAN inside VXLAN on HQ2:

1. Configure VXLAN:

```
config system vxlan
   edit "vxlan2"
      set interface port25
      set vni 1000
      set remote-ip 173.1.1.2
   next
end
```

2. Configure system interface:

```
config system interface
      edit vlan100
      set vdom root
      set vlanid 100
      set interface port20
   next
   edit vxlan100
      set type vlan
```

```
        set vlanid 100
        set vdom root
        set interface vxlan2
    next
end
```

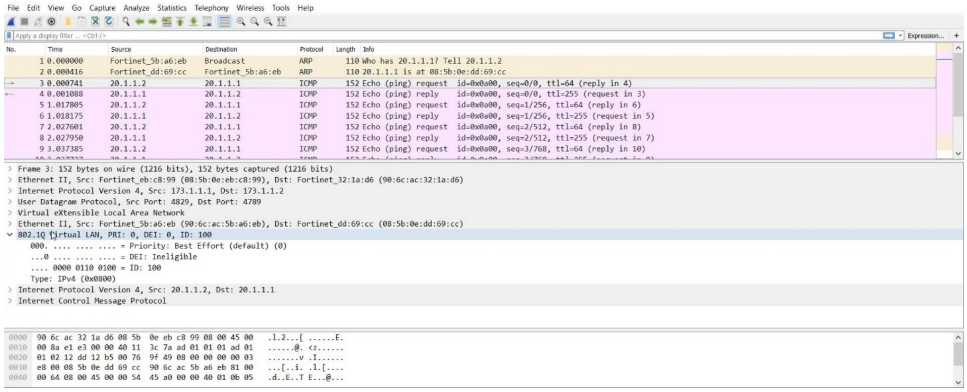
3. Configure software-switch:

```
config system switch-interface
    edit sw1
        set vdom root
        set member vlan100 vxlan100
    next
end
```

To verify the configuration:

Ping PC1 from PC2.

The following is captured on HQ2:

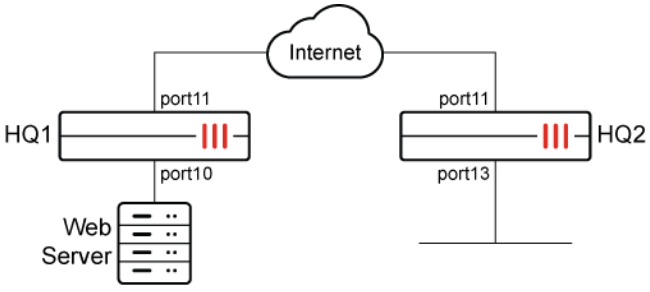


This captures the VXLAN traffic between 172.1.1.1 and 172.1.1.2 with the VLAN 100 tag inside.

Virtual wire pair with VXLAN

Virtual wire pairs can be used with VXLAN interfaces.

In this examples, VXLAN interfaces are added between FortiGate HQ1 and FortiGate HQ2, a virtual wire pair is added in HQ1, and firewall policies are created on both HQ1 and HQ2.



To create VXLAN interface on HQ1:

```
config system interface
    edit "port11"
        set vdom "root"
        set ip 10.2.2.1 255.255.255.0
        set allowaccess ping https ssh snmp telnet
    next
end
config system vxlan
    edit "vxlan1"
        set interface "port11"
        set vni 1000
        set remote-ip "10.2.2.2"
    next
end
```

To create VXLAN interface on HQ2:

```
config system interface
    edit "port11"
        set vdom "root"
        set ip 10.2.2.2 255.255.255.0
        set allowaccess ping https ssh snmp http
    next
end
config system vxlan
    edit "vxlan1"
        set interface "port11"
        set vni 1000
        set remote-ip "10.2.2.1"
    next
end
config system interface
    edit "vxlan1"
        set vdom "root"
        set ip 10.1.100.2 255.255.255.0
        set allowaccess ping https ssh snmp
    next
end
```

To create a virtual wire pair on HQ1:

```
config system virtual-wire-pair
    edit "vwp1"
        set member "port10" "vxlan1"
    next
end
```

To create a firewall policy on HQ1:

```
config firewall policy
    edit 5
        set name "vxlan-policy"
        set srcintf "port10" "vxlan1"
        set dstintf "port10" "vxlan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set av-profile "default"
        set webfilter-profile "default"
        set dnsfilter-profile "default"
        set ips-sensor "default"
        set application-list "default"
        set fsso disable
    next
end
```

To create a firewall policy on HQ2:

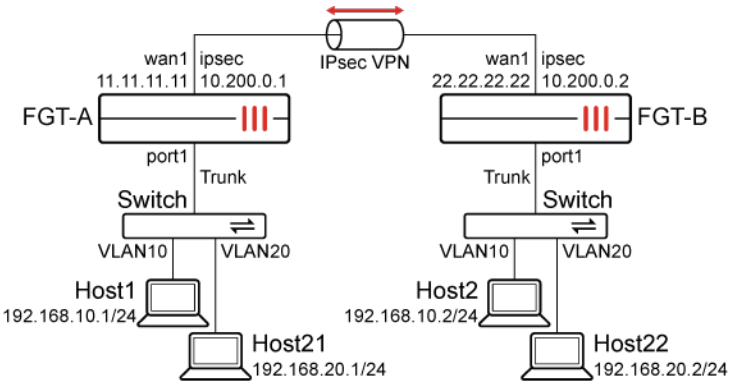
```
config firewall policy
    edit 5
        set name "1"
        set srcintf "port13"
        set dstintf "vxlan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set fsso disable
        set nat enable
    next
end
```

VXLAN over IPsec tunnel with virtual wire pair

VXLAN can be used to encapsulate VLAN traffic over a Layer 3 network. Using IPsec VPN tunnels to secure a connection between two sites, VXLAN can encapsulate VLAN traffic over the VPN tunnel to extend the VLANs between the two sites.

In this example, a site-to-site VPN tunnel is formed between two FortiGates. A VXLAN is configured over the IPsec interface. Multiple VLANs are connected to a switch behind each FortiGate. Host1 and Host2 are connected to VLAN10 on the switches on each site, and Host21 and Host22 are connected to VLAN20. Using

virtual wire pairs, the internal interface (port1) will be paired with the VXLAN interface (vxlan) to allow VLAN traffic to pass through in either direction.



To configure FGT-A:

1. Configure the WAN interface:

```
config system interface
    edit "wan1"
        set vdom "root"
        set ip 11.11.11.11 255.255.255.0
        set allowaccess ping https ssh http fgfm
        set type physical
        set role wan
        set snmp-index 1
    next
end
```

2. Configure a static route to send all traffic out the WAN interface:

```
config router static
    edit 1
        set gateway 11.11.11.1
        set device "wan1"
    next
end
```

3. Configure the IPsec tunnel:

```
config vpn ipsec phase1-interface
    edit "ipsec"
        set interface "wan1"
        set peertype any
        set proposal aes256-sha1
        set remote-gw 22.22.22.22
        set psksecret **********
    next
end
config vpn ipsec phase2-interface
    edit "ipsec"
```

```
        set phase1name "ipsec"
        set proposal aes256-sha1
        set auto-negotiate enable
    next
end
```

4. Configure local and remote IP addresses for the IPsec interface:

```
config system interface
    edit "ipsec"
        set ip 10.200.0.1 255.255.255.255
        set remote-ip 10.200.0.2 255.255.255.252
    next
end
```

5. Configure the VXLAN interface and bind it to the IPsec interface:

```
config system vxlan
    edit "vxlan"
        set interface "ipsec"
        set vni 10
        set remote-ip "10.200.0.2"
    next
end
```

The remote IP address is the address of the remote IPsec peer.

6. Configure a virtual wire pair with the port1 and vxlan interfaces as members:

```
config system virtual-wire-pair
    edit "vwp"
        set member "port1" "vxlan"
        set wildcard-vlan enable
    next
end
```

The interfaces added to the virtual wire pair cannot be part of a switch, such as the default internal interface.

By enabling wildcard VLANs on the virtual wire pair, all VLAN tagged traffic that is allowed by the virtual wire pair firewall policies passes through the pair.

7. Configure a virtual wire pair firewall policy to allow traffic between the port1 and vxlan interfaces:

```
config firewall policy
    edit 4
        set name "vwp-pol"
        set srcintf "port1" "vxlan"
        set dstintf "port1" "vxlan"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
```

```
   next
end
```

To configure FGT-B

1. Configure the WAN interface:

```
config system interface
    edit "wan1"
        set vdom "root"
        set ip 22.22.22.22 255.255.255.0 255.255.255.0
        set allowaccess ping https ssh http fgfm
        set type physical
        set role wan
        set snmp-index 1
    next
end
```

2. Configure a static route to send all traffic out the WAN interface:

```
config router static
    edit 1
        set gateway 22.22.22.2
        set device "wan1"
    next
end
```

3. Configure the IPsec tunnel:

```
config vpn ipsec phase1-interface
    edit "ipsec"
        set interface "wan1"
        set peertype any
        set proposal aes256-sha1
        set remote-gw 11.11.11.11
        set psksecret **********
    next
end
config vpn ipsec phase2-interface
    edit "ipsec"
        set phase1name "ipsec"
        set proposal aes256-sha1
        set auto-negotiate enable
    next
end
```

4. Configure local and remote IP addresses for the IPsec interface:

```
config system interface
    edit "ipsec"
        set ip 10.200.0.2 255.255.255.255
        set remote-ip 10.200.0.1 255.255.255.252
```

```
    next
end
```

5. Configure the VXLAN interface and bind it to the IPsec interface:

```
config system vxlan
    edit "vxlan"
        set interface "ipsec"
        set vni 10
        set remote-ip "10.200.0.1"
    next
end
```

   The remote IP address is the address of the remote IPsec peer.

6. Configure a virtual wire pair with the port1 and vxlan interfaces as members:

```
config system virtual-wire-pair
    edit "vwp"
        set member "port1" "vxlan"
        set wildcard-vlan enable
    next
end
```

7. Configure a firewall policy to allow traffic between the port1 and vxlan interfaces:

```
config firewall policy
    edit 4
        set name "vwp-pol"
        set srcintf "port1" "vxlan"
        set dstintf "port1" "vxlan"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
    next
end
```

Test the configuration

To test the configuration, ping Host2 (VLAN10: 192.168.10.2/24) from Host1 (VLAN10: 192.168.10.1/24):

```
C:\>ping 192.168.10.2

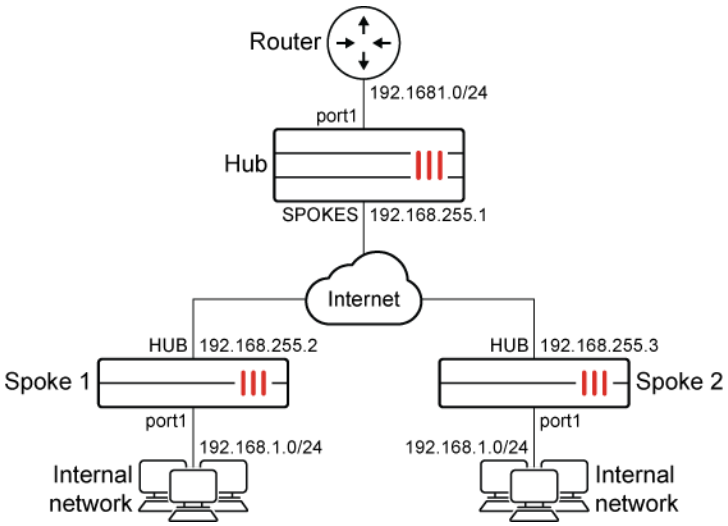
Pinging 192.168.10.2 with 32 bytes of data:
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=11ms TTL=56
```

```
Ping statistics for 192.168.10.2:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 8ms, Maximum = 11ms, Average = 8ms
```

Host21 should also be able to ping Host22.

VXLAN over IPsec using a VXLAN tunnel endpoint

This example describes how to implement VXLAN over IPsec VPN using a VXLAN tunnel endpoint (VTEP).



This example uses a hub and spoke topology. Dialup VPN is used because it allows a single phase 1 dialup definition on the hub FortiGate. Additional spoke tunnels are added with minimal changes to the hub by adding a user account and VXLAN interface for each spoke. Spoke-to-spoke communication is established through the hub. This example assumes that the authentication users and user groups have already been created. While this topology demonstrates hub and spoke with dialup tunnels with XAuth authentication, the same logic can be applied to a static VPN with or without XAuth.

IPsec tunnel interfaces are used to support VXLAN tunnel termination. An IP address is set for each tunnel interface. Ping access is allowed for troubleshooting purposes.

VTEPs are created on the hub and each spoke to forward VXLAN traffic through the IPsec tunnels. VXLAN encapsulates OSI layer 2 Ethernet frames within layer 3 IP packets. You will need to either combine the internal port1 and VXLAN interface into a soft switch, or create a virtual wire pair so that devices behind port1 have direct layer 2 access to remote peers over the VXLAN tunnel. This example uses a switch interface on the hub and a virtual wire pair on the spokes to demonstrate the two different methods.

In order to apply an IPsec VPN interface on the VXLAN interface setting, `net-device` must be disabled in the IPsec VPN phase 1 settings.

To configure the hub FortiGate:

1. Configure the IPsec phase 1 interface:

```
config vpn ipsec phase1-interface
    edit "SPOKES"
        set type dynamic
        set interface "port2"
        set mode aggressive
        set peertype one
        set net-device disable
        set proposal aes256-sha256
        set xauthtype auto
        set authusrgrp "SPOKES"
        set peerid "SPOKES"
        set psksecret <secret>
    next
end
```

2. Configure the IPsec phase 2 interface:

```
config vpn ipsec phase2-interface
    edit "SPOKES"
        set phase1name "SPOKES"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm aes256gcm
chacha20poly1305
    next
end
```

3. Configure the IPsec VPN policy that allows VXLAN traffic between the spokes:

```
config firewall policy
    edit 1
        set name "VXLAN_SPOKE_to_SPOKE"
        set srcintf "SPOKES"
        set dstintf "SPOKES"
        set srcaddr "NET_192.168.255.0"
        set dstaddr "NET_192.168.255.0"
        set action accept
        set schedule "always"
        set service "UDP_4789"
        set logtraffic all
        set fsso disable
    next
end
```

4. Configure the IPsec tunnel interfaces (the remote IP address is not used, but it is necessary for this configuration):

```
config system interface
    edit "SPOKES"
        set vdom "root"
        set ip 192.168.255.1 255.255.255.255
```

```
        set allowaccess ping
        set type tunnel
        set remote-ip 192.168.255.254 255.255.255.0
        set snmp-index 12
        set interface "port2"
    next
end
```

5. Configure the VXLAN interfaces. Each spoke requires a VXLAN interface with a different VNI. The remote IP is the tunnel interfaces IP of the spokes.
   a. Spoke 1:

```
config system VXLAN
    edit "SPOKES_VXLAN1"
        set interface "SPOKES"
        set vni 1
        set remote-ip "192.168.255.2"
    next
end
```

   b. Spoke 2:

```
config system VXLAN
    edit "SPOKES_VXLAN2"
        set interface "SPOKES"
        set vni 2
        set remote-ip "192.168.255.3"
    next
end
```

To configure the spoke FortiGates:

1. Configure the IPsec phase 1 interface:

```
config vpn ipsec phase1-interface
    edit "HUB"
        set interface "port2"
        set mode aggressive
        set peertype any
        set net-device disable
        set proposal aes256-sha256
        set localid "SPOKES"
        set xauthtype client
        set authusr "SPOKE1"
        set authpasswd <secret>
        set remote-gw <hub public IP>
        set psksecret <secret>
    next
end
```

2. Configure the IPsec phase 2 interface:

```
config vpn ipsec phase2-interface
    edit "HUB"
        set phase1name "HUB"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm aes256gcm
chacha20poly1305
        set auto-negotiate enable
        set src-subnet 192.168.255.2 255.255.255.255
    next
end
```

The hub FortiGate inserts a reverse route pointing to newly established tunnel interfaces for any of the subnets that the spoke FortiGate's source quick mode selectors provides. This is why you should set the tunnel IP address here.

3. Configure the IPsec VPN policy:

```
config firewall policy
    edit 1
        set name "VTEP_IPSEC_POLICY"
        set srcintf "HUB"
        set dstintf "HUB"
        set srcaddr "none"
        set dstaddr "none"
        set action accept
        set schedule "always"
        set service "PING"
        set logtraffic disable
        set fsso disable
    next
end
```

4. Configure the IPsec tunnel interface:

```
config system interface
    edit "HUB"
        set vdom "root"
        set ip 192.168.255.2 255.255.255.255
        set allowaccess ping
        set type tunnel
        set remote-ip 192.168.255.1 255.255.255.0
        set snmp-index 12
        set interface "port2"
    next
end
```

5. Configure the VXLAN interfaces (the remote IP is the tunnel interface IP of the hub):
   a. Spoke 1:

```
config system VXLAN
    edit "HUB_VXLAN"
        set interface "HUB"
```

```
        set vni 1
        set remote-ip "192.168.255.1"
    next
end
```

b. Spoke 2:

```
config system VXLAN
    edit "HUB_VXLAN"
        set interface "HUB"
        set vni 2
        set remote-ip "192.168.255.1"
    next
end
```

To bind the VXLAN interface to the internal interface:

1. Configure a switch interface on the hub:

```
config system switch-interface
    edit "SW"
        set vdom "root"
        set member "port1" "SPOKES_VXLAN1" "SPOKES_VXLAN2"
        set intra-switch-policy {implicit | explicit}
    next
end
```

Allowing intra-switch traffic is implicitly allowed by default. Use `set intra-switch-policy explicit` to require firewall policies to allow traffic between switch interfaces.

2. Configure a virtual wire pair on the spokes:

```
config system virtual-wire-pair
    edit "VWP"
        set member "HUB_VXLAN" "port1"
    next
end
```

The virtual wire pair requires an explicit policy to allow traffic between interfaces.

To test the configuration:

1. Ping the hub FortiGate from the spoke FortiGate:

```
user@pc-spoke1:~$ ping 192.168.1.1 -c 3
PING 192.168.1.1 (192.168.1.1) 56(84) bytes of data.
```

```
64 bytes from 192.168.1.1: icmp_seq=1 ttl=64 time=1.24 ms
64 bytes from 192.168.1.1: icmp_seq=2 ttl=64 time=0.672 ms
64 bytes from 192.168.1.1: icmp_seq=3 ttl=64 time=0.855 ms
--- 192.168.1.1 ping statistics ---
3 packets transmitted, 3 received, 0% packet loss, time 2002 ms
rtt min/avg/max/mdev = 0.672/0.923/1.243/0.239 ms
```

2. Sniff traffic on the hub FortiGate:

```
# diagnose sniffer packet any 'icmp or (udp and port 4789)' 4 0
interfaces=[any] filters=[icmp or (udp and port 4789)]
15:00:01.438230 SPOKES in 192.168.255.2.4790 -&gt; 192.168.255.1.4789: udp 106
15:00:01.438256 SPOKES_VXLAN1 in 192.168.1.2 -&gt; 192.168.1.1: icmp: echo request
15:00:01.438260 port1 out 192.168.1.2 -&gt; 192.168.1.1: icmp: echo request
15:00:01.438532 port1 in 192.168.1.1 -&gt; 192.168.1.2: icmp: echo reply
15:00:01.438536 SPOKES_VXLAN1 out 192.168.1.1 -&gt; 192.168.1.2: icmp: echo reply
15:00:01.438546 SPOKES out 192.168.255.1.4851 -&gt; 192.168.255.2.4789: udp 106
```

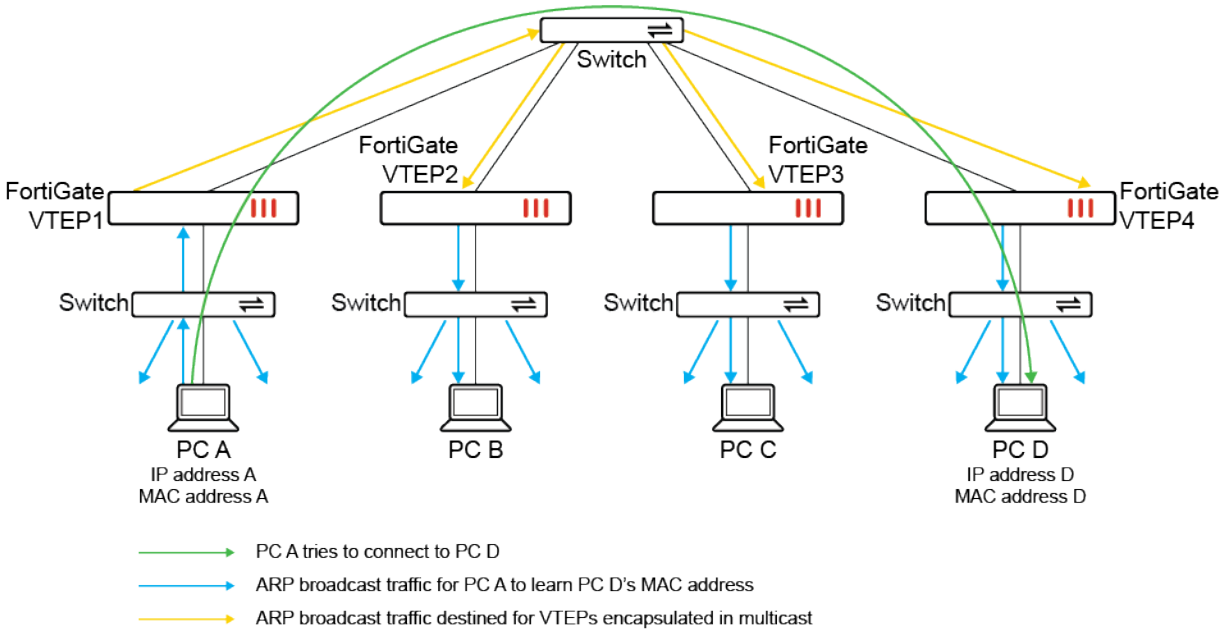
VXLAN with MP-BGP EVPN

FortiOS supports VXLAN as implemented according to RFC 7348. Currently, VXLAN relies on determining the MAC address of the destination host by using address resolution protocol (ARP) broadcast frames encapsulated in multicast packets.

- A multicast group is maintained with all the VXLAN tunnel endpoints (VTEPs) associated with the same VXLAN, namely, with the same VXLAN network identifier (VNI).
- The multicast packets that encapsulate ARP broadcast frames are sent to this multicast group, and then the destination host replies to the source host using unicast IP packet encapsulated using VXLAN.
- The source and destination FortiGates as VTEPs each maintain a mapping of MAC addresses to remote VTEPs.

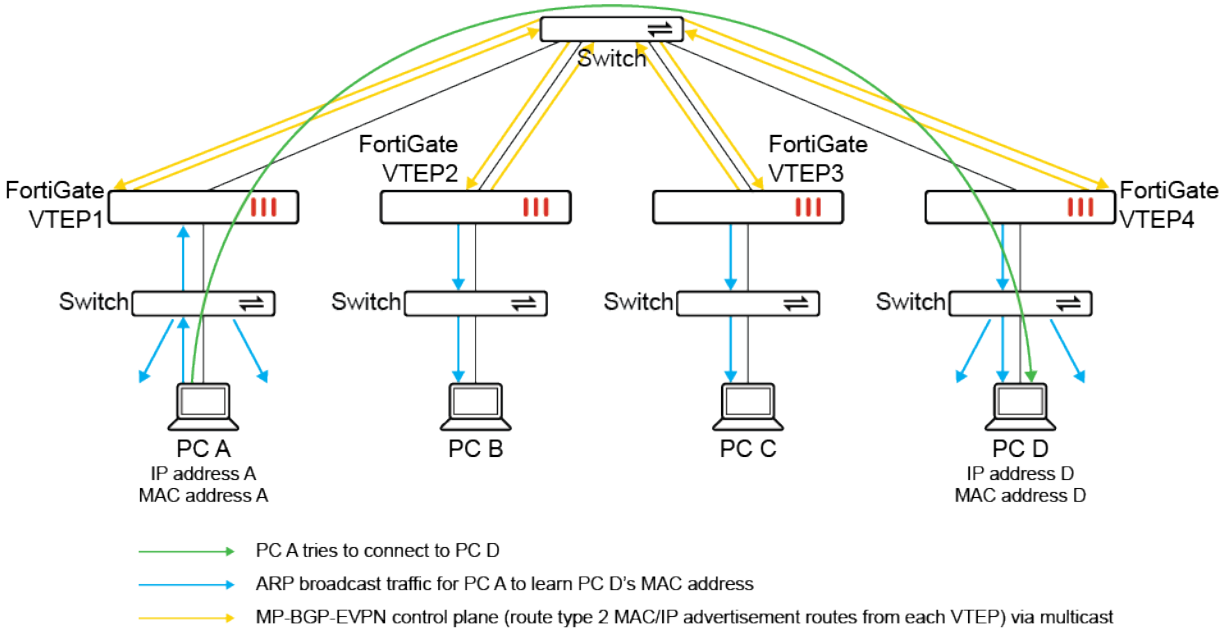
As with non-VXLAN traffic, VXLAN relies on the preceding ARP process, commonly known as flood-and-learn that floods the network with broadcast frames encapsulated as multicast packets to learn MAC addresses. In the RFC 7348 implementation of VXLAN, the data plane is simultaneously used as a control plane.

The following topology demonstrates how flood-and-learn uses ARP broadcast traffic flooded throughout the VXLAN for PC A to learn PC D's MAC address when PC A tries to connect to PC D.



Multiprotocol Border Gateway Protocol Ethernet Virtual Private Network (MP-BGP EVPN) support for VXLAN allows for learning MAC addresses in a way that is more suitable for large deployments than flood-and-learn.

MP-BGP EVPN is a standards-based control plane that supports the distribution of attached host MAC and IP addresses using MP-BGP, namely, using the EVPN address family and MAC addresses treated as routing entries in BGP. As a control plane that is separate from the data plane, MP-BGP EVPN avoids flood-and-learn in the network, and the wide use of BGP as an external gateway protocol on the internet proves its ability to scale well with large deployments. The following topology demonstrates how MP-BGP EVPN distributes route type 2 MAC/IP advertisement routes among VTEPs in the VXLAN, and minimizes ARP broadcast traffic required for PC A to learn PC D's MAC address when PC A tries to connect to PC D.



MP-BGP EVPN supports the following features:

- Route type 2 (MAC/IP advertisement route) and route type 3 (inclusive multicast Ethernet tag route)
- Intra-subnet communication
- Single-homing use cases
- VLAN-based service, namely, there is only one broadcast domain per EVPN instance (EVI). This is due to the current VXLAN design that supports a single VNI for a VXLAN interface.
- EVPN running on IPv4 unicast VXLAN
- Egress replication for broadcast, unknown unicast, and multicast (BUM) traffic
- VXLAN MAC learning from traffic
- IP address local learning
- ARP suppression

For more information about MP-BGP EVPN, see RFC 7432. For more information about EVPN and VXLAN, see RFC 8365.

Currently, MP-BGP EVPN supports only VRF 0.

Basic MP-BGP EVPN configuration

The MP-BGP EVPN feature builds on the CLI commands used for configuring VXLAN using a VXLAN tunnel endpoint (VTEP). See General VXLAN configuration and topologies on page 251 for more details.

After configuring VXLAN using a VTEP, the following CLI commands are configured to enable MP-BGP EVPN on each VTEP.

To configure MP-BGP EVPN on each VTEP:

1. Configure the EVPN settings:

```
config system evpn
    edit <id>
        set rd {AA | AA:NN | A.B.C.D:NN}
        set import-rt <AA:NN>
        set export-rt <AA:NN>
        set ip-local-learning {enable | disable}
        set arp-suppression {enable | disable}
    next
end
```

The `ip-local-learning` setting is used to enable/disable monitoring the local ARP table of the switch interface to learn the IP/MAC bindings, and advertise them to neighbors. This setting is disabled by default, but must be enabled when configuring MP-BGP EVPN.

The `arp-suppression` setting is used to enable/disable using proxy ARP to perform suppression of ARP discovery using the flood-and-learn approach. This setting is disabled by default. When enabled, proxy ARP entries are added on the switch interface to suppress the ARP flooding of known IP/MAC bindings, which were learned by the MP-BGP EVPN control plane.

2. Configure the EVPN settings within the VXLAN settings:

```
config system vxlan
    edit <name>
        set interface <string>
        set vni <integer>
        set evpn-id <integer>
        set learn-from-traffic {enable | disable}
    next
end
```

The `learn-from-traffic` setting is used to enable/disable learning of remote VNIs from VXLAN traffic. This setting is disabled by default, and should only be enabled when local and all remote peers are using same VNI value, and some of the peers do not have MP-BGP EVPN capability.

3. Configure the BGP settings:

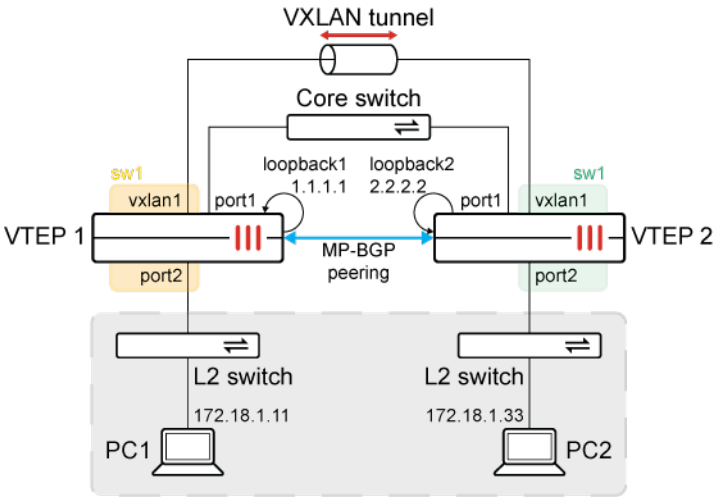
```
config router bgp
    set ibgp-multipath {enable | disable}
    set recursive-next-hop {enable | disable}
    set graceful-restart {enable | disable}
    config neighbor
        edit <WAN_IP_of_other_VTEP>
            set ebgp-enforce-multihop {enable | disable}
            set next-hop-self {enable | disable}
            set next-hop-self-vpnv4 {enable | disable}
            set soft-reconfiguration {enable | disable}
            set soft-reconfiguration-evpn {enable | disable}
            set remote-as <AS_number>
        next
    end
end
```

4. Configure the EVPN setting within the HA settings:

```
config system ha
    set evpn-ttl <integer>
end
```

Example

In this example, two FortiGates are configured as VXLAN tunnel endpoints (VTEPs). A VXLAN is configured to allow L2 connectivity between the networks behind each FortiGate. The VXLAN interface vxlan1 and port2 are placed on the same L2 network using a software switch (sw1). An L2 network is formed between PC1 and PC2. MP-BGP EVPN is used as the control plane to learn and distribute MAC address information within a single L2 domain identified using a specific VNI.



The VTEPs have the following MAC address tables:

Interface/endpoint	VTEP1	VTEP2
vxlan1	82:51:d1:44:bf:93	d2:21:00:c9:e6:98
port2	50:00:00:03:00:01	50:00:00:04:00:01
sw1	50:00:00:03:00:01	50:00:00:04:00:01

The MAC address of PC1 is 00:50:00:00:06:00. The MAC address of PC2 is 00:50:00:00:07:00.

This example assumes that the WAN interface and default route settings have already been configured on the VTEP 1 and VTEP 2 FortiGates. These configurations are omitted from the example. All peers are configured for MP-BGP EVPN.

To configure the VTEP1 FortiGate:

1. Configure the loopback interface:

```
config system interface
    edit "loopback1"
        set vdom "root"
        set ip 1.1.1.1 255.255.255.255
        set allowaccess ping https ssh http
        set type loopback
    next
end
```

2. Configure the EVPN settings:

```
config system evpn
    edit 100
        set rd "100:100"
        set import-rt "1:1"
        set export-rt "1:1"
        set ip-local-learning enable
```

```
        set arp-suppression enable
    next
end
```

3. Configure the local interface and EVPN settings within the VXLAN settings:

```
config system vxlan
    edit "vxlan1"
        set interface "loopback1"
        set vni 1000
        set evpn-id 100
    next
end
```

4. Configure the EVPN settings within the BGP settings:

```
config router bgp
    set as 65001
    set router-id 1.1.1.1
    set ibgp-multipath enable
    set recursive-next-hop enable
    set graceful-restart enable
    config neighbor
        edit "172.25.160.101"
            set ebgp-enforce-multihop enable
            set next-hop-self enable
            set next-hop-self-vpnv4 enable
            set soft-reconfiguration enable
            set soft-reconfiguration-evpn enable
            set remote-as 65001
        next
    end
    config network
        edit 1
            set prefix 1.1.1.1 255.255.255.255
        next
    end
end
```

172.27.16.237 is the WAN IP address of the VTEP2 FortiGate.

5. Configure the software switch:

```
config system switch-interface
    edit "sw1"
        set vdom "root"
        set member "port2" "vxlan1"
        set intra-switch-policy explicit
    next
end
```

6. Configure the software switch interface settings:

```
config system interface
    edit "sw1"
        set vdom "root"
        set ip 172.18.1.253 255.255.255.0
        set allowaccess ping
        set type switch
    next
end
```

7. Configure the firewall policies between the member interfaces in the software switch:

```
config firewall policy
     edit 1
         set srcintf "port2"
         set dstintf "vxlan1"
         set action accept
         set srcaddr "all"
         set dstaddr "all"
         set schedule "always"
         set service "ALL"
     next
     edit 2
         set srcintf "vxlan1"
         set dstintf "port2"
         set action accept
         set srcaddr "all"
         set dstaddr "all"
         set schedule "always"
         set service "ALL"
     next
end
```

To configure the VTEP2 FortiGate:

1. Configure the loopback interface:

```
config system interface
    edit "loopback2"
        set vdom "root"
        set ip 2.2.2.2 255.255.255.255
        set allowaccess ping https ssh http
        set type loopback
    next
end
```

2. Configure the EVPN settings:

```
config system evpn
    edit 100
        set rd "100:100"
        set import-rt "1:1"
        set export-rt "1:1"
```

```
        set ip-local-learning enable
        set arp-suppression enable
    next
end
```

3. Configure the local interface and EVPN settings within the VXLAN settings:

```
config system vxlan
    edit "vxlan1"
        set interface "loopback2"
        set vni 1000
        set evpn-id 100
    next
end
```

4. Configure the EVPN settings within the BGP settings:

```
config router bgp
    set as 65001
    set router-id 2.2.2.2
    set ibgp-multipath enable
    set recursive-next-hop enable
    set graceful-restart enable
    config neighbor
        edit "172.25.160.100"
            set ebgp-enforce-multihop enable
            set next-hop-self enable
            set next-hop-self-vpnv4 enable
            set soft-reconfiguration enable
            set soft-reconfiguration-evpn enable
            set remote-as 65001
        next
    end
    config network
        edit 1
            set prefix 2.2.2.2 255.255.255.255
        next
    end
end
```

172.27.16.236 is the WAN IP address of the VTEP1 FortiGate.

5. Configure the software switch:

```
config system switch-interface
    edit "sw1"
        set vdom "root"
        set member "port2" "vxlan1"
        set intra-switch-policy explicit
    next
end
```

6. Configure the software switch interface settings:

```
config system interface
    edit "sw1"
        set vdom "root"
        set ip 172.18.1.254 255.255.255.0
        set allowaccess ping
        set type switch
    next
end
```

7. Configure the firewall policies between the member interfaces in the software switch:

```
config firewall policy
     edit 1
         set srcintf "port2"
         set dstintf "vxlan1"
         set action accept
         set srcaddr "all"
         set dstaddr "all"
         set schedule "always"
         set service "ALL"
     next
     edit 2
         set srcintf "vxlan1"
         set dstintf "port2"
         set action accept
         set srcaddr "all"
         set dstaddr "all"
         set schedule "always"
         set service "ALL"
     next
end
```

To verify the MP-BGP EVPN status on the VTEP1 FortiGate:

1. From a host computer with IP address 172.18.1.11, perform the following.
   a. Check the ARP cache:

```
# arp
Address                  HWtype  HWaddress           Flags Mask            Iface
172.18.1.253             ether   50:00:00:03:00:01   C                     ens3
```

   b. Ping the host computer with IP address 172.18.1.33:

```
# ping 172.18.1.33 -c 4
PING 172.18.1.33 (172.18.1.33) 56(84) bytes of data.
64 bytes from 172.18.1.33: icmp_seq=1 ttl=64 time=1325 ms
64 bytes from 172.18.1.33: icmp_seq=2 ttl=64 time=319 ms
64 bytes from 172.18.1.33: icmp_seq=3 ttl=64 time=3.96 ms
64 bytes from 172.18.1.33: icmp_seq=4 ttl=64 time=1.66 ms

--- 172.18.1.33 ping statistics ---
```

```
4 packets transmitted, 4 received, 0% packet loss, time 3007ms
rtt min/avg/max/mdev = 1.660/412.614/1325.209/542.530 ms
```

c. Check the ARP cache again:

```
# arp
Address                  HWtype  HWaddress           Flags Mask            Iface
172.18.1.33              ether   00:50:00:00:07:00   C                     ens3
172.18.1.253             ether   50:00:00:03:00:01   C                     ens3
```

2. On the VTEP1 FortiGate, run the switch and VXLAN debug commands.

a. Verify the forwarding database for vxlan1:

```
# diagnose sys vxlan fdb list vxlan1
mac=00:00:00:00:00:00 state=0x0082 remote_ip=2.2.2.2 port=4789 vni=1000 ifindex0
mac=00:50:00:00:07:00 state=0x0082 remote_ip=2.2.2.2 port=4789 vni=1000 ifindex0

total fdb num: 2
```

b. Verify the forwarding database statistics for vxlan1:

```
# diagnose sys vxlan fdb stat vxlan1
fdb_table_size=256 fdb_table_used=2 fdb_entry=2 fdb_max_depth=1 cleanup_idx=0 c2
```

c. Verify the bridging information for sw1:

```
# diagnose netlink brctl name host sw1
show bridge control interface sw1 host.
fdb: hash size=32768, used=5, num=5, depth=1, gc_time=4, ageing_time=3, arp-sups
Bridge sw1 host table
port no device  devname mac addr                ttl     attributes
  2     15      vxlan1  00:00:00:00:00:00       28       Hit(28)
  2     15      vxlan1  00:50:00:00:07:00       18       Hit(18)
  2     15      vxlan1  82:51:d1:44:bf:93       0       Local Static
  1     4       port2   00:50:00:00:06:00       14       Hit(14)
  1     4       port2   50:00:00:03:00:01       0       Local Static
```

3. Run the BGP EVPN commands and observe the route type 2 (MAC/IP advertisement route) and route type 3 (inclusive multicast Ethernet tag route).

a. Verify the BGP L2 VPN EVPN summary information:

```
# get router info bgp evpn summary

VRF 0 BGP router identifier 1.1.1.1, local AS number 65001
BGP table version is 2
1 BGP AS-PATH entries
0 BGP community entries

Neighbor       V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/Pd
172.25.160.101 4      65001       9       9        1    0    0 00:04:02        3

Total number of neighbors 1
```

b. Verify the BGP L2 VPN EVPN network information:

```
# get router info bgp evpn network
   Network          Next Hop            Metric     LocPrf Weight RouteTag Path
Route Distinguisher: 100:100 (Default for VRF 0)
*> [2][0][48][00:50:00:00:06:00][0]/72
                    1.1.1.1             0              100  32768        0 i <-/>
*> [2][0][48][00:50:00:00:06:00][32][172.18.1.11]/104

```

c. Verify the BGP L2 VPN EVPN context:

```
# get router info bgp evpn context
L2VPN EVPN context for VRF 0
ID 100 vlan-based, RD is [100:100]
 Import RT: RT:1:1
 Export RT: RT:1:1
  Bridge domain 0 VNI 1000
   Encapsulation 8(VXLAN)
   Source interface loopback1
   Source address 1.1.1.1
```

d. Verify the BGP L2 VPN EVPN information for VRF 0:

```
# get router info bgp evpn vrf 0
   Network          Next Hop            Metric     LocPrf Weight RouteTag Path
Route Distinguisher: 100:100 (Default for VRF 0)
*> [2][0][48][00:50:00:00:06:00][0]/72
                    1.1.1.1             0              100  32768        0 i <-/>
*> [2][0][48][00:50:00:00:06:00][32][172.18.1.11]/104
                    1.1.1.1             0              100  32768        0 i <-/>

                    2.2.2.2             0             100      0        0 i <-/>

Total number of prefixes 6
```

4. Run the following EVPN get commands.

a. Verify the EVPN instances:

```
# get l2vpn evpn instance
EVPN instance: 100
IP local learning enabled
ARP suppression enabled
HA primary
   Number of bridge domain: 1
   Bridge domain: TAGID 0 VNI 1000 ADDR 1.1.1.1 VXLAN vxlan1 SWITCH sw1
```

b. Verify the EVPN table:

```
# get l2vpn evpn table
EVPN instance 100
 Broadcast domain VNI 1000 TAGID 0

  EVPN instance 100
 Broadcast domain VNI 1000 TAGID 0

  EVPN MAC table:
  MAC               VNI      Remote Addr     Binded Address
  00:50:00:00:07:00 1000     2.2.2.2         172.18.1.33
                    1000     2.2.2.2         -

  EVPN IP table:
  Address         VNI      Remote Addr     MAC
  172.18.1.33     1000     2.2.2.2         00:50:00:00:07:00

  EVPN Local MAC table:
  "Inactive" means this MAC/IP pair will not be sent to peer.
  Flag code: S - Static F - FDB. Trailing * means HA
  MAC               Flag Status   Binded Address
  00:50:00:00:06:00      Active   172.18.1.11
                    F    Active   -

  EVPN Local IP table:
  Address         MAC
  172.18.1.11     00:50:00:00:06:00

  EVPN PEER table:
  VNI      Remote Addr     Binded Address
  1000     2.2.2.2         2.2.2.2
```

5. Run the proxy ARP diagnose command:

```
# diagnose ip parp list
Address           Hardware Addr     Interface
172.18.1.33       00:50:00:00:07:00 sw1
```

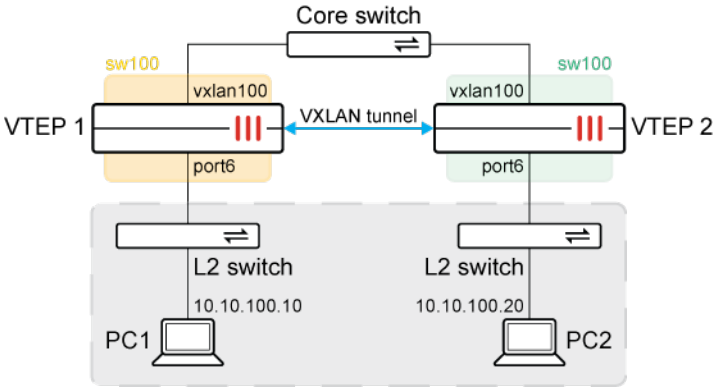
VXLAN troubleshooting

The following commands can be used to troubleshoot VXLAN connectivity:

- `diagnose sys vxlan fdb list <VXLAN_interface>`
- `diagnose sys vxlan fdb stat <VXLAN_interface>`
- `diagnose netlink brctl name host <switch_interface>`
- `diagnose sniffer packet any 'udp and port 4789' 4 0 l`
- `diagnose debug enable`
- `diagnose debug flow filter port 4789`
- `diagnose debug flow trace start <repeat_#>`

Topology

The following topology is used as an example configuration to demonstrate VXLAN troubleshooting steps.



In this example, two FortiGates are configured as VXLAN tunnel endpoints (VTEPs). A VXLAN is configured to allow L2 connectivity between the networks behind each FortiGate. The VXLAN interface and port6 are placed on the same L2 network using a software switch (sw100). An L2 network is formed between PC1 and PC2.

The VTEPs have the following MAC address tables:

Interface/endpoint	VTEP 1	VTEP 2
vxlan100	7e:f2:d1:84:75:0f	ca:fa:31:23:8d:c1
port6	00:0c:29:4e:5c:1c	00:0c:29:d0:3e:0d
sw100	00:0c:29:4e:5c:1c	00:0c:29:d0:3e:0d

The MAC address of PC1 is 00:0c:29:90:4f:bf. The MAC address of PC2 is 00:0c:29:f0:88:2c.

To configure the VTEP 1 FortiGate:

1. Configure the local interface:

```
config system vxlan
    edit "vxlan100"
        set interface "port2"
        set vni 100
        set remote-ip "192.168.2.87"
    next
end
```

2. Configure the interface settings:

```
config system interface
    edit "port2"
        set vdom "root"
        set ip 192.168.2.86 255.255.255.0
        set allowaccess ping https ssh http fabric
    next
    edit "vxlan100"
        set vdom "root"
        set type vxlan
        set interface "port2"
    next
end
```

3. Configure the software switch:

```
config system switch-interface
    edit "sw100"
        set vdom "root"
        set member "port6" "vxlan100"
    next
end
```

4. Configure the software switch interface settings:

```
config system interface
    edit "sw100"
        set vdom "root"
        set ip 10.10.100.86 255.255.255.0
        set allowaccess ping
        set type switch
        set device-identification enable
        set lldp-transmission enable
        set role lan
    next
end
```

To configure the VTEP 2 FortiGate:

1. Configure the local interface:

```
config system vxlan
    edit "vxlan100"
        set interface "port2"
        set vni 100
        set remote-ip "192.168.2.86"
    next
end
```

2. Configure the interface settings:

```
config system interface
    edit "port2"
        set vdom "root"
        set ip 192.168.2.87 255.255.255.0
        set allowaccess ping https ssh snmp http
    next
    edit "vxlan100"
        set vdom "root"
        set type vxlan
        set interface "port2"
    next
end
```

3. Configure the software switch:

```
config system switch-interface
    edit "sw100"
        set vdom "root"
        set member "port6" "vxlan100"
    next
end
```

4. Configure the software switch interface settings:

```
config system interface
    edit "sw100"
        set vdom "root"
        set ip 10.10.100.87 255.255.255.0
        set allowaccess ping
        set type switch
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 42
    next
end
```

To run diagnostics and debugs:

1. Start a ping from PC1 10.10.100.10 to PC2 10.10.100.20:

```
C:\Users\fortidocs>ping 10.10.100.20

Pinging 10.10.100.20 with 32 bytes of data:
Reply from 10.10.100.20: bytes=32 time=2ms TTL=128
Reply from 10.10.100.20: bytes=32 time=1ms TTL=128
Reply from 10.10.100.20: bytes=32 time=1ms TTL=128
Reply from 10.10.100.20: bytes=32 time<1ms TTL=128

Ping statistics for 10.10.100.20:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 0ms, Maximum = 2ms, Average = 1ms
```

2. Verify the ARP table:

```
C:\Users\fortidocs>arp /a

Interface: 10.10.100.10 --- 0x21
  Internet Address      Physical Address      Type
  10.10.100.20          00-0c-29-f0-88-2c     dynamic
  10.10.100.86          00-0c-29-4e-5c-1c     dynamic
  10.10.100.255         ff-ff-ff-ff-ff-ff     static
  224.0.0.22            01-00-5e-00-00-16     static
  224.0.0.252           01-00-5e-00-00-fc     static
```

3. Run diagnostics on the VTEP 1 FortiGate.
   a. Verify the forwarding database of VXLAN interface vxlan100:

```
# diagnose sys vxlan fdb list vxlan100
mac=00:00:00:00:00:00 state=0x0082 remote_ip=192.168.2.87 port=4789 vni=100 ifindex=6
mac=00:0c:29:f0:88:2c state=0x0002 remote_ip=192.168.2.87 port=4789 vni=100 ifindex=6

total fdb num: 2
```

   The MAC address 00:0c:29:f0:88:2c is learned from PC2 10.10.100.20.

   b. Verify the summary of statistics from the VXLAN's forwarding database:

```
# diagnose sys vxlan fdb stat vxlan100
fdb_table_size=256 fdb_table_used=2 fdb_entry=2 fdb_max_depth=1 cleanup_idx=0 cleanup_
timer=252
```

   c. Verify the software switch's forwarding table:

```
# diagnose netlink brctl name host sw100
show bridge control interface sw100 host.
fdb: hash size=32768, used=6, num=6, depth=1, gc_time=4, ageing_time=3, simple=switch
Bridge sw100 host table
port no device  devname mac addr                ttl     attributes
  1     7       port6   00:0c:29:4e:5c:1c       0       Local Static
```

```
  2     33      vxlan100        7e:f2:d1:84:75:0f       0       Local Static
  2     33      vxlan100        00:00:00:00:00:00       26       Hit(26)
  1     7       port6   00:0c:29:90:4f:bf       0        Hit(0)
  1     7       port6   00:0c:29:d0:3e:ef       7        Hit(7)
  2     33      vxlan100        00:0c:29:f0:88:2c       0        Hit(0)
```

The MAC address of port6 is 00:0c:29:4e:5c:1c. The MAC address of vxlan100 is 7e:f2:d1:84:75:0f. The MAC address 00:0c:29:f0:88:2c of PC2 is learned from the remote network.

4. Run diagnostics on the VTEP 2 FortiGate.
   a. Verify the forwarding database of VXLAN interface vxlan100:

```
# diagnose sys vxlan fdb list vxlan100
mac=00:00:00:00:00:00 state=0x0082 remote_ip=192.168.2.86 port=4789 vni=100 ifindex=6
mac=00:0c:29:90:4f:bf state=0x0002 remote_ip=192.168.2.86 port=4789 vni=100 ifindex=6

total fdb num: 2
```

   The MAC address 00:0c:29:90:4f:bf is learned from PC1 10.10.100.10.

   b. Verify the summary of statistics from the VXLAN's forwarding database:

```
# diagnose sys vxlan fdb stat vxlan100
fdb_table_size=256 fdb_table_used=2 fdb_entry=2 fdb_max_depth=1 cleanup_idx=0 cleanup_
timer=304
```

   c. Verify the software switch's forwarding table:

```
# diagnose netlink brctl name host sw100
show bridge control interface sw100 host.
fdb: hash size=32768, used=5, num=5, depth=1, gc_time=4, ageing_time=3, simple=switch
Bridge sw100 host table
port no device  devname mac addr                ttl     attributes
  2     50      vxlan100        00:00:00:00:00:00       10       Hit(10)
  2     50      vxlan100        00:0c:29:90:4f:bf       2        Hit(2)
  1     7       port6   00:0c:29:d0:3e:0d       0       Local Static
  2     50      vxlan100        ca:fa:31:23:8d:c1       0       Local Static
  1     7       port6   00:0c:29:f0:88:2c       0        Hit(0)
```

   The MAC address of port6 is 00:0c:29:d0:3e:0d. The MAC address of vxlan100 is ca:fa:31:23:8d:c1. The MAC address 00:0c:29:90:4f:bf of PC1 is learned from the remote network.

5. Perform a sniffer trace on the VTEP 1 FortiGate to view the life of the packets as they pass through the FortiGate:

```
# diagnose sniffer packet any 'host 10.10.100.20 or (udp and host 192.168.2.87)' 4 0 l
Using Original Sniffing Mode
interfaces=[any]
filters=[host 10.10.100.20 or (udp and host 192.168.2.87)]
2022-11-04 14:35:18.567602 port6 in arp who-has 10.10.100.20 tell 10.10.100.10
2022-11-04 14:35:18.567629 vxlan100 out arp who-has 10.10.100.20 tell 10.10.100.10
2022-11-04 14:35:18.567642 port2 out 192.168.2.86.4804 -> 192.168.2.87.4789: udp 68
2022-11-04 14:35:18.567658 sw100 in arp who-has 10.10.100.20 tell 10.10.100.10

2022-11-04 14:35:18.568912 port2 in 192.168.2.87.4789 -> 192.168.2.86.4789: udp 68
2022-11-04 14:35:18.568925 vxlan100 in arp who-has 10.10.100.10 tell 10.10.100.20
2022-11-04 14:35:18.568935 port6 out arp who-has 10.10.100.10 tell 10.10.100.20
2022-11-04 14:35:18.568945 sw100 in arp who-has 10.10.100.10 tell 10.10.100.20
2022-11-04 14:35:18.569070 port6 in arp reply 10.10.100.10 is-at 00:0c:29:90:4f:bf
2022-11-04 14:35:18.569076 vxlan100 out arp reply 10.10.100.10 is-at 00:0c:29:90:4f:bf
2022-11-04 14:35:18.569081 port2 out 192.168.2.86.4806 -> 192.168.2.87.4789: udp 68
2022-11-04 14:35:18.569417 port2 in 192.168.2.87.4789 -> 192.168.2.86.4789: udp 82
2022-11-04 14:35:18.569427 vxlan100 in 10.10.100.20 -> 10.10.100.10: icmp: echo reply
2022-11-04 14:35:18.569431 port6 out 10.10.100.20 -> 10.10.100.10: icmp: echo reply
```

In the output, the following packet sequence is seen on the FortiGate:

a. The FortiGate receives an ARP request from PC1 10.10.100.10 on port6.

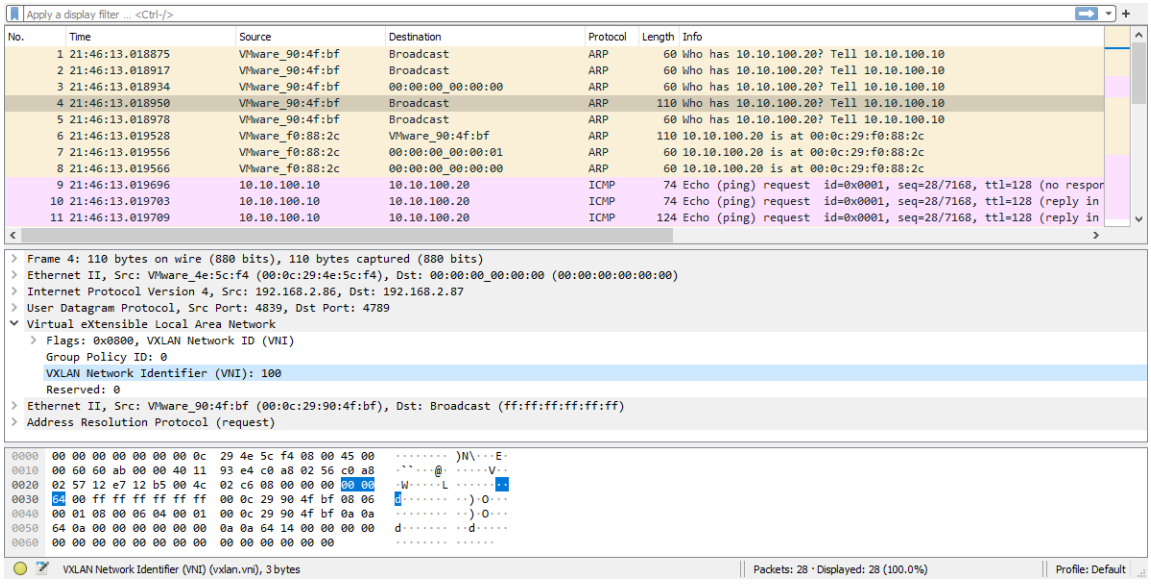
b. The ARP request is forwarded to vxlan100 on the same software switch, where it gets encapsulated and sent out as a UDP port 4789 packet on port2.

c. A reply is received on port2 from the remote VTEP with the ARP response encapsulated in UDP port 4789 again.

d. The ARP reply is forwarded back out of port6 to PC1.

e. PC1 sends the ICMP request using the same steps.

6. Perform the same sniffer trace filter with a level 6 verbose level. In this example, the packet capture is converted into a Wireshark file.



The packet that leaves the physical port2 is encapsulated in UDP and has a VXLAN header with VNI 100 as the identifier. There is an additional 50 B overhead of the UDP encapsulated VXLAN packets as opposed to the unencapsulated packets (for example, packet 4 versus packets 1 and 2).

DNS

Domain name system (DNS) is used by devices to locate websites by mapping a domain name to a website's IP address.

A FortiGate can serve different roles based on user requirements:

- A FortiGate can control what DNS server a network uses.
- A FortiGate can function as a DNS server.

FortiGuard Dynamic DNS (DDNS) allows a remote administrator to access a FortiGate's Internet-facing interface using a domain name that remains constant even when its IP address changes.

FortiOS supports DNS configuration for both IPv4 and IPv6 addressing. When a user requests a website, the FortiGate looks to the configured DNS servers to provide the IP address of the website in order to know which server to contact to complete the transaction.

The FortiGate queries the DNS servers whenever it needs to resolve a domain name into an IP address, such as for NTP or web servers defined by their domain names.

The following topics provide information about DNS:

- Important DNS CLI commands on page 289
- DNS domain list on page 294
- FortiGate DNS server on page 296
- DDNS on page 313
- DNS latency information on page 317
- DNS over TLS and HTTPS on page 319
- Transparent conditional DNS forwarder on page 323
- Interfaces in non-management VDOMs as the source IP address of the DNS conditional forwarding server on page 328
- DNS session helpers on page 330
- DNS troubleshooting on page 331

Important DNS CLI commands

DNS settings can be configured with the following CLI command:

```
config system dns
    set primary <ip_address>
    set secondary <ip_address>
    set protocol {cleartext dot doh}
    set ssl-certificate <string>
    set server-hostname <hostname>
    set domain <domains>
    set ip6-primary <ip6_address>
    set ip6-secondary <ip6_address>
    set timeout <integer>
```

```
    set retry <integer>
    set dns-cache-limit <integer>
    set dns-cache-ttl <integer>
    set cache-notfound-responses {enable | disable}
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
    set source-ip <class_ip>
    set source-ip-interface <string>
    set root-servers <DNS root name server IP address>
    set server-select-method {least-rtt | failover}
    set alt-primary <ip_address>
    set alt-secondary <ip_address>
    set log {disable |error | all}
    set fqdn-cache-ttl <integer>
    set fqdn-min-refresh <integer>
    set fqdn-max-refresh <integer>
end
```

For a FortiGate with multiple logical CPUs, you can set the DNS process number from 1 to the number of logical CPUs. The default DNS process number is 1.

```
config system global
    set dnsproxy-worker-count <integer>
end
```

DNS protocols

The following DNS protocols can be enabled:

- `cleartext`: Enable clear text DNS over port 53 (default).
- `dot`: Enable DNS over TLS.
- `doh`: Enable DNS over HTTPS.

For more information, see DNS over TLS and HTTPS on page 319.

cache-notfound-responses

When enabled, any DNS requests that are returned with `NOT FOUND` can be stored in the cache. The DNS server is not asked to resolve the host name for `NOT FOUND` entries. By default, this option is disabled.

dns-cache-limit

Set the number of DNS entries that are stored in the cache (0 to 4294967295, default = 5000). Entries that remain in the cache provide a quicker response to requests than going out to the Internet to get the same information.

dns-cache-ttl

The duration that the DNS cache retains information, in seconds (60 to 86400 (1 day), default = 1800).

fqdn-cache-ttl

FQDN cache time to live (TTL), in seconds (0 - 86400, default = 0).

This is the amount of time an FQDN's address record can live if not refreshed. This setting applies globally, across all VDOMs, to FQDNs that have unspecified firewall address `cache-ttl` settings. If the `cache-ttl` value is configured for an FQDN address, it will supersede the `fqdn-cache-ttl` setting for that address.

For example, configure the FQDN cache TTL on the global VDOM:

```
config system dns
    set fqdn-cache-ttl 2000
end
```

```
# diagnose test application dnsproxy 6
```

```
...
vfid=0 name=test.bb.com ver=IPv4 wait_list=0 timer=985 min_ttl=1000 cache_ttl=2000 slot=-1 num=1
wildcard=0
         1.1.1.1 (ttl=1000:991:1991)
vfid=0 name=*.google.com ver=IPv4 wait_list=0 timer=0 min_ttl=0 cache_ttl=2000 slot=-1 num=0
wildcard=
...
```

Change the cache TTL in a VDOM for a specific address:

```
config firewall address
    edit "test.bb.com"
        set cache-ttl 1000
    next
end
```

```
# sudo global diagnose test application dnsproxy 6
...
vfid=0 name=test.bb.com ver=IPv4 wait_list=0 timer=864 min_ttl=1000 cache_ttl=1000 slot=-1 num=1
wildcard=0
1.1.1.1 (ttl=1000:870:1870)
vfid=0 name=*.google.com ver=IPv4 wait_list=0 timer=0 min_ttl=0 cache_ttl=2000 slot=-1 num=0
wildcard=1
...
```

fqdn-min-refresh

FQDN cache minimum refresh time, in seconds (10 - 3600, default = 60).

An FQDN normally requeries for updates according to the lowest TTL interval returned from all the DNS records in a DNS response. The FortiGate has a default minimum refresh interval of 60 seconds; if a TTL interval is shorter than 60 seconds, it still requires a minimum of 60 seconds for the FortiGate to requery for new addresses. The `fqdn-min-refresh` setting changes the interval. The settings could be shortened if there are FQDNs that require fast resolutions based on a short TTL interval.

For example, if `fqdn_min_refresh` is unspecified:

```
# diagnose test application dnsproxy 3
worker idx: 0
...
FQDN: min_refresh=60 max_refresh=3600
...
```

```
# diagnose test application dnsproxy 6
worker idx: 0
vfid=0 name=aa.com ver=IPv4 wait_list=0 timer=28 min_ttl=20 cache_ttl=0 slot=-1 num=1 wildcard=0
         23.202.195.114 (ttl=20:0:0)
```

The `min_refresh` is the default value of 60 seconds. Although the `min_ttl` (TTL returned) value is shorter, the FortiGate only requeries for updates based on the `min_refresh` value. the `timer` value is the countdown until the next refresh is triggered. The FortiGate triggers a refresh slightly earlier than the larger of the `min_refresh` or `min_ttl` value.

If `fqdn_min_refresh` is configured:

```
config system dns
    set fqdn-min-refresh 20
end
```

```
# diagnose test application dnsproxy 3
worker idx: 0
...
FQDN: min_refresh=20 max_refresh=3600
...
```

```
# diagnose test application dnsproxy 6
worker idx: 0
vfid=0 name=aa.com ver=IPv4 wait_list=0 timer=8 min_ttl=20 cache_ttl=0 slot=-1 num=1 wildcard=0
         23.202.195.114 (ttl=20:14:14)
```

This setting can be used in combination with `fqdn-cache-ttl` and `cache-ttl` to send more frequent queries and store more resolved addresses in cache. This is useful in scenarios where the FQDN has many resolutions and changes very frequently.

fqdn-max-refresh

FQDN cache maximum refresh time, in seconds (3600 - 86400, default = 3600).

The `fqdn-max-refresh` setting is used to control the global upper limit of the FQDN refresh timer. FQDN entries with a TTL interval that is longer than the `fqdn-max-refresh` value will have their refresh timer reduced to this

upper limit. This allows the FortiGate to dictate the upper limit in querying for DNS updates for its FQDN addresses.

VDOM DNS

When the FortiGate is in multi-vdom mode, DNS is handled by the management VDOM. However in some cases, administrators may want to configure custom DNS settings on a non-management VDOM. For example, in a multi-tenant scenario, each VDOM might be occupied by a different tenant, and each tenant might require its own DNS server. For more information on VDOM DNS, see Interfaces in non-management VDOMs as the source IP address of the DNS conditional forwarding server on page 328.

To configure a custom VDOM within a non-management VDOM:

```
config vdom
    edit <vdom>
        config system vdom-dns
            set vdom-dns enable
            set primary <primary_DNS>
            set secondary <secondary_DNS>
            set protocol {cleartext dot doh}
            set ip6-primary <primary_IPv6_DNS>
            set ip6-secondary <secondary_IPv6_DNS>
            set source-ip <IP_address>
            set interface-select-method {auto | sdwan | specify}
        end
    next
end
```

Source IP interface

Use the `source-ip-interface` option to synchronize the DNS setting across a cluster.

In this example, a private DNS is used. Port2 is configured with an IP address, and the private DNS is configured to use the IP address for port2 as its source IP address.

To set the source IP interface for a private DNS:

1. Configure port2 with an IP address. You can either specify an IP address or configure the interface to receive an IP address from a DHCP server.

   Example fixed IP address configuration:

   ```
   config system interface
       edit "port2"
           set vdom "vdom1"
           set ip 10.1.100.1 255.255.255.0
           set allowaccess ping https ssh snmp http telnet
           set type physical
           set snmp-index 4
   ```

```
        set secondary-IP enable
    next
end
```

Example DHCP configuration:

```
config system interface
     edit "port2"
         set mode dhcp
     next
end
```

2. Configure port2 as the source IP interface for DNS:

```
config system dns
    set primary 172.17.254.148
    set secondary 172.17.254.151
    set source-ip-interface "port2"
end
```

3. Sniff port2:

```
# diagnose sniffer packet port2 ""
....
3.336987 10.1.100.1.2264 -> 172.17.254.148.53: udp 43
```

DNS domain list

You can configure up to eight domains in the DNS settings using the GUI or the CLI.

When a FortiGate requests a URL that does not include an FQDN, FortiOS resolves the URL by traversing through the DNS domain list and performing a query for each domain until the first match is found.

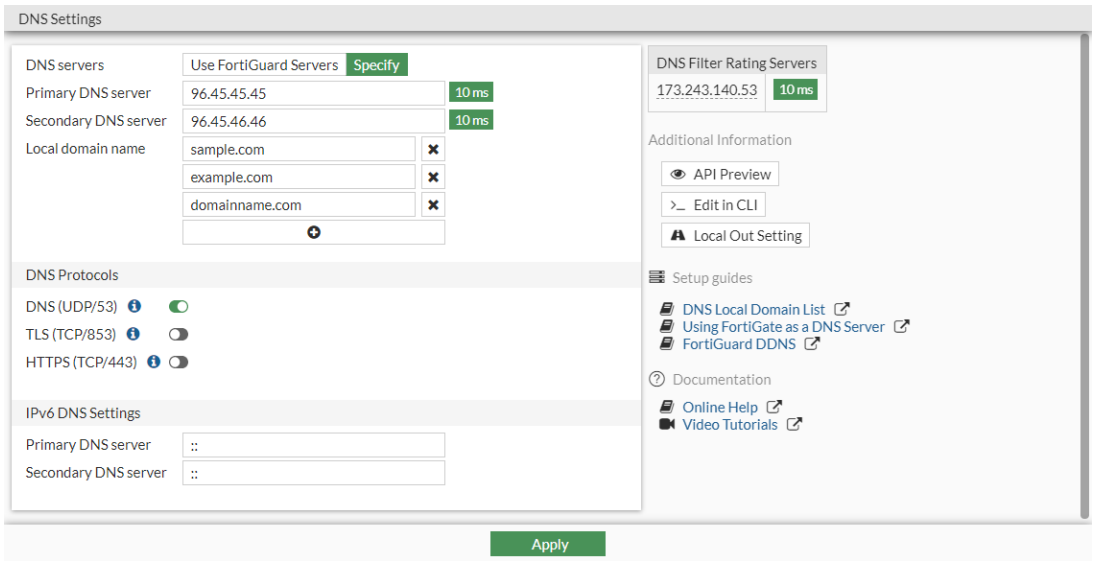
By default, FortiGates use FortiGuard's DNS servers:

- Primary: 96.45.45.45
- Secondary: 96.45.46.46

You can also customize the DNS timeout time and the number of retry attempts.

To configure a DNS domain list in the GUI:

1. Go to *Network* > *DNS*.
2. Set *DNS Servers* to *Specify*.
3. Configure the primary and secondary DNS servers as needed.
4. In the *Local Domain Name* field, enter the first domain (`sample.com` in this example).
5. Click the *+* to add more domains (`example.com` and `domainname.com` in this example). You can enter up to eight domains.
6. Configure additional DNS protocol and IPv6 settings as needed.



7. Click *Apply*.

To configure a DNS domain list in the CLI:

```
config system dns
    set primary 96.45.45.45
    set secondary 96.45.46.46
    set domain "sample.com" "example.com" "domainname.com"
end
```

Verify the DNS configuration

In the following example, the local DNS server has the entry for *host1* mapped to the FQDN of *host1.sample.com*, and the entry for *host2* is mapped to the FQDN of *host2.example.com*.

To verify that the DNS domain list is configured:

1. Open the FortiGate CLI.
2. Enter `execute ping host1`.
   The system returns the following response:

   ```
   PING host1.sample.com (1.1.1.1): 56 data bytes
   ```

   As the request does not include an FQDN, FortiOS traverses the configured DNS domain list to find a match. Because *host1* is mapped to the *host1.sample.com*, FortiOS resolves *host1* to *sample.com*, the first entry in the domain list.
3. Enter `execute ping host2`.
   The system returns the following response:

   ```
   PING host2.example.com (2.2.2.2): 56 data bytes
   ```

FortiOS traverses the domain list to find a match. It first queries sample.com, the first entry in the domain list, but does not find a match. It then queries the second entry in the domain list, example.com. Because *host2* is mapped to the FQDN of *host2.example.com*, FortiOS resolves *host2* to *example.com*.

DNS timeout and retry settings

The DNS timeout and retry settings can be customized using the CLI.

```
config system dns
    set timeout <integer>
    set retry <integer>
end
```

`timeout <integer>`	The DNS query timeout interval, in seconds (1 - 10, default = 5).
`retry <integer>`	The number of times to retry the DNS query (0 - 5, default - 2).

FortiGate DNS server

You can create local DNS servers for your network. Depending on your requirements, you can either manually maintain your entries (primary DNS server), or use it to refer to an outside source (secondary DNS server).

A local, primary DNS server requires that you to manually add all URL and IP address combinations. Using a primary DNS server for local services can minimize inbound and outbound traffic, and access time. Making it authoritative is not recommended, because IP addresses can change, and maintaining the list can become labor intensive.

A secondary DNS server refers to an alternate source to obtain URL and IP address combinations. This is useful when there is a primary DNS server where the entry list is maintained.

FortiGate as a DNS server also supports TLS and HTTPS connections to a DNS client. See DNS over TLS and HTTPS on page 319 for details.

DNS over QUIC (DoQ) and DNS over HTTP3 (DoH3) are supported in proxy mode inspection for transparent and local-in explicit modes. See DNS over QUIC and DNS over HTTP3 for transparent and local-in DNS modes on page 2069 for details.

See Basic DNS server configuration example on page 300 for a sample configuration.

By default, DNS server options are not available in the FortiGate GUI.

To enable DNS server options in the GUI:

1. Go to *System* > *Feature Visibility*.
2. Enable *DNS Database* in the *Additional Features* section.
3. Click *Apply*.

To configure the FortiGate as a DNS server in the GUI:

1. Go to *Network* > *DNS Servers*.
2. Enable DNS services on an interface:
   a. In the *DNS Service on Interface* table, click *Create New*.
   b. Configure the following:

Interface	Select the interface to enable DNS service on.
Mode	Set the DNS server mode: • *Recursive*: The system first checks for the requested record in the shadow DNS database. If the record is not found locally, the query is then forwarded to the system's DNS server for further lookup. This mode ensures a comprehensive search for the requested record, utilizing both local and system DNS resources. • *Non-Recursive*: Search is restricted to the Public DNS database only. If the requested record is not found, the query will not be forwarded to the system's DNS server. This mode is useful when you need to limit queries strictly to local resources. • *Forward to System DNS*: The local DNS database is bypassed and all queries are forwarded directly to the system's DNS server. This is beneficial when you need to rely solely on system-level DNS resources for resolving queries. • *Resolver*: As a resolver, the FortiGate can directly interact with root name servers, TLD name servers, and finally authoritative name servers to resolve DNS queries. The FortiGate will iterate through these DNS servers to get the final IP address for the FQDN, as opposed to forwarding the request to external resolvers in forwarder mode for example. Clients can then use the FortiGate as their DNS server to perform DNS resolution. See FortiGate as a recursive DNS resolver on page 303 for more information.
DNS Filter	Apply a DNS filter profile to DNS server. This option is not available when *Mode* is *Non-Recursive*. See Applying DNS filter to FortiGate DNS server on page 2064 for more information.
DNS over HTTPS	Enable DNS over HTTPS (DoH). DoH is a method of performing DNS resolution over a secure HTTPS connection. See DNS over TLS and HTTPS on page 319 for more information
DNS over HTTP3	Enable DNS over HTTP3 (DoH3). DoH3 is a method of performing DNS resolution over an HTTP3 connection. See DNS over QUIC and DNS over HTTP3 for transparent and local-in DNS modes on page 2069 for more information
DNS over QUIC	Enable DNS over QUIC (DoQ). DoQ is a method of performing DNS resolution over a QUICK UDP Internet Connection (QUIC) connection. See DNS over QUIC and DNS over HTTP3 for transparent and local-in DNS modes on page 2069 for more information

   c. Click *OK*.

3. Build the DNS database:
   a. In the *DNS Database* table, click *Create New*.
   b. Configure the following:

Type	Select the zone type: • *Primary*: The primary DNS zone, to manage entries directly. • *Secondary*: The secondary DNS zone, to import entries from other DNS zones. The purpose of a secondary DNS zone is to provide redundancy and load balancing. If the primary DNS server fails, the secondary DNS server can continue to resolve queries for the domain.
View	Select the zone view: • *Shadow*: This type of DNS zone is designed for both internal and external clients, allowing them to resolve DNS queries with the recursive DNS server on FortiGate. It creates a shadow of your public DNS records within your private network. • *Public*: This type of DNS zone is intended to serve external clients only, allowing them to resolve DNS queries with the non-recursive DNS server on FortiGate. It contains records that map the domain names of your publicly accessible services to their respective IP addresses. These records are propagated across the internet, allowing anyone in the world to find and connect to your services. • *Proxy*: This special type of shadow DNS zone is specifically designed for explicit proxy. It allows the explicit proxy to perform DNS lookups using a local database, providing faster and more efficient resolution of domain names. Internal users can experience improved performance and reduced latency when accessing websites and online services through the explicit proxy.
DNS Zone	The name of the DNS zone.
Domain Name	The domain name.
Hostname of Primary DNS	The domain name of the default DNS server for this zone. This option is only available when *Type* is *Primary*.
IP of Primary	The IP address of the primary DNS server. This option is only available when *Type* is *Secondary*.
Contact Email Address	The email address of the administrator for this zone. You can specify only the username, such as admin, or the full email address, such as admin@test.com. When using only a username, the domain of the email is the zone. This option is only available when *Type* is *Primary*.
TTL	The default time-to-live value for the entries of this DNS zone. This option is only available when *Type* is *Primary*.

Authoritative	Enabling *Authoritative* makes this server is the primary and sole source of information for this specific DNS zone. It prevents the FortiGate from seeking DNS records further upstream. Enabling authoritative is not recommended.
DNS Forwarder	A DNS forwarder routes DNS queries to specific servers based on the domain name. Specify one or two DNS zone forwarder IP addresses. Use the CLI to add more than two DNS forwarder addresses.

c. Add DNS entries:

i. In the *DNS Entries* table, click *Create New*.

ii. Configure the following:

Type	The resource record type. The availability of the subsequent settings vary depending on the selected type. • *Address (A)*: This is the host type. It maps a hostname to an IPv4 address in the DNS system, allowing a browser or other client to access a server using its domain name. • *Name Server (NS)*: This is the name server type. It indicates which DNS server is authoritative for that domain • *Canonical Name (CNAME)*: This is the canonical name type. It's used to alias one name to another. • *Mail Exchange (MX)*: This is the mail exchange type. It routes email to a specified mail server based on the information in the record. • *IPv6 Address (AAAA)*: This is the IPv6 host type. Similar to the *A* record, but it maps a hostname to an IPv6 address. • *IPv4 Pointer (PTR)*: This is the pointer type for IPv4. It provides a mapping of the IP address to a hostname, essentially the reverse of what an *A* record does. • *IPv6 Pointer (PTR)*: This is the pointer type for IPv6. It functions similarly to the IPv4 PTR record, but for IPv6 addresses.
TTL	The time-to-live for this entry.

iii. Click *OK*.

d. Click *OK*.

To configure the FortiGate as a DNS server in the CLI:

1. Configure DNS servers:

```
config system dns-server
    edit <name>
        set dnsfilter-profile {string}
        set doh {enable | disable}
        set doh3 {enable | disable}
```

```
        set doq {enable | disable}
        set mode {recursive | non-recursive | forward-only}
    next
end
```

See config system dns-server in the CLI reference for a comprehensive list of commands.

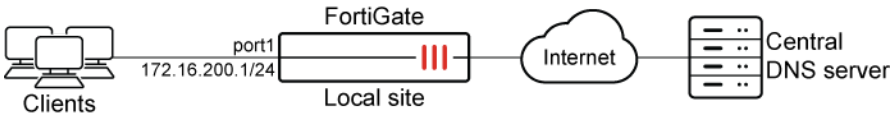
2. Configure DNS database:

```
config system dns-database
    edit <name>
        set authoritative {enable | disable}
        set contact {string}
        set domain {string}
        set forwarder {user}
        set primary-name {string}
        set ttl {integer}
        set type {primary | secondary}
        set view {shadow | public | shadow-ztna | proxy}
        config dns-entry
            edit <id>
                set status {enable | disable}
                set type {A | NS | CNAME | MX | AAAA | PTR | PTR_V6}
                set ttl {integer}
                set ip {ipv4-address-any}
                set ipv6 {ipv6-address}
                set hostname {string}
                set canonical-name {string}
            next
        end
    next
end
```

See config system dns-database in the CLI reference for a comprehensive list of commands.

Basic DNS server configuration example

This section describes how to create a non-authoritative primary DNS server. The interface mode is recursive so that, if the request cannot be fulfilled, the external DNS servers will be queried.

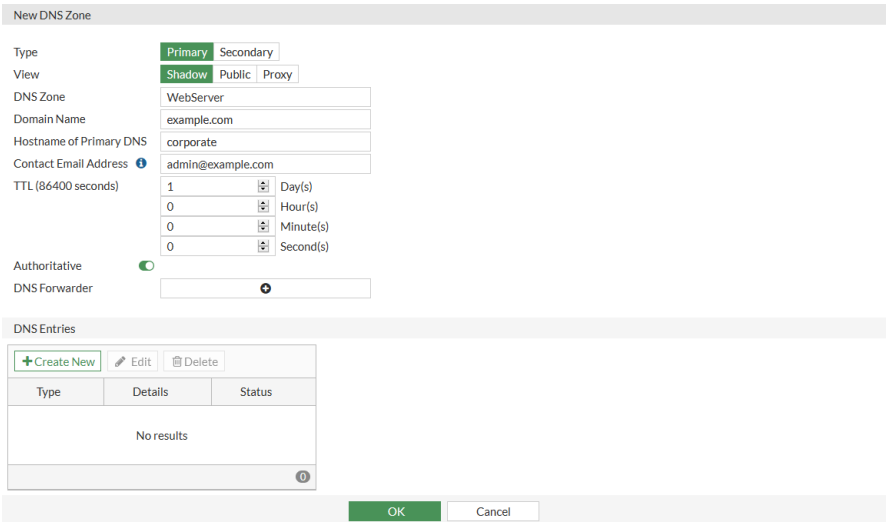


In this example, the Local site is configured as a non-authoritative primary DNS server.

To configure FortiGate as a primary DNS server in the GUI:

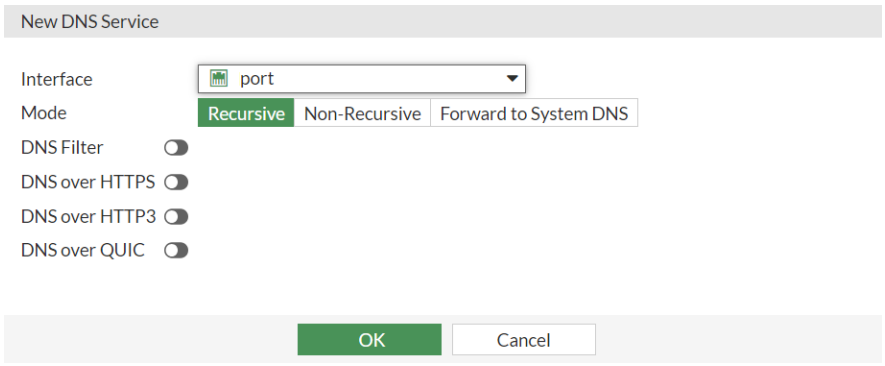
1. Go to *Network* > *DNS Servers*.
2. In the *DNS Database* table, click *Create New*.
3. Set *Type* to *Primary*.

4. Set *View* to *Shadow*.
   The *View* setting controls the accessibility of the DNS server. If you select *Public*, external users can access or use the DNS server. If you select *Shadow*, only internal users can use it.
5. Enter a *DNS Zone*, for example, *WebServer*.
6. Enter the *Domain Name* of the zone, for example, *example.com*.
7. Enter the *Hostname* of the DNS server, for example, *corporate*.
8. Enter the *Contact Email Address* for the administrator, for example, *admin@example.com*.
9. Disable *Authoritative*.



10. Add DNS entries:
    a. In the *DNS Entries* table, click *Create New*.
    b. Select a *Type*, for example *Address (A)*.
    c. Set the *Hostname*, for example *web*.

    d. Configure the remaining settings as needed. The options might vary depending on the selected *Type*.
    e. Click *OK*.
11. Add more DNS entries as needed.
12. Click *OK*.
13. Enable DNS services on an interface:
    a. Go to *Network* > *DNS Servers*.
    b. In the *DNS Service on Interface* table, click *Create New*.
    c. Select the *Interface* for the DNS server, such as *port1*.
    d. Set the *Mode* to *Recursive*.



e. Click *OK*.

To configure FortiGate as a primary DNS server in the CLI:

```
config system dns-database
    edit WebServer
        set domain example.com
        set type primary
        set view shadow
        set ttl 86400
        set primary-name corporate
        set contact admin@example.com
        set authoritative disable
        config dns-entry
            edit 1
                set status enable
                set hostname web
                set type A
                set ip 172.16.200.254
            next
        end
    next
end
```

```
config system dns-server
    edit port1
        set mode recursive
    next
end
```

To verify the configuration:

1. Send a DNS query for a DNS entry configured locally on the Local site FortiGate:

```
C:\Users\demo>nslookup office.microsoft.com
Server:  Unknown
Address:  172.16.200.1
Non-authoritative answer:
```

```
Name:     web.example.com
Address:  172.16.200.254
```

The query is resolved to the IP address configured in the shadow DNS database on the Local site FortiGate.

2. Send a DNS query for a domain that is not configured on the Local site FortiGate:

```
C:\Users\demo>nslookup facebook.com
Server:  Unknown
Address:  172.16.200.1
Non-authoritative answer:
Name:    facebook.com
Addresses:  157.240.22.35
```

The query is resolved by the central DNS server.

FortiGate as a recursive DNS resolver

FortiOS supports being configured as a recursive DNS resolver. As a resolver, the FortiGate can directly interact with root name servers, Top-Level Domain (TLD) name servers, and finally authoritative name servers to resolve DNS queries. The FortiGate will iterate through these DNS servers to get the final IP address for the FQDN, as opposed to forwarding the request to external resolvers in forwarder mode for example. This can avoid hitting limitations from external resolvers which may limit the number of queries per second. Finally, clients can then use the FortiGate as their DNS server to perform DNS resolution.

To configure the recursive resolver mode in the CLI:

```
config system dns-server
    edit <DNS server name>
        set mode resolver
    next
end
```

To configure recursive resolver mode in the GUI:

1. Go to *Network* > *DNS Servers*.
2. Under *DNS Service on Interface*, click *Create New*.
3. Select the *Interface* to listen to DNS queries.
4. Set the *Mode* to *Resolver*.
5. Click *OK*.

Furthermore, FortiOS also adds support for prioritizing root name servers. By default, a list of 13 public root name servers are known to the FortiGate. These DNS servers can be viewed with `diagnose test application dnsproxy 19`.

Prioritized root name servers will be highlighted among the total list of root servers. Prioritized (highlighted) root servers will be queried in round robin fashion. Default (non-highlighted) root servers will only be queried if there are no prioritized root servers.

You may configure root servers from the list of 13 default servers, or you can configure your own custom root name server. Any custom root name servers you configure will be defined with an auto-generated name.

The root name servers can be prioritized and configured with the following:

```
config system dns
    set primary <class IP address>
    set root-servers <DNS root name server IP address>
end
```

At most, two root-servers can be configured.

Example 1

In the following example, we will configure the FortiGate's WAN interface (port3) in resolver mode and configure 1 DNS entry to return results for override.fortinet.com in the fortinet.com domain.

To configure the FortiGate as DNS resolver in the GUI:

1. Go to *Network > DNS Servers*.
2. Under *DNS Service on Interface*, click *Create New*.
3. For *Interface*, select *WAN (port3)*.
4. For *Mode*, select *Resolver*.
5. Click *OK*.
6. Under *DNS Database*, click *Create New* and configure the following:

Type	Primary
View	Shadow
DNS Zone	fortinet
Domain Name	fortinet.com
Authoritative	Disable

   a. Under *DNS Entries*, click *Create New* and configure the following:

Type	Address (A)
Hostname	override
IP Address	10.88.0.30

   b. Click *OK*.
7. Click *OK*.

To configure the FortiGate as DNS resolver in the CLI:

```
config system dns-server
    edit "port3"
        set mode resolver
    next
end
config system dns-database
    edit "fortinet"
```

```
        set domain "fortinet.com"
        set authoritative disable
        config dns-entry
            edit 1
                set hostname "override"
                set ip 10.88.0.30
            next
        end
    next
end
```

To verify:

1. On the FortiGate, enable dnsproxy debugs:

```
# diagnose debug application dnsproxy -1
# diagnose debug enable
```

2. From a client, use dig to issue a lookup for override.fortinet.com.

```
>dig @10.0.3.254 override.fortinet.com

; <<>> DiG 9.16.23 <<>> @10.0.3.254 override.fortinet.com
; (1 server found)
;; global options: +cmd

```

6. From the FortiGate, change the DNS server setting for WAN (port3) to recursive mode.
7. Restart the dnsproxy:

```
# diagnose test application dnsproxy 99
```

8. From the client, use dig to issue a lookup for www.fortinet.com again
9. From the FortiGate debugs, observe the FortiGate now forwards the query to a resolver instead of resolving the query itself.

Example 2

In the following example, the root name servers that should be prioritized will be defined, and the DNS server will be highlighted from the list root name servers.

To define the root name servers:

1. Define the root name servers to prioritize:

```
config system dns
    set primary 8.8.8.8
    set root-servers "199.7.83.42" "192.33.4.12"
end
```

2. Display the DNS server for the root name servers:

```
# diagnose test application dnsproxy 19
worker idx: 0
name=. label_count=0 ns_count=13
    ns=a.root-servers.net A=198.41.0.4 use=1
    ns=b.root-servers.net A=199.9.14.201 use=1
    *ns=c.root-servers.net A=192.33.4.12 use=1
    ns=d.root-servers.net A=199.7.91.13 use=1
    ns=e.root-servers.net A=192.203.230.10 use=1
    ns=f.root-servers.net A=192.5.5.241 use=1
    ns=g.root-servers.net A=192.112.36.4 use=1
    ns=h.root-servers.net A=198.97.190.53 use=1
    ns=i.root-servers.net A=192.36.148.17 use=1
    ns=j.root-servers.net A=192.58.128.30 use=1
    ns=k.root-servers.net A=193.0.14.129 use=1
    *ns=l.root-servers.net A=199.7.83.42 use=1
    ns=m.root-servers.net A=202.12.27.33 use=1
```

Example 3

In the following example, the user configures a custom root server which will be added to the root zone cache. The name of the new user-defined root server will be auto-generated.

To configure a specific root name server:

1. Configure the user-defined root name server:

```
config system dns
    set primary 8.8.8.8
```

```
    set root-servers "172.16.200.55"
end
```

2. Display the DNS server for the user-defined root name server:

```
# diagnose test application dnsproxy 19
worker idx: 0
name=. label_count=0 ns_count=14
    ns=a.root-servers.net A=198.41.0.4 use=1
    ns=b.root-servers.net A=199.9.14.201 use=1
    ns=c.root-servers.net A=192.33.4.12 use=1
    ns=d.root-servers.net A=199.7.91.13 use=1
    ns=e.root-servers.net A=192.203.230.10 use=1
    ns=f.root-servers.net A=192.5.5.241 use=1
    ns=g.root-servers.net A=192.112.36.4 use=1
    ns=h.root-servers.net A=198.97.190.53 use=1
    ns=i.root-servers.net A=192.36.148.17 use=1
    ns=j.root-servers.net A=192.58.128.30 use=1
    ns=k.root-servers.net A=193.0.14.129 use=1
    ns=l.root-servers.net A=199.7.83.42 use=1
    ns=m.root-servers.net A=202.12.27.33 use=1
    *ns=a.user-root-servers.fgt A=172.16.200.55 use=1
```

Implement the interface name as the source IP address in RADIUS, LDAP, and DNS configurations

To account for dynamic IP address changes, such as those governed by SD-WAN rules, interface names can be used to define the source IP addresses in RADIUS, LDAP, and DNS configurations using the `source-ip-interface` command. The interface's current IP address will be used as the source IP address in the configuration; enhancing network flexibility and resolving potential connectivity issues. See RADIUS servers on page 3032and LDAP servers on page 3014 for more information.

The following examples demonstrate configuring the interface name as the source IP address in RADIUS and LDAP servers, and local DNS databases, respectively. The server configuration on the FortiGate will need to have a source IP address included. This source IP address can be any interface, including the IP address of a loopback interface.

Example 1: RADIUS server

In this example, the loopback interface is used as the source IP address and the interface method is set to `specify`.

To configure the interface name as the source IP address in a RADIUS server:

1. Configure the loopback interface:

```
config system interface
    edit "loop1"
        set vdom "vdom1"
```

```
        set ip 10.1.10.9 255.255.255.0
        set allowaccess ping
        set type loopback
    next
end
```

2. Configure the RADIUS user object:

```
config user radius
    edit "radius-142"
        set server "10.1.100.142"
        set secret XXXXXX
        set source-ip-interface "loop1"
        set interface-select-method specify
        set interface "testvlink1"
    next
end
```

3. Test the basic communication:
   a. Perform a local credential check with a known user and password:

```
# diagnose test authserver radius radius-142 pap test1 test1
authenticate 'test1' against 'pap' succeeded, server=primary assigned_rad_session_
id=105510201667592 session_timeout=3600 secs idle_timeout=300 secs!
Group membership(s) - group1
```

   b. Perform a sniffer check in a separate SSH session to verify that the source IP address contains the expected IP address of the loop interface:

```
# diagnose sniffer packet any 'host 10.1.100.142 and port 1812' 4
interfaces=[any]
filters=[host 10.1.100.142 and port 1812]
5.144791 testvlink1 out 10.1.10.9.17437 -> 10.1.100.142.1812: udp 110
5.144794 testvlink0 in 10.1.10.9.17437 -> 10.1.100.142.1812: udp 110
5.144812 port2 out 10.1.10.9.17437 -> 10.1.100.142.1812: udp 110
5.149570 port2 in 10.1.100.142.1812 -> 10.1.10.9.17437: udp 169
5.149581 testvlink0 out 10.1.100.142.1812 -> 10.1.10.9.17437: udp 169
5.149583 testvlink1 in 10.1.100.142.1812 -> 10.1.10.9.17437: udp 169
```

Example 2: LDAP server

In this example, a VDOM link is used as the source IP address and the interface method is set to `sdwan`.

To configure the interface name as the source IP address in an LDAP server:

1. Configure the VDOM link:

```
config system interface
    edit "testvlink1"
        set vdom "vdom1"
        set ip 10.12.1.10 255.255.255.0
```

```
        set allowaccess ping
        set type vdom-link
    next
end
```

2. Configure the LDAP user object:

```
config user ldap
    edit "ldap-2"
        set server "172.18.60.214"
        set source-ip-interface "testvlink1"
        set cnid "cn"
        set dn "dc=qafsso,dc=com"
        set type regular
        set username "cn=Manager,dc=qafsso,dc=com"
        set password ENC XXXXXXXXXXXXXXXXXX
        set interface-select-method sdwan
    next
end
```

3. Confirm in a packet capture that the correct IP address is used in the outgoing and incoming packets:

```
# diagnose sniffer packet any  'port 389' 4
interfaces=[any]
filters=[port 389]
11.356977 testvlink1 out 10.12.1.10.11742 -> 172.18.60.214.389: syn 1099805903
11.356979 testvlink0 in 10.12.1.10.11742 -> 172.18.60.214.389: syn 1099805903
11.357001 port1 out 172.16.200.9.11742 -> 172.18.60.214.389: syn 1099805903
11.357548 port1 in 172.18.60.214.389 -> 172.16.200.9.11742: syn 2083328609 ack 1099805904
11.357556 testvlink0 out 172.18.60.214.389 -> 10.12.1.10.11742: syn 2083328609 ack 1099805904
11.357558 testvlink1 in 172.18.60.214.389 -> 10.12.1.10.11742: syn 2083328609 ack 1099805904
11.357566 testvlink1 out 10.12.1.10.11742 -> 172.18.60.214.389: ack 2083328610
11.357564 testvlink0 in 10.12.1.10.11742 -> 172.18.60.214.389: ack 2083328610
11.357571 port1 out 172.16.200.9.11742 -> 172.18.60.214.389: ack 2083328610
```

Example 3: DNS database

In this example, the system DNS database uses a customized DNS server and a loopback interface as the source IP address.

To configure the interface name as the source IP address in a DNS database:

1. Configure the loopback interface:

```
config system interface
    edit "loop"
        set vdom "root"
        set ip 10.3.10.9 255.255.255.0
        set allowaccess ping
        set type loopback
        set role lan
        set snmp-index 28
```

```
    next
end
```

2. Configure the DNS database:

```
config system dns-database
    edit "1"
        set domain "fortinet-fsso.com"
        set authoritative disable
        set forwarder "10.1.100.150"
        set source-ip-interface "loop"
    next
end
```

3. Clear the DNS host cache and ping any FQDN in the DNS domain:

```
# execute ping login.fortinet-fsso.com
PING login.fortinet-fsso.com (10.1.100.5): 56 data bytes
64 bytes from 10.1.100.5: icmp_seq=0 ttl=255 time=0.1 ms
64 bytes from 10.1.100.5: icmp_seq=1 ttl=255 time=0.0 ms
64 bytes from 10.1.100.5: icmp_seq=2 ttl=255 time=0.0 ms
64 bytes from 10.1.100.5: icmp_seq=3 ttl=255 time=0.0 ms
64 bytes from 10.1.100.5: icmp_seq=4 ttl=255 time=0.0 ms

--- login.fortinet-fsso.com ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.0/0.0/0.1 ms
```

4. Perform a sniffer check on the FortiGate to confirm that the loopback interface was used as the source IP address in a DNS query:

```
# diagnose sniffer packet any 'host 10.1.100.150 and port 53' 4
interfaces=[any]
filters=[host 10.1.100.150 and port 53]
91.180362 port2 out 10.3.10.9.1328 -> 10.1.100.150.53: udp 41
91.180733 port2 in 10.1.100.150.53 -> 10.3.10.9.1328: udp 57
468.753163 port2 out 10.3.10.9.3990 -> 10.1.100.150.53: udp 41
468.753533 port2 in 10.1.100.150.53 -> 10.3.10.9.3990: udp 57
523.470007 port2 out 10.3.10.9.3990 -> 10.1.100.150.53: udp 44
523.470017 port2 out 10.3.10.9.3990 -> 10.1.100.150.53: udp 45
523.470025 port2 out 10.3.10.9.3990 -> 10.1.100.150.53: udp 47
523.470350 port2 in 10.1.100.150.53 -> 10.3.10.9.3990: udp 60
523.470380 port2 in 10.1.100.150.53 -> 10.3.10.9.3990: udp 85
523.470396 port2 in 10.1.100.150.53 -> 10.3.10.9.3990: udp 95
^C
10 packets received by filter
0 packets dropped by kernel
```

DDNS

If your external IP address changes regularly and you want a static domain name, you can configure the external interface to use a dynamic DNS (DDNS) service. This ensures that external users and customers can always connect to your company firewall. You can configure FortiGuard as the DDNS server using the GUI or CLI.

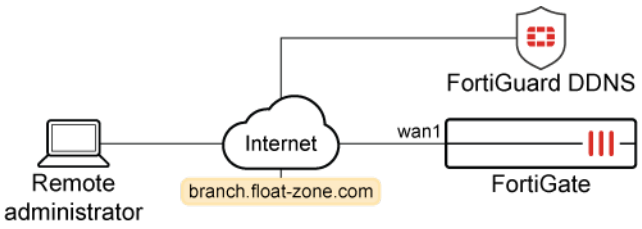
Multiple DDNS interfaces can be configured in the GUI. The number of DDNS entries that can be configured is restricted by table size, with limits of 16, 32, and 64 entries for entry-level, mid-range, and high-end FortiGates respectively.

A license or subscription is not required to use the DDNS service, but configuring DDNS in the GUI is not supported if:

- The FortiGate model is a 1000-series or higher.
- The FortiGate is a VM.
- The DNS server is not using FortiGuard as the DNS.

DDNS is not supported in transparent mode.

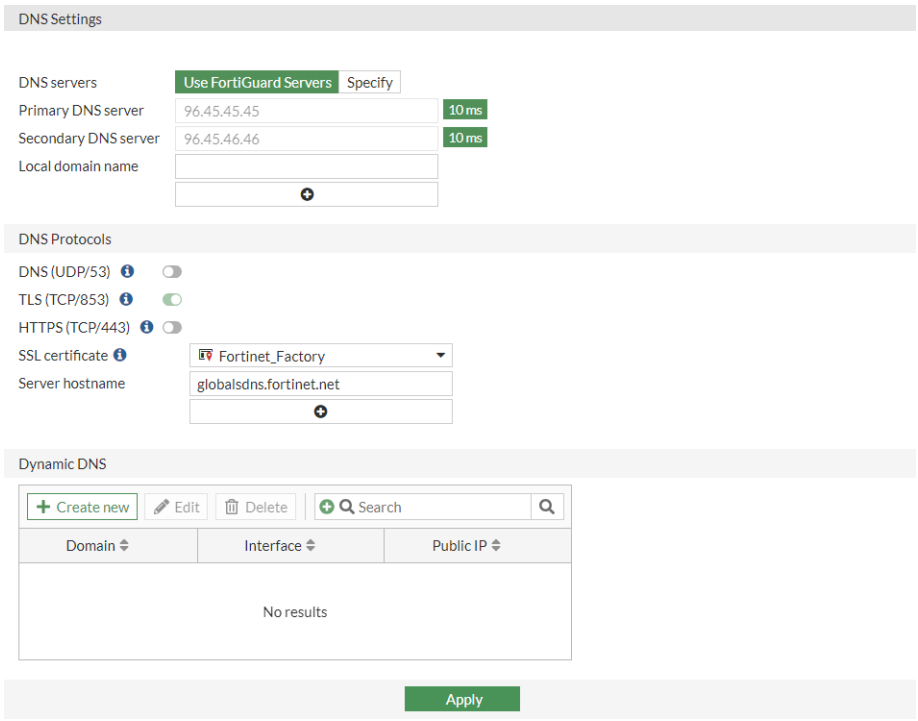
Sample topology



In this example, FortiGuard DDNS is enabled and the DDNS server is set to *float-zone.com*. Other DDNS server options include *fortiddns.com* and *fortidyndns.com*.

To configure multiple DDNS entries in the GUI:

1. Go to *Network* > *DNS*.
2. In the *Dynamic DNS* table, click *Create new*.



The *New DDNS Entry* pane opens.

3. Configure the DDNS entry settings:
   a. Select the *Interface* with the dynamic connection.
   b. Select the *Server* that you have an account with.
   c. Enter the *Unique Location*.

   d. Click *OK*.

4. Click *Create new* and repeat step 3 to add more entries.
5. Click *Apply*.

To configure the FortiGuard DDNS service as an IPv4 DDNS server in the CLI:

```
config system ddns
    edit 1
        set ddns-server FortiGuardDDNS
        set server-type ipv4
        set ddns-domain "branch.float-zone.com"
        set addr-type ipv4
        set use-public-ip enable
        set monitor-interface "wan1"
    next
end
```

To configure the FortiGuard DDNS service as an IPv6 DDNS server in the CLI:

```
config system ddns
    edit 1
        set ddns-server FortiGuardDDNS
        set server-type ipv6
        set ddns-domain "fgtatest001.float-zone.com"
        set addr-type ipv6
        set monitor-interface "wan1"
    next
end
```

DDNS servers other than FortiGuard

If you do not have a FortiGuard subscription, or want to use a different DDNS server, you can configure a DDNS server for each interface. Only the first configure port appears in the GUI.

The available commands vary depending on the selected DDNS server.

To configure DDNS servers other than FortiGuard in the CLI:

```
config system ddns
    edit <DDNS_ID>
        set monitor-interface <external_interface>
        set ddns-server <ddns_server_selection>
        set server-type {ipv4 | ipv6}
        set ddns-server-addr <address>
        set addr-type ipv6 {ipv4 | ipv6}
    next
end
```

To configure an IPv6 DDNS client with generic DDNS on port 3 in the CLI:

```
config system ddns
    edit 1
        set ddns-server genericDDNS
        set server-type ipv6
        set ddns-server-addr "2004:16:16:16::2" "16.16.16.2" "ddns.genericddns.com"
        set ddns-domain "test.com"
        set addr-type ipv6
        set monitor-interface "port3"
    next
end
```

Refresh DDNS IP addresses

When using a public IP that is not assigned to the FortiGate, the FortiGate cannot trigger an update when the IP address changes. The FortiGate can be configured to refresh DDNS IP addresses by periodically checking the DDNS server at an update interval.

To configure FortiGate to refresh DDNS IP addresses in the CLI:

```
config system ddns
    edit 1
        set use-public-ip enable
        set update-interval <seconds>
    next
end
```

When `update-interval` is set to `0`:

- For FortiGuard DDNS, the interval is 300 seconds.
- For third part DDNS servers, the interval is assigned by the DDNS server.

Disable cleartext

When `clear-text` is disabled, FortiGate uses the SSL connection to send and receive DDNS updates.

To disable cleartext and set the SSL certificate in the CLI:

```
config system ddns
    edit 2
        set clear-text disable
        set ssl-certificate <cert_name>
    next
end
```

DDNS update override

A DHCP server has an override command option that allows DHCP server communications to go through DDNS to perform updates for the DHCP client. This enforces a DDNS update of the A field every time even if the DHCP client does not request it. This allows support for the `allow`, `ignore`, and `deny client-updates` options.

To enable DDNS update override in the CLI:

```
config system dhcp server
    edit 1
        set ddns-update enable
        set ddns-update-override enable
        set ddns-server-ip <ddns_server_ip>
        set ddns-zone <ddns_zone>
    next
end
```

Troubleshooting

To debug DDNS:

```
# diagnose debug application ddnscd -1
# diagnose debug enable
```

To check if a DDNS server is available:

```
# diagnose test application ddnscd 3
```

Not available:

```
FortiDDNS status:
ddns_ip=0.0.0.0, ddns_ip6=::, ddns_port=443 svr_num=0 domain_num=0
```

Available:

```
FortiDDNS status:

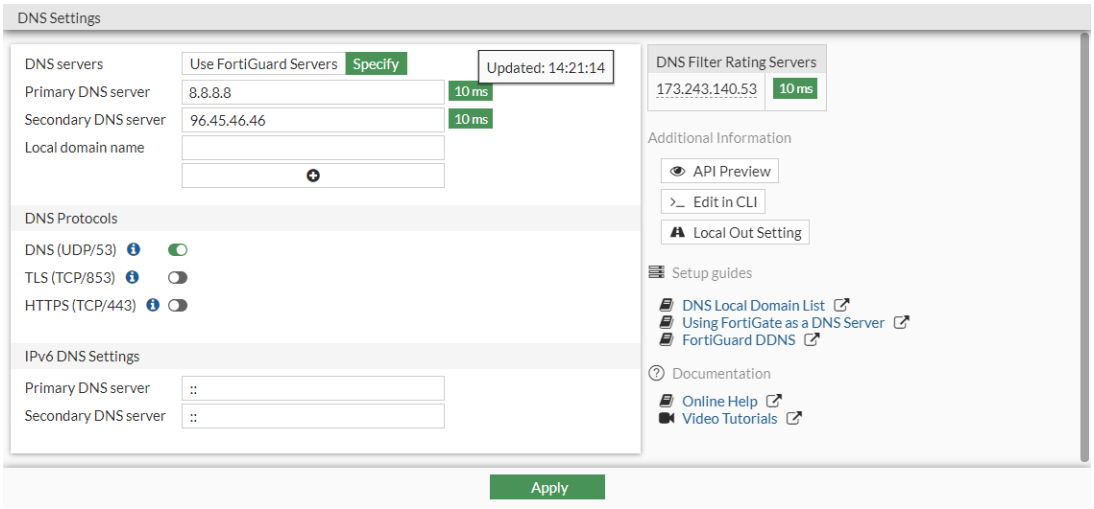
```

DNS latency information

High latency in DNS traffic can result in an overall sluggish experience for end-users. In the *DNS Settings* pane, you can quickly identify DNS latency issues in your configuration.

Go to *Network* > *DNS* to view DNS latency information in the right side bar. If you use FortiGuard DNS, latency information for DNS, DNS filter, web filter, and outbreak prevention servers is also visible. Hover your pointer over a latency value to see when it was last updated.



To view DNS latency information using the CLI:

```
# diagnose test application dnsproxy 2
worker idx: 0
worker: count=1 idx=0
retry_interval=500 query_timeout=1495
DNS latency info:
vfid=0 server=2001::1 latency=1494 updated=73311
vfid=0 server=96.45.46.46 latency=1405 updated=2547
vfid=0 server=8.8.8.8 latency=19 updated=91
SDNS latency info:
vfid=0 server=173.243.140.53 latency=1 updated=707681
DNS_CACHE: alloc=35, hit=26
RATING_CACHE: alloc=1, hit=49
DNS UDP: req=66769 res=63438 fwd=83526 alloc=0 cmp=0 retrans=16855 to=3233
          cur=111 switched=8823467 num_switched=294 v6_cur=80 v6_switched=7689041 num_v6_
switched=6
         ftg_res=8 ftg_fwd=8 ftg_retrans=0
DNS TCP: req=0, res=0, fwd=0, retrans=0 alloc=0, to=0

```

DNS over TLS and HTTPS

DNS over TLS (DoT) is a security protocol for encrypting and encapsulating DNS queries and responses over the TLS protocol. DoT increases user privacy and security by preventing eavesdropping and manipulation of DNS data via man-in-the-middle attacks. Similarly, DNS over HTTPS (DoH) provides a method of performing DNS resolution over a secure HTTPS connection. DoT and DoH are supported in explicit mode where the FortiGate acts as an explicit DNS server that listens for DoT and DoH requests. Local-out DNS traffic over TLS and HTTPS is also supported.

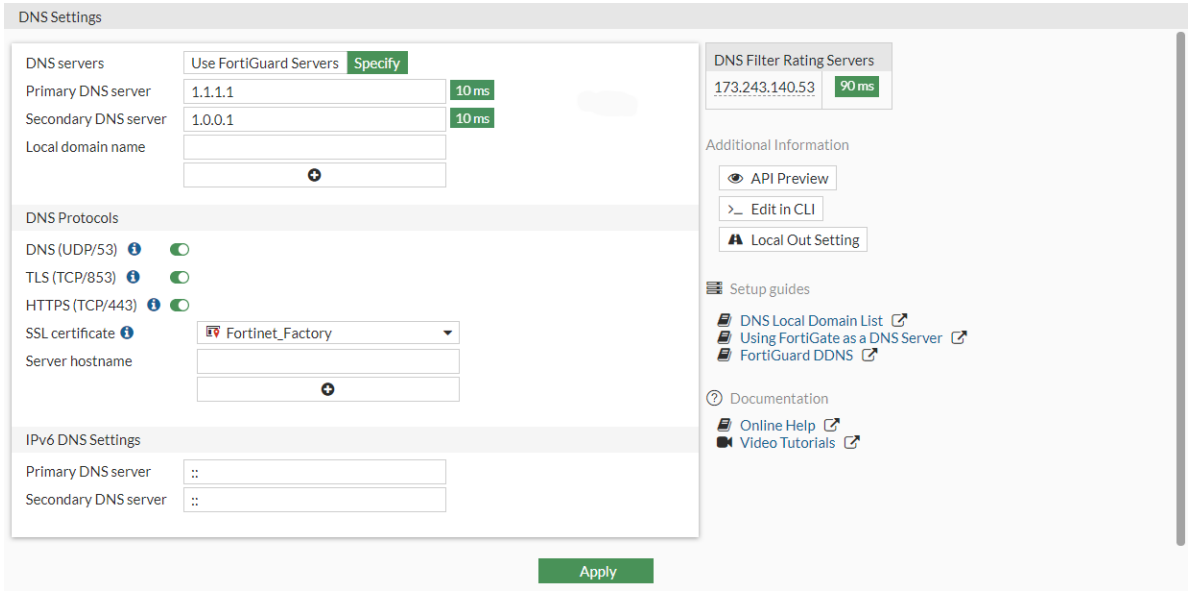
Basic configurations for enabling DoT and DoH for local-out DNS queries

Before enabling DoT or DoH, ensure that they are supported by the DNS servers. The legacy FortiGuard DNS servers (208.91.112.53 and 208.91.112.52) do not support DoT or DoH queries, and will drop these packets. At times, the latency status of the DNS servers might also appear high or unreachable.

Disabling DoT and DoH is recommended when they are not supported by the DNS servers.

To enable DoT and DoH DNS in the GUI:

1. Go to *Network* > *DNS*.
2. Enter the primary and secondary DNS server addresses.
3. In the *DNS Protocols* section, enable *TLS (TCP/853)* and *HTTPS (TCP/443)*.



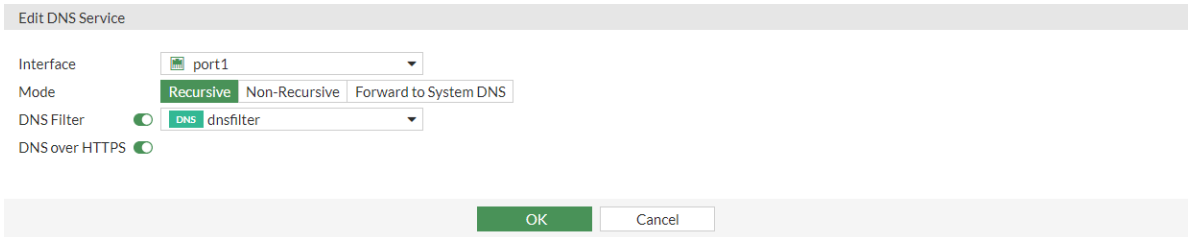
4. Configure the other settings as needed.
5. Click *Apply*.

To enable DoT and DoH DNS in the CLI:

```
config system dns
    set primary 1.1.1.1
    set secondary 1.0.0.1
    set protocol {cleartext dot doh}
end
```

To enable DoH on the DNS server in the GUI:

1. Go to *Network* > *DNS Servers*.
2. In the *DNS Service on Interface* section, edit an existing interface, or create a new one.
3. Select a *Mode*, and *DNS Filter* profile.
4. Enable *DNS over HTTPS*.



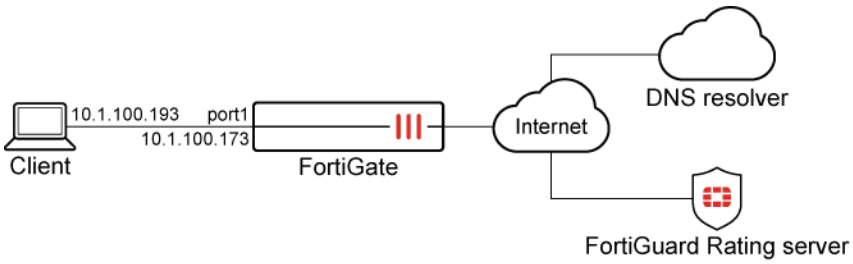
5. Click *OK*.

To enable DoH on the DNS server in the CLI:

```
config system dns-server
    edit "port1"
        set dnsfilter-profile "dnsfilter"
        set doh enable
    next
end
```

Examples

The following examples demonstrate how configure DNS settings to support DoT and DoH queries made to the FortiGate.



DoT

The following example uses a DNS filter profile where the education category is blocked.

To enable scanning DoT traffic in explicit mode with a DNS filter:

1. Configure the DNS settings:

```
config system dns
    set primary 1.1.1.1
    set secondary 1.0.0.1
    set protocol dot
end
```

2. Configure the DNS filter profile:

```
config dnsfilter profile
    edit "dnsfilter"
        config ftgd-dns
            config filters
                edit 1
                    set category 30
                    set action block
                next
            end
        end
```

```
   next
end
```

3. Configure the DNS server settings:

```
config system dns-server
    edit "port1"
        set dnsfilter-profile "dnsfilter"
    next
end
```

4. Send a DNS query over TLS (this example uses kdig on an Ubuntu client) using the FortiGate as the DNS server. The www.ubc.ca domain belongs to the education category:

```
root@client:/tmp# kdig -d @10.1.100.173 +tls +header +all www.ubc.ca
;; DEBUG: Querying for owner(www.ubc.ca.), class(1), type(1), server(10.1.100.173), port(853),
protocol(TCP)
;; DEBUG: TLS, received certificate hierarchy:
;; DEBUG:  #1,
C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=FortiGate,CN=FG3H1E5818903681,EMAIL=support@forti
net.com
;; DEBUG:      SHA-256 PIN: Xhkpv9ABEhxDLtWG+lGEndNrBR7B1xjRYlGn2ltlkb8=
;; DEBUG:  #2, C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=Certificate Authority,CN=fortinet-
subca2001,EMAIL=support@fortinet.com
;; DEBUG:      SHA-256 PIN: 3T8EqFBjpRSkxQNPFagjUNeEUghXOEYp904ROlJM8yo=
;; DEBUG:  #3, C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=Certificate Authority,CN=fortinet-
ca2,EMAIL=support@fortinet.com
;; DEBUG:      SHA-256 PIN: /QfV4N3k5oxQR5RHtW/rbn/HrHgKpMLN0DEaeXY5yPg=
;; DEBUG: TLS, skipping certificate PIN check
;; DEBUG: TLS, skipping certificate verification
;; TLS session (TLS1.2)-(ECDHE-RSA-SECP256R1)-(AES-256-GCM)
;; ->>HEADER<<- opcode: QUERY; status: NOERROR; id: 56719
;; Flags: qr rd; QUERY: 1; ANSWER: 1; AUTHORITY: 0; ADDITIONAL: 0

;; QUESTION SECTION:
;; www.ubc.ca.                  IN      A

;; ANSWER SECTION:
www.ubc.ca.             60      IN      A       208.91.112.55

;; Received 44 B
;; Time 2021-03-12 23:11:27 PST
;; From 10.1.100.173@853(TCP) in 0.2 ms
root@client:/tmp#
```

The IP returned by the FortiGate for ubc.ca belongs to the FortiGuard block page, so the query was blocked successfully.

DoH

The following example uses a DNS filter profile where the education category is blocked.

To configure scanning DoH traffic in explicit mode with a DNS filter:

1. Configure the DNS settings:

```
config system dns
    set primary 1.1.1.1
    set secondary 1.0.0.1
    set protocol doh
end
```

2. Configure the DNS filter profile:

```
config dnsfilter profile
    edit "dnsfilter"
        config ftgd-dns
            config filters
                edit 1
                    set category 30
                    set action block
                next
            end
        end
    next
end
```

3. Configure the DNS server settings:

```
config system dns-server
    edit "port1"
        set dnsfilter-profile "dnsfilter"
        set doh enable
    next
end
```

4. In your browser, enable DNS over HTTPS.
5. On your computer, edit the TCP/IP settings to use the FortiGate interface address as the DNS server.
6. In your browser, go to a website in the education category (www.ubc.ca). The website is redirected to the block page.

Transparent conditional DNS forwarder

The transparent conditional DNS forwarder allows the FortiGate to intercept and reroute DNS queries for specific domains to a specific DNS server. For example, when a client's DNS is located in a distant location, in order to resolve destination addresses (such as SaaS applications) to the closest application server, the FortiGate can intercept and reroute the requests to a local DNS to resolve.

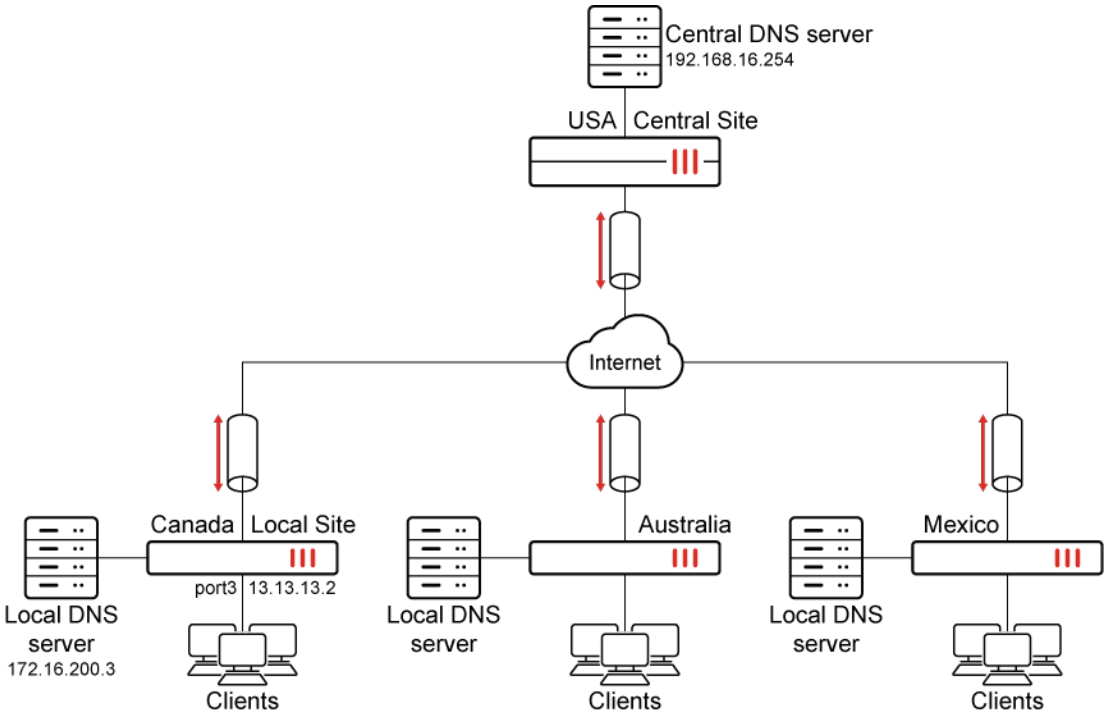
This is done by parsing entries and creating a list of filters based on the domain names of zones. When a DNS request matches one of these filters, the DNS proxy will retrieve the zone's data. The DNS request will then be handled based on the zone's forwarder settings and whether a local answer is available. It may be forwarded to the original destination address, the forwarder address, or not forwarded at all if a local answer is available.

This provides greater control over DNS requests, especially when the administrator is not managing the DNS server configuration of the client devices. This can improve network efficiency and performance by resolving IPs local to the client's PCs rather than IPs local to the central DNS server.

This feature is not supported on FortiGate models with 2 GB RAM or less. See Proxy-related features not supported on FortiGate 2 GB RAM models on page 98 for more information.

Example

In this example, FortiGates at various locations are connected to a central site by VPN tunnels where the corporate DNS server is located. Typically, DNS queries from different sites are sent to the central DNS server and resolved to an IP local to the central site, which might cause latency and performance issues for certain destinations, such as SaaS applications.



The Local Site FortiGate is configured with the Microsoft domain and a local DNS entry. Traffic matching the Microsoft domain is either forwarded to the local DNS server or resolved by the FortiGate, which resolves it to an IP local to the Local Site, thus improving performance.

This example assumes the following have been configured:

- A successfully operational site-to-site VPN between the Local Site and the Central Site FortiGates (see Site-to-site VPN on page 2414 for more information).
- Appropriate routing and network interfaces.
- The client PCs are configured to use the Central DNS Server.

The transparent conditional DNS forwarder feature only works with a proxy-based firewall policy.

By default, DNS server options are not available in the GUI.

To enable DNS server options in the GUI:

1. Go to *System* > *Feature Visibility*.
2. In the *Additional Features* section, enable *DNS Database*.
3. Click *Apply*.

To configure the DNS zone and local DNS entries on the Local Site FortiGate in the GUI:

1. Go to *Network* > *DNS Servers*.
2. In the *DNS Database* table, click *Create New*.
3. Enter a *DNS Zone* name (*SaaS_applications*).
4. Enter a *Domain Name* (*microsoft.com*).
5. Disable the *Authoritative* setting.
6. In the *DNS Forwarder* field, click the *+* and enter the DNS Forwarder address (*172.16.200.3*).
7. Configure the DNS entry:
   a. In the *DNS Entries* table, click *Create New*.
   b. Set the *Type* to *Address (A)*.
   c. Enter a *Hostname* (*office*).
   d. Configure the remaining settings as needed. The options vary depending on the selected *Type*.
   e. Click *OK*.
   f. Optionally, add more DNS entries if needed.
8. In the CLI, configure the source IP:

```
config system dns-database
    edit "SaaS_applications"
        set source-ip 13.13.13.2
    next
end
```

If the DNS server is accessed over a VPN, it may be necessary to specify a source IP for the FortiGate to reach the DNS server. See How to let the FortiGate access internal DNS through site-to-site IPsec VPN for more information.

Site-to-site VPN is not a mandatory requirement for this feature to work and is only applicable to this example.

To configure the DNS zone and local DNS entries on the Local Site FortiGate in the CLI:

```
config system dns-database
    edit "SaaS_applications"
        set domain "microsoft.com"
        set authoritative disable
        set forwarder "172.16.200.3"
        set source-ip 13.13.13.2
        config dns-entry
            edit 1
                set hostname "office"
                set ip 172.16.200.55
            next
        end
    next
end
```

To add the DNS database to a DNS filter profile:

```
config dnsfilter profile
    edit "SaaS"
        set transparent-dns-database "SaaS_applications"
    next
end
```

Multiple DNS databases can be selected for `transparent-dns-database`.

After selecting a DNS database, users are not permitted to modify the domain name of the zone. Before making any changes to the domain name, remove the reference from the `dnsfilter profile`.

To apply the DNS filter profile in a firewall policy in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy* and edit the outbound policy towards the IPsec VPN tunnel.
2. Set the *Inspection Mode* to *Proxy-based*.
3. In the *Security Profiles* section, enable *DNS filter* and select the profile created in the previous procedure (*SaaS*).
4. In the *Logging Options* section, enable *Log allowed traffic*.
5. Configure the remaining settings as needed.
6. Click *OK*.

To apply the DNS filter profile to the outbound policy towards the IPsec VPN tunnel in the CLI:

```
config firewall policy
    edit 1
        set name "outbound_VPN"
        ...
        set inspection-mode proxy
        set dnsfilter-profile "SaaS"
```

```
        set logtraffic enable
        ...
    next
end
```

To verify the configuration:

From one of the Windows client desktops, use the `nslookup` command to send various DNS queries.

1. Send a DNS query for a DNS entry configured locally on the Local Site FortiGate:

   ```
   C:\Users\demo>nslookup office.microsoft.com
   Server:  Unknown
   Address:  192.168.16.254
   Non-authoritative answer:
   Name:     osiprod-wus-pineapple-100.westus.cloudapp.azure.com
   Address:  172.16.200.55
   ```

   The query is resolved to the IP address configured on the Local Site FortiGate.
2. Send a DNS query for the domain configured on the Local Site FortiGate:

   ```
   C:\Users\demo>nslookup teams.microsoft.com
   Server:  Unknown
   Address:  192.168.16.254
   Non-authoritative answer:
   Name:     s-0005.s-msedge.net
   Address:  172.16.200.254
   ```

   The query is resolved by the local DNS server.
3. Send a DNS query for a domain that is not configured on the Local Site FortiGate:

   ```
   C:\Users\demo>nslookup facebook.com
   Server:  Unknown
   Address:  192.168.16.254
   Non-authoritative answer:
   Name:    facebook.com
   Addresses:  157.240.249.35
   ```

   The query is resolved by the central DNS server.

IPv6 support for conditional DNS forwarder

The configuration for IPv6 is similar to an IPv4 conditional DNS forwarder. When configuring the DNS forwarder address, the IPv6 address must be specified.

To configure a DNS forwarder:

```
config system dns-database
    edit <name>
        set source-ip6 <IPv6_address>
        set forwarder6 <IPv6_address>
```

```
    next
end
```

If the DNS server is accessed over a VPN, it may be necessary to specify a source IP for the FortiGate to reach the DNS server. See How to let the FortiGate access internal DNS through site-to-site IPsec VPN for more information.

Interfaces in non-management VDOMs as the source IP address of the DNS conditional forwarding server

Interfaces that are in non-management VDOMs can be the source IP address of the DNS conditional forwarding server.

- When `vdom-dns` is enabled in a VDOM, only the IP addresses of interfaces in that VDOM can be configured as the `source-ip`.
- When `vdom-dns` is disabled (default), only the IP address of interfaces in the management VDOM can be configured as the `source-ip`.

For more information on VDOM DNS, see Important DNS CLI commands on page 289.

In this example:

- `vdom1` is a non-management VDOM
- `port8` is assigned to `vdom1` and has IP address 13.13.13.13
- `port1` is assigned to the management VDOM (root) and has IP address 172.16.200.1

To configure the interfaces:

```
config global
    config system interface
        edit "port8"
            set vdom "vdom1"
            set ip 13.13.13.13 255.255.255.0
        next
        edit "port1"
            set vdom "root"
            set ip 172.16.200.1 255.255.255.0
        next
    end
end
```

To test configuring a source IP address when `vdom-dns` is disabled:

```
config vdom
    edit vdom1
        config system vdom-dns
            set vdom-dns disable
```

```
        end
    next
end
```

- port8 cannot be used as the source IP address in a DNS database because it is assigned to vdom1, and not to a management VDOM:

```
config vdom
    edit vdom1
        config system dns-database
            edit "1"
                set source-ip 13.13.13.13
13.13.13.13 does not match any interface ip in vdom root.
node_check_object fail! for source-ip 13.13.13.13
```

- port1 can be used as the source IP address in a DNS database because it is assigned to the management VDOM:

```
config vdom
    edit vdom1
        config system dns-database
            edit "1"
                set source-ip 172.16.200.1
            next
        end
    next
end
```

To test configuring a source IP address when vdom-dns is enabled:

```
config vdom
    edit vdom1
        config system vdom-dns
            set vdom-dns enable
        end
    next
end
```

- port8 can be used as the source IP address in a DNS database because it is assigned to the vdom1:

```
config vdom
    edit vdom1
        config system dns-database
            edit "1"
                set source-ip 13.13.13.13
            next
        end
    next
end
```

- port1 cannot be used as the source IP address in a DNS database because it is assigned to the management VDOM, and not to vdom1:

```
config vdom
    edit vdom1
        config system dns-database
            edit "1"
                set source-ip 172.16.200.1
172.16.200.1 does not match any interface ip in vdom vdom1.
node_check_object fail! for source-ip 172.16.200.1
```

DNS session helpers

DNS session helpers work in the background, passively learning hostnames and A/AAAA records from the DNS traffic that is being forwarded through the FortiGate. The learned address records are then stored as a hostname cache and FQDN addresses. These stored address records are subsequently utilized by the DNS proxy. This passive learning approach enables FortiOS to correspond with DNS traffic and acquire address records when possible, eliminating the need for active FQDN queries or reverse DNS lookups. This reduces the necessity to connect to the actual server, effectively diminishing the overall FortiGate traffic to the DNS server.

FortiOS incorporates two types of DNS session helpers: `dns-udp` and `dns-tcp`.

By default, FortiOS enables the `dns-udp` session helper and disables the `dns-tcp` session helper. This default configuration is based on the fact that the majority of DNS traffic occurs over UDP due to its lower overhead and faster response times. However, FortiOS provides the flexibility to enable `dns-tcp` if required.

To enable the DNS session helper from listening on TCP port 53:

```
config system session-helper
    edit 0
        set name dns-tcp
        set port 53
        set protocol 6
    next
end
```

Use the `show system session-helper` command to view the current session helper configuration.

To accept DNS sessions you must add a security policy with service set to *ALL* or to the DNS predefined service (which listens on TCP and UDP ports 53).

Disabling DNS session helper

In certain scenarios, you might consider disabling the DNS session helper. This action essentially removes it from the session-helper list, preventing the session helper from listening on port 53. Once the DNS session helper is disabled, the hostname cache and FQDN addresses will no longer be curated from the DNS traffic. Consequently, the DNS proxy will need to dispatch requests to servers to retrieve the necessary information, which could potentially increase the load on the DNS proxy.

DNS session helper is required for wildcard FQDN addresses, as they are initially empty. The FortiGate analyzes client DNS responses, adding any IP addresses found to the relevant wildcard FQDN object. See Using wildcard FQDN addresses in firewall policies on page 1752.

To disable the DNS session helper from listening on UDP port 53:

1. Enter the following command to find the DNS session helper entry that listens on UDP port 53:

```
#show system session-helper
…
    edit 14
        set name dns-udp
        set protocol 17
        set port 53
    next
…
```

2. Enter the following command to delete DNS session helper:

```
config system session-helper
    delete 14
end
```

Similarly, the DNS session helper can be disabled from listening on TCP port 53.

DNS troubleshooting

The following diagnose command can be used to collect DNS debug information. If you do not specify worker ID, the default worker ID is `0`.

```
# diagnose test application dnsproxy
worker idx: 0
1. Clear DNS cache
2. Show stats
3. Dump DNS setting
4. Reload FQDN
5. Requery FQDN
6. Dump FQDN
7. Dump DNS cache
8. Dump DNS DB
9. Reload DNS DB
10. Dump secure DNS policy/profile
11. Dump Botnet domain
12. Reload Secure DNS setting
13. Show Hostname cache
14. Clear Hostname cache
15. Show SDNS rating cache
16. Clear SDNS rating cache
```

```
17. DNS debug bit mask
18. DNS debug obj mem
99. Restart dnsproxy worker
```

To view useful information about the ongoing DNS connection:

```
# diagnose test application dnsproxy 3
worker idx: 0
vdom: root, index=0, is primary, vdom dns is disabled, mip-169.254.0.1 dns_log=1 tls=0 cert=
dns64 is disabled

FGD_REDIR_V4:208.91.112.55 FGD_REDIR_V6:
```

Important fields include:

`tls`	1 if the connection is TLS, 0 if the connection is not TLS.
`rt`	The round trip time of the DNS latency.
`probe`	The number of probes sent.

To dump the second DNS worker's cache:

```
# diagnose test application dnsproxy 7 1
```

To enable debug on the second worker:

```
# diagnose debug application dnsproxy -1 1
```

To enable debug on all workers by specifying -1 as worker ID:

```
# diagnose debug application dnsproxy -1 -1
```

Explicit and transparent proxies

This section contains instructions for configuring explicit and transparent proxies.

- Explicit web proxy on page 334
- Transparent proxy on page 342
- FTP proxy on page 338
- Proxy policy addresses on page 344
- Proxy policy security profiles on page 351
- Explicit proxy authentication on page 356
- Transparent web proxy forwarding on page 362
- Transparent web proxy forwarding over IPv6 on page 366
- Upstream proxy authentication in transparent proxy mode on page 369
- Multiple dynamic header count on page 371
- Restricted SaaS access on page 374
- Explicit proxy and FortiGate Cloud Sandbox on page 382
- Proxy chaining on page 385
- WAN optimization SSL proxy chaining on page 390
- Agentless NTLM authentication for web proxy on page 398
- Multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers on page 402
- Learn client IP addresses on page 403
- Explicit proxy authentication over HTTPS on page 404
- mTLS client certificate authentication on page 406
- CORS protocol in explicit web proxy when using session-based, cookie-enabled, and captive portal-enabled SAML authentication on page 412
- Display CORS content in an explicit proxy environment on page 415
- HTTP connection coalescing and concurrent multiplexing for explicit proxy on page 417
- Secure explicit proxy on page 419
- Secure explicit proxy with client certificates on page 422

- Configuring fast fallback for explicit proxy on page 434
- Forward HTTPS requests to a web server without the need for an HTTP CONNECT message on page 438
- Specifying outgoing interface and VRF for a web proxy forward server or isolator server on page 440

- Isolator servers in proxy policies on page 442

This feature is not supported on FortiGate models with 2 GB RAM or less. See Proxy-related features not supported on FortiGate 2 GB RAM models on page 98 for more information.

Explicit web proxy

Explicit web proxy can be configured on FortiGate for proxying HTTP and HTTPS traffic.

To deploy explicit proxy, individual client browsers can be manually configured to send requests directly to the proxy, or they can be configured to download proxy configuration instructions from a Proxy Auto-Configuration (PAC) file.

When explicit proxy is configured on an interface, the interface IP address can be used by client browsers to forward requests directly to the FortiGate. FortiGate also supports PAC file configuration.

For FortiOS 7.4.0, SSL VPN web mode, explicit web proxy, and interface mode IPsec VPN features will not work with the following configuration:

1. An IP pool with ARP reply enabled is configured.
2. This IP pool is configured as the source IP address in a firewall policy for SSL VPN web mode, in a proxy policy for explicit web proxy, or as the local gateway in the Phase 1 settings for an interface mode IPsec VPN.
3. A matching blackhole route is configured for IP pool reply traffic.

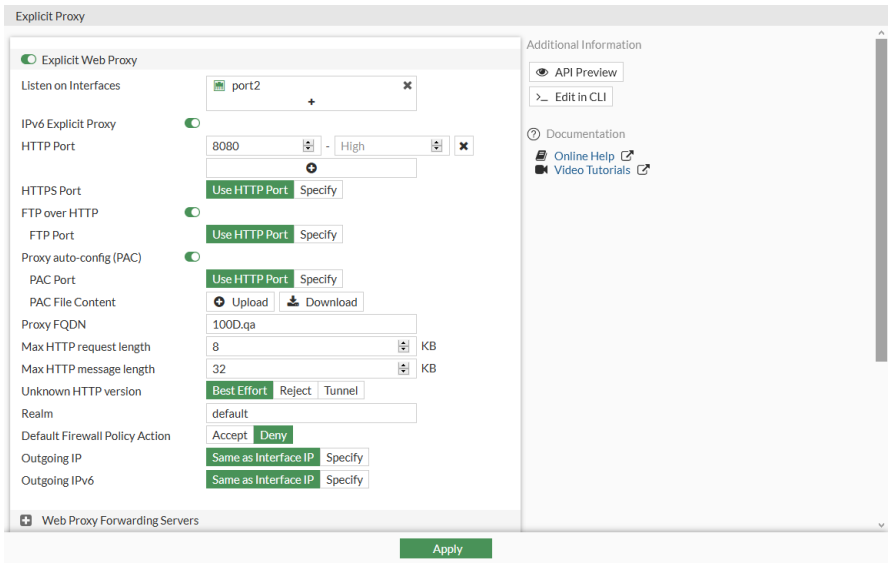
Configuring an IP pool as the source NAT IP address in a regular firewall policy works as before.

For details, see Technical Tip: IP pool and virtual IP behaviour changes in FortiOS 6.4, 7.0, 7.2, and 7.4.

Isolator servers can be applied in explicit proxy policies to distinguish isolated traffic from normal traffic in logs. See Isolator servers in proxy policies on page 442.

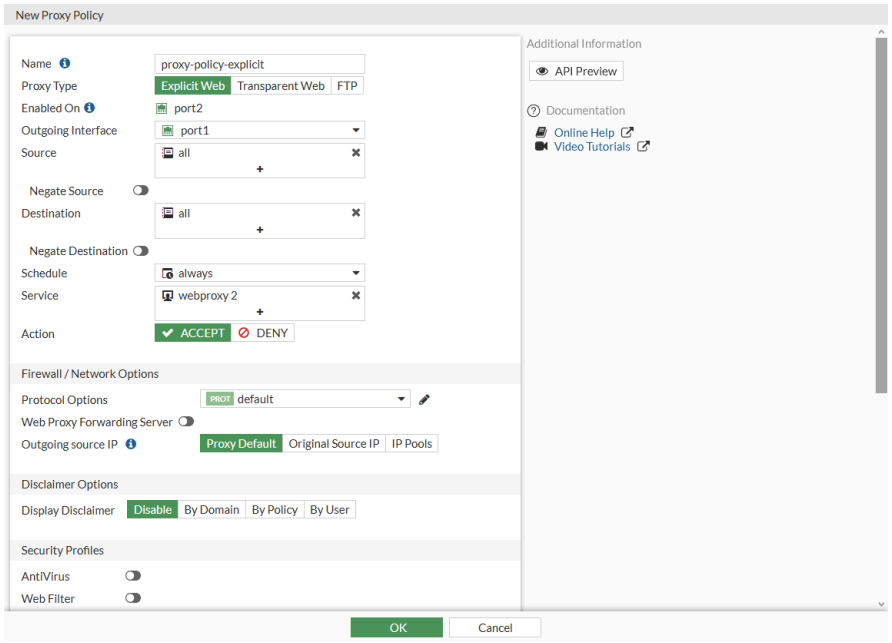
To configure explicit web proxy in the GUI:

1. Enable and configure explicit web proxy:
   a. Go to *Network* > *Explicit Proxy*.
   b. Enable *Explicit Web Proxy*.
   c. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *8080*.
   d. Configure the remaining settings as needed.



e. Click *Apply*.

2. Create an explicit web proxy policy:
   a. Go to *Policy & Objects* > *Proxy Policy*.
   b. Click *Create New*.
   c. Set *Proxy Type* to *Explicit Web* and *Outgoing Interface* to *port1*.
   d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.



e. Click *OK* to create the policy.

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. Configure a client to use the FortiGate explicit proxy:
   Set the FortiGate IP address as the proxy IP address in the browser, or use an automatic configuration script for the PAC file.

To configure explicit web proxy in the CLI:

1. Enable and configure explicit web proxy:

```
config web-proxy explicit
    set status enable
    set ftp-over-http enable
    set socks enable
    set http-incoming-port 8080
    set ipv6-status enable
    set unknown-http-version best-effort
end
config system interface
    edit "port2"
        set vdom "vdom1"
        set ip 10.1.100.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set explicit-web-proxy enable
        set snmp-index 12
        end
    next
end
```

2. Create an explicit web proxy policy:

```
config firewall proxy-policy
    edit 1
        set name "proxy-policy-explicit"
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
    next
end
```

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. Configure a client to use the FortiGate explicit web proxy:
   Set the FortiGate IP address as the proxy IP address in the browser, or use an automatic configuration script for the PAC file.

Downloading a PAC file using HTTPS

PAC files can be downloaded for an explicit proxy through the FortiGate's captive portal using HTTPS to ensure a secure download.

In this example, a Windows PC has an HTTPS URL configured in its proxy settings to download a PAC file from a FortiGate by using a download link, https://cp.myqalab.local:7831/proxy.pac, through a captive portal. Once the PAC file is securely downloaded using HTTPS, browsers installed on the PC can use the proxy in the PAC file to visit a website.

The global web proxy settings must be configured to use a customized SSL certificate because the default Fortinet_Factory certificate will not be accepted by Windows due to security restrictions. The customized SSL certificate is used as the HTTPS server's certificate on the FortiGate. All CA certificates in the server certificate must be installed and trusted on the Windows PC.

To download a PAC file using HTTPS:

1. Configure the explicit web proxy to get a PAC file through HTTPS:

```
config web-proxy explicit
    set pac-file-server-status enable
    unset pac-file-server-port
    set pac-file-name "proxy.pac"
    set pac-file-data "function FindProxyForURL(url, host) {
   // testtest
   return \"PROXY 10.1.100.1:8080\";
}
"
    set pac-file-through-https enable
end
```

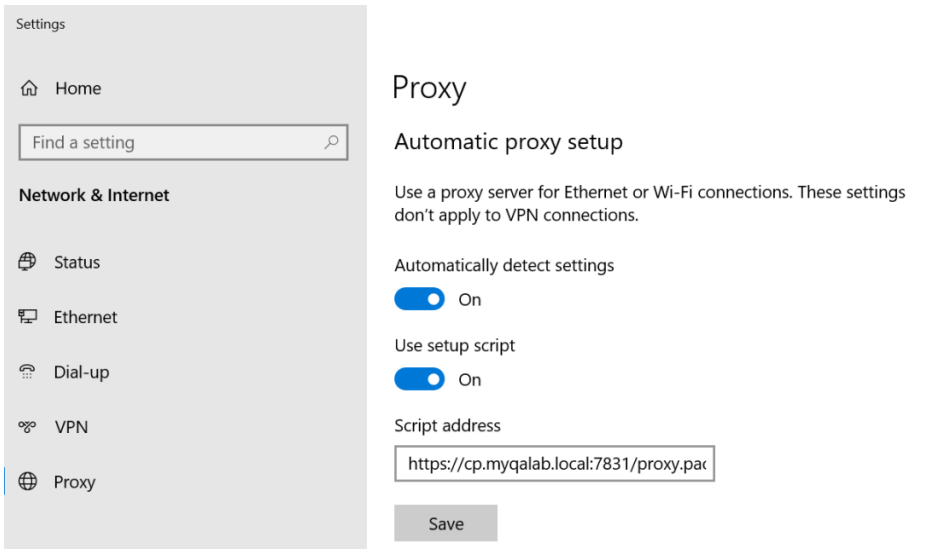
2. Configure the captive portal to be used as an HTTPS server to provide the service to download the PAC file:

```
config authentication setting
    set captive-portal-type ip
    set captive-portal-ip 10.1.100.1
    set captive-portal-ssl-port 7831
end
```

3. Configure the global web proxy settings to use a customized SSL certificate:

```
config web-proxy global
    set ssl-cert "server_cert"
end
```

4. On the Windows PC, go to *Settings* > *Network & Internet* > *Proxy*.



5. In the *Automatic proxy setup* section, click *Save* to trigger the PAC file download from the HTTPS URL.

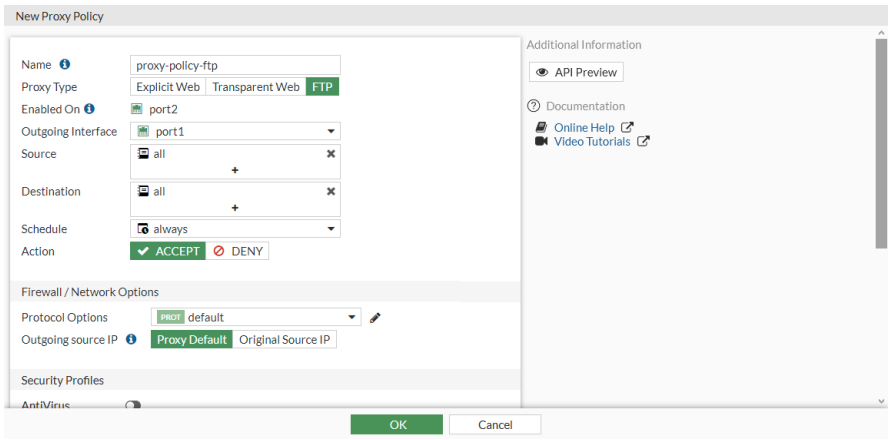
FTP proxy

FTP proxies can be configured on the FortiGate so that FTP traffic can be proxied. When the FortiGate is configured as an FTP proxy, FTP client applications should be configured to send FTP requests to the FortiGate.

To configure explicit FTP proxy in the GUI:

1. Enable and configure explicit FTP proxy:
   a. Go to *Network* > *Explicit Proxy*.
   b. Enable *Explicit FTP Proxy*.
   c. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *21*.
   d. Configure the *Default Firewall Policy Action* as needed.

   e. Click *Apply*.
2. Create an explicit FTP proxy policy:
   a. Go to *Policy & Objects* > *Proxy Policy*.
   b. Click *Create New*.
   c. Set *Proxy Type* to *FTP* and *Outgoing Interface* to *port1*.
   d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, and *Action* to *ACCEPT*.



e. Click *OK* to create the policy.

This example creates a basic policy. If required, security profiles can be enabled.

3. Configure the FTP client application to use the FortiGate IP address.

To configure explicit FTP proxy in the CLI:

1. Enable and configure explicit FTP proxy:

```
config ftp-proxy explicit
    set status enable
    set incoming-port 21
end
config system interface
    edit "port2"
        set vdom "vdom1"
        set ip 10.1.100.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set explicit-ftp-proxy enable
        set snmp-index 12
    next
end
```

2. Create an explicit FTP proxy policy:

```
config firewall proxy-policy
    edit 4
        set name "proxy-policy-ftp"
        set proxy ftp
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
```

```
    next
end
```

This example creates a basic policy. If required, security profiles can be enabled.

3. Configure the FTP client application to use the FortiGate IP address.

Changing the FTP mode from active to passive for explicit proxy

An explicit FTP proxy can convert an active FTP connection initiated by an FTP client to a passive FTP connection between the explicit FTP proxy and FTP server.

```
config ftp-proxy explicit
    set server-data-mode {client | passive}
end
```

`server-data-mode {client | passive}`	Set the data selection mode on the FTP server side: • `client`: use the same transmission mode for client and server data sessions (default). • `passive`: use passive mode for server data sessions.

In this example, a client that only supports active mode FTP connects to a remote FTP server through the explicit FTP proxy to download a text file (test1.txt). The explicit FTP proxy converts the active FTP connection to a passive connection between the explicit FTP proxy and the FTP server.

To configure passive mode for FTP server data sessions:

1. Configure the web proxy:

```
config ftp-proxy explicit
    set status enable
    set incoming-port 21
    set server-data-mode passive
end
```

2. Enable the explicit FTP proxy on port1:

```
config system interface
    edit "port1"
        set ip 10.1.100.2 255.255.255.0
        set explicit-ftp-proxy enable
```

```
   next
end
```

3. Configure the firewall policy:

```
config firewall proxy-policy
    edit 1
        set proxy ftp
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
    next
end
```

4. Get the client to download the text file from the FTP server (NcFTP is used in this example):

```
ncftpget -E -r 0 -d stdout -u pc4user1@172.16.200.44 -p 123456 10.1.100.2 ./
/home/pc4user1/test1.txt
...
Cmd: PORT 10,1,100,11,151,115
200: PORT command successful. Consider using PASV.
Cmd: RETR /home/pc4user1/test1.txt
```

5. In the FTP server logs, verify that the explicit FTP proxy converted the active FTP connection to a passive connection:

```
...
2023-01-28 01:56:39,909 webproxy_pc04 proftpd[1104] webproxy_pc04 (172.16.200.2

```

Transparent proxy

In a transparent proxy deployment, the user's client software, such as a browser, is unaware that it is communicating with a proxy.

Users request internet content as usual, without any special client configuration, and the proxy serves their requests. FortiGate also allows users to configure in transparent proxy mode.

To redirect HTTPS traffic, SSL deep inspection is required.

HTTP and HTTPS traffic that is successfully redirected to a proxy policy is subject to security profiles configured on the proxy policy, not the base firewall policy. Security profiles configured on the base firewall policy still apply to other traffic, such as FTP.

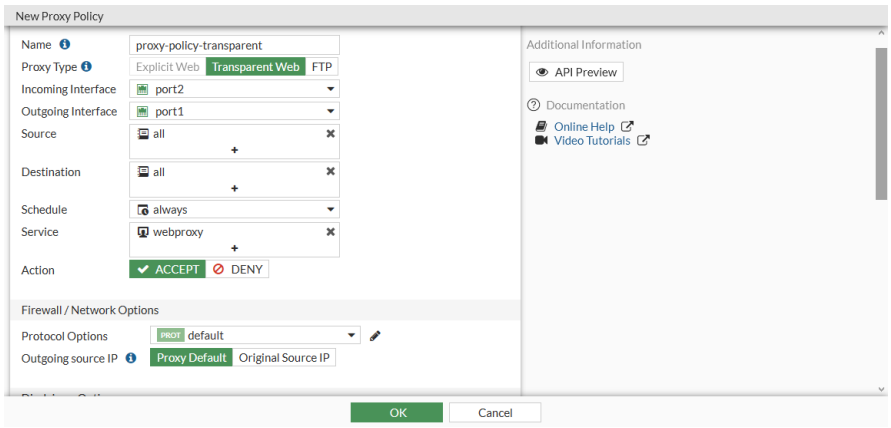
Isolator servers can be applied in transparent proxy policies to distinguish isolated traffic from normal traffic in logs. See Isolator servers in proxy policies on page 442.

To configure transparent proxy in the GUI:

1. Configure a regular firewall policy with HTTP redirect:
   a. Go to *Policy & Objects* > *Firewall Policy*.
   b. Click *Create New*.
   c. Name the policy appropriately, set the *Incoming interface* to *port2*, and set the *Outgoing interface* to *port1*.
   d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, *Service* to *ALL*, and *Action* to *ACCEPT*.
   e. Set *Inspection Mode* to *Proxy-based* and *SSL Inspection* to *deep-inspection*.
   f. Configure the remaining settings as needed.
   g. Click *OK*.

   By default, HTTP redirect can only be enabled in the CLI. Enable *Policy Advanced Options* in *Feature Visibility* to configure it in the GUI. See Feature visibility on page 3595 on page 1 for more information.

2. Configure a transparent proxy policy:
   a. Go to *Policy & Objects* > *Proxy Policy*.
   b. Click *Create New*.
   c. Set *Proxy Type* to *Transparent Web*, set the *Incoming Interface* to *port2*, and set the *Outgoing Interface* to *port1*.
   d. Also set *Source* and *Destination* to *all*, *Schedule*to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.



e. Configure the remaining settings as needed.

f. Click *OK* to create the policy.

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

---

3. No special configuration is required on the client to use FortiGate transparent proxy. As the client is using the FortiGate as its default gateway, requests will first hit the regular firewall policy, and then be redirected to the transparent proxy policy.

To configure transparent proxy in the CLI:

1. Configure a regular firewall policy with HTTP redirect:

```
config firewall policy
    edit 1
        set name "LAN To WAN"
        set srcintf "port2"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set inspection-mode proxy
        set http-policy-redirect enable
        set fsso disable
        set ssl-ssh-profile "deep-inspection"
        set nat enable
    next
end
```

2. Configure a transparent proxy policy:

```
config firewall proxy-policy
    edit 5
        set name "proxy-policy-transparent"
```

```
        set proxy transparent-web
        set srcintf "port2"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
    next
end
```

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. No special configuration is required on the client to use FortiGate transparent proxy. As the client is using the FortiGate as its default gateway, requests will first hit the regular firewall policy, and then be redirected to the transparent proxy policy.

Proxy policy addresses

Proxy addresses are designed to be used only by proxy policies. The following address types are available:

- Host regex match on page 345
- URL pattern on page 345
- URL category on page 346
- HTTP method on page 347
- HTTP header on page 348
- User agent on page 348
- Advanced (source) on page 349
- Advanced (destination) on page 350

Fast policy match

The fast policy match function improves the performance of IPv4 explicit and transparent web proxies on FortiGate devices.

When enabled, after the proxy policies are configured, the FortiGate builds a fast searching table based on the different proxy policy matching criteria. When fast policy matching is disabled, web proxy traffic is compared to the policies one at a time from the beginning of the policy list.

Fast policy matching is enabled by default, and can be configured with the following CLI command:

```
config web-proxy global
    set fast-policy-match {enable | disable}
end
```

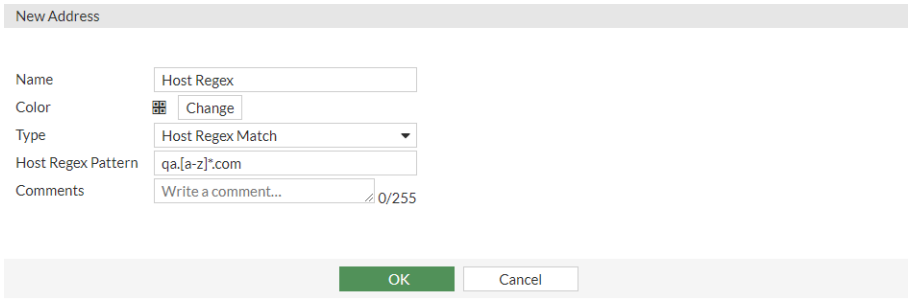
Host regex match

In this address type, a user can create a hostname as a regular expression to match the Host field in the Layer 7 header of a packet. Once created, the hostname address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the regular expression.

This example creates a host regex match address with the pattern *qa.[a-z]*.com*.

To create a host regex match address in the GUI:

1. Go to *Policy & Objects* > *Addresses* and select *Proxy* > *Address*.
2. Click *Create new*.
3. Set the following:
   - *Name* to *Host Regex*,
   - *Type* to *Host Regex Match*, and
   - *Host Regex Pattern* to *qa.[a-z]*.com*.



4. Click *OK*.

To create a host regex match address in the CLI:

```
config firewall proxy-address
    edit "Host Regex"
        set type host-regex
        set host-regex "qa.[a-z]*.com"
    next
end
```

URL pattern

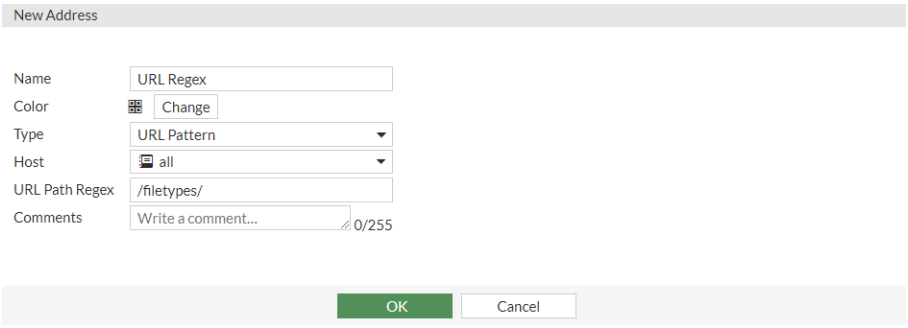
In this address type, a user can create a URL path as a regular expression. Once created, the path address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the regular expression.

This example creates a URL pattern address with the pattern */filetypes/*.

To create a URL pattern address in the GUI:

1. Go to *Policy & Objects* > *Addresses* and select *Proxy* > *Address*.
2. Click *Create new*.

3. Set the following:
   - *Name* to *URL Regex*,
   - *Type* to *URL Pattern*,
   - *Host* to *all*, and
   - *URL Path Regex* to */filetypes/*.



4. Click *OK*.

To create a URL pattern address in the CLI:

```
config firewall proxy-address
    edit "URL Regex"
        set type url
        set host "all"
        set path "/filetypes/"
    next
end
```

URL category

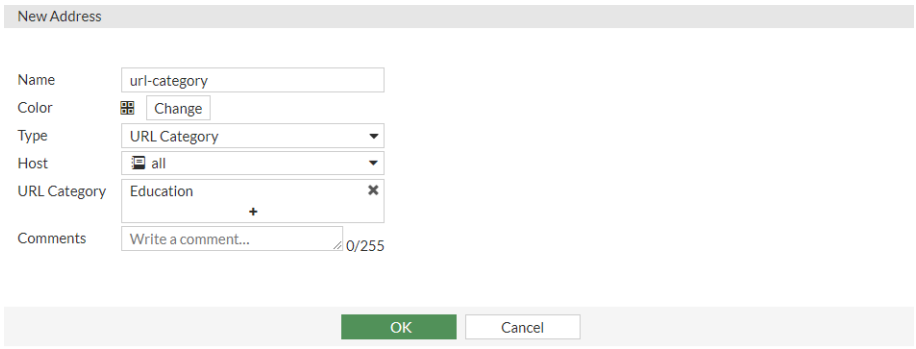
In this address type, a user can create a URL category based on a FortiGuard URL ID. Once created, the address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the URL category.

The example creates a URL category address for URLs in the *Education* category. For more information about categories, see https://fortiguard.com/webfilter/categories.

For information about creating and using custom local and remote categories, see Web rating override on page 2345, Using local and remote categories on page 2354, and External feeds on page 4068.

To create a URL category address in the GUI:

1. Go to *Policy & Objects* > *Addresses* and select *Proxy* > *Address*.
2. Click *Create new*.
3. Set the following:
   - *Name* to *url-category*,
   - *Type* to *URL Category*,
   - *Host* to *all*, and
   - *URL Category* to *Education*.



4. Click *OK*.

To create a URL category address in the CLI:

```
config firewall proxy-address
    edit "url-category"
        set type category
        set host "all"
        set category 30
    next
end
```

To see a list of all the categories and their numbers, when editing the address, enter `set category ?`.

HTTP method

In this address type, a user can create an address based on the HTTP request methods that are used. Multiple method options are supported, including: *CONNECT*, *DELETE*, *GET*, *HEAD*, *OPTIONS*, *OTHER*, *PATCH*, *POST*, *PUT*, *TRACE*, and *UPDATE*. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests that match the selected HTTP method.

The example creates a HTTP method address that uses the GET method.

To create a HTTP method address in the GUI:

1. Go to *Policy & Objects* > *Addresses* and select *Proxy* > *Address*.
2. Click *Create new*.
3. Set the following:
   - *Name* to *method_get*,
   - *Type* to *HTTP Method*,
   - *Host* to *all*, and
   - *Request Method* to *GET*.
4. Click *OK*.

To create a HTTP method address in the CLI:

```
config firewall proxy-address
    edit "method_get"
        set type method
        set host "all"
        set method get
    next
end
```

HTTP header

In this address type, a user can create a HTTP header as a regular expression. Once created, the header address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests where the HTTP header matches the regular expression.

This example creates a HTTP header address with the pattern *Q[A-B]*.

To create a HTTP header address in the GUI:

1. Go to *Policy & Objects* > *Addresses* and select *Proxy* > *Address*.
2. Click *Create new*.
3. Set the following:
   - *Name* to *HTTP-header*,
   - *Type* to *HTTP Header*,
   - *Host* to *all*,
   - *Header Name* to *Header_Test*, and
   - *Header Regex* to *Q[A-B]*.
4. Click *OK*.

To create a HTTP header address in the CLI:

```
config firewall proxy-address
    edit "method_get"
        set type header
        set host "all"
        set header-name "Header_Test"
        set header "Q[A-B]"
    next
end
```

User agent

In this address type, a user can create an address based on the names of the browsers that are used as user agents. Multiple browsers are supported, such as Chrome, Firefox, Internet Explorer, and others. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests from the specified user agent.

This example creates a user agent address for Google Chrome.

To create a user agent address in the GUI:

1. Go to *Policy & Objects* > *Addresses* and select *Proxy* > *Address*.
2. Click *Create new*.
3. Set the following:
   - *Name* to *UA-Chrome*,
   - *Type* to *User Agent*,
   - *Host* to *all*, and
   - *User Agent* to *Google Chrome*.
4. Click *OK*.

To create a user agent address in the CLI:

```
config firewall proxy-address
    edit "UA-Chrome"
        set type ua
        set host "all"
        set ua chrome
    next
end
```

Browser version control

For security reasons, the user can restrict the browser version by specifying a range of the supported versions which can be set from the CLI using `set ua-min-ver` and `set ua-max-ver`. This option is available when the address *Type* is either *User Agent* or *Advanced (Source)*.

To restrict the browser version:

```
config firewall proxy-address
    edit "ua-ver"
        set type ua
        set ua firefox
        set ua-min-ver "100.0.1"
        set ua-max-ver "160"
    next
end
```

Advanced (source)

In this address type, a user can create an address based on multiple parameters, including HTTP method, User Agent, and HTTP header. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests that match the selected address.

This example creates an address that uses the get method, a user agent for Google Chrome, and an HTTP header with the pattern *Q[A-B]*.

To create an advanced (source) address in the GUI:

1. Go to *Policy & Objects* > *Addresses* and select *Proxy* > *Address*.
2. Click *Create new*.
3. Set the following:
   - *Name* to *advanced_src*,
   - *Type* to *Advanced (Source)*,
   - *Host* to *all*,
   - *Request Method* to *GET*,
   - *User Agent* to *Google Chrome*, and
   - *HTTP header* to *Header_Test* : *Q[A-B]*.
4. Click *OK*.

To create an advanced (source) address in the CLI:

```
config firewall proxy-address
    edit "advance_src"
        set type src-advanced
        set host "all"
        set method get
        set ua chrome
        config header-group
            edit 1
                set header-name "Header_Test"
                set header "Q[A-B]"
            next
        end
    next
end
```

Advanced (destination)

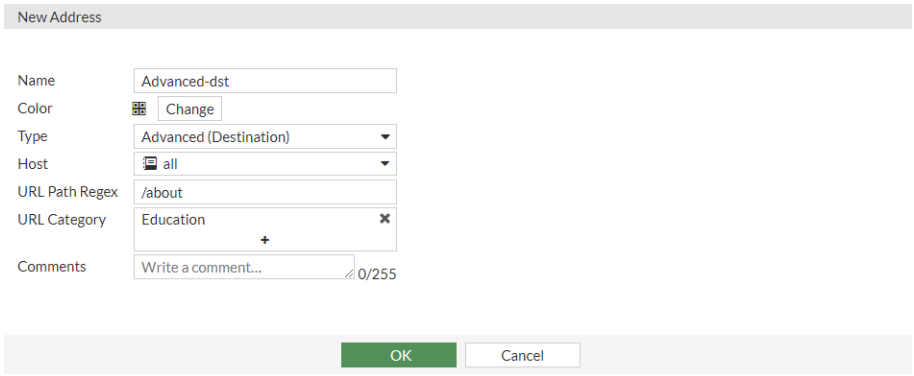
In this address type, a user can create an address based on URL pattern and URL category parameters. Once created, the address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the selected address.

This example creates an address with the URL pattern */about* that are in the *Education* category. For more information about categories, see https://fortiguard.com/webfilter/categories.

To create an advanced (destination) address in the GUI:

1. Go to *Policy & Objects* > *Addresses* and select *Proxy* > *Address*.
2. Click *Create new*.
3. Set the following:
   - *Name* to *Advanced-dst*,
   - *Type* to *Advanced (Destination)*,
   - *Host* to *all*,

- *URL Path Regex* to */about*, and
- *URL Category* to *Education*.



4. Click *OK*.

To create an advanced (destination) address in the CLI:

```
config firewall proxy-address
    edit "Advanced-dst"
        set type dst-advanced
        set host "ubc"
        set path "/about"
        set category 30
    next
end
```

Proxy policy security profiles

Web proxy policies support most security profile types.

Security profiles must be created before they can be used in a policy, see Security Profiles on page 1899 for information.

Explicit web proxy policy

The security profiles supported by explicit web proxy policies are:

- *AntiVirus*
- *Web Filter*
- *Video Filter*
- *DNS Filter*
- *Application Control*
- *IPS*
- *DLP Profile*

- *ICAP*
- *Web Application Firewall*
- *File Filter*
- *SSL Inspection*

To configure security profiles on an explicit web proxy policy in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	Explicit Web
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	webproxy
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Web Filter	urlfiler
Application Control	app
IPS	Sensor-1
DLP Profile	dlp
ICAP	default
Web Application Firewall	default
SSL Inspection	deep-inspection

6. Click *OK* to create the policy.

To configure security profiles on an explicit web proxy policy in the CLI:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
```

```
        set action accept
        set schedule "always"
        set utm-status enable
        set av-profile "av"
        set webfilter-profile "urlfilter"
        set dlp-profile "dlp"
        set ips-sensor "sensor-1"
        set application-list "app"
        set icap-profile "default"
        set waf-profile "default"
        set ssl-ssh-profile "deep-inspection"
    next
end
```

Transparent proxy

The security profiles supported by transparent proxy policies are:

- *AntiVirus*
- *Web Filter*
- *Video Filter*
- *DNS Filter*
- *Application Control*
- *IPS*
- *DLP Profile*
- *ICAP*
- *Web Application Firewall*
- *File Filter*
- *SSL Inspection*

To configure security profiles on a transparent proxy policy in the GUI:

1. Go to *Policy & Objects* > *Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	Transparent Web
Incoming Interfae	port2
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	webproxy
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Web Filter	urlfiler
Application Control	app
IPS	Sensor-1
DLP Profile	dlp
ICAP	default
Web Application Firewall	default
SSL Inspection	deep-inspection

6. Click *OK* to create the policy.

To configure security profiles on a transparent proxy policy in the CLI:

```
config firewall proxy-policy
    edit 2
        set proxy transparent-web
        set srcintf "port2"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set utm-status enable
        set av-profile "av"
        set webfilter-profile "urlfilter"
        set dlp-profile "dlp"
        set ips-sensor "sensor-1"
        set application-list "app"
        set icap-profile "default"
        set waf-profile "default"
        set ssl-ssh-profile "certificate-inspection"
    next
end
```

FTP proxy

The security profiles supported by FTP proxy policies are:

- *AntiVirus*
- *Application Control*
- *IPS*

- *File Filter*
- *DLP Profile*

To configure security profiles on an FTP proxy policy in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	FTP
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Application Control	app
IPS	Sensor-1
DLP Profile	dlp

6. Click *OK* to create the policy.

To configure security profiles on an FTP proxy policy in the CLI:

```
config firewall proxy-policy
    edit 3
        set proxy ftp
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set utm-status enable
        set av-profile "av"
        set dlp-profile "dlp"
        set ips-sensor "sensor-1"
        set application-list "app"
    next
end
```

Explicit proxy authentication

FortiGate supports multiple authentication methods. This topic explains using an external authentication server with Kerberos as the primary and NTLM as the fallback.

To configure Explicit Proxy with authentication:

1. Enable and configure the explicit proxy on page 356.
2. Configure the authentication server and create user groups on page 357.
3. Create an authentication scheme and rules on page 359.
4. Create an explicit proxy policy and assign a user group to the policy on page 360.
5. Verify the configuration on page 361.

Enable and configure the explicit proxy

To enable and configure explicit web proxy in the GUI:

1. Go to *Network* > *Explicit Proxy*.
2. Enable *Explicit Web Proxy*.
3. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *8080*.
4. Configure the remaining settings as needed.
5. Click *Apply*.

To enable and configure explicit web proxy in the CLI:

```
config web-proxy explicit
    set status enable
    set ftp-over-http enable
    set socks enable
    set http-incoming-port 8080
    set ipv6-status enable
    set unknown-http-version best-effort
end
config system interface
    edit "port2"
        set vdom "vdom1"
        set ip 10.1.100.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set explicit-web-proxy enable
        set snmp-index 12
        end
    next
end
```

Configure the authentication server and create user groups

Since we are using an external authentication server with Kerberos authentication as the primary and NTLM as the fallback, Kerberos authentication is configured first and then FSSO NTLM authentication is configured.

For successful authorization, the FortiGate checks if user belongs to one of the groups that is permitted in the security policy.

When configuring an LDAP connection to an Active Directory server, an administrator must provide Active Directory user credentials.

- To secure this connection, use LDAPS on both the Active Directory server and FortiGate. See Configuring an LDAP server on page 3014 and Configuring client certificate authentication on the LDAP server on page 3029.
- Apply the principle of least privilege. For the LDAP regular bind operation, do not use credentials that provide full administrative access to the Windows server when using credentials. See Configuring least privileges for LDAP admin account authentication in Active Directory on page 3022.

To configure an authentication server and create user groups in the GUI:

1. Configure Kerberos authentication:
   a. Go to *User & Authentication > LDAP Servers*.
   b. Click *Create New*.
   c. Set the following:

Name	ldap-kerberos
Server IP	172.18.62.220
Server Port	389
Common Name Identifier	cn
Distinguished Name	dc=fortinetqa,dc=local

   d. Click *OK*
2. Define Kerberos as an authentication service. This option is only available in the CLI. For information on generating a keytab, see Generating a keytab on a Windows server on page 361.
3. Configure FSSO NTLM authentication:
   FSSO NTLM authentication is supported in a Windows AD network. FSSO can also provide NTLM authentication service to the FortiGate unit. When a user makes a request that requires authentication, the FortiGate initiates NTLM negotiation with the client browser, but does not process the NTLM packets itself. Instead, it forwards all the NTLM packets to the FSSO service for processing.
   a. Go to *Security Fabric > External Connectors*.
   b. Click *Create New* and select *FSSO Agent on Windows AD* from the *Endpoint/Identity* category.
   c. Set the *Name* to *FSSO*, *Primary FSSO Agent* to *172.16.200.220*, and enter a password.
   d. Click *OK*.
4. Create a user group for Kerberos authentication:

a. Go to *User & Authentication* > *User Groups*.
b. Click *Create New*.
c. Set the *Name* to *Ldap-Group*, and *Type* to *Firewall*.
d. In the *Remote Groups* table, click *Add*, and set the *Remote Server* to the previously created *ldap-kerberos* server.
e. Click *OK*.

5. Create a user group for NTLM authentication:
a. Go to *User & Authentication* > *User Groups*.
b. Click *Create New*.
c. Set the *Name* to *NTLM-FSSO-Group*, *Type* to *Fortinet Single Sign-On (FSSO)*, and add *FORTINETQA/FSSO* as a member.
d. Click *OK*.

To configure an authentication server and create user groups in the CLI:

1. Configure Kerberos authentication:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.220"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *********
    next
end
```

2. Define Kerberos as an authentication service:

```
config user krb-keytab
    edit "http_service"
        set pac-data disable
        set principal "HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL"
        set ldap-server "ldap-kerberos"
        set keytab
"BQIAAABFAAIAEEZPUlRJTkVUUUEuTE9DQUwABEhUVFAAFEZHVC5GT1JUSU5FVFFBLkxPQ0FMAAAAAQAAAAAEAAEACKLCM
onpitnVAAAARQACABBGT1JUSU5FVFFBLkxPQ0FMAARIVFRQABRGR1QuRk9SVElORVRRQS5MT0NBTAAAAAEAAAAABAADAAi
iwjKJ6YrZ1QAAAE0AAgAQRk9SVElORVRRQS5MT0NBTAAESFRUUAAURkdULkZPUlRJTkVUUUEuTE9DQUwAAAABAAAAAAQAF
wAQUHo9uqR9cSkzyxdzKCEXdwAAAF0AAgAQRk9SVElORVRRQS5MT0NBTAAESFRUUAAURkdULkZPUlRJTkVUUUEuTE9DQUw
AAAABAAAAAAQAEgAgzee854Aq1HhQiKJZvV4tL2Poy7hMIARQpK8MCB//BIAAAABNAAIAEEZPUlRJTkVUUUEuTE9DQUwAB
EhUVFAAFEZHVC5GT1JUSU5FVFFBLkxPQ0FMAAAAAQAAAAAEABEAEG49vHEiiBghr63Z/lnwYrU="
    next
end
```

For information on generating a keytab, see Generating a keytab on a Windows server on page 361.

3. Configure FSSO NTLM authentication:

```
config user fsso
    edit "1"
```

```
        set server "172.18.62.220"
        set password *********
    next
end
```

4. Create a user group for Kerberos authentication:

```
config user group
    edit "Ldap-Group"
        set member "ldap" "ldap-kerberos"
    next
end
```

5. Create a user group for NTLM authentication:

```
config user group
    edit "NTLM-FSSO-Group"
        set group-type fsso-service
        set member "FORTINETQA/FSSO"
    next
end
```

Create an authentication scheme and rules

Explicit proxy authentication is managed by authentication schemes and rules. An authentication scheme must be created first, and then the authentication rule.

To create an authentication scheme and rules in the GUI:

1. Create an authentication scheme:
   a. Go to *Policy & Objects* > *Authentication Rules*.
   b. Click *Create New* > *Authentication Schemes*.
   c. Set the *Name* to *Auth-scheme-Negotiate* and select *Negotiate* as the *Method*.
   d. Click *OK*.
2. Create an authentication rule:
   a. Go to *Policy & Objects* > *Authentication Rules*.
   b. Click *Create New* > *Authentication Rules*.
   c. Set the *Name* to *Auth-Rule*, *Source Address* to *all*, and *Protocol* to *HTTP*.
   d. Enable *Authentication Scheme*, and select the just created *Auth-scheme-Negotiate* scheme.
   e. Click *OK*.

To create an authentication scheme and rules in the CLI:

1. Create an authentication scheme:

```
config authentication scheme
    edit "Auth-scheme-Negotiate"
        set method negotiate       <<< Accepts both Kerberos and NTLM as fallback
```

```
    next
end
```

2. Create an authentication rule:

```
config authentication rule
    edit "Auth-Rule"
        set status enable
        set protocol http
        set srcaddr "all"
        set ip-based enable
        set active-auth-method "Auth-scheme-Negotiate"
        set comments "Testing"
    next
end
```

Create an explicit proxy policy and assign a user group to the policy

To create an explicit proxy policy and assign a user group to it in the GUI:

1. Go to *Policy & Objects* > *Proxy Policy*.
2. Click *Create New*.
3. Set *Proxy Type* to *Explicit Web* and *Outgoing Interface* to *port1*.
4. Set *Source* to *all*, and the just created user groups *NTLM-FSSO-Group* and *Ldap-Group*.
5. Also set *Destination* to *all*, *Schedule* to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.
6. Click *OK*.

To create an explicit proxy policy and assign a user group to it in the CLI:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set logtraffic all
        set groups "NTLM-FSSO-Group" "Ldap-Group"
        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
    next
end
```

Verify the configuration

Log in using a domain and system that would be authenticated using the Kerberos server, then enter the `diagnose wad user list` CLI command to verify:

```
# diagnose wad user list
ID: 8, IP: 10.1.100.71, VDOM: vdom1
  user name   : test1@FORTINETQA.LOCAL
  duration    : 389
  auth_type   : IP
  auth_method : Negotiate
  pol_id      : 1
  g_id        : 1
  user_based  : 0
  expire      : no
  LAN:
    bytes_in=4862 bytes_out=11893
  WAN:
    bytes_in=7844 bytes_out=1023
```

Log in using a system that is not part of the domain. The NTLM fallback server should be used:

```
# diagnose wad user list

Generating a keytab on a Windows server

A keytab is used to allow services that are not running Windows to be configured with service instance accounts in the Active Directory Domain Service (AD DS). This allows Kerberos clients to authenticate to the service through Windows Key Distribution Centers (KDCs).

For an explanation of the process, see https://docs.microsoft.com/en-us/windows-server/administration/windows-commands/ktpass.

To generate a keytab on a Windows server:

1. On the server, create a user for the FortiGate:
   - The service name is the FQDN for the explicit proxy interface, such as the hostname in the client browser proxy configuration. In this example, the service name is *FGT*.
   - The account only requires *domain users* membership.
   - The password must be very strong.
   - The password is set to never expire.
2. Add the FortiGate FQDN in to the Windows DNS domain, as well as in-addr.arpa.
3. Generate the Kerberos keytab using the `ktpass` command on Windows servers and many domain workstations:

   ```
   # ktpass -princ HTTP/<domain name of test fgt>@realm -mapuser <user> -pass <password> -crypto
   all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
   ```

   For example:

   ```
   ktpass -princ HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL -mapuser FGT -pass ********** -
   crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
   ```

   If the FortiGate is handling multiple keytabs in Kerberos authentication, use different passwords when generating each keytab.

4. Encode the keytab to base64 in a text file:
   - On Windows: `certutil -encode fgt.keytab tmp.b64 && findstr /v /c:- tmp.b64 > fgt.txt`
   - On Linux: `base64 fgt.keytab > fgt.txt`
   - On MacOS: `base64 -i fgt.keytab -o fgt.txt`
5. Use the code in `fgt.txt` as the keytab parameter when configuring the FortiGate.

Transparent web proxy forwarding

In FortiOS, there is an option to enable proxy forwarding for transparent web proxy policies and regular firewall policies for HTTP and HTTPS.

In previous versions of FortiOS, you could forward proxy traffic to another proxy server (proxy chaining) with explicit proxy. Now, you can forward web traffic to the upstream proxy without having to reconfigure your browsers or publish a proxy auto-reconfiguration (PAC) file.

Once configured, the FortiGate forwards traffic generated by a client to the upstream proxy. The upstream proxy then forwards it to the server.

To configure proxy forwarding:

1. Configure the web proxy forwarding server:

   ```
   config web-proxy forward-server
       edit "upStream_proxy_1"
   ```

```
        set ip 172.16.200.20
        set healthcheck enable
        set monitor "http://www.google.ca"
    next
end
```

2. Append the web proxy forwarding server to a firewall policy:

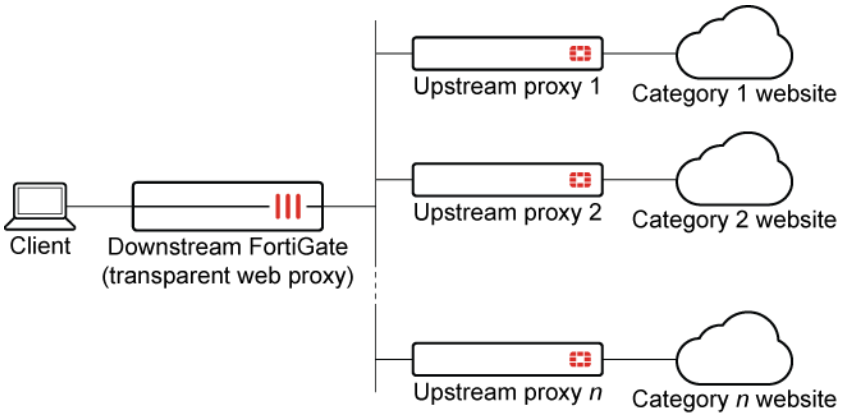
```
config firewall policy
    edit 1
        set name "LAN To WAN"
        set srcintf "port10"
        set dstintf "port9"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set logtraffic all
        set webproxy-forward-server "upStream_proxy_1"
        set fsso disable
        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
        set nat enable
    next
end
```

Selectively forward web requests to a transparent web proxy

Web traffic over HTTP/HTTPS can be forwarded selectively by the FortiGate's transparent web proxy to an upstream web proxy to avoid overwhelming the proxy server. Traffic can be selected by specifying the proxy address, which can be based on a FortiGuard URL category.

The FortiGuard web filter service must be enabled on the downstream FortiGate.

Topology



Forwarding behavior

The forward server will be ignored if the proxy policy matching for a particular session needs the FortiGate to see authentication information inside the HTTP (plain text) message. For example, assume that user authentication is required and a forward server is configured in the transparent web proxy, and the authentication method is an active method (such as basic). When the user or client sends the HTTP request over SSL with authentication information to the FortiGate, the request cannot be forwarded to the upstream proxy. Instead, it will be forwarded directly to the original web server (assuming deep inspection and `http-policy-redirect` are enabled in the firewall policy).

The FortiGate will close the session before the client request can be forwarded if all of the following conditions are met:

- The certificate inspection is configured in the firewall policy that has the `http-policy-redirect` option enabled.
- A previously authenticated IP-based user record cannot be found by the FortiGate's memory during the SSL handshake.
- Proxy policy matching needs the FortiGate to see the HTTP request authentication information.

This means that in order to enable user authentication and use `webproxy-forward-server` in the transparent web proxy policy at the same time, the following best practices should be followed:

- In the firewall policy that has the `http-policy-redirect` option enabled, set `ssl-ssh-profile` to use the `deep-inspection` profile.
- Use IP-based authentication rules; otherwise, the `webproxy-forward-server` setting in the transparent web proxy policy will be ignored.
- Use a passive authentication method such as FSSO. With FSSO, once the user is authenticated as a domain user by a successful login, the web traffic from the user's client will always be forwarded to the upstream proxy as long as the authenticated user remains unexpired. If the authentication method is an active authentication method (such as basic, digest, NTLM, negotiate, form, and so on), the first session containing authentication information will bypass the forward server, but the following sessions will be connected through the upstream proxy.

Sample configuration

On the downstream FortiGate proxy, there are two category proxy addresses used in two separate transparent web proxy policies as the destination address:

- In the policy with `upstream_proxy_1` as the forward server, the proxy address `category_infotech` is used to match URLs in the information technology category.
- In the policy with `upstream_proxy_2` as the forward server, the proxy address `category_social` is used to match URLs in the social media category.

To configure forwarding requests to transparent web proxies:

1. Configure the proxy forward servers:

```
config web-proxy forward-server
    edit "upStream_proxy_1"
        set ip 172.16.200.20
    next
    edit "upStream_proxy_2"
        set ip 172.16.200.46
    next
end
```

2. Configure the web proxy addresses:

```
config firewall proxy-address
    edit "category_infotech"
        set type category
        set host "all"
        set category 52
    next
    edit "category_social"
        set type category
        set host "all"
        set category 37
    next
end
```

3. Configure the firewall policy:

```
config firewall policy
    edit 1
        set srcintf "port10"
        set dstintf "port9"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set http-policy-redirect enable
```

```
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
        set nat enable
    next
end
```

4. Configure the proxy policies:

```
config firewall proxy-policy
    edit 1
        set proxy transparent-web
        set srcintf "port10"
        set dstintf "port9"
        set srcaddr "all"
        set dstaddr "category_infotech"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set webproxy-forward-server "upStream_proxy_1"
        set utm-status enable
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
    next
    edit 2
        set proxy transparent-web
        set srcintf "port10"
        set dstintf "port9"
        set srcaddr "all"
        set dstaddr "category_social"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set webproxy-forward-server "upStream_proxy_2"
        set utm-status enable
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
    next
end
```

Transparent web proxy forwarding over IPv6

The IPv6-enabled forward server works the same way as the IPv4 forward server. For example, you can configure an IPv6 address or an FQDN that resolves to an IPv6 address for the forward server, and you can also use the IPv6 forward server in a forward server group.

```
config web-proxy forward-server
    edit <name>
        set addr-type {ip | ipv6 | fqdn}
```

```
        set ipv6 <IPv6-address>
    next
end
```

addr-type	Specify the type of IP address for the web proxy forward server: • ip: use an IPv4 address. • ipv6: use an IPv6 address. • fqdn: use a fully qualified domain name (FQDN).
ipv6	Specify the IPv6 address for the web proxy forward server. Available when addr-type is set to ipv6.

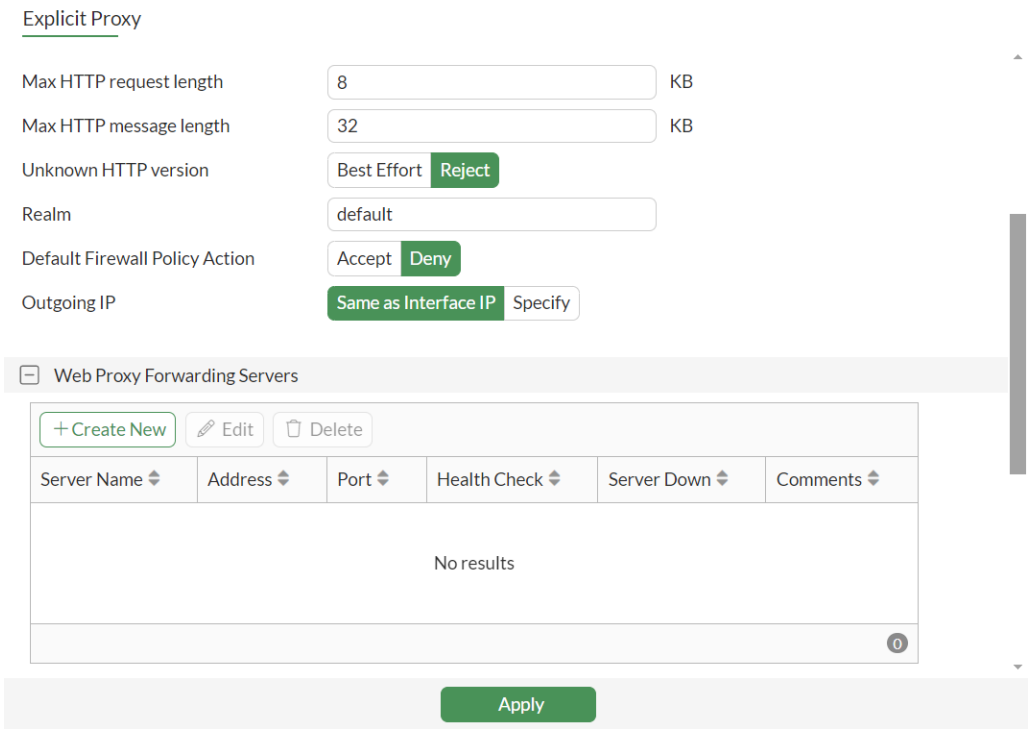
Example

In this example, an explicit web proxy with a forward server can be reached by an IPv6 address, and a client PC uses this explicit web proxy forward server to access a website, such as www.google.com.

The IPv6 address is configured for the web proxy forward server, and then the configuration is added to a proxy policy. The web proxy forward server configuration could also be added to a proxy mode policy or a transparent web proxy policy.

To configure an IPv6 address in the GUI:

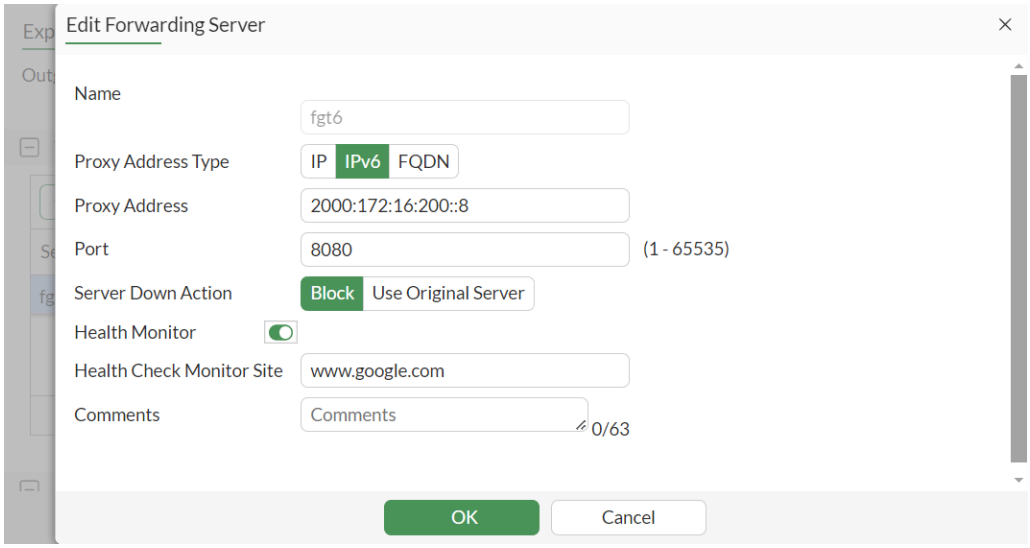
1. Go to *Network* > *Explicit Proxy*.
2. If disabled, enable *Explicit Web Proxy*.
3. Under *Web Proxy Forwarding Servers*, click *Create New*.



The *New Forwarding Server* pane opens.

4. Set the following options, and click *OK* to create the forwarding server.

Proxy Address Type	IPv6
Proxy Address	2000:172:16:200::8
Port	8080
Health Monitor	Enable
Health Check Monitor Site	www.google.com



5. Set the remaining options as needed, and click *OK* to save the explicit web proxy.
6. Add the web proxy forward server to a proxy policy.

To configure an IPv6 address in the CLI:

1. Configure an IPv6 address for the web proxy forward server.
   In this example, address type is set to IPv6, and an IPv6 address is specified in a configuration (fgt6) for a web proxy forward server.

```
config web-proxy forward-server
    edit "fgt6"
        set addr-type ipv6
        set ipv6 2000:172:16:200::8
        set port 8080
    next
end
```

2. Add the web proxy forward server to a proxy policy.
   The web proxy forward server configuration (fgt6) is added to the firewall proxy policy.

```
config firewall proxy-policy
    edit 1
        set uuid 560d8520-fa7b-51ed-e06a-df05ec145542
```

```
        set proxy explicit-web
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set srcaddr6 "all"
        set dstaddr6 "all"
        set webproxy-forward-server "fgt6"
        set utm-status enable
        set ssl-ssh-profile "deep-custom"
        set av-profile "av"
    next
end
```

3. View the traffic logs.

   An HTTP request to www.google.com was sent through the web proxy forward server over IPv6.

```
12: date=2023-08-10 time=23:44:43 eventtime=1691736283529768562 tz="-0700" logid="0000000010"

```

Upstream proxy authentication in transparent proxy mode

A downstream proxy FortiGate that needs to be authenticated by the upstream web proxy can use the basic authentication method to send its username and password, in the base64 format, to the upstream web proxy for authentication. If the authentication succeeds, web traffic that is forwarded from the downstream proxy FortiGate to the upstream proxy can be accepted and forwarded to its destinations.

In this example, a school has a FortiGate acting as a downstream proxy that is configured with firewall policies for each user group (students and staff). In each policy, a forwarding server is configured to forward the web traffic to the upstream web proxy.

The username and password that the upstream web proxy uses to authenticate the downstream proxy are configured on the forwarding server, and are sent to the upstream web proxy with the forwarded HTTP requests.

	Username	Password
student.proxy.local:8080	students	ABC123
staff.proxy.local:8081	staff	123456

On the downstream FortiGate, configure forwarding servers with the usernames and passwords for authentication on the upstream web proxy, then apply those servers to firewall policies for transparent proxy. For explicit web proxy, the forwarding servers can be applied to proxy policies.

When the transparent proxy is configured, clients can access websites without configuring a web proxy in their browser. The downstream proxy sends the username and password to the upstream proxy with forwarded HTTP requests to be authenticated.

To configure the forwarding server on the downstream FortiGate:

```
config web-proxy forward-server
    edit "Student_Upstream_WebProxy"
        set addr-type fqdn
        set fqdn "student.proxy.local"
        set port 8080
        set username "student"
        set password ABC123
    next
    edit "Staff_Upstream_WebProxy"
        set addr-type fqdn
        set fqdn "staff.proxy.local"
        set port 8081
        set username "staff"
        set password 123456
    next
end
```

To configure firewall policies for transparent proxy:

```
config firewall policy
    edit 1
        set srcintf "Vlan_Student"
        set dstintf "port9"
        set srcaddr "Student_Subnet"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
        set webproxy-forward-server "Student_Upstream_WebProxy"
        set nat enable
    next
    edit 2
        set srcintf "Vlan_Staff"
        set dstintf "port9"
        set srcaddr "Staff_Subnet"
        set dstaddr "all"
        set action accept
```

```
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
        set webproxy-forward-server "Staff_Upstream_WebProxy"
        set nat enable
    next
end
```

Multiple dynamic header count

Multiple dynamic headers are supported for web proxy profiles, as well as Base64 encoding and the append/new options.

Administrators only have to select the dynamic header in the profile. The FortiGate will automatically display the corresponding static value. For example, if the administrator selects the `$client-ip` header, the FortiGate will display the actual client IP address.

The supported headers are:

`$client-ip`	Client IP address
`$user`	Authentication user name
`$domain`	User domain name
`$local_grp`	Firewall group name
`$remote_grp`	Group name from authentication server
`$proxy_name`	Proxy realm name

To configure dynamic headers using the CLI:

Since authentication is required, FSSO NTLM authentication is configured in this example.

1. Configure LDAP:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.220"
        set cnid "cn"a
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *********
    next
end
```

2. Configure FSSO:

```
config user fsso
    edit "1"
        set server "172.18.62.220"
        set password *********
    next
end
```

3. Configure a user group:

```
config user group
    edit "NTLM-FSSO"
        set group-type fsso-service
        set member "FORTINETQA/FSSO"
    next
end
```

4. Configure an authentication scheme:

```
config authentication scheme
    edit "au-sch-ntlm"
        set method ntlm
    next
end
```

5. Configure an authentication rule:

```
config authentication rule
    edit "au-rule-fsso"
        set srcaddr "all"
        set active-auth-method "au-sch-ntlm"
    next
end
```

6. Create a web proxy profile that adds a new dynamic and custom `Via` header:

```
config web-proxy profile
    edit "test"
        set log-header-change enable
        config headers
            edit 1
                set name "client-ip"
                set content "$client-ip"
            next
            edit 2
                set name "Proxy-Name"
                set content "$proxy_name"
            next
            edit 3
                set name "user"
                set content "$user"
            next
            edit 4
```

```
                set name "domain"
                set content "$domain"
            next
            edit 5
                set name "local_grp"
                set content "$local_grp"
            next
            edit 6
                set name "remote_grp"
                set content "$remote_grp"
            next
            edit 7
                set name "Via"
                set content "Fortigate-Proxy"
            next
        end
    next
end
```

7. In the proxy policy, append the web proxy profile created in the previous step:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set logtraffic all
        set groups "NTLM-FSSO"
        set webproxy-profile "test"
        set utm-status enable
        set av-profile "av"
        set webfilter-profile "content"
        set ssl-ssh-profile "deep-custom"
    next
end
```

8. Once traffic is being generated from the client, look at the web filter logs to verify that it is working.

   The corresponding values for all the added header fields are shown in the *Web Filter* card at *Log & Report > Security Events*, in the *Change headers* section at the bottom of the *Log Details* pane.

```
1: date=2019-02-07 time=13:57:24 logid="0344013632" type="utm" subtype="webfilter"
eventtype="http_header_change" level="notice" vd="vdom1" eventtime=1549576642 policyid=1

FSSO|remote_grp: FORTINETQA/FSSO|Via: Fortigate-Proxy"
```

Restricted SaaS access

Large organizations may want to restrict SaaS access to resources like Microsoft Office 365, Google Workspace, and Dropbox by tenant to block non-company login attempts and secure the users from accessing non-approved cloud resources. Many cloud vendors enable this by applying tenant restrictions for access control. For example, users accessing Microsoft 365 applications with tenant restrictions through the corporate proxy will only be allowed to log in as the company's tenant and access the organization's applications.

To implement this, access requests from the clients pass through the company's web proxy, which inserts headers to notify the SaaS service to apply tenant restrictions with the permitted tenant list. Users are redirected the SaaS service login page, and are only allowed to log in if they belong to the permitted tenant list.

For more information, refer to the vendor-specific documentation:

- Office 365: Restrict access to a tenant
- Google Workspace: Block access to consumer accounts
- Dropbox: Network control

Basic configuration

A web proxy profile can specify access permissions for Microsoft Office 365, Google Workspace, and Dropbox by inserting vendor-defined headers that restrict access to the specific accounts. Custom headers can also be inserted for any destination. The web proxy profile can then be applied to a firewall policy to control the header's insertion.

To implement Office 365 tenant restriction, Google Workspace account access control, and Dropbox network access control:

1. Configure a web proxy profile according to the vendors' specifications:
   a. Set the header name (defined by the service provider).
   b. Set the traffic destination (the service provider).
   c. Set the HTTP header content to be inserted into the traffic (defined by your settings).

```
config web-proxy profile
    edit <name>
        config headers
            edit <id>
                set name <string>
                set dstaddr <address>
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content <string>
            next
        end
    next
end
```

2. Apply the web proxy profile to a policy. SSL deep inspection must be used in the firewall policy:

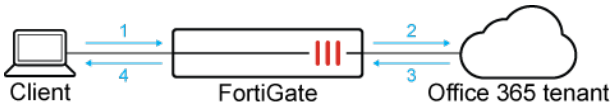
The following table lists the vendor-specific `config headers` settings that must be configured in the web proxy profile (`config web-proxy profile`):

Setting	Vendor specification		
	Microsoft Office 365	Google Workspace	Dropbox
`name <string>`	• `Restrict-Access-To-Tenants` • `Restrict-Access-Context`	• `X-GoogApps-Allowed-Domains`	• `X-Dropbox-allowed-Team-Ids`
`dstaddr <address>`	• Use the built-in `Microsoft Office 365` address.	• Use the built-in `G Suite` address.	• Use the built-in `wildcard.dropbox.com` address.
`content <string>`	• Enter the domain for `Restrict-Access-To-Tenants`. • Enter the directory ID for `Restrict-Access-Context`.	• Enter the domain.	• Enter the Dropbox team ID.

Due to vendors' changing requirements, these settings may no longer comply with the vendors' official guidelines. See the vendor documentation for more details.

Microsoft Office 365 example

In this example, a web proxy profile is created to control permissions for Microsoft Office 365 to allow corporate domains and deny personal accounts, such as Hotmail and Outlook that are accessed through login.live.com.



1. When a user attempts to access login.microsoftonline.com, login.microsoft.com, or login.windows.net, the traffic will match a proxy inspection mode firewall policy with the assigned web proxy profile.
2. The web proxy profile adds new headers to the customer tenant, indicating the allowed domain and restricted access for personal accounts. Next, the FortiGate starts a new connection with the Microsoft Office 365 domain controller including the new headers.
3. The Microsoft Office 365 domain controller assesses this data and will allow or deny this access, then sends a reply to the FortiGate.
4. The FortiGate sends a reply to the client.

The FortiGate will only indicate the correct domains to be allowed or denied through the headers to Microsoft. The custom sign-in portal in the browser is generated by Microsoft.

Configuration summary

The following must be configured in FortiOS:

- An FQDN address for login.live.com
- An SSL inspection profile that applies deep inspection for login.live.com

Ensure that the firewall certificate is installed on the client machines. A company certificate signed by an internal CA is recommended.

- A web filter profile in proxy mode with static URL filters for the SNI URLs
- A web proxy profile that adds new headers to the customer tenant
- A firewall policy using proxy mode inspection that applies the configured SSL SSL inspection, web filter, and web proxy profiles

The `Restrict-Access-To-Tenants` and `Restrict-Access-Context` headers are inserted for incoming requests to: login.microsoftonline.com, login.microsoft.com, and login.windows.net, which are part of the `Microsoft Office 365` address group.

To restrict access to personal accounts using the login.live.com domain, the `sec-Restrict-Tenant-Access-Policy` header is inserted and uses `restrict-msa` as the header content.

Before configuring the FortiGate, collect the information related to the company domain in the Office 365 contract.

- `Restrict-Access-To-Tenants`: your <domain.com>
- `Restrict-Access-Context`: Directory ID

To find the Directory ID related to the domain, locate it in the Azure portal, or use the whatismytenantid.com open tool.

To configure the FortiGate:

1. Add the FQDN address for login.live.com:

```
config firewall address
    edit "login.live.com"
        set type fqdn
        set fqdn "login.live.com"
    next
end
```

2. Configure the SSL inspection profile. In this example, the `deep-inspection` profile is cloned, and the `live.com` FQDN is removed from the exemption list.
   a. Clone the `deep-inspection` profile:

```
config firewall ssl-ssh-profile
    clone "deep-inspection" to "Tenant"
end
```

   b. Edit the `Tenant` profile and remove `live.com` from the `config ssl-exempt` list.
3. Configure the URL filter list:

```
config webfilter urlfilter
    edit 1
        set name "Auto-webfilter-urlfilter"
        config entries
            edit 1
                set url "login.microsoftonline.com"
                set action allow
            next
            edit 2
                set url "login.microsoft.com"
                set action allow
            next
            edit 3
                set url "login.windows.net"
                set action allow
            next
            edit 4
                set url "login.live.com"
                set action allow
            next
        end
    next
end
```

4. Configure the web filter profile:

```
config webfilter profile
    edit "Tenant"
        set comment "Office 365"
        set feature-set proxy
        config web
            set urlfilter-table 1
        end
    next
end
```

5. Configure the web proxy profile (enter the header names exactly as shown):

```
config web-proxy profile
    edit "SaaS-Tenant-Restriction"
        set header-client-ip pass
        set header-via-request pass
        set header-via-response pass
        set header-x-forwarded-for pass
        set header-x-forwarded-client-cert pass
        set header-front-end-https pass
        set header-x-authenticated-user pass
        set header-x-authenticated-groups pass
        set strip-encoding disable
        set log-header-change disable
        config headers
            edit 1
```

```
                set name "Restrict-Access-To-Tenants"
                set dstaddr "login.microsoft.com" "login.microsoftonline.com"
"login.windows.net"
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content <domain>
            next
            edit 2
                set name "Restrict-Access-Context"
                set dstaddr "login.microsoftonline.com" "login.microsoft.com"
"login.windows.net"
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content <directory_ID>
            next
            edit 3
                set name "sec-Restrict-Tenant-Access-Policy"
                set dstaddr "login.live.com"
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content "restrict-msa"
            next
        end
    next
end
```

6. Configure the firewall policy:

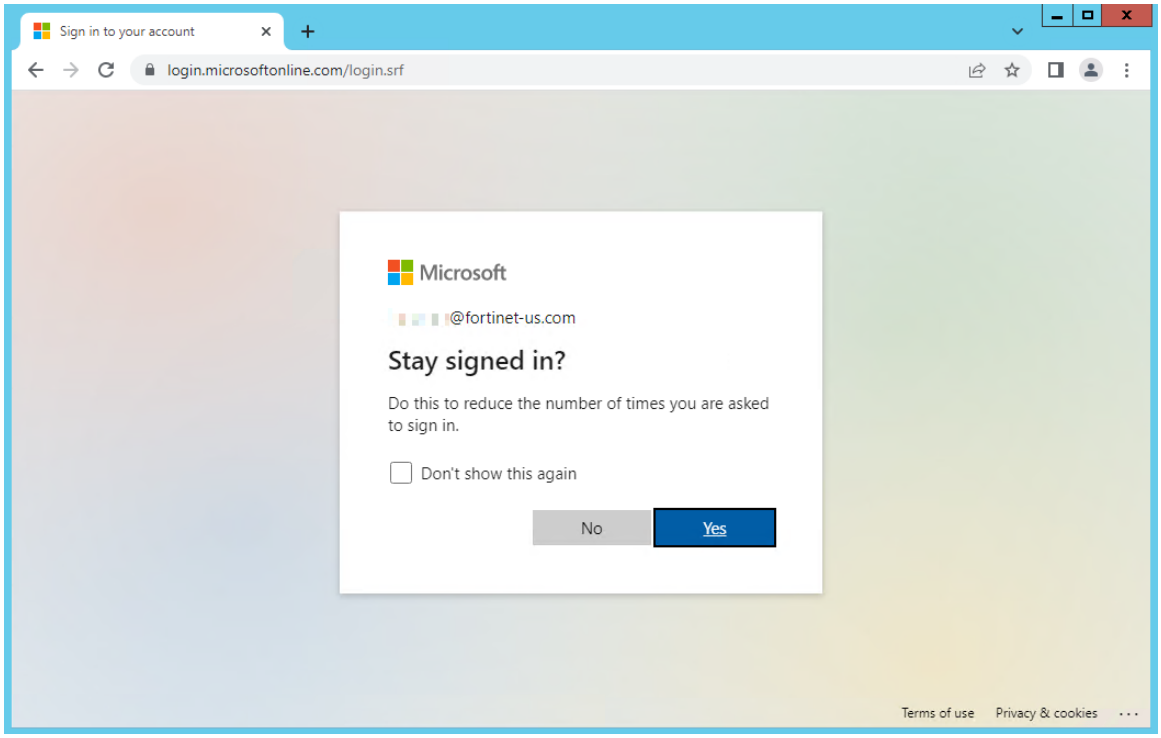
```
config firewall policy
    edit 10
        set name "Tenant"
        set srcintf "port2"
        set dstintf "port1"
        set action accept
        set srcaddr "users-lan"
        set dstaddr "login.microsoft.com" "login.microsoftonline.com" "login.windows.net"
"login.live.com"
        set schedule "always"
        set service "HTTP" "HTTPS"
        set utm-status enable
        set inspection-mode proxy
        set webproxy-profile "SaaS-Tenant-Restriction"
        set ssl-ssh-profile "Tenant"
        set webfilter-profile "Tenant"
        set logtraffic all
        set nat enable
```

```
    next
end
```

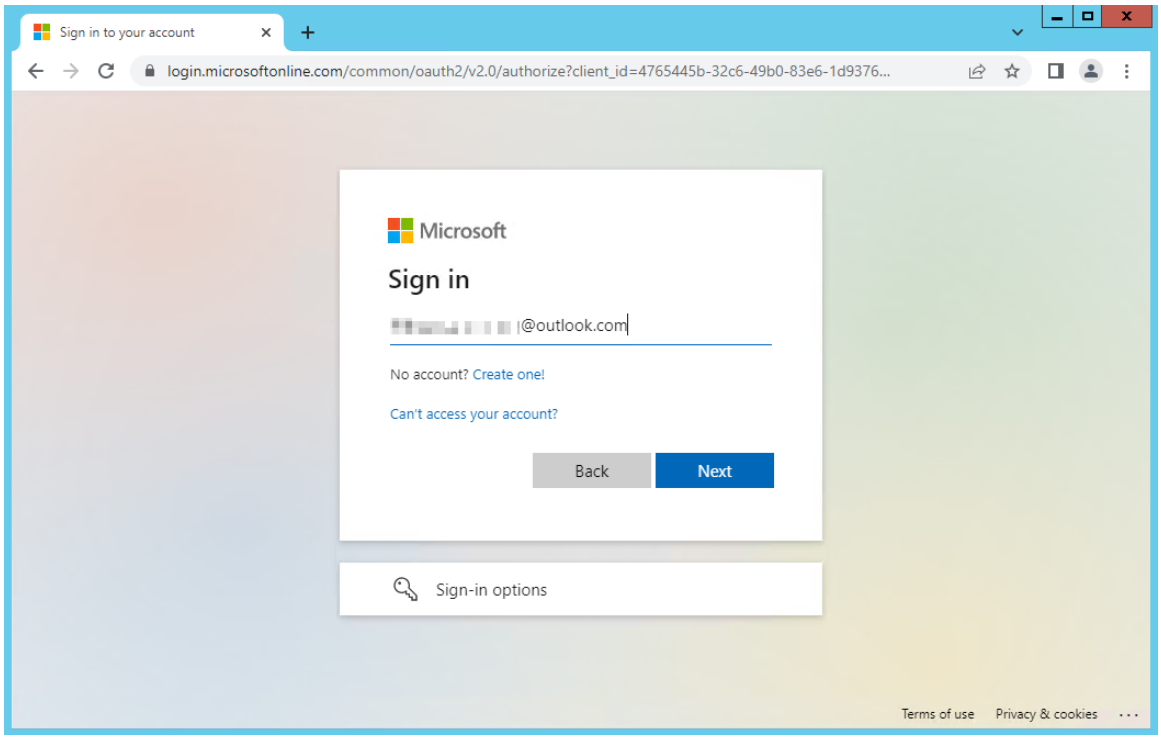
Testing the access

To test the access to corporate domains and personal accounts:

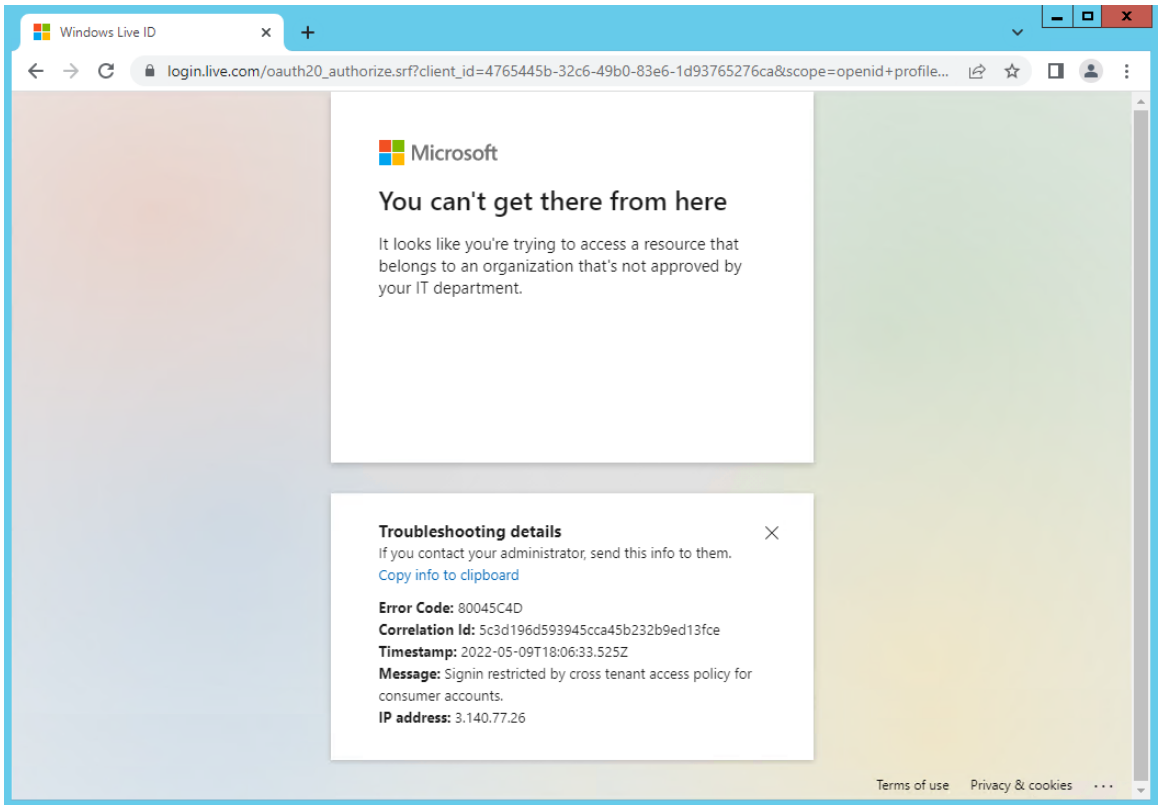
1. Get a client to log in with their corporate email using the login.microsoftonline.com domain.



2. The client is able to enter their credentials and log in successfully.
3. Get a client to log in to their personal Outlook account.



4. After the client enters their credentials, a message appears that they cannot access this resource because it is restricted by the cross-tenant access policy.



Verifying the header insertion

To verify the header insertion for corporate domains and personal accounts:

1. On the FortiGate, start running the WAD debugs:

```
# diagnose wad debug enable category http
# diagnose wad debug enable level info
# diagnose debug enable
```

2. After a client attempts to access corporate domains, verify that the header information is sent to the Microsoft Active Directory:

```
[I][p:234][s:2481][r:33] wad_dump_fwd_http_req             :2567  hreq=0x7fc75f0cd468 Forward
request to server:
POST /common/GetCredentialType?mkt=en-US HTTP/1.1
Host: login.microsoftonline.com
Connection: keep-alive
Content-Length: 1961

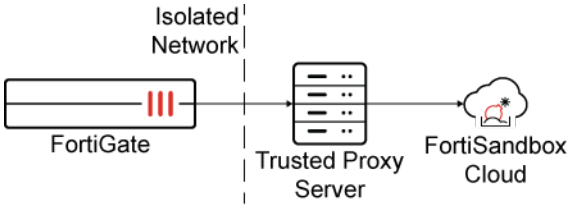
Explicit proxy and FortiGate Cloud Sandbox

Explicit proxy connections can leverage FortiGate Cloud Sandbox for advanced threat scanning and updates. This allows FortiGates behind isolated networks to connect to FortiCloud services.



To configure FortiGuard services to communicate with an explicit proxy server:

```
config system fortiguard
    set proxy-server-ip 172.16.200.44
    set proxy-server-port 3128
    set proxy-username "test1"
    set proxy-password *********
end
```

To verify the explicit proxy connection to FortiGate Cloud Sandbox:

```
# diagnose debug application forticldd -1
Debug messages will be on for 30 minutes.
# diagnose debug enable
[2942] fds_handle_request: Received cmd 23 from pid-2526, len 0

Proxy chaining

For the explicit web proxy you can configure web proxy forwarding servers to use proxy chaining to redirect web proxy sessions to other proxy servers. Proxy chaining can be used to forward web proxy sessions from the FortiGate unit to one or more other proxy servers on your network or on a remote network. You can use proxy chaining to integrate the FortiGate explicit web proxy with a web proxy solution that you already have in place.

A FortiGate unit can forward sessions to most web proxy servers including a remote FortiGate unit with the explicit web proxy enabled. No special configuration of the explicit web proxy on the remote FortiGate unit is required.

You can deploy the explicit web proxy with proxy chaining in an enterprise environment consisting of small satellite offices and a main office. If each office has a FortiGate unit, users at each of the satellite offices can use their local FortiGate unit as an explicit web proxy server. The satellite office FortiGate units can forward explicit web proxy sessions to an explicit web proxy server at the central office. From here the sessions can connect to web servers on the Internet.

FortiGate proxy chaining does not support web proxies in the proxy chain authenticating each other.

The following examples assume explicit web proxy has been enabled.

To enable explicit web proxy in the GUI:

1. Go to *System* > *Feature Visibility*.
2. In the *Security Features* column, enable *Explicit Proxy*.
3. Configure the explicit web proxy settings. See Explicit web proxy on page 334.

To add a web proxy forwarding server in the GUI:

1. Go to *Network* > *Explicit Proxy*. The *Explicit Proxy* page opens.
2. In the *Web Proxy Forwarding Servers* section, click *Create New*.
3. Configure the server settings:

Name	Enter the name of the forwarding server.
Proxy Address Type	Select the type of IP address of the forwarding server. A forwarding server can have an *FQDN* or *IP* address.
Proxy Address	Enter the IP address of the forwarding server.
Port	Enter the port number on which the proxy receives connections. Traffic leaving the FortiGate explicit web proxy for this server has its destination port number changed to this number.
Server Down Action	Select the action the explicit web proxy will take if the forwarding server is down. • *Block*: Blocks the traffic if the remote server is down. • *Use Original Server*: Forwards the traffic from the FortiGate to its destination as if no forwarding server is configured.
Health Monitor	Select to enable health check monitoring.
Health Check Monitor Site	Enter the address of a remote site.

4. Click *OK*.

Example

The following example adds a web proxy forwarding server named `fwd-srv` at address `proxy.example.com` and port `8080`.

To add a web proxy forwarding server in the CLI:

```
config web-proxy forward-server
    edit fwd-srv
        set addr-type fqdn
        set fqdn proxy.example.com
        set port 8080
    next
end
```

Web proxy forwarding server monitoring and health checking

By default, a FortiGate unit monitors a web proxy forwarding server by forwarding a connection to the remote server every 10 seconds. The remote server is assumed to be down if it does not respond to the connection. FortiGate continues checking the server. The server is assumed to be back up when the server sends a response. If you enable health checking, the FortiGate unit attempts to get a response from a web server every 10 seconds by connecting through the remote forwarding server.

You can configure health checking for each remote server and specify a different website to check for each one.

If the remote server is found to be down you can configure the FortiGate unit to block sessions until the server comes back up or to allow sessions to connect to their destination, bypassing the remote forwarding server. You cannot configure the FortiGate unit to fail over to another remote forwarding server.

To configure proxy server monitor and health checking in the GUI:

1. Go to *Network* > *Explicit Proxy*. The *Explicit Proxy* page opens.
2. In the *Web Proxy Forwarding Servers* section, edit a server.
3. Configure the *Server Down Action* and *Health Monitor* settings.

Server Down Action	Select the action the explicit web proxy will take if the forwarding server is down. • *Block*: Blocks the traffic if the remote server is down. • *Use Original Server*: Forwards the traffic from the FortiGate to its destination as if no forwarding server configured.
Health Monitor	Select to enable health check monitoring.
Health Check Monitor Site	Enter the address of a remote site.

4. Click *OK*.

Example

The following example enables health checking for a web proxy forwarding server and sets the server down option to bypass the forwarding server if it is down.

To configure proxy server monitor and health checking in the CLI:

```
config web-proxy forward-server
    edit fwd-srv
        set healthcheck enable
        set monitor http://example.com
        set server-down-option pass
    next
end
```

Grouping forwarding servers and load balancing traffic to the servers

You can add multiple web proxy forwarding servers to a forwarding server group and then add the server group to an explicit web proxy policy instead of adding a single server. Forwarding server groups are created from the FortiGate CLI but can be added to policies from the web-based manager (or from the CLI).

When you create a forwarding server group you can select a load balancing method to control how sessions are load balanced to the forwarding servers in the server group. Two load balancing methods are available:

- *Weighted* load balancing sends more sessions to the servers with higher weights. You can configure the weight for each server when you add it to the group.
- *Least-session* load balancing sends new sessions to the forwarding server that is processing the fewest sessions.

When you create a forwarding server group you can also enable *affinity*. Enable affinity to have requests from the same client processed by the same server. This can reduce delays caused by using multiple servers for a single multi-step client operation. Affinity takes precedence over load balancing.

You can also configure the behavior of the group if all of the servers in the group are down. You can select to block traffic or you can select to have the traffic pass through the FortiGate explicit proxy directly to its destination instead of being sent to one of the forwarding servers.

Example

The following example adds a forwarding server group that uses weighted load balancing to load balance traffic to three forwarding servers. Server weights are configured to send most traffic to `server2`. The group has `affinity` enabled and blocks traffic if all of the forward servers are down.

To configure load balancing in the CLI:

```
config web-proxy forward-server
    edit server_1
        set ip 172.20.120.12
```

```
        set port 8080
    next
    edit server_2
        set ip 172.20.120.13
        set port 8000
    next
    edit server_3
        set ip 172.20.120.14
        set port 8090
    next
end
```

```
config web-proxy forward-server-group
    edit New-fwd-group
        set affinity enable
        set ldb-method weighted
        set group-down-option block
        config server-list
            edit server_1
                set weight 10
            next
            edit server_2
                set weight 40
            next
            edit server_3
                set weight 10
            next
        end
    next
end
```

Adding proxy chaining to an explicit web proxy policy

You can enable proxy chaining for web proxy sessions by adding a web proxy forwarding server or server group to an explicit web proxy policy. In a policy you can select one web proxy forwarding server or server group. All explicit web proxy traffic accepted by this security policy is forwarded to the specified web proxy forwarding server or server group.

To add an explicit web proxy forwarding server in the GUI:

1. Go to *Policy & Objects* > *Proxy Policy* and click *Create New*.
2. Configure the policy settings:

Proxy Type	Explicit Web
Outgoing Interface	wan1
Source	Internal_subnet
Destination	all

Schedule	always
Service	webproxy
Action	Accept

3. Enable *Web Proxy Forwarding Server* and select the forwarding server, (for example,*fwd-srv*).
4. Click *OK*.

Example

The following example adds a security policy that allows all users on the `10.31.101.0` subnet to use the explicit web proxy for connections through the `wan1` interface to the Internet. The policy forwards web proxy sessions to a remote forwarding server named *fwd-srv*.

To add an explicit web proxy forwarding server in the CLI:

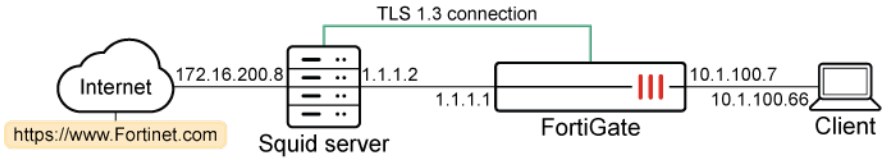
```
config firewall proxy-policy
    edit 0
        set proxy explicit-web
        set dstintf "wan1"
        set srcaddr "Internal_subnet"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set webproxy-forward-server "fwd-srv"
    next
end
```

Using TLS 1.3 with web proxy forward servers

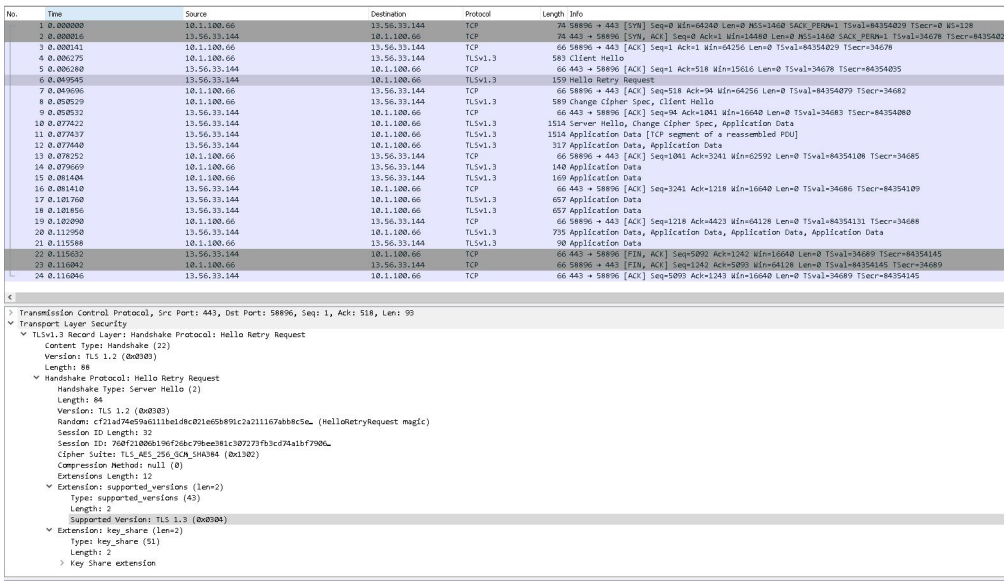
A FortiGate can handle TLS 1.3 traffic in both deep and certificate inspection modes.

Example

The following example demonstrates that the Squid server and the FortiGate can handle TLS 1.3 traffic.



The following output from the Squid server demonstrates that the FortiGate supports TLS 1.3 traffic and forwards the hello retry request back to the client PC. The client PC then sends the client hello again, and the connection is successfully established.



WAN optimization SSL proxy chaining

An SSL server does not need to be defined for WAN optimization (WANOpt) SSL traffic offloading (traffic acceleration). The server side FortiGate uses an SSL profile to resign the HTTP server's certificate, both with and without an external proxy, without an SSL server configured. GCM and ChaCha ciphers can also be used in the SSL connection.

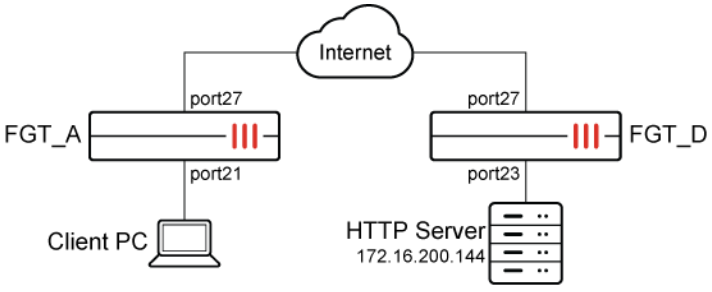
Examples

In these examples, HTTPS traffic is accelerated without configuring an SSL server, including with a proxy in between, and when the GCM or ChaCha ciphers are used.

Example 1

In this example, the server certificate is resigned by the server side FortiGate, and HTTPS traffic is accelerated without configuring an SSL server.

HTTPS traffic with the GCM or ChaCha cipher can pass though WANOpt tunnel.



To configure FGT_A:

1. Configure the hard disk to perform WANOpt:

```
config system storage
    edit "HDD2"
        set status enable
        set usage wanopt
        set wanopt-mode mix
    next
end
```

2. Configure the WANOpt peer and profile:

```
config wanopt peer
    edit "FGT-D"
        set ip 120.120.120.172
    next
end
```

```
config wanopt profile
    edit "test"
        config http
            set status enable
            set ssl enable
        end
    next
end
```

3. Create an SSL profile with deep inspection on HTTPS port 443:

```
config firewall ssl-ssh-profile
    edit "ssl"
        config https
            set ports 443
            set status deep-inspection
        end
    next
end
```

4. Configure a firewall policy in proxy mode with WANOpt enabled and the WANOpt profile selected:

```
config firewall policy
    edit 1
        set name "WANOPT-A"
        set srcintf "port21"
        set dstintf "port27"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
```

```
        set inspection-mode proxy
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
        set wanopt enable
        set wanopt-profile "test"
        set nat enable
    next
end
```

To configure FGT_D:

1. Configure the hard disk to perform WANOpt:

```
config system storage
    edit "HDD2"
        set status enable
        set usage wanopt
        set wanopt-mode mix
    next
end
```

2. Configure the WANOpt peer:

```
config wanopt peer
    edit "FGT-A"
        set ip 110.110.110.171
    next
end
```

3. Create an SSL profile with deep inspection on HTTPS port 443. The default *Fortinet_CA_SSL* certificate is used to resign the server certificate:

```
config firewall ssl-ssh-profile
    edit "ssl"
        config https
            set ports 443
            set status deep-inspection
        end
    next
end
```

4. Configure a firewall policy in proxy mode with WANOpt enabled and passive WANOpt detection:

```
config firewall policy
    edit 1
        set name "WANOPT-B"
        set srcintf "port27"
        set dstintf "port23"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
```

```
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set wanopt enable
        set wanopt-detection passive
        set nat enable
    next
end
```

5. Configure a proxy policy to apply the SSL profile:

```
config firewall proxy-policy
    edit 100
        set proxy wanopt
        set dstintf "port23"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        set action accept
        set schedule "always"
        set utm-status enable
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
    next
end
```

To confirm that traffic is accelerated:

1. On the client PC, curl a 10MB test sample for the first time:

```
root@client:/tmp# curl -k https://172.16.200.144/test_10M.pdf -O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100 9865k  100 9865k    0     0   663k      0  0:00:14  0:00:15 --:--:-- 1526k
```

   It takes 15 seconds to finish the download.

2. On FGT_A, check the WAD statistics:

```
# diagnose wad stats worker.tunnel
comp.n_in_raw_bytes                  10155840
comp.n_in_comp_bytes                 4548728
comp.n_out_raw_bytes                 29624
comp.n_out_comp_bytes                31623
```

```
# diagnose wad stats worker.protos.http
wan.bytes_in                         0
wan.bytes_out                        0
lan.bytes_in                         760
lan.bytes_out                        10140606
tunnel.bytes_in                      4548728
tunnel.bytes_out                     31623
```

3. Curl the same test sample a second time:

```
root@client:/tmp# curl -k https://172.16.200.144/test_10M.pdf -O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100 9865k  100 9865k    0     0   663k      0  0:00:01  0:00:01 --:--:-- 1526k
```

It now takes less than one second to finish the download.

4. On FGT_A, check the WAD statistics again:

```
# diagnose wad stats worker.tunnel
comp.n_in_raw_bytes                  10181157
comp.n_in_comp_bytes                 4570331
comp.n_out_raw_bytes                 31627
comp.n_out_comp_bytes                34702
```

```
# diagnose wad stats worker.protos.http
wan.bytes_in                         0
wan.bytes_out                        0
lan.bytes_in                         1607
lan.bytes_out                        20286841
tunnel.bytes_in                      4570331
tunnel.bytes_out                     34702
```

The tunnel bytes are mostly unchanged, but the LAN bytes are doubled. This means that the bytes of the second curl come from the cache, showing that the traffic is accelerated.

To confirm that a curl using the GCM cipher is accepted and accelerated:

1. On the client PC, curl a 10MB test sample with the GCM cipher:

```
root@client:/tmp# curl -v -k --ciphers DHE-RSA-AES128-GCM-SHA256 https://172.16.200.144/test_
10M.pdf -O
*   Trying 172.16.200.144...
* TCP_NODELAY set
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
  0     0    0     0    0     0      0      0 --:--:-- --:--:-- --:--:--     0* Connected to
172.16.200.144 (172.16.200.144) port 443 (#0)
* ALPN, offering h2
* ALPN, offering http/1.1
* Cipher selection: DHE-RSA-AES128-GCM-SHA256
* successfully set certificate verify locations:

```

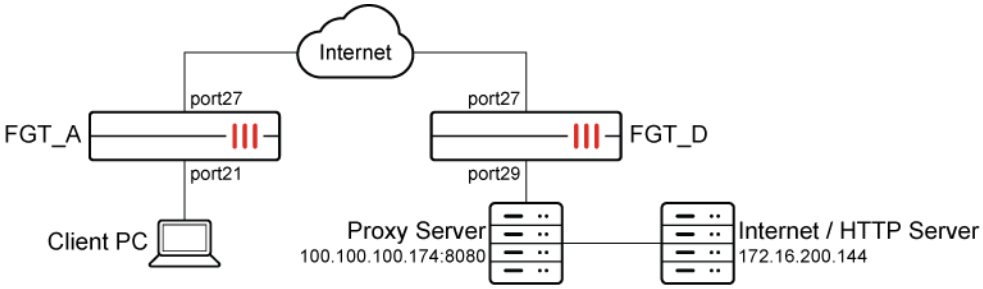
Example 2

In this example, an external proxy is added to the configuration in Example 1.



To reconfigure FGT_A:

```
config firewall profile-protocol-options
    edit "protocol"
        config http
            set ports 80 8080
            unset options
            unset post-lang
        end
    next
end
```

To reconfigure FGT_D:

1. Configure a new firewall policy for traffic passing from port27 to port29:

```
config firewall policy
    edit 1
        set name "WANOPT-B"
        set srcintf "port27"
        set dstintf "port29"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
```

```
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set wanopt enable
        set wanopt-detection passive
        set nat enable
    next
end
```

2. Configure a proxy policy for traffic on destination interface port29:

```
config firewall proxy-policy
    edit 100
        set proxy wanopt
        set dstintf "port29"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        set action accept
        set schedule "always"
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
    next
end
```

To confirm that HTTPS traffic is still being accelerated:

1. On the client PC, curl the same 10MB test sample through the explicit proxy:

```
root@client:/tmp# curl -x 100.100.100.174:8080 -v -k https://172.16.200.144/test_10M.pdf -O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100 9865k  100 9865k    0     0   663k      0  0:00:01  0:00:01 --:--:-- 1526k
```

   It takes less than a second to finish the download.

Agentless NTLM authentication for web proxy

Agentless Windows NT LAN Manager (NTLM) authentication includes support for the following items:

- Multiple servers
- Individual users

You can use multiple domain controller servers for the agentless NTLM. They can be used for load balancing and high service stability.

You can also use user-based matching in groups for Kerberos and agentless NTLM. In these scenarios, FortiOS matches the user's group information from an LDAP server.

To support multiple domain controllers for agentless NTLM using the CLI:

1. Configure an LDAP server:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.177"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *********
    next
end
```

2. Configure multiple domain controllers:

```
config user domain-controller
    edit "dc1"
        set ip-address 172.18.62.177
        config extra-server
            edit 1
                set ip-address 172.18.62.220
            next
        end
        set ldap-server "ldap-kerberos"
    next
end
```

3. Create an authentication scheme and rule:

```
config authentication scheme
    edit "au-ntlm"
        set method ntlm
        set domain-controller "dc1"
    next
end
```

```
config authentication rule
    edit "ru-ntlm"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "au-ntlm"
    next
end
```

4. In the proxy policy, append the user group for authorization:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
```

```
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set groups "ldap-group"
        set utm-status enable
        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
    next
end
```

This configuration uses a round-robin method. When the first user logs in, the FortiGate sends the authentication request to the first domain controller. Later when another user logs in, the FortiGate sends the authentication request to another domain controller.

5. Verify the behavior after the user successfully logs in:

```
# diagnose wad user list
ID: 1825, IP: 10.1.100.71, VDOM: vdom1
    user name   : test1
    duration    : 497
    auth_type   : Session
    auth_method : NTLM
    pol_id      : 1   g_id        : 5
    user_based  : 0   e
    xpire      : 103
    LAN:
        bytes_in=2167 bytes_out=7657
    WAN:
        bytes_in=3718 bytes_out=270
```

To support individual users for agentless NTLM using the CLI:

1. Configure an LDAP server:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.177"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *********
    next
end
```

2. Configure the user group and allow user-based matching:

```
config user group
    edit "ldap-group"
        set member "ldap" "ldap-kerberos"
        config match
            edit 1
```

```
                set server-name "ldap-kerberos"
                set group-name "test1"
            next
        end
    next
end
```

3. Create an authentication scheme and rule:

```
config authentication scheme
    edit "au-ntlm"
        set method ntlm
        set domain-controller "dc1"
    next
end
```

```
config authentication rule
    edit "ru-ntlm"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "au-ntlm"
    next
end
```

4. In the proxy policy, append the user group for authorization:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set groups "ldap-group"
        set utm-status enable
        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
    next
end
```

This implementation lets you configure a single user instead of a whole group. The FortiGate will now allow the user named `test1`.

To verify the configuration using the CLI:

```
diagnose wad user list
    ID: 1827, IP: 10.1.15.25, VDOM: vdom1
    user name   : test1
    duration    : 161
```

```
    auth_type   : Session
    auth_method : NTLM
    pol_id      : 1
    g_id        : 5
    user_based  : 0
    expire      : 439
    LAN:
            bytes_in=1309 bytes_out=4410
      WAN:
            bytes_in=2145 bytes_out=544
```

Multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers

Multiple LDAP servers can be configured in Kerberos keytabs and agentless NTLM domain controllers for multi-forest deployments.

To use multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers:

1. Add multiple LDAP servers:

```
config user ldap
    edit "ldap-kerberos"
        set server "172.16.200.98"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password xxxxxxxxx
    next
    edit "ldap-two"
        set server "172.16.106.128"
        set cnid "cn"
        set dn "OU=Testing,DC=ad864r2,DC=com"
        set type regular
        set username "cn=Testadmin,cn=users,dc=AD864R2,dc=com"
        set password xxxxxxxxx
    next
end
```

2. Configure a Kerberos keytab entry that uses both LDAP servers:

```
config user krb-keytab
    edit "http_service"
        set pac-data disable
        set principal "HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL"
        set ldap-server "ldap-kerberos" "ldap-two"
        set keytab xxxxxxxxx
```

```
    next
end
```

3. Configure a domain controller that uses both LDAP servers:

```
config user domain-controller
    edit "dc1"
        set ip-address 172.16.200.98
        set ldap-server "ldap-two" "ldap-kerberos"
    next
end
```

Learn client IP addresses

Learning the actual client IP addresses is imperative for authorization. This function identifies the real client IP address when there is a NATing device between the FortiGate and the client.

```
config web-proxy global
    set learn-client-ip {enable | disable}
    set learn-client-ip-from-header {true-client-ip | x-real-ip | x-forwarded-for}
    set learn-client-ip-srcaddr <address> ... <address>
end
```

`learn-client-ip {enable | disable}`	Enable/disable learning the client's IP address from headers.
`learn-client-ip-from-header {true-client-ip | x-real-ip | x-forwarded-for}`	Learn client IP addresses from the specified headers.
`learn-client-ip-srcaddr <address> ... <address>`	The source address names.

Example

In this example, the real client IP address is used to match a policy for FSSO authentication.

To enable learning the client IP address:

```
config web-proxy global
    set proxy-fqdn "default.fqdn"
    set webproxy-profile "default"
    set learn-client-ip enable
       set learn-client-ip-from-header x-forwarded-for
    set learn-client-ip-srcaddr "all"
end
```

To configure the proxy policy:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "mgmt1"
        set srcaddr "all"
        set dstaddr "all"
        set service "w"
        set action accept
        set schedule "always"
        set groups "fsso1"
        set utm-status enable
        set av-profile "default"
        set dlp-profile "default"
        set profile-protocol-options "default"
        set ssl-ssh-profile "deep-inspection"
    next
end
```

To configure the authentication scheme and rule:

```
config authentication scheme
    edit "scheme1"
        set method fsso
    next
end
```

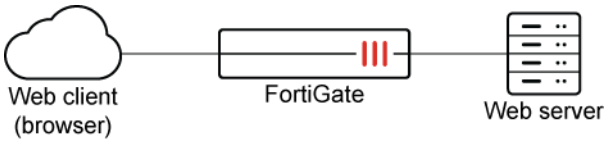
```
config authentication rule
    edit "rule1"
        set srcaddr "all"
        set sso-auth-method "scheme1"
    next
end
```

Explicit proxy authentication over HTTPS

When a HTTP request requires authentication in an explicit proxy, the authentication can be redirected to a secure HTTPS captive portal. Once authentication is complete, the client can be redirected back to the original destination over HTTP.

Example

A user visits a website via HTTP through the explicit web proxy on a FortiGate. The user is required to authenticate by either basic or form IP-based authentication for the explicit web proxy service. The user credentials need to be transmitted over the networks in a secured method over HTTPS rather than in plain text. The user credentials are protected by redirecting the client to a captive portal of the FortiGate over HTTPS for authentication where the user credentials are encrypted and transmitted over HTTPS.



In this example, explicit proxy authentication over HTTPS is configured with form IP-based authentication. Once configured, you can enable authorization for an explicit web proxy by configuring users or groups in the firewall proxy policy.

To configure explicit proxy authentication over HTTPS:

1. Configure the authentication settings:

```
config authentication setting
    set captive-portal-type fqdn
    set captive-portal "fgt-cp"
    set auth-https enable
end
```

2. Configure the authentication scheme:

```
config authentication scheme
    edit "form"
        set method form
        set user-database "local-user-db"
    next
end
```

3. Configure the authentication rule:

```
config authentication rule
    edit "form"
        set srcaddr "all"
        set active-auth-method "form"
    next
end
```

If a session-based basic authentication method is used, enable `web-auth-cookie`.

4. Configure the firewall address:

```
config firewall address
    edit "fgt-cp"
        set type fqdn
        set fqdn "fgt.fortinetqa.local"
    next
end
```

5. Configure the interface:

```
config system interface
    edit "port10"
        set ip 10.1.100.1 255.255.255.0
        set explicit-web-proxy enable
        set proxy-captive-portal enable
    next
end
```

6. Configure a firewall proxy policy with users or groups (see Explicit web proxy on page 334).

Verification

When a client visits a HTTP website, the client will be redirected to the captive portal for authentication by HTTPS. For example, the client could be redirected to a URL by a HTTP 303 message similar to the following:

HTTP/1.1 303 See Other

Connection: close

Content-Type: text/html

Cache-Control: no-cache

Location: https://fgt.fortinetqa.local:7831/XX/YY/ZZ/cpauth?scheme=http&4Tmthd=0&host=172.16.200.46&port=80&rule=75&uri=Lw==&

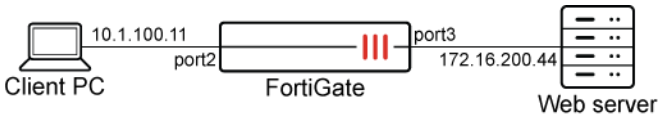
Content-Length: 0

The captive portal URL used for authentication is *https://fgt.fortinetqa.local:7831/...*. Once the authentication is complete with all user credentials protected by HTTPS, the client is redirected to the original HTTP website they intended to visit.

mTLS client certificate authentication

FortiGate supports client certificate authentication used in mutual Transport Layer Security (mTLS) communication between a client and server. Clients are issued certificates by the CA, and an access proxy configured on the FortiGate uses the new certificate method in the authentication scheme to identify and approve the certificate provided by the client when they try to connect to the access proxy. The FortiGate can also add the HTTP header X-Forwarded-Client-Cert to forward the certificate information to the server.

Examples



In these examples, the access proxy VIP IP address is 10.1.100.200.

Example 1

In this example, clients are issued unique client certificates from your CA. The FortiGate authenticates the clients by their user certificate before allowing them to connect to the access proxy. The access server acts as a reverse proxy for the web server that is behind the FortiGate.

This example assumes that you have already obtained the public CA certificate from your CA, the root CA of the client certificate has been imported (`CA_Cert_1`), and the client certificate has been distributed to the endpoints.

To configure the FortiGate:

1. Configure user authentication. Both an authentication scheme and rule must be configured, as the authentication is applied on the access proxy:

```
config authentication scheme
    edit "mtls"
        set method cert
        set user-cert enable
    next
end
```

```
config authentication rule
    edit "mtls"
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set active-auth-method "mtls"
    next
end
```

2. Select the CA or CAs used to verify the client certificate:

```
config authentication setting
    set user-cert-ca "CA_Cert_1"
end
```

3. Configure the users. Users can be matched based on either the common-name on the certificate or the trusted issuer.
   - Verify the user based on the common name on the certificate:

```
config user certificate
    edit "single-certificate"
        set type single-certificate
        set common-name "client.fortinet.com"
    next
end
```

   - Verify the user based on the CA issuer:

```
config user certificate
    edit "trusted-issuer"
        set type trusted-issuer
```

```
        set issuer "CA_Cert_1"
    next
end
```

4. Configure the access proxy VIP. The SSL certificate is the server certificate that is presented to the user as they connect. To request the client certificate for authentication, `client-cert` is enabled:

```
config firewall vip
    edit "mTLS"
        set type access-proxy
        set extip 10.1.100.200
        set extintf "port2"
        set server-type https
        set empty-cert-action accept
        set client-cert enable
        set extport 443
        set ssl-certificate "Fortinet_SSL"
    next
end
```

5. Configure the access proxy policy, including the real server to be mapped:

```
config firewall access-proxy
    edit "mTLS-access-proxy"
        set vip "mTLS"
        config api-gateway
            edit 1
                config realservers
                    edit 1
                        set ip 172.16.200.44
                    next
                end
            next
        end
    next
end
```

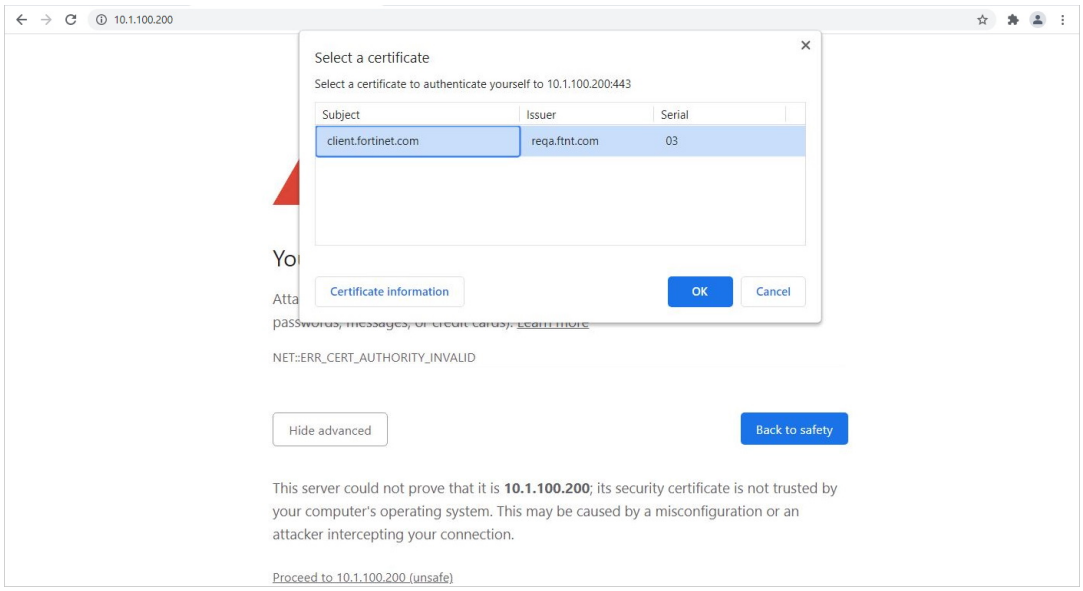
6. Configure the proxy policy to apply authentication and the security profile, selecting the appropriate user object depending on the user type:

```
config firewall proxy-policy
    edit 3
        set proxy access-proxy
        set access-proxy "mTLS-access-proxy"
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set users {"single-certificate" | "trusted-issuer"}
        set utm-status enable
        set ssl-ssh-profile "deep-inspection-clone"
```

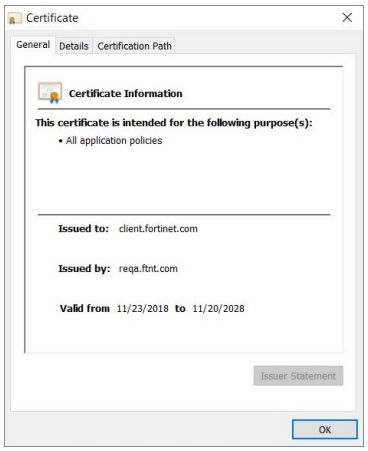
```
        set av-profile "av"
    next
end
```

To verify the results:

1. In a web browser, access the VIP address. This example uses Chrome.
2. When prompted, select the client certificate, then click *OK*.



3. Click *Certificate information* to view details about the certificate.



4. On the FortiGate, check the traffic logs.
   - If client certificate authentication passes:

```
1: date=2021-06-03 time=15:48:36 eventtime=1622760516866635697 tz="-0700"
logid="0000000010" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=45532 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=172.16.200.44 dstport=443
dstintf="vdom1" dstintfrole="undefined" sessionid=154900 service="HTTPS"
wanoptapptype="web-proxy" proto=6 action="accept" policyid=3 policytype="proxy-policy"
```

```
poluuid="af5e2df2-c321-51eb-7d5d-42fa58868dcb" duration=0 user="single-certificate"
wanin=2550 rcvdbyte=2550 wanout=627 lanin=4113 sentbyte=4113 lanout=2310
appcat="unscanned"
```

- If the CA issuer is used to verify the client:

```
1: date=2021-06-03 time=15:43:02 eventtime=1622760182384776037 tz="-0700"
logid="0000000010" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=45514 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=10.1.100.200 dstport=443 dstintf="vdom1"
dstintfrole="undefined" sessionid=153884 service="HTTPS" wanoptapptype="web-proxy" proto=6
action="accept" policyid=3 policytype="proxy-policy" poluuid="af5e2df2-c321-51eb-7d5d-
42fa58868dcb" duration=0 user="trusted-issuer" wanin=0 rcvdbyte=0 wanout=0 lanin=4089
sentbyte=4089 lanout=7517 appcat="unscanned" utmaction="block" countweb=1 crscore=30
craction=8 utmref=65535-0
```

- If the client certificate authentication fails, and the traffic is blocked:

```
1: date=2021-06-03 time=15:45:53 eventtime=1622760353789703671 tz="-0700"
logid="0000000013" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=45518 srcintf="port2" srcintfrole="undefined"
dstip=172.16.200.44 dstport=443 dstintf="vdom1" dstintfrole="undefined"
srccountry="Reserved" dstcountry="Reserved" sessionid=154431 proto=6 action="deny"
policyid=0 policytype="proxy-policy" user="single-certificate" service="HTTPS"
trandisp="noop" url="https://10.1.100.200/" agent="curl/7.68.0" duration=0 sentbyte=0
rcvdbyte=0 sentpkt=0 rcvdpkt=0 appcat="unscanned" crscore=30 craction=131072
crlevel="high" msg="Traffic denied because of explicit proxy policy"
```

Example 2

In this example, the same configuration as in Example 1 is used, with a web proxy profile added to enable adding the client certificate to the HTTP header X-Forwarded-Client-Cert. The header is then forwarded to the server.

To configure the FortiGate:

1. Repeat steps 1 to 6 of Example 1, using the common name on the certificate to verify the user.
2. Configure a web proxy profile that adds the HTTP x-forwarded-client-cert header in forwarded requests:

```
config web-proxy profile
    edit "mtls"
        set header-x-forwarded-client-cert add
    next
end
```

3. Configure the proxy policy to apply authentication, the security profile, and web proxy profile:

```
config firewall proxy-policy
    edit 3
        set uuid af5e2df2-c321-51eb-7d5d-42fa58868dcb
        set proxy access-proxy
        set access-proxy "mTLS-access-proxy"
```

```
        set srcintf "port2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set logtraffic all
        set users "single-certificate"
        set webproxy-profile "mtls"
        set utm-status enable
        set ssl-ssh-profile "deep-inspection-clone"
        set av-profile "av"
    next
end
```

To verify the results:

The WAD debug shows that the FortiGate adds the client certificate information to the HTTP header. The added header cannot be checked using the sniffer, because the FortiGate encrypts the HTTP header to forward it to the server.

1. Enable WAD debug on all categories:

```
# diagnose wad debug enable category all
```

2. Set the WAD debug level to verbose:

```
# diagnose wad debug enable level verbose
```

3. Enable debug output:

```
# diagnose debug enable
```

4. Check the debug output.
   - When the FortiGate receives the client HTTP request:

```
[0x7fc8d4bc4910] Received request from client: 10.1.100.11:45544

GET / HTTP/1.1
Host: 10.1.100.200
User-Agent: curl/7.68.0
Accept: */*
```

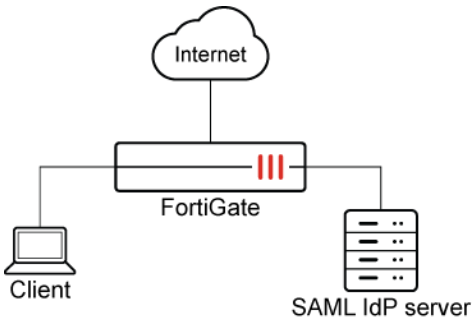
   - When the FortiGate adds the client certificate in to the HTTP header and forwards the client HTTP request:

```
[0x7fc8d4bc4910] Forward request to server:
GET / HTTP/1.1
Host: 172.16.200.44
User-Agent: curl/7.68.0
Accept: */*
X-Forwarded-Client-Cert: -----BEGIN CERTIFICATE-----
MIIFXzCCA0egAwI...aCFHDHlR+wb39s=
```

```
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIFpTCCA42gAwI...OtDtetkNoFLbvb
-----END CERTIFICATE-----
```

CORS protocol in explicit web proxy when using session-based, cookie-enabled, and captive portal-enabled SAML authentication

The FortiGate explicit web proxy supports the Cross-Origin Resource Sharing (CORS) protocol, which allows the FortiGate to process a CORS preflight request and an actual CORS request properly, in addition to a simple CORS request when using session-based, cookie-enabled, and captive portal-enabled SAML authentication. This allows a FortiGate explicit web proxy user with this specific configuration to properly view a web page requiring CORS with domains embedded in it other than its own domain.



To configure the FortiGate:

1. Configure the authentication rule:

```
config authentication rule
    edit "saml"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "saml"
        set web-auth-cookie enable
    next
end
```

2. Configure the captive portal:

```
config authentication setting
    set captive-portal "fgt9.myqalab.local"
end
```

3. Configure the proxy policy

```
config firewall proxy-policy
    edit 3
        set proxy explicit-web
        set dstintf "port9"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set groups "ldap-group-saml"
        set utm-status enable
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "deep-custom"
        set av-profile "av"
        set application-list "fff"
    next
end
```

CORS request scenarios

Preflight CORS request

The client sends the initial CORS preflight request (`OPTIONS` with the origin header) to the web server through FortiGate's web proxy and receives a CORS `200 OK` response (with headers, such as `Access-Control-Allow-Origin`). The FortiGate will not redirect the client to the captive capital for authentication:

```
> OPTIONS /bidRequest HTTP/1.1
> Host: c2shb.pubgw.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Access-Control-Request-Method: GET
> Access-Control-Request-Headers: content-type,x-openrtb-version
> Origin: https://www.cnn.com
...
< HTTP/1.1 200 OK
< Date: Thu, 19 May 2022 01:49:17 GMT
< Content-Length: 0
< Server: ATS/9.1.0.46
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Methods: GET,POST,OPTIONS
< Access-Control-Allow-Headers: X-Requested-With,Content-Type,X-Openrtb-Version
< Access-Control-Allow-Credentials: true
< Access-Control-Max-Age: 600
< Age: 0
< Connection: keep-alive
< Set-Cookie: A3=d=AQABBB2ihWICEIUyD_Du5ol8tMdKKWxspR8FEgEBAQHzhmKPYgAAAAAA_
eMAAA&S=AQAAAlU0dAheQx6euvcPs8ErK4I; Expires=Fri, 19 May 2023 07:49:17 GMT; Max-Age=31557600;
Domain=.yahoo.com; Path=/; SameSite=None; Secure; HttpOnly
```

Real CORS request

Once the initial preflight request for the client is successful, the client sends the real CORS request (`GET` request with origin header) to the FortiGate, The FortiGate then replies with a 30x response to redirect the client to the captive portal. The 30x response includes CORS headers such as `Access-Control-Allow-Origin`:

```
> GET /bidRequest HTTP/1.1
> Host: c2shb.pubgw.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Origin: https://www.cnn.com
...
< HTTP/1.1 303 See Other
< Access-Control-Max-Age: 1
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Credentials: true
< Set-Cookie: FTNT-EP-
FG900D3915800054=pqWlpdswdcCnpaWli6WlpcjEwszGmJbGksbBwMCVwcPBlpKRnMGTl52QxJeUwYPW18aYlJWLlIuUlZWLl
JalpQ==; Path=/; Domain=.pubgw.yahoo.com; HttpOnly; SameSite=None; Secure
< Connection: close
< Content-Type: text/html
< Cache-Control: no-cache
< Location:
https://fgt9.myqalab.local:7831/test/saml/login/?cptype=ckauth&scheme=https&4Tmthd=0&host=c2shb.pu
bgw.yahoo.com&port=443&rule=98&uri=L2JpZFJlcXVlc3Q=&cdata=pqWlpdswdcCnpaWli6WlpcjEwszGmJbGksbBwMCV
wcPBlpKRnMGTl52QxJeUwYPW18aYlJWLlIuUlZWLlJalpQ==
< Content-Length: 0
```

Redirection to captive portal

Once the client's real CORS request is redirected to the captive portal, the client senda another preflight to the captive portal. The captive portal then replies with a 20x response, which includes CORS headers such as `Access-Control-Allow-Origin`:

```
> OPTIONS
/test/saml/login/?cptype=ckauth&scheme=https&4Tmthd=1&host=gql.reddit.com&port=443&rule=98&uri=Lw=
=&cdata=pqWlpQM5dcCnpaWliqWlpcjEwszGmJbGksbAk5WTl8aTwJDGnJ2Tl52QxpHDkYPW18aYlJWLlIuUlZWLlJGWpQ==
HTTP/1.1
> Host: fgt9.myqalab.local:7831
> Connection: keep-alive
> Accept: */*
> Access-Control-Request-Method: GET
> Access-Control-Request-Headers: authorization,content-type,x-reddit-compression,x-reddit-loid,x-
reddit-session
> Origin: null
> User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like Gecko)
Chrome/100.0.4896.75 Safari/537.36 Edg/100.0.1185.36
> Sec-Fetch-Mode: cors
> Sec-Fetch-Site: cross-site
> Sec-Fetch-Dest: empty
> Referer: https://www.reddit.com/
> Accept-Encoding: gzip, deflate, br
```

```
> Accept-Language: en-US,en;q=0.9
...
< HTTP/1.1 204 No Content
< Access-Control-Max-Age: 86400
< Access-Control-Allow-Methods: GET
< Access-Control-Allow-Headers: authorization,content-type,x-reddit-compression,x-reddit-loid,x-
reddit-session
< Access-Control-Allow-Origin: null
< Access-Control-Allow-Credentials: true
```

Simple CORS request

If a simple CORS request (no preflight request sent before it) is used, when the FortiGate receives the simple request, it replies with a 30x response that includes CORS headers, such as `Access-Control-Allow-Origin`:

```
> Host: www.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Origin: https://www.cnn.com
...
< HTTP/1.1 303 See Other
< Access-Control-Max-Age: 1
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Credentials: true
< Set-Cookie: FTNT-EP-
FG900D3915800000=pqWlpaw7dcCnpaWli6WlpcjEwszGmJbGksbAkpOcxMDDlpbGlMSTl52QwcGcl4PW18aYlJWLlIuUlZWLl
JalpQ==; Path=/; Domain=.yahoo.com; HttpOnly; SameSite=None; Secure
< Connection: close
< Content-Type: text/html
< Cache-Control: no-cache
< Location:
https://fgt9.myqalab.local:7831/test/saml/login/?cptype=ckauth&scheme=https&4Tmthd=0&host=www.yaho
o.com&port=443&rule=98&uri=Lw==&cdata=pqWlpaw7dcCnpaWli6WlpcjEwszGmJbGksbAkpOcxMDDlpbGlMSTl52QwcGc
l4PW18aYlJWLlIuUlZWLlJalpQ==
< Content-Length: 0
```

Display CORS content in an explicit proxy environment

Webpages can display Cross-Origin Resource Sharing (CORS) content in an explicit proxy environment when using session-based, cookie-enabled, and captive portal assisted authentication. This ensures that webpages are displayed correctly and improves the user experience.

```
config authentication rule
    edit <name>
        set web-auth-cookie enable
        set cors-stateful {enable | disable}
        set cors-depth <integer>
    next
end
```

`cors-stateful {enable | disable}`	Enable/disable allowing CORS access (default = disable). This setting is only available when `web-auth-cookie` is enabled.
`cors-depth <integer>`	Set the depth to allow CORS access (1 - 8, default = 3). For example, when visiting domain A, the returned web page may refer the browser to a cross-origin domain B (depth of 1). When the browser visits domain B, the returned web content may further refer the browser to another cross-origin domain C (depth of 2).

Example

CORS access is enabled in this example. When a user access the Microsoft *Sign in* page using an explicit proxy, the page appears and the user can log in. This example assumes the web proxy and user group have already been configured, and that the proxy captive portal setting has been enabled on the appropriate interface.

To view CORS content in an explicit proxy environment:

1. Configure the authentication scheme:

```
config authentication scheme
    edit "form"
        set method form
        set user-database "local-user-db"
    next
end
```

2. Configure the authentication rule:

```
config authentication rule
    edit "form"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "form"
        set web-auth-cookie enable
        set cors-stateful enable
        set cors-depth 3
    next
end
```

3. Configure the captive portal:

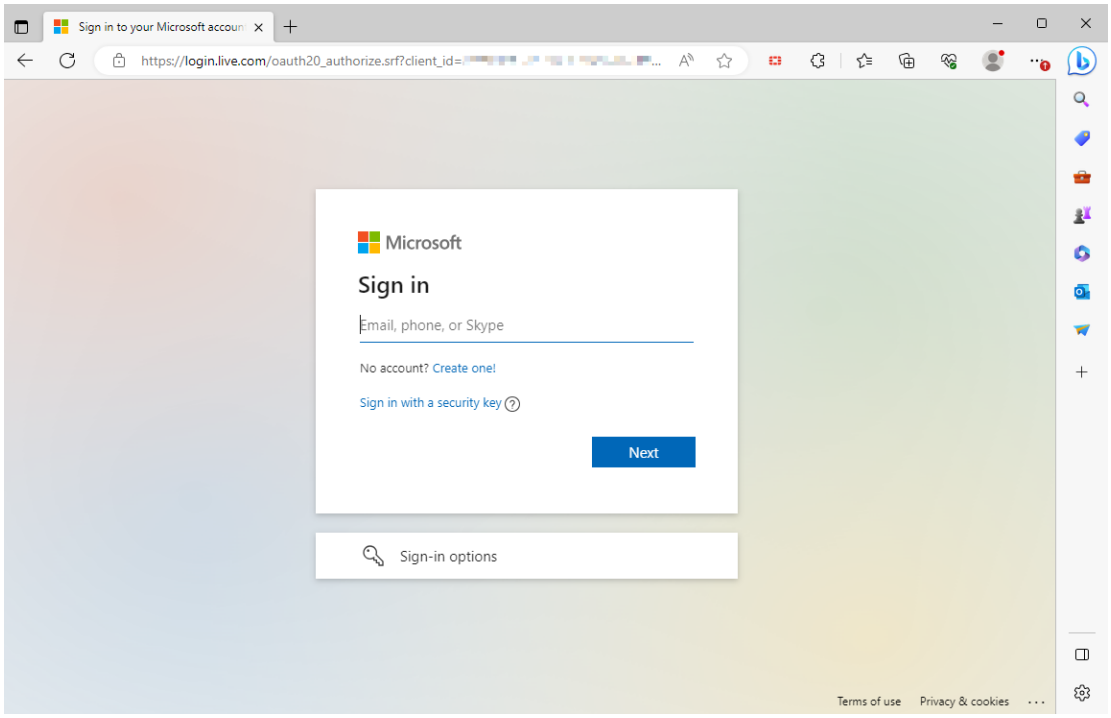
```
config authentication setting
    set captive-portal "fgt9.myqalab.local"
end
```

4. Configure the proxy policy:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port9"
```

```
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set groups "localgroup"
        set utm-status enable
        set ssl-ssh-profile "deep-custom"
        set av-profile "av"
    next
end
```

5. Get a user to access login.microsoftonline.com trough the explicit web proxy. The *Sign in* page appears, and the user can log in.



If CORS access (`cors-stateful`) was disabled, the browser would load a blank page.

HTTP connection coalescing and concurrent multiplexing for explicit proxy

HTTP connection coalescing and concurrent multiplexing allows multiple HTTP requests to share the same TCP three-way handshake when the destination IP is the same.

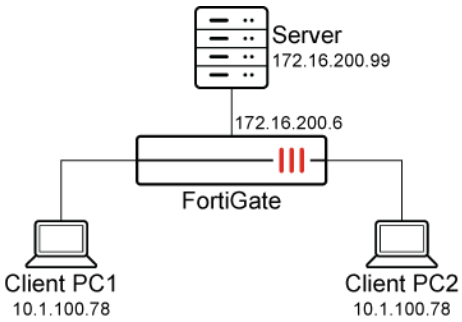
To configure the explicit web proxy:

```
config web-proxy explicit
    set http-connection-mode {static | multiplex | serverpool}
end
```

`http-connection-mode {static | multiplex | serverpool}`	Set the HTTP connection mode: • static: only one server connection exists during the proxy session (default). • multiplex: hold established connections until the proxy session ends. • serverpool: share established connections with other proxy sessions.

Example

In this example, multiple clients submit requests in HTTP. The requests hit the VIP address, and then FortiGate opens a session between itself (172.16.200.6) and the server (172.16.200.99). The coalescing occurs in this session as the multiple streams share the same session to connect to the same destination server.



To configure connection coalescing and concurrent multiplexing with an explicit proxy:

1. Configure the explicit web proxy:

```
config web-proxy explicit
    set status enable
    set http-incoming-port 8080
    set http-connection-mode serverpool
end
```

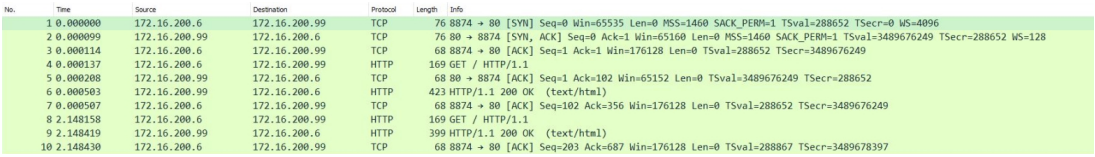
2. Enable explicit web proxy on port2:

```
config system interface
    edit "port2"
        set ip 10.1.100.6 255.255.255.0
        set explicit-web-proxy enable
    next
end
```

3. Configure the proxy policy:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set utm-status enable
        set profile-protocol-options "default-clone"
        set ssl-ssh-profile "deep-inspection-clone"
    next
end
```

4. Get the clients to access the server through the explicit web proxy (10.1.100.6:8080). The FortiGate shares the first connection TCP three-way handshake with later connections that connect to same destination address.
5. Verify the sniffer packet capture on the FortiGate server side. There is one TCP three-way handshake, but there are two HTTP connections.

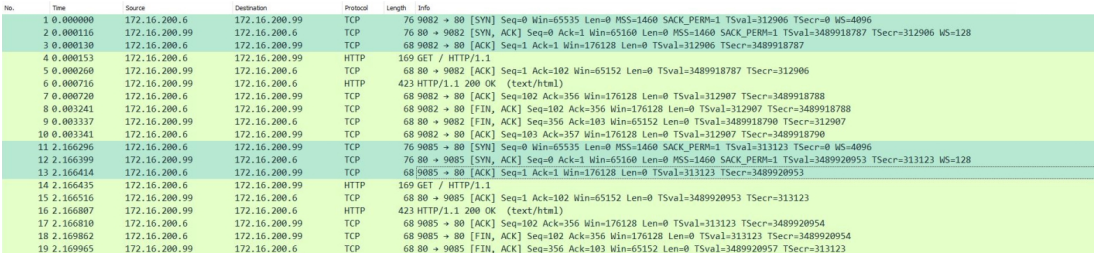


No.	Time	Source	Destination	Protocol	Length	Info
1	0.000000	172.16.200.6	172.16.200.99	TCP	76	8874 → 80 [SYN] Seq=0 Win=65535 Len=0 MSS=1460 SACK_PERM=1 TSval=288652 TSecr=0 WS=4096
2	0.000099	172.16.200.99	172.16.200.6	TCP	76	80 → 8874 [SYN, ACK] Seq=0 Ack=1 Win=65160 Len=0 MSS=1460 SACK_PERM=1 TSval=3489676249 TSecr=288652 WS=128
3	0.000114	172.16.200.6	172.16.200.99	TCP	68	8874 → 80 [ACK] Seq=1 Ack=1 Win=176128 Len=0 TSval=288652 TSecr=3489676249
4	0.000137	172.16.200.6	172.16.200.99	HTTP	169	GET / HTTP/1.1
5	0.000208	172.16.200.99	172.16.200.6	TCP	68	80 → 8874 [ACK] Seq=1 Ack=102 Win=65152 Len=0 TSval=3489676249 TSecr=288652
6	0.000503	172.16.200.99	172.16.200.6	HTTP	423	HTTP/1.1 200 OK (text/html)
7	0.000507	172.16.200.6	172.16.200.99	TCP	68	8874 → 80 [ACK] Seq=102 Ack=356 Win=176128 Len=0 TSval=288652 TSecr=3489676249
8	2.148158	172.16.200.6	172.16.200.99	HTTP	169	GET / HTTP/1.1
9	2.148419	172.16.200.99	172.16.200.6	HTTP	399	HTTP/1.1 200 OK (text/html)
10	2.148430	172.16.200.6	172.16.200.99	TCP	68	8874 → 80 [ACK] Seq=203 Ack=687 Win=176128 Len=0 TSval=288867 TSecr=3489678397

6. Change the HTTP connection mode to static:

```
config web-proxy explicit
    set status enable
    set http-incoming-port 8080
    set http-connection-mode static
end
```

7. Verify the sniffer packet capture. This time, the FortiGate establishes a TCP connection for each client.



No.	Time	Source	Destination	Protocol	Length	Info
1	0.000000	172.16.200.6	172.16.200.99	TCP	76	9082 → 80 [SYN] Seq=0 Win=65535 Len=0 MSS=1460 SACK_PERM=1 TSval=312906 TSecr=0 WS=4096

Secure explicit proxy

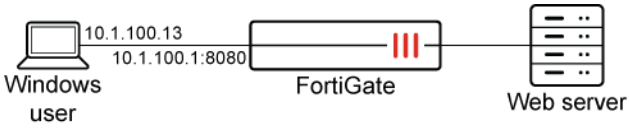
Secure explicit web proxy with HTTPS connections is supported between web clients and the FortiGate.

```
config web-proxy explicit
    set secure-web-proxy {disable | enable | secure}
    set secure-web-proxy-cert <certificate1> <certificate2> ...
    set ssl-dh-bits {768 | 1024 | 1536 | 2048}
end
```

`secure-web-proxy {disable | enable | secure}`	Enable/disable/require the secure web proxy for HTTP and HTTPS session. • `disable`: disable secure web proxy (default) • `enable`: enable secure web proxy access, allowing both HTTPS and HTTP connections to the explicit proxy • `secure`: require secure web proxy access, allowing only HTTPS connections to the explicit proxy
`secure-web-proxy-cert <certificate1> <certificate2> ...`	Enter the names of the server certificates in the local certificate store of the FortiGate used to establish a TLS connection between the user's browser and the FortiGate. Multiple server certificates can be configured, and different certificate types can be used. The SNI tries to match the right server certificate for the connection. If the SNI cannot not match with the certificates' CN or SAN, the first server certificate will be offered.
`ssl-dh-bits {768 | 1024 | 1536 | 2048}`	Set the bit size of Diffie-Hellman (DH) prime used in the DHE-RSA negotiation. • `768`: use 768-bit Diffie-Hellman prime • `1024`: use 1024-bit Diffie-Hellman prime • `1536`: use 1536-bit Diffie-Hellman prime • `2048`: use 2048-bit Diffie-Hellman prime (default)

Example

In this example, a Windows PC user configures an HTTPS URL (https://cp.myqalab.local) as the proxy address for the explicit web proxy. When the user opens a browser (such as Edge or Chrome), the browser will use the HTTPS URL to connect to the explicit web proxy and send any HTTP requests to the proxy over HTTPS. The certificate (server_cert) contains the explicit web proxy's name (cp.myqalab.local) as its CN, so the browser will accept this certificate for the TLS connection.

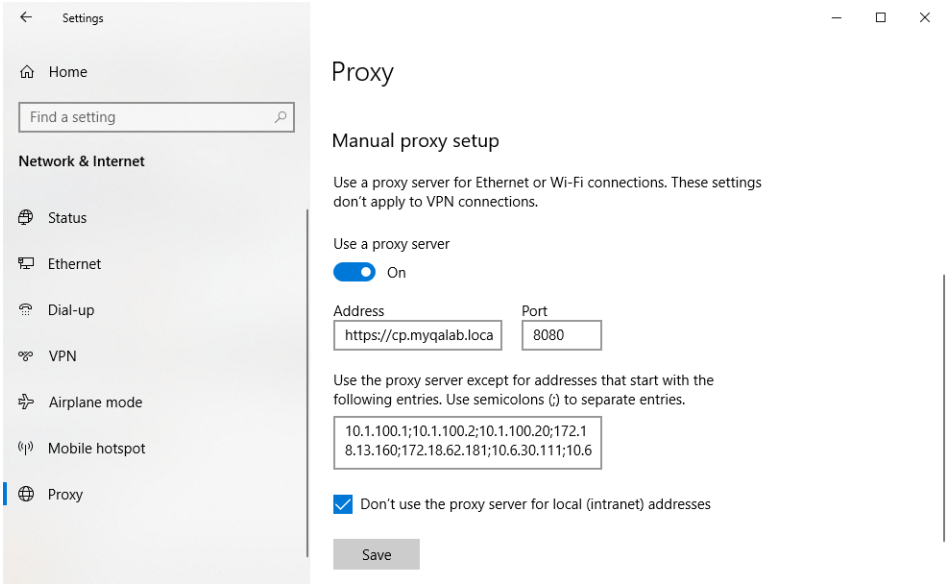


To configure the Windows proxy settings:

1. On the Windows PC, go to *Settings* > *Network & Internet* > *Proxy*.
2. In the *Manual proxy setup* section configure the following:
   a. Enable *Use a proxy server*.
   b. Set the *Address* to *https://cp.myqalab.local*.
   c. Set the *Port* to *8080*.

d. If needed, enter any addresses to exempt in the text box (use a semicolon to separate entries).

e. Enable *Don't use the proxy server for local (intranet) addresses*.



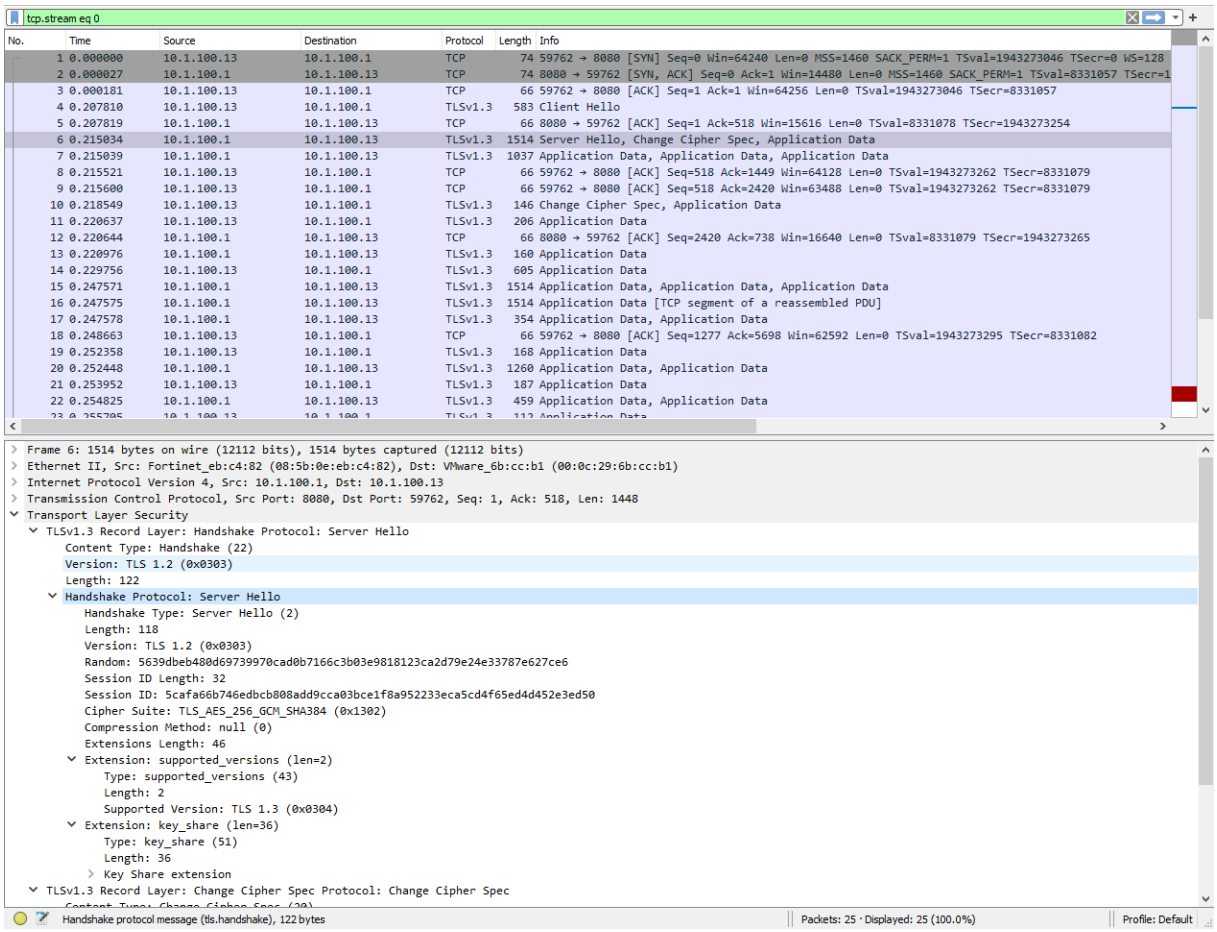
3. Click *Save*.

To configure the secure explicit web proxy:

```
config web-proxy explicit
    set status enable
    set secure-web-proxy enable
    set ftp-over-http enable
    set socks enable
    set http-incoming-port 8080
    set secure-web-proxy-cert "server_cert"
    set socks-incoming-port 1080
    set ipv6-status enable
    set unknown-http-version best-effort
    set pac-file-server-status enable
    set pac-file-data "function FindProxyForURL(url, host) {
   // testtest
   return \"PROXY 10.1.100.1:8080\";
}
"
    set pac-file-through-https enable
end
```

To verify the TLS connection:

1. Perform a packet capture of HTTPS traffic between the web client and the web server. Wireshark is used in this example.
2. Locate the exchange between the web client (10.1.100.13) and the explicit web proxy (10.1.100.1:8080):



After the client initiates the TLS connection to the explicit web proxy with a client hello packet, the web proxy is able to respond appropriately with a server hello packet to establish a TLS connection first before any HTTP messages are exchanged, and all HTTP messages will be protected by the TLS connection.

Secure explicit proxy with client certificates

The explicit web proxy policy can use client certificates for validation. In this example, a CA signs a client certificate. The client certificate is installed on an endpoint, and the root CA is imported to FortiGate. A web proxy policy is configured to require the client certificate.

When the user accesses a web site, the explicit web proxy policy uses the client certificate from the endpoint device to authenticate the user and grant access to the web site.

To configure client certificates with explicit proxies:

1. Prepare the certificate:
   a. Use a CA to sign the client certificate.
   b. Import the root CA certificate that signed the client certificate to FortiGate. In this scenario, the certificate is root_ca.
   c. Install the client certificate on an endpoint.

2. Configure the explicit web-proxy policy to request the client certificate from the endpoint.

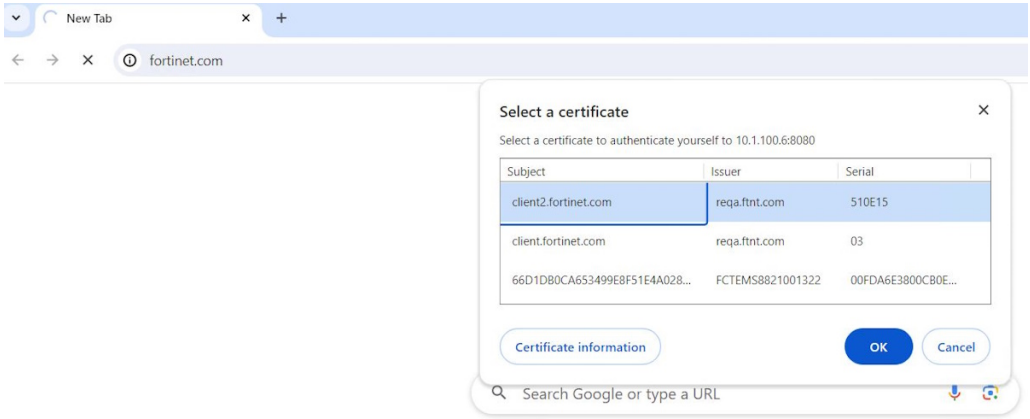
```
config web-proxy explicit
    set secure-web-proxy enable
    set secure-web-proxy-cert "proxy"
    set client-cert enable
    set empty-cert-action block
end
```

3. Configure verification of the client certificate with the root CA.

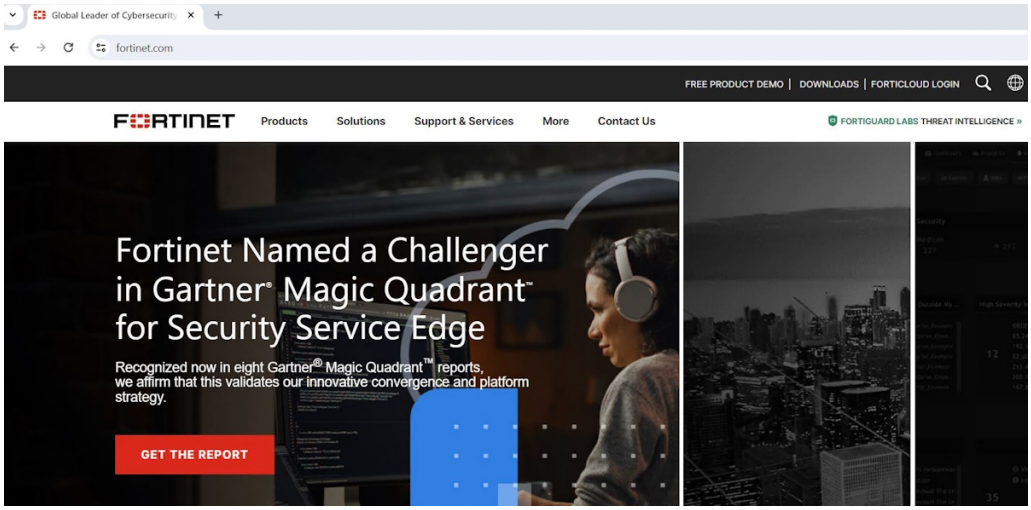
```
config authentication setting
    set user-cert-ca "root_ca"
end
```

When the user accesses a web site:

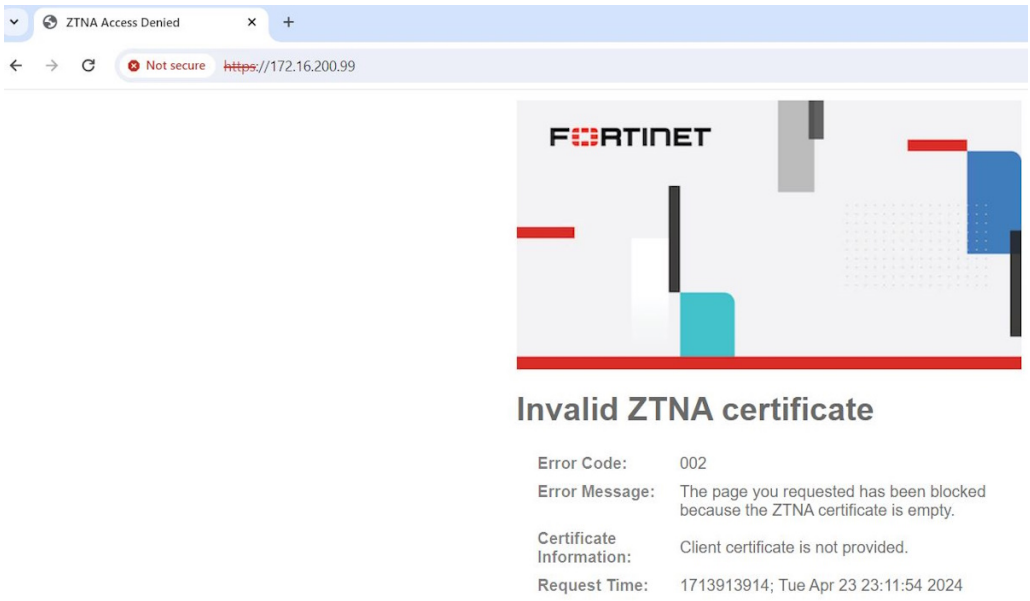
1. FortiGate requests client certificate authentication, and the web browser displays the available certificates. The user selects a client certificate (client2.fortinet.com) issued by the reqa.ftnt.com CA, and clicks *OK*.



2. Once the client certificate is successfully verified against the root CA certificate imported on the FortiGate, access to the web site is granted.



When the endpoint device fails to present a client certificate, a message is displayed, and access to the web site is blocked.



Explicit proxy logging

Explicit proxy traffic logging can be used to troubleshoot the HTTP proxy status for each HTTP transaction with the following:

- Monitor HTTP header requests and responses in the UTM web filter log. This requires an SSL deep inspection profile to be configured in the corresponding firewall policy.
- Log the explicit web proxy forward server name using `set log-forward-server`, which is disabled by default.

```
config web-proxy global
    set log-forward-server {enable | disable}
end
```

- Log TCP connection failures in the traffic log when a client initiates a TCP connection to a remote host through the FortiGate and the remote host is unreachable.
- Log HTTP transaction details

Basic configuration

The following FortiGate configuration is used in the three explicit proxy traffic logging use cases in this topic.

To configure the FortiGate:

1. Configure the web proxy profile:

```
config web-proxy profile
    edit "header"
        config headers
```

```
            edit 1
                set name "test_request_header"
                set action monitor-request
            next
            edit 2
                set name "ETag"
                set action monitor-response
            next
        end
    next
end
```

2. Enable forward server name logging in traffic:

```
config web-proxy global
    set proxy-fqdn "100D.qa"
    set log-forward-server enable
end
```

3. Configure the web filter banned word table to block any HTTP response containing the text, `works`:

```
config webfilter content
    edit 1
        set name "default"
        config entries
            edit "works"
                set status enable
                set action block
            next
        end
    next
end
```

4. Configure the web filter profile:

```
config webfilter profile
    edit "header"
        set feature-set proxy
        config web
            set bword-table 1
        end
        config ftgd-wf
            unset options
        end
        set log-all-url enable
        set extended-log enable
        set web-extended-all-action-log enable
    next
end
```

5. Configure the web proxy forwarding server:

```
config web-proxy forward-server
    edit "fgt-b"
        set ip 172.16.200.20
    next
end
```

6. Configure the firewall policy:

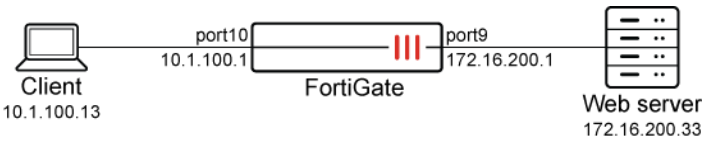
```
config firewall policy
    edit 1
        set srcintf "port10"
        set dstintf "port9"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set webproxy-profile "header"
        set webproxy-forward-server "fgt-b"
        set ssl-ssh-profile "deep-inspection"
        set webfilter-profile "header"
        set logtraffic all
        set nat enable
    next
end
```

A firewall policy is used in this basic configuration example and the specific examples that follow. This feature also works for the explicit web proxy or transparent web proxy with proxy policies, and the configurations are similar:

- Example 1: apply the `web-proxy profile` and `webfilter profile` to the proxy policy.
- Example 2: apply the `webproxy-forward-server`.

Example 1: monitoring HTTP header requests

In this example, the user wants to monitor some HTTP headers in HTTP messages forwarded through a FortiGate proxy (either transparent or explicit proxy with a firewall policy in proxy mode or a proxy policy). When the monitored headers are detected, they will be logged in the UTM web filter log.



In the web proxy profile configuration, the following HTTP headers are monitored:

- `test_request_header`: this is a user-customized HTTP header.
- `ETag`: this is a HTTP header returned by the web server's 200 OK response.

Based on the web filter profile configuration, the monitored headers in the web proxy profile will only be logged when the HTTP response received by the FortiGate triggers a block action by the banned word table. The `log-all-url`, `extended-log`, and `web-extended-all-action-log` settings in the web filter profile must be enabled.

The following settings are required in the firewall policy:

- `set inspection-mode proxy`
- `set webproxy-profile "header"`
- `set ssl-ssh-profile "deep-inspection"`
- `set webfilter-profile "header"`
- `set logtraffic all`

To verify the configuration:

1. Send a HTTP request from the client:

   ```
   curl -kv https://172.16.200.33 -H "test_request_header: aaaaa"
   ```

   This command sends a HTTP request with the header `test_request_header: aaaaa` through the FortiGate. Since the response from the web server contains the word `works`, the response will be blocked by the web filter profile (`header`). During this process, two logs will be generated.
2. On the FortiGate, check the traffic logs:

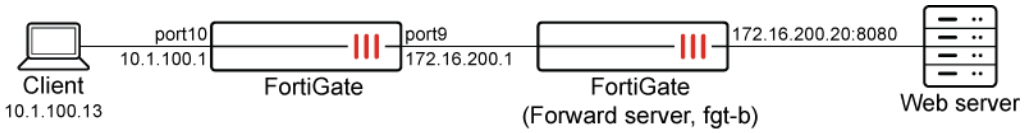
   ```
   # execute log filter category 3
   1: date=2023-04-19 time=19:01:19 eventtime=1681956079146481995 tz="-0700" logid="0314012288"
   type="utm" subtype="webfilter" eventtype="content" level="warning" vd="vdom1" policyid=1
   poluuid="4d8dc396-46e3-51ea-7f3f-ee328a5bd07b" policytype="policy" sessionid=40980
   srcip=10.1.100.13 srcport=54512 srccountry="Reserved" srcintf="port10" srcintfrole="undefined"
   srcuuid="6ce0b8ca-30ae-51ea-a388-ceacbb4fb045" dstip=172.16.200.33 dstport=443
   dstcountry="Reserved" dstintf="port9" dstintfrole="undefined" dstuuid="6ce0b8ca-30ae-51ea-
   a388-ceacbb4fb045" proto=6 httpmethod="GET" service="HTTPS" hostname="172.16.200.33"
   agent="curl/7.61.1" profile="header" reqtype="direct" url="https://172.16.200.33/" sentbyte=0
   rcvdbyte=0 direction="incoming" action="blocked" banword="works" msg="URL was blocked because
   it contained banned word(s)." rawdata="[REQ] test_request_header=aaaaa||[RESP] Content-
   Type=text/html|ETag=\"34-5b23b9d3b67f4\""

   2: date=2023-04-19 time=19:01:19 eventtime=1681956079144896978 tz="-0700" logid="0319013317"
   type="utm" subtype="webfilter" eventtype="urlmonitor" level="notice" vd="vdom1" policyid=1
   poluuid="4d8dc396-46e3-51ea-7f3f-ee328a5bd07b" policytype="policy" sessionid=40980
   srcip=10.1.100.13 srcport=54512 srccountry="Reserved" srcintf="port10" srcintfrole="undefined"
   srcuuid="6ce0b8ca-30ae-51ea-a388-ceacbb4fb045" dstip=172.16.200.33 dstport=443
   dstcountry="Reserved" dstintf="port9" dstintfrole="undefined" dstuuid="6ce0b8ca-30ae-51ea-
   a388-ceacbb4fb045" proto=6 httpmethod="GET" service="HTTPS" hostname="172.16.200.33"
   agent="curl/7.61.1" profile="header" action="passthrough" reqtype="direct"
   url="https://172.16.200.33/" sentbyte=724 rcvdbyte=2769 direction="outgoing" msg="URL has been
   visited" ratemethod="ip" cat=255 rawdata="[REQ] test_request_header=aaaaa"
   ```

   Log 1 is for the blocked HTTP response that contains both monitored headers, `test_request_header` and `ETag`, and their values, `aaaaa` and `34-5b23b9d3b67f4`, respectively. Log 2 is for the HTTP request passing through the FortiGate proxy that contains `test_request_header` and its `aaaaa` value in the `rawdata` field.

Example 2: logging the explicit web proxy forward server name

In this example, the user wants to see the name of the web proxy forward server in the traffic log when the traffic is forwarded by a web proxy forward server.



In the global web proxy settings, `log-forward-server` must be enabled.

The following settings are required in the firewall policy:

- `set inspection-mode proxy`
- `set webproxy-forward-server "fgt-b"`
- `set logtraffic all`

When a HTTP request is sent through the FortiGate proxy, the request will be forwarded by the FortiGate to the upstream proxy (fgt-b), and the forward server's name will be logged in the traffic log.

To verify the configuration:

1. Send a HTTP request from the client:

```
curl -kv https://www.google.com
```

2. On the FortiGate, check the traffic logs:

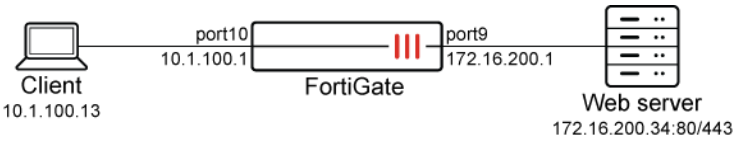
```
# execute log filter category 3
1: date=2023-04-19 time=19:51:33 eventtime=1681959093510003961 tz="-0700" logid="0000000013"
type="traffic" subtype="forward" level="notice" vd="vdom1" srcip=10.1.100.13 srcport=49762
srcintf="port10" srcintfrole="undefined" dstip=142.250.217.100 dstport=443 dstintf="port9"
dstintfrole="undefined" srccountry="Reserved" dstcountry="United States" sessionid=43292
proto=6 action="client-rst" policyid=1 policytype="policy" poluuid="4d8dc396-46e3-51ea-7f3f-
ee328a5bd07b" service="HTTPS" trandisp="snat" transip=172.16.200.1 transport=49762
duration=120 sentbyte=0 rcvdbyte=37729 sentpkt=0 rcvdpkt=33 appcat="unscanned" wanin=3779
wanout=682 lanin=879 lanout=36005 fwdsrv="fgt-b" utmaction="block" countssl=1 utmref=65506-14
```

Example 3: logging TCP connection failures

In this example, a client initiates a TCP connection to a remote network node through the FortiGate. The connection fails because the IP address or port of the remote node is unreachable. A `Connection Failed` message appears in the logs. In the firewall policy configuration, the `inspection-mode` can be set to either `proxy` or `flow` mode.

Based on the basic FortiGate configuration used in examples 1 and 2, the forward server may need to be removed from the firewall policy if the forward server's TCP IP port is actually reachable. If the forward server proxy tries to set up back-to-back TCP connections with the downstream FortiGate and the remote server as in the case of deep-inspection, then when the client tries to connect to a remote node (even if the IP address or port is unreachable), the downstream FortiGate is able to establish a TCP connection with the upstream forward server, so there will be no `Connection Failed` message in the downstream FortiGate's log.

Currently, the `Connection Failed` message in the downstream FortiGate's log is visible for the case when there is an unreachable TCP port only when explicit web proxy with a proxy policy is configured. Therefore, the following example that makes use of a firewall policy demonstrates this log message is only supported for the unreachable IP address case.



To verify the configuration:

1. Send a HTTP request from the client to an unreachable IP:

```
curl -kv https://172.16.200.34
```

2. On the FortiGate, check the traffic logs:

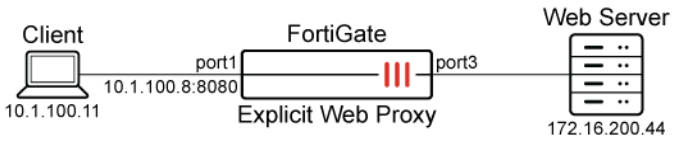
```
# execute log filter category 3
1: date=2023-04-19 time=20:25:55 eventtime=1681961155100007061 tz="-0700" logid="0000000013"
type="traffic" subtype="forward" level="notice" vd="vdom1" srcip=10.1.100.13 srcport=52452
srcintf="port10" srcintfrole="undefined" dstip=172.16.200.34 dstport=443 dstintf="port9"
dstintfrole="undefined" srccountry="Reserved" dstcountry="Reserved" sessionid=44903 proto=6
action="server-rst" policyid=1 policytype="policy" poluuid="4d8dc396-46e3-51ea-7f3f-
ee328a5bd07b" service="HTTPS" trandisp="snat" transip=172.16.200.1 transport=52452 duration=20
sentbyte=180 rcvdbyte=164 sentpkt=3 rcvdpkt=3 appcat="unscanned" wanin=0 wanout=0 lanin=0
lanout=0 crscore=5 craction=262144 crlevel="low" msg="Connection Failed"
```

Example 4: logging HTTP transaction details

HTTP transaction details are logged in a traffic log when HTTP traffic is routed through a proxy. After an HTTP transaction is proxied through the FortiGate, traffic logs of the http-transaction subtype are generated in addition to the forward subtype log. HTTP transaction logs are based on each transaction, such as an HTTP request and response pair. When there are multiple HTTP transactions completed over the TCP connection there will be multiple http-transaction logs and only one forward traffic log.

HTTP transaction logging can be enabled in explicit-web proxy, transparent-web proxy, access-proxy, and proxy-mode firewall policies.

```
config firewall proxy-policy
    edit 1
        set proxy {explicit-web | transparent-web | access-proxy}
        logtraffic {utm | all}
        set log-http-transaction {enable | disable}
    next
end
config firewall policy
    edit 1
        set inspection-mode proxy
        logtraffic {utm | all}
        set log-http-transaction {enable | disable}
    next
end
```



One http-transaction log is generated for each HTTP transaction. A TCP connection can have multiple HTTP transactions, so there can be multiple http-transaction logs for one forward traffic log.

- Explicit-web proxy logs:

  In the http-transaction logs (logs 2 and 3), transaction information such as `httpmethod` and `statuscode` are recorded.

```
1: date=2024-05-21 time=20:06:17 eventtime=1716347177537010993 tz="-0700" logid="0000000010"

resptype="normal" reqtime=1716532330 resptime=1716532330 respfinishtime=1716532330
appcat="unscanned"
```

For HTTPS with explicit-web proxy, there is an additional piece of http-transaction log for each CONNECT request and response:

```
3: date=2024-05-21 time=20:34:44 eventtime=1716348884524284243 tz="-0700" logid="0006000026"
type="traffic" subtype="http-transaction" level="notice" vd="vdom1" srcip=10.1.100.11
srcport=46030 dstip=172.16.200.44 dstport=443 sessionid=316483736 transid=50331683 action="accept"
policyid=1 policytype="proxy-policy" poluuid="1e1e0b2e-14c1-51ef-7b4c-6b789be487f2"
url="https://172.16.200.44/" agent="curl/7.68.0" duration=0 reqlength=118 resplength=0 rcvdbyte=0
sentbyte=118 scheme="https" hostname="172.16.200.44" resptype="generated" httpmethod="CONNECT"
statuscode="200" reqtime=1716348884 resptime=0 respfinishtime=1716348884 appcat="unscanned"
```

For HTTPS with certificate-inspection or no inspection, there is only one http-transaction log for each TCP connection because the encrypted HTTP messages are not decrypted:

- Firewall policy:

```
2: date=2024-05-23 time=21:38:56 eventtime=1716525535340969183 tz="-0700" logid="0006000026"

Configuring fast fallback for explicit proxy

The fast fallback (also named "Happy Eyeballs") algorithm, as outlined in RFC 8305, is supported for explicit web proxy. This feature operates by attempting to connect to a web server that is available at multiple IPv4 and IPv6 addresses, either sequentially or simultaneously. As a result, the web server can be connected with reduced user-visible delay, which enhances the overall browsing experience.

```
config web-proxy fast-fallback
    edit <name>
        set status {enable | disable}
```

```
        set connection-mode {sequentially | simultaneously}
        set protocol {IPv4-first | IPv6-first | IPv4-only | IPv6-only}
        set connection-timeout <integer>
    next
end
```

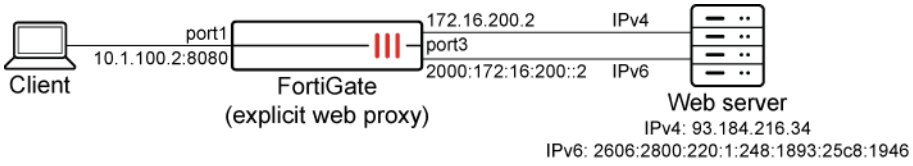
`status {enable | disable}`	Enable/disable the fast fallback entry (default = `enable`).
`connection-mode {sequentially | simultaneously}`	Set the connection mode for multiple destinations. • `sequentially`: connect the different destinations sequentially (default). • `simultaneously`: connect the different destinations simultaneously.
`protocol {IPv4-first | IPv6-first | IPv4-only | IPv6-only}`	Set the connection protocols for multiple destinations. • `IPv4-first`: connect IPv4 destinations first (default). • `IPv6-first`: connect IPv6 destinations first. • `IPv4-only`: connect IPv4 destinations only. • `IPv6-only`: connect IPv6 destinations only.
`connection-timeout <integer>`	Start another connection if a connection takes longer than the timeout value, in milliseconds (200 - 1800000, default = 200).

Based on the settings for `connection-mode` and `protocol`, the explicit web proxy will try connecting to the web server in different ways:

- If the `connection-mode` is set to `sequential` (default), then the explicit web proxy will try connecting to the web server by IPv4 first, or by IPv6 first depending on the `protocol` setting. If the connection attempt over IPv4 or IPv6 succeeds, then the connection is kept; but if the connection fails, then it falls back to try a connection over IPv6 or IPv4 instead.
- If the `connection-mode` is set to `simultaneously`, then the explicit web proxy will try connecting to the web server by IPv4 and IPv6 at the same time. If the connection over IPv4 is established first, then the connection is kept for the session and the IPv6 connection is discarded and vice-versa.
- If the user only wants to connect by IPv4 but not IPv6, or by IPv6 but not IPv4, then the `protocol` option can be set to `IPv4-only` or `IPv6-only` accordingly. The explicit web proxy will try connecting to the web server only by IPv4 or IPv6, even though both IPv4 and IPv6 may work.

Example

In this example, a client visits a web server through a FortiGate explicit web proxy that has IPv4 and IPv6 connections to the web server (www.example.com), which can resolve to IPv4 address 93.184.216.34 and IPv6 address 2606:2800:220:1:248:1893:25c8:1946.



The configuration uses sequential connection mode, the IPv4 first protocol, and the default connection timeout (200 ms).

To configure the FortiGate:

1. Configure the IPv4 static route:

```
config router static
    edit 1
        set gateway 172.16.200.251
        set device "port3"
    next
end
```

2. Configure the IPv6 static route:

```
config router static6
    edit 1
        set gateway 2000:172:16:200::254
        set device "port3"
    next
end
```

3. Configure the proxy destination connection fast fallback:

```
config web-proxy fast-fallback
    edit "ffbk"
        set status enable
        set connection-mode sequentially
        set protocol IPv4-first
        set connection-timeout 200
    next
end
```

4. Configure the exempt URL of the web server from web proxy forwarding and caching:

```
config web-proxy url-match
    edit "ffbk"
        set url-pattern "example.com"
        set fast-fallback "ffbk"
    next
end
```

5. Configure the proxy policy:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set srcaddr6 "all"
```

```
        set dstaddr6 "all"
        set utm-status enable
        set ssl-ssh-profile "deep-custom"
        set av-profile "av"
    next
end
```

Verifying the connection

Scenario 1:

The TCP connection from the explicit web proxy to the web server is established successfully over IPv4 within 200 ms.

As shown in the forward traffic log, the web session data is transmitted over IPv4 between the explicit web proxy and the web server.

```
2: date=2023-06-26 time=18:46:18 eventtime=1687830378260927765 tz="-0700" logid="0000000010"
type="traffic" subtype="forward" level="notice" vd="vdom1" srcip=10.1.100.11 srcport=33304
srcintf="port1" srcintfrole="undefined" dstcountry="United States" srccountry="Reserved"
dstip=93.184.216.34 dstport=80 dstintf="port3" dstintfrole="undefined" sessionid=1688881487
service="HTTP" proxyapptype="web-proxy" proto=6 action="accept" policyid=1 policytype="proxy-
policy" poluuid="560d8520-fa7b-51ed-e06a-df05ec145542" trandisp="snat" transip=0.0.0.0 transport=0
duration=0 wanin=0 rcvdbyte=0 wanout=0 lanin=131 sentbyte=131 lanout=1591 appcat="unscanned"
```

Scenario 2:

The TCP connection from the explicit web proxy to the web server is not established over IPv4 within 200 ms and falls back to IPv6 successfully.

The IPv4 path to the server is interrupted, and the TCP connection between the explicit web proxy and web server cannot be established. The explicit web proxy waits until the 200 ms connection timeout timer expires, then attempts to connect to the server by IPv6, which is successful. The web session data is transmitted over IPv6, as shown in the forward traffic log.

```
2: date=2023-06-26 time=18:47:27 eventtime=1687830447277653089 tz="-0700" logid="0000000010"
type="traffic" subtype="forward" level="notice" vd="vdom1" srcip=10.1.100.11 srcport=36636
srcintf="port1" srcintfrole="undefined" dstcountry="United States" srccountry="Reserved"
dstip=2606:2800:220:1:248:1893:25c8:1946 dstport=80 dstintf="port3" dstintfrole="undefined"
sessionid=1688881488 service="HTTP" proxyapptype="web-proxy" proto=6 action="accept" policyid=1
policytype="proxy-policy" poluuid="560d8520-fa7b-51ed-e06a-df05ec145542" trandisp="snat"
transport=0 duration=1 wanin=0 rcvdbyte=0 wanout=0 lanin=131 sentbyte=131 lanout=1591
appcat="unscanned"
```

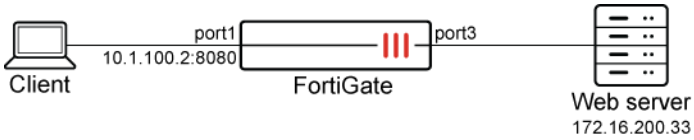
Forward HTTPS requests to a web server without the need for an HTTP CONNECT message

An explicit web proxy can forward HTTPS requests to a web server without the need for an HTTP CONNECT message. The FortiGate explicit web proxy can be configured to detect the HTTPS scheme in the request line of a plain text HTTP request and forward it as an HTTPS request to the web server. This allows applications that cannot use the CONNECT message for sending an HTTPS request to communicate with the web server through an explicit web proxy.

```
config firewall proxy-policy
    edit <id>
        set detect-https-in-http-request {enable | disable}
    next
end
```

Example

Based on the following topology, an HTTPS request is sent to a web server through an explicit web proxy.



To enable detection of HTTPS in an HTTP request:

1. Configure the explicit web proxy:

```
config web-proxy explicit
    set status enable
    set ftp-over-http enable
    set socks enable
    set http-incoming-port 8080
    set ipv6-status enable
    set unknown-http-version best-effort
end
```

2. Enable the explicit web proxy on port1:

```
config system interface
    edit "port1"
        set ip 10.1.100.2 255.255.255.0
        set explicit-web-proxy enable
    next
end
```

3. Configure the proxy policy:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set utm-status enable
        set ssl-ssh-profile "deep-inspection"
        set av-profile "av"
        set detect-https-in-http-request enable
    next
end
```

An SSL-SSH profile with deep inspection must be applied in order to decrypt the server response in HTTPS and forward the response to the client by HTTP.

4. Using Telnet, send an HTTP request with an HTTPS scheme as follows:

```
telnet 10.1.100.2 8080
Trying 10.1.100.2...
Connected to 10.1.100.2.
Escape character is '^]'.
POST https://172.16.200.33/ HTTP/1.1
Host: 172.16.200.33
User-Agent: curl/7.68.0
Accept: */*
Content-Type: application/x-www-form-urlencoded
Content-Length: 0

HTTP/1.1 200 OK
```

5. Verify the traffic log. The HTTP request is forwarded to the server successfully by HTTPS:

```
# execute log filter category 3
...
2: date=2023-07-31 time=16:02:22 eventtime=1690844541296891542 tz="-0700" logid="0000000010"
type="traffic" subtype="forward" level="notice" vd="vdom1" srcip=10.1.100.11 srcport=46074
srcintf="port1" srcintfrole="undefined" dstcountry="Reserved" srccountry="Reserved"
dstip=172.16.200.33 dstport=443 dstintf="port3" dstintfrole="undefined" sessionid=1799884153
service="HTTPS" proxyapptype="web-proxy" proto=6 action="accept" policyid=1 policytype="proxy-
policy" poluuid="73379360-2d21-51ee-77d8-154efc517a6a" trandisp="snat" transip=172.16.200.2
transport=2713 duration=4 wanin=3053 rcvdbyte=3053 wanout=757 lanin=169 sentbyte=169
lanout=279 appcat="unscanned"
```

Specifying outgoing interface and VRF for a web proxy forward server or isolator server

You can specify the outgoing interface and VRF for a web proxy forward server or a web proxy isolator server, such as FortiIsolator. See Virtual routing and forwarding on page 656.

The following CLI command options can be configured:

```
config web-proxy forward-server
   edit <name>
    set interface-select-method specify
    set interface <port>
    set vrf-select <vrf-id>
  next
end

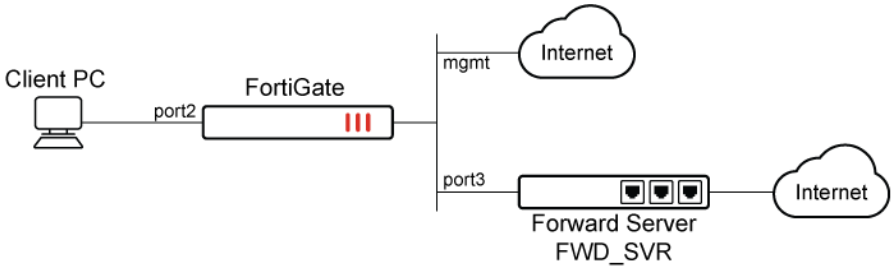
config web-proxy isolator-server
   edit <name>
     set interface-select-method specify
     set interface <port>
     set vrf-select <vrf-id>
   next
end
```

Example

In the following example, a forward server is applied to the FortiGate in an explicit proxy policy. A interface that is not in the policy, such as port3, can be specified to forward traffic.

Without this feature, the FortiGate would have to forward traffic through the management interface which is the destination interface of the policy.

This example uses the following topology:



To specify a outgoing interface and VRF for a web proxy forward server:

1. Enable and configure the explicit web proxy:

```
config web-proxy explicit
    set status enable
    set ftp-over-http enable
    set http-incoming-port 8080
    set ipv6-status enable
    set unknown-http-version best-effort
end
```

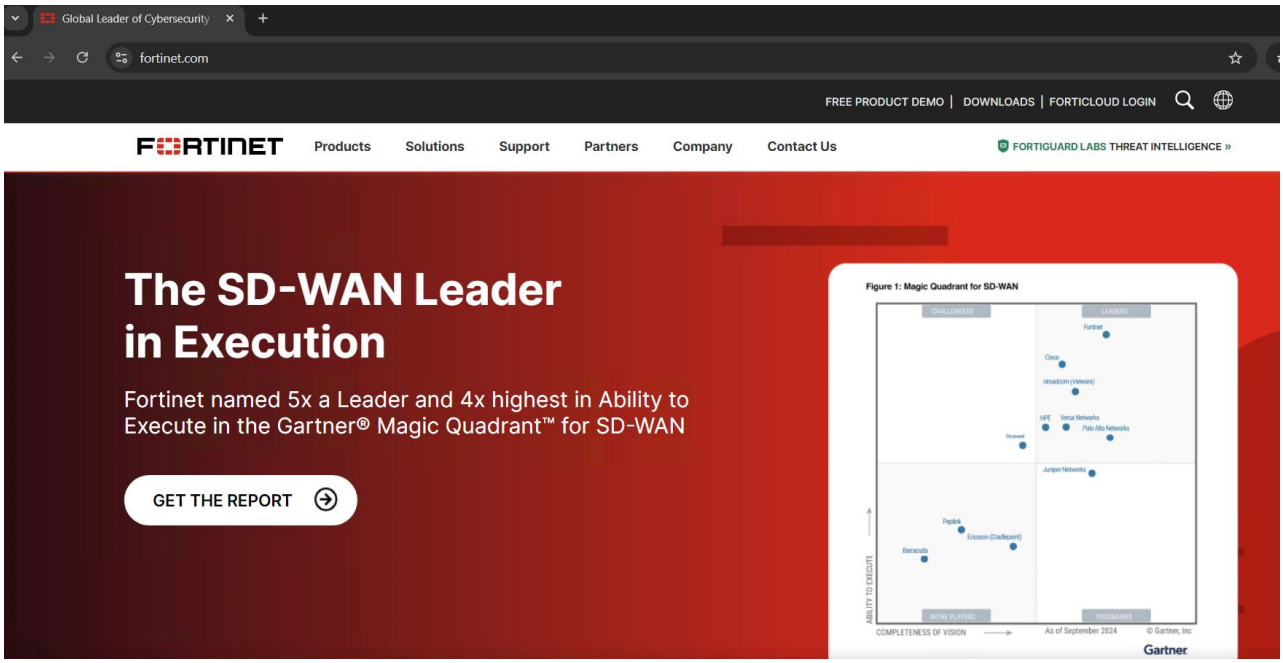
2. Configure the web proxy forward server with a interface that is not included in the policy:

```
config web-proxy forward-server
    edit "FWD_SVR"
        set ip 172.16.200.7
        set port 8080
        set interface-select-method specify
        set interface "port3"
        set vrf-select 10
    next
end
```

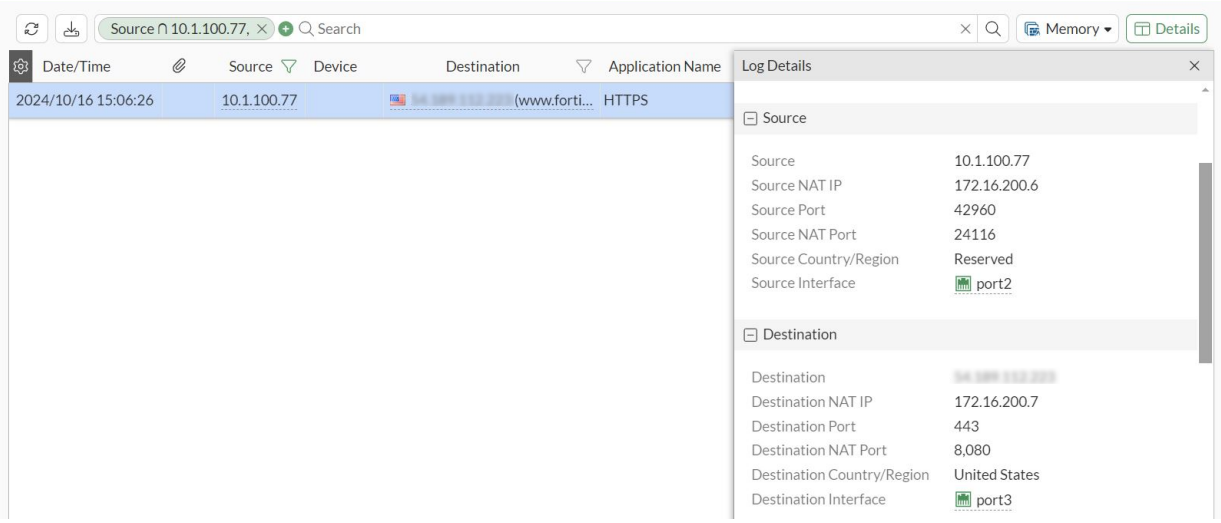
3. Specify the destination interface and web proxy forward server in the proxy policy:

```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "mgmt"
        set srcaddr "all"
        set dstaddr "all"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set webproxy-forward-server "FWD_SVR"
    next
end
```

4. Access a website in the browser, such as www.fortinet.com.



5. Go to *Log & Report* > *Forward Traffic* and review the traffic log. The *Destination Interface* is *port3* instead of the management interface.



Isolator servers in proxy policies

Web proxy isolator servers, such as FortiIsolator, are supported in proxy policies. Isolators are fundamentally the same as web proxy forward servers because both will redirect HTTP and HTTPS requests to an HTTP or HTTPS proxy server. However, isolators have the specific function of isolating potentially unsafe traffic from a user environment.

The `isolate` action in proxy policies can be used to distinguish isolated traffic from normal traffic in logs. Isolator servers can only be applied in explicit and transparent proxy policies. See Explicit web proxy on page 334 and Transparent proxy on page 342.

The following CLI commands support isolator servers:

```
config web-proxy isolator-server
    edit <name>
        set addr-type {ip | ipv6 | fqdn}
        set ip <any_ip>
        set ipv6 <IPv6 address>
        set fqdn <string>
        set port <port>
    next
end
```

```
config firewall proxy-policy
    edit <id>
        set action isolate
        set isolator-server <name>
    next
end
```

Example

The following example demonstrates how to apply an isolator server to a proxy policy. Two explicit proxy policies are configured:

- A web proxy forward server is applied to one policy with the action set to accept.
- An isolator server is applied to the other policy with the action set to isolate.

Each proxy policy uses a different destination IP address to separate traffic. Once traffic passes, logs are generated for the specific actions.

To configure an isolator server:

1. Configure the isolator server:

```
config web-proxy isolator-server
    edit "isolator"
        set ip 172.16.200.7
        set port 8080
    next
end
```

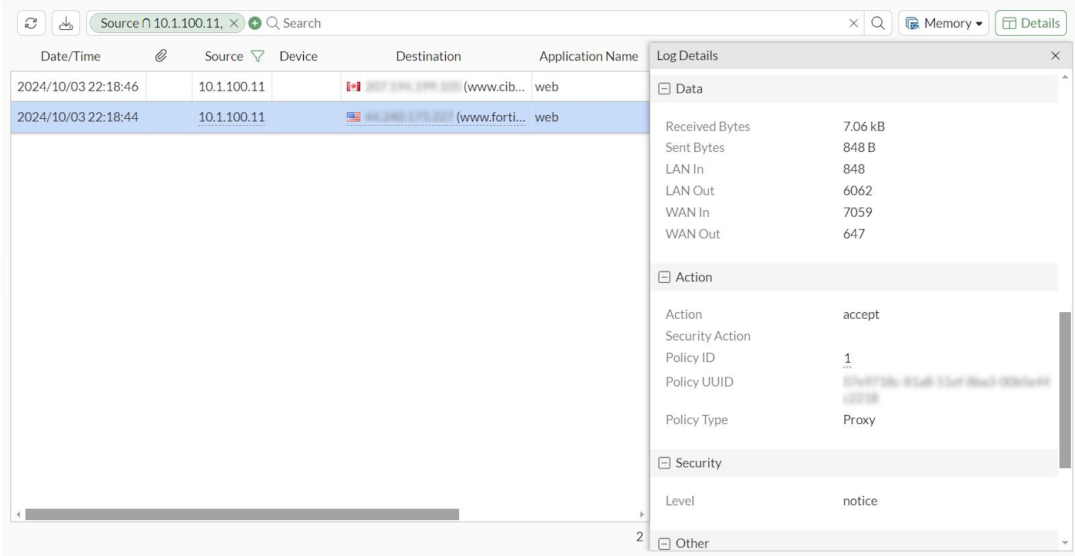
2. Configure the forward server:

```
config web-proxy forward-server
    edit "fgt-b"
        set ip 172.16.200.7
        set port 8080
    next
end
```

3. Apply each server to a proxy policy:

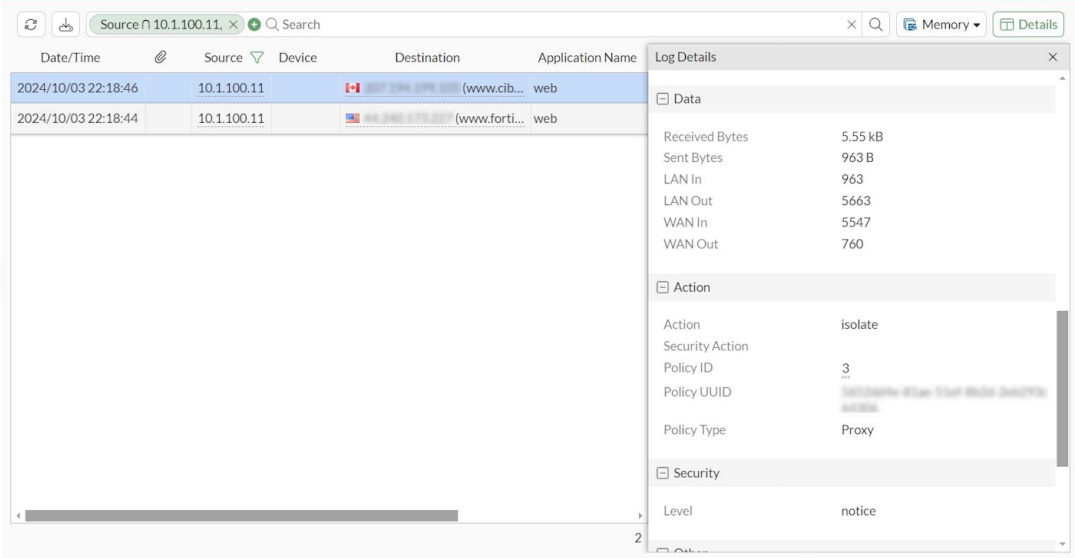
```
config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "IT"
        set service "webproxy"
        set action accept
        set schedule "always"
        set logtraffic all
        set webproxy-forward-server "fgt-b"
        set utm-status enable
        set ssl-ssh-profile "deep-custom"
        set av-profile "av"
    next
    edit 3
        set proxy explicit-web
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "Finance"
        set service "webproxy"
        set action isolate
        set schedule "always"
        set logtraffic all
        set isolator-server "isolator"
        set utm-status enable
        set ssl-ssh-profile "deep-custom"
        set av-profile "av"
    next
end
```

4. Generate traffic for the proxy policies and go to *Log & Report > Forward Traffic* in the GUI to review the logs:
   a. When accessing www.fortinet.com, the traffic hits proxy policy 1 and is accepted.
      Since the traffic matches the destination address, it goes to the forward server and then to the internet. A traffic log is generated with the action set to *accept*.



b. When accessing www.cibc.com, the traffic hits proxy policy 3 and is isolated.

Since the traffic matches the destination address, it goes to the isolator server and then to the internet. A traffic log is generated with the action set to *isolate*.



DHCP servers and relays

A DHCP server dynamically assigns IP addresses to hosts on the network connected to the interface. The host computers must be configured to obtain their IP addresses using DHCP. You can configure one or more DHCP servers on any FortiGate interface.

A DHCP server can be in server or relay mode. In server mode, you can define up to ten address ranges to assign addresses from, and options such as the default gateway, DNS server, lease time, and other advanced settings. In relay mode, the interface forwards DHCP requests from DHCP clients to an external DHCP server

and returns the responses to the DHCP clients. The DHCP server must have appropriate routing so that its response packets to the DHCP clients arrive at the unit.

If an interface is connected to multiple networks through routers, you can add a DHCP server for each network. The IP range of each DHCP server must match the network address range. The routers must be configured for DHCP relay.

Default DHCP server for entry-level FortiGates

On entry-level FortiGates, a DHCP server is configured on the internal interface, by default, with the following values:

Field	Value
Address Range	192.168.1.110 to 192.168.1.210
Netmask	255.255.255.0
Default Gateway	192.168.1.99
Lease Time	7 days
DNS Server 1	192.168.1.99

These settings are appropriate for the default internal interface IP address of 192.168.1.99. If you change this address to a different network, you need to change the DHCP server settings to match.

- Basic configuration on page 446
- DHCP options on page 450
- DHCP addressing mode on an interface on page 458
- VCI pattern matching for DHCP assignment on page 461
- DHCP shared subnet on page 463
- Multiple DHCP relay servers on page 465
- DHCP smart relay on interfaces with a secondary IP on page 466
- FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses on page 469

Basic configuration

The following contains information on basic configurations.

Configure a DHCP server on an interface

A DHCP server can be configured on an interface in the GUI from *Network* > *Interfaces*.

To configure a DHCP server in the GUI:

1. Go to *Network* > *Interfaces*.
2. Edit an interface.
3. Enable the *DHCP Server* option and configure the settings.
4. Click *OK*.

Field	Description
Address Range	By default, the FortiGate unit assigns an address range based on the address of the interface for the complete scope of the address. For example, if the interface address is 172.20.120.230, the default range created is 172.20.120.231 to 172.20.120.254. Select the range and select *Edit* to adjust the range or select *Create New* to add a different range.
Netmask	Enter the netmask of the addresses that the DHCP server assigns.
Default Gateway	Select this to use either *Same as Interface IP* or select *Specify* and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
DNS Server	Select this to use *Same as system DNS*, *Same as Interface IP* or select *Specify* and enter the IP address of the DNS server.
Mode	Select the type of DHCP server FortiGate will be. By default, it is a *Server*. Select *Relay* if needed. When *Relay* is selected, the above configuration is replaced by a field to enter the *DHCP Server IP* address.
DHCP Server IP	This appears only when *Mode* is *Relay*. Enter the IP address of the DHCP server where FortiGate obtains the requested IP address.
Type	Select this to use the DHCP in *Regular* or *IPsec* mode.
Additional DHCP Options	Use this to create new DHCP options.
Add from DHCP Client List	If the client is currently connected and using an IP address from the DHCP server, you can select this option to select the client from the list.

To configure a DHCP server in the CLI:

```
config system dhcp server
    edit 1
        set dns-service default
        set default-gateway 192.168.1.2
        set netmask 255.255.255.0
        set interface "port1"
        config ip-range
            edit 1
                set start-ip 192.168.1.1
                set end-ip 192.168.1.1
            next
            edit 2
```

```
                set start-ip 192.168.1.3
                set end-ip 192.168.1.254
            next
        end
        set timezone-option default
        set tftp-server "172.16.1.2"
    next
end
```

Configure a DHCP relay on an interface

To configure a DHCP relay in the GUI:

1. Go to *Network* > *Interfaces*.
2. Edit an interface.
3. Expand the *Advanced* section and set *Mode* to *Relay*.
4. Enter the *DHCP Server IP*.
5. Click *OK*.

To configure a DHCP relay in the CLI:

1. Configure the interface, making sure to configure set `dhcp-relay-ip`:

```
config system interface
    edit "port2"
        set vdom "root"
        set dhcp-relay-service enable
        set ip 10.1.1.5 255.255.255.0
        set allowaccess ping https ssh fabric
        set type physical
        set snmp-index 4
        set dhcp-relay-ip "192.168.20.10"
    next
end
```

Configure a DHCP server and relay on an interface

A FortiGate interface can be configured to work in DHCP server mode to lease out addresses, and at the same time relay the DHCP packets to another device, such as a FortiNAC to perform device profiling.

The DHCP message to be forwarded to the relay server under the following conditions:

- `dhcp-relay-request-all-server` is enabled
- Message type is either DHCPDISCOVER or DHCPINFORM
- Client IP address in client message is 0
- Server ID is NULL in the client message
- Server address is a broadcast address (255.255.255.255)
- Server address is 0

Configuring a DHCP server and relay on the same interface is currently only supported in the CLI.

To configure a DHCP server and relay in the CLI:

1. Configure the interface:

```
config system interface
    edit "port2"
        set vdom "root"
        set dhcp-relay-service enable
        set ip 10.1.1.5 255.255.255.0
        set allowaccess ping https ssh fabric
        set type physical
        set snmp-index 4
        set dhcp-relay-ip "192.168.20.10"
        set dhcp-relay-request-all-server enable
    next
end
```

2. Configure the DHCP server settings:

```
config system dhcp server
    edit 17
        set status enable
        set dns-service default
        set default-gateway 10.1.1.5
        set netmask 255.255.255.0
        set interface "port2"
        config ip-range
            edit 1
                set start-ip 10.1.1.6
                set end-ip 10.1.1.254
            next
        end
    next
end
```

Excluding addresses in DHCP

If you have a large address range for the DHCP server, you can block a range of addresses that will not be included in the available addresses for the connecting users using the `config exclude-range` subcommand.

To exclude addresses in DHCP:

```
config system dhcp server
    edit <id>
        config exclude-range
```

```
            edit <sequence_number>
                set start-ip <address>
                set end-ip <address>
            next
        end
    next
end
```

Viewing information about DHCP server connections

To view information about DHCP server connections, go to *Dashboard* > *Network* and expand the *DHCP* monitor widget. On this page, you can also add IP addresses to the reserved IP address list.

DHCP options

When adding a DHCP server, you can include DHCP options. The DHCP options are BOOTP vendor information fields that provide additional vendor-independent configuration parameters to manage the DHCP server. For example, you might need to configure a FortiGate DHCP server that gives out a separate option as well as an IP address, such as an environment that needs to support PXE boot with Windows images. The *Option code* is specific to the application. The documentation for the application indicates the values to use. The *Option code* is a value between 1 and 255.

For detailed information about DHCP options, see RFC 2132, DHCP Options and BOOTP Vendor Extensions.

The FortiOS DHCP server supports up to a maximum of 30 options per DHCP server. These optional fields can be set in either the GUI or CLI.

DHCP server options are not available in transparent mode.

The DHCP options include:

- Common DHCP options on page 450
- Additional DHCP options on page 453
- IP address assignment with relay agent information option on page 456

Common DHCP options

All FortiGate models come with predefined DHCP options. These DHCP options are widely used and required in most scenarios. The following DHCP options can be set straight from the *DHCP server* section of the *Edit Interface* dialog:

Option Code	Option Name	Purpose
***1**	*Netmask*	Assign subnet mask to the DHCP client.

Option Code	Option Name	Purpose
***3**	*Default Gateway*	Assign default gateway to the DHCP client.
6	*DNS server*	Assign DNS server to the DHCP client.
42	*NTP server*	Assign NTP server to the DHCP client.
***51**	*Lease time*	Lease time for the DHCP client.
138	*Wireless controllers*	Assign CAPWAP Access Controller addresses to the DHCP client.
150	*TFTP server(s)*	Assign TFTP server to the DHCP client.

The parameter marked with an asterisk (*) are mandatory and must be filled in.

Configuring the lease time

This configuration implements DHCP option code 51. The global lease time (measured in seconds, 300 - 864000) determines the length of time an IP address remains assigned to a client. Once the lease expires, the address is released for allocation to the next client that requests an IP address.

To configure the global lease time:

```
config system dhcp server
    edit <id>
        set interface <interface>
        set netmask <netmask>
        set lease-time <integer>
    next
end
```

The default lease time is seven days (604800 seconds). To have an unlimited lease time, set the value to zero.

The lease time can also be configured in the GUI in the *Lease time* field within the *DHCP server* section of the *Edit Interface* dialog.

Configuring the lease time for IP ranges

The lease time can be also be configured for an IP range. Measured in seconds, the range is similar to the global lease time (300 - 864000), but the default value is zero (0). If the default (0) is used for an IP range, it applies the global DHCP server lease time value.

To configure the lease time for an IP range:

```
config system dhcp server
    edit <id>
        config ip-range
            edit <id>
                set lease-time <integer>
            next
        end
```

```
    next
end
```

This setting can only be configured in the CLI.

Customizing DHCP lease backup during power cycles

FortiOS allows customization of the backup interval of DHCP leases during power cycles using the `dhcp-lease-backup-interval` command. This provides enhanced control and flexibility, ensuring lease preservation during events like outages or reboots. After a power cycle, expired IP addresses are released from the lease list and unexpired IP addresses are retained.

The backup interval can be set between 10 and 3600 seconds, with the default value being 60.

```
config system global
    set dhcp-lease-backup-interval <integer>
end
```

Breaking an address lease

If you need to end an IP address lease, you can break the lease. This is useful if you have limited addresses and longer lease times when some leases are no longer necessary, for example, with corporate visitors.

To break a lease:

```
# execute dhcp lease-clear <ip_address>
```

To break a lease for all IP addresses for the DHCP servers in the current VDOM:

```
# execute dhcp lease-clear all
```

Configuring NTP servers

This configuration implements DHCP option code 42. NTP server can be used by the client to synchronize their time which is very important as for many features to work, including scheduling, logging, and SSL-dependent features, the FortiOS system time must be accurate. This option specifies a list of the NTP servers available to the client by IP address.

To configure NTP servers:

```
config system dhcp server
    edit 2
        set ntp-service {local | default | specify}
        set ntp-server1 <class_ip>
        set ntp-server2 <class_ip>
        set ntp-server3 <class_ip>
    next
end
```

NTP servers can also be configured in the GUI in the *NTP server* field within the *DHCP server > Advanced* section of the *Edit Interface* dialog.

`ntp-service {local | default | specify}`	Set the option for assigning NTP servers to DHCP clients: • `local`: the IP address of the interface that the DHCP server is added to becomes the client's NTP server IP address. • `default`: clients are assigned the FortiGate's configured NTP servers. • `specify`: specify up to three NTP servers in the DHCP server configuration.

Configuring TFTP servers

This configuration implements DHCP option code 150. TFTP server are used by VoIP phones to obtain the VoIP Configuration. You can configure multiple TFTP servers for a DHCP server. For example, you may want to configure a main TFTP server and a backup TFTP server.

The `tftp-server` command allows you to configure the TFTP servers, using either their hostnames or IP addresses. Separate multiple server entries with spaces.

To configure TFTP servers:

```
config system dhcp server
    edit <id>
        set interface <interface>
        set netmask <netmask>
        set tftp-server <hostname/IP address> <hostname/IP address>
    next
end
```

TFTP servers can also be configured in the GUI in the *TFTP server(s)* field within the *DHCP server > Advanced* section of the *Edit Interface* dialog.

Additional DHCP options

The FortiGate can be used to provide additional DHCP options that can be useful for different scenarios.

A few of the options are explained below:

- Option 82 on page 455
- Option 77 on page 455

To configure the DHCP options in the GUI:

1. Go to *Network > Interfaces*, click *Create New* or *Edit* the existing interface.
2. Enable *DHCP Server*.
3. Expand the *Advanced* section and select *Create New* under *Additional DHCP options*.
4. Select a predefined *Option code* from the list or select *Specify* to enter a custom *Option code*.
5. Configure the rest of the parameters as required and click *OK* to save the options.
6. Click *OK* to save the setting.

To configure the DHCP options in the CLI:

```
config system dhcp server
    edit <id>
        config options
            edit <integer>
                set code <integer>
                set type {hex | string | ip | fqdn}
                set value <string>
            next
        end
    next
end
```

Variable	Description
`code <integer>`	DHCP client option code (0 - 255, default = 0). See Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) Parameters for a list of possible options.
`type {hex | string | ip | fqdn}`	DHCP server option type (default = hex).
`value <string>`	DHCP server option value.
`ip <ip address>`	DHCP server option IP address. This option is only available when `type` is `ip`.

Example

To configure option 252 with value http://192.168.1.1/wpad.dat:

```
config system dhcp server
    edit <id>
        config options
            edit <id>
                set code 252
                set type hex
                set value 687474703a2f2f3139322e3136382e312e312f777061642e646174
            next
        end
    next
end
```

In the example above, `687474703a2f2f3139322e3136382e312e312f777061642e646174` is the hexadecimal equivalent of the ASCII text `http://192.168.1.1/wpad.dat`.

Option 82

The DHCP relay agent information option (option 82 in RFC 3046) helps protect the FortiGate against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation.

This option is disabled by default. However, when `dhcp-relay-service` is enabled, `dhcp-relay-agent-option` becomes enabled.

To configure the DHCP relay agent option:

```
config system interface
    edit <interface>
        set vdom root
        set dhcp-relay-service enable
        set dhcp-relay-ip <ip>
        set dhcp-relay-agent-option enable
        set vlanid <id>
    next
end
```

See IP address assignment with relay agent information option on page 456 for an example.

Option 77

This option can be used for User Class information (UCI) matching. When enabled, only DHCP requests with a matching UCI are served with the specified range.

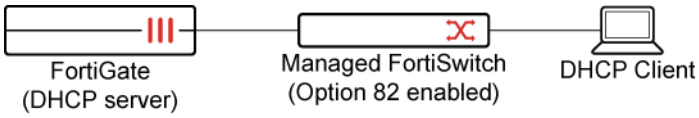
To configure UCI matching:

```
config system dhcp server
    edit <id>
        config ip-range
            edit <id>
                set uci-match {enable | disable}
                set uci-string <string>
            next
        end
        config options
            edit <id>
                set uci-match {enable | disable}
                set uci-string <string>
            next
        end
    next
end
```

`uci-match {enable | disable}`	Enable/disable User Class information (UCI) matching for option 77.
`uci-string <string>`	Enter one or more UCI strings in quotation marks separated by spaces.

IP address assignment with relay agent information option

Option 82 (DHCP relay information option) helps protect the FortiGate against attacks such as spoofing (or forging) of IP and MAC addresses, and DHCP IP address starvation.



The following CLI variables are included in the `config system dhcp server` > `config reserved-address` command:

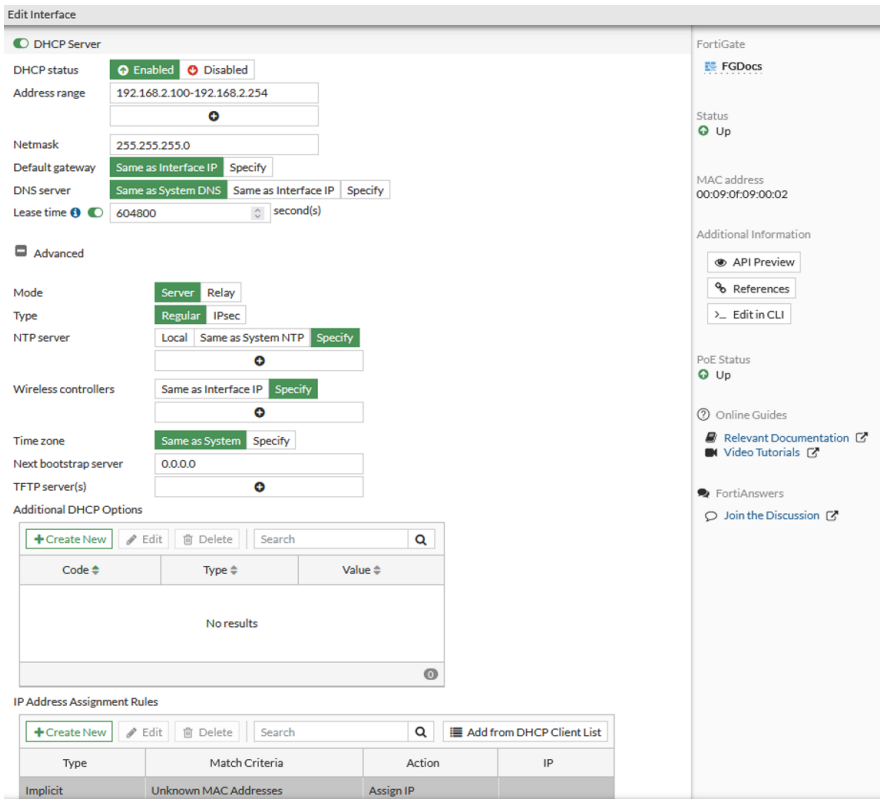
`circuit-id-type {hex | string}`	DHCP option type; hex or string (default).
`circuit-id <value>`	Option 82 circuit ID of the client that will get the reserved IP address. Format: *vlan-mod-port* • vlan: VLAN ID (2 bytes) • mod: 1 = snoop, 0 = relay (1 byte) • port: port number (1 byte)
`remote-id-type {hex | string}`	DHCP option type; hex or string (default).
`remote-id <value>`	Option 82 remote ID of the client that will get the reserved IP address. Format: the MAC address of the client.
`type {mac | option82}`	The DHCP reserved address type; mac (default) or option82.

To create an IP address assignment rule using option 82 in the GUI:

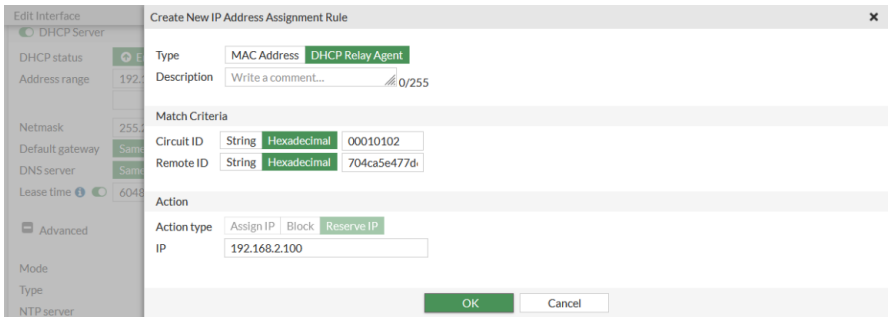
1. Go to *Network* > *Interfaces*.
2. Edit an existing port, or create a new one.

   The port *Role* must be *LAN* or *Undefined*.

3. Enable *DHCP Server*.
4. Configure the address ranges and other settings as needed.
5. Click *+* to expand the *Advanced* options.



6. In the *IP Address Assignment Rules* table, click *Create New*.
   The *Create New IP Address Assignment Rule* pane opens.
7. Configure the new rule:
   a. For the *Type*, select *DHCP Relay Agent*.
   b. Enter the *Circuit ID* and *Remote ID*.
   c. Enter the *IP* address that will be reserved.



8. Click *OK*.

To create an IP address assignment rule using option 82 with the CLI:

```
config system dhcp server
    edit 1
        set netmask 255.255.255.0
        set interface "port4"
        config ip-range
```

```
            edit 1
                set start-ip 192.168.2.100
                set end-ip 192.168.2.254
            next
        end
        config reserved-address
            edit 1
                set type option82
                set ip 192.168.2.100
                set circuit-id-type hex
                set circuit-id "00010102"
                set remote-id-type hex
                set remote-id "704ca5e477d6"
            next
        end
    next
end
```

DHCP addressing mode on an interface

Any FortiGate interface can be configured to obtain an IP address dynamically using DHCP. If you configure DHCP on an interface on the FortiGate, the FortiGate automatically broadcasts a DHCP request from the interface. The interface is configured with the IP address, any DNS server addresses, and the default gateway address that the DHCP server provides.

Configuring an Interface as a DHCP Client

You can configure interface as a DHCP client.

To configure an interface as a DHCP client in the GUI:

1. Go to *Network* > *Interfaces*.
2. Edit an interface.
3. Select the *DHCP* option in the *Addressing mode*.
4. Configure the rest of the setting as required.
5. Click *OK*.

The following table describes the DHCP status information when DHCP is configured for an interface.

Field	Description
Status	Displays DHCP status messages as the interface connects to the DHCP server and gets addressing information. Status can be one of the following values: • *Initializing*: No activity. • *Connecting*: Interface attempts to connect to the DHCP server. • *Connected*: Interface retrieves an IP address, netmask, and other

Field	Description
	settings from the DHCP server. • *Failed*: Interface was unable to retrieve an IP address and other settings from the DHCP server.
Obtained IP/Netmask	The IP address and netmask leased from the DHCP server. This is only displayed if the *Status* is *Connected*.
Renew	Select this to renew the DHCP license for this interface. This is only displayed if the *Status* is *Connected*.
Expiry Date	The time and date when the leased IP address and netmask is no longer valid for the interface. The IP address is returned to the pool to be allocated to the next user request for an IP address. This is only displayed if the *Status* is *Connected*.
Default Gateway	The IP address of the gateway defined by the DHCP server. This is displayed only if the *Status* is *Connected*, and if *Retrieve default gateway from server* is enabled.
Acquired DNS	The DNS server IP defined by the DHCP server. This is displayed only if the *Status* is *Connected*.
Retrieve default gateway from server	Enable this to retrieve a default gateway IP address from the DHCP server. The default gateway is added to the static routing table.
Distance	Enter the administrative distance for the default gateway retrieved from the DHCP server. The administrative distance is an integer from 1 to 255 that specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route.
Override internal DNS	Enable this to use the DNS addresses retrieved from the DHCP server instead of the DNS server IP addresses on the DNS page. When VDOMs are enabled, you can override the internal DNS only on the management VDOM.

To configure an interface as a DHCP client in the CLI:

```
config system interface
    edit <name>
        set mode dhcp
        set defaultgw {enable | disable}
        set distance <integer>
        set dns-server-override {enable | disable}
    next
end
```

Configuring the DHCP renew time

You can set a minimum DHCP renew time for an interface acting as a DHCP client. This option is available only when mode is set to DHCP.

To set the DHCP renew time:

```
config system interface
    edit <name>
        set vdom <vdom>
        set interface <interface>
        set mode dhcp
        set dhcp-renew-time <integer>
    next
end
```

The possible values for `dhcp-renew-time` are 300 to 605800 seconds (five minutes to seven days). To use the renew time that the server provides, set this entry to 0.

DHCP client options

When an interface is in DHCP addressing mode, DHCP client options can be configured in the CLI. For example, a vendor class identifier (usually DCHP client option 60) can be specified so that a request can be matched by a specific DHCP offer.

Multiple options can be configured, but any options not recognized by the DHCP server are discarded.

To configure client option 60 - vendor class identifier:

```
config system interface
    edit port1
        set vdom vdom1
        set mode dhcp
        config client-options
            edit 1
                set code 60
                set type hex
                set value aabbccdd
            next
        end
        set type physical
        set snmp-index 4
    next
end
```

Variable	Description
`code <integer>`	DHCP client option code (0 - 255, default = 0).

Variable	Description
	See Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) Parameters for a list of possible options.
`type {hex | string | ip | fqdn}`	DHCP client option type (default = hex).
`value <string>`	DHCP client option value.
`ip <ip>`	DHCP client option IP address. This option is only available when `type` is `ip`.

VCI pattern matching for DHCP assignment

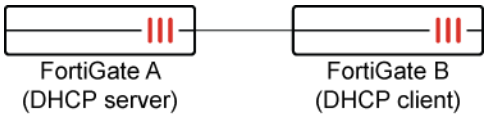
VCIs (vendor class identifiers) are supported in DHCP to allow VCI pattern matching as a condition for IP or DHCP option assignment. A single IP address, IP ranges of a pool, and dedicated DHCP options can be mapped to a specific VCI string.

```
config system dhcp server
    edit <id>
        config ip-range
            edit <id>
                set vci-match {enable | disable}
                set vci-string <string>
            next
        end
        config options
            edit <id>
                set vci-match {enable | disable}
                set vci-string <string>
            next
        end
    next
end
```

`vci-match {enable | disable}`	Enable/disable VCI matching. When enabled, only DHCP requests with a matching VCI are served with this range.
`vci-string <string>`	Set the VCI string. Enter one or more VCI strings in quotation marks separated by spaces.

Example

In this example, any DHCP client that matches the FortiGate-201F VCI will get their IP from the pool of 10.2.2.133-10.2.2.133, and options 42 (NTP servers) and 150 (TFTP server address). Any DHCP client that matches the FortiGate-101F VCI will get their IP from the default pool (10.2.2.132-10.2.2.132/10.2.2.134-10.2.2.254) and only get the 150 option.



To configure VCI pattern matching on FortiGate A:

```
config system dhcp server
    edit 1
        set dns-service default
        set default-gateway 10.2.2.131
        set netmask 255.255.255.0
        set interface "port3"
        config ip-range
            edit 1
                set start-ip 10.2.2.132
                set end-ip 10.2.2.132
            next
            edit 2
                set start-ip 10.2.2.133
                set end-ip 10.2.2.133
                set vci-match enable
                set vci-string "FortiGate-201F"
            next
            edit 3
                set start-ip 10.2.2.134
                set end-ip 10.2.2.254
            next
        end
        config options
            edit 1
                set code 42
                set type ip
                set vci-match enable
                set vci-string "FortiGate-201F"
                set ip "8.8.8.8"
            next
            edit 2
                set code 150
                set type ip
                set ip "172.16.200.55"
            next
        end
        set vci-match enable
        set vci-string "FortiGate-201F" "FortiGate-101F"
    next
end
```

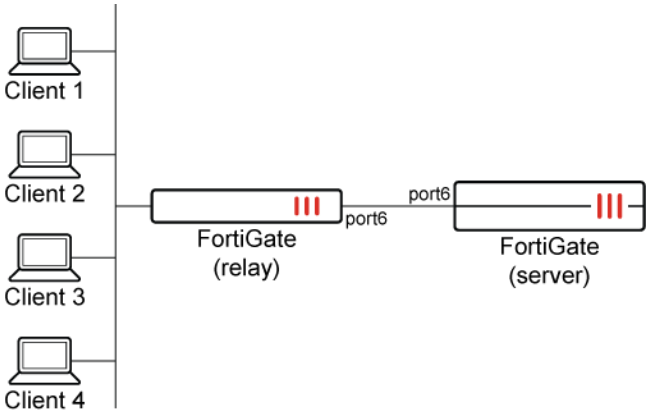
DHCP shared subnet

A FortiGate can act as a DHCP server and assign IP addresses from different subnets to clients on the same interface or VLAN based on the requests coming from the same DHCP relay agent. A FortiGate may have more than one server and pool associated with the relay agent, and it can assign IP addresses from the next server when the current one is exhausted. This way, the FortiGate can allocate IP addresses more efficiently and avoid wasting unused addresses in each subnet.

```
config system dhcp server
    edit <id>
        set shared-subnet {enable | disable}
        set relay-agent <ip_address>
    next
end
```

Example

In this example, there are two DHCP servers configured on the FortiGate. The first two clients (1 and 2) get their IP from the DHCP server 1. Once the DHCP server 1's IP pool is exhausted, subsequent clients (3 and 4) get their IP from DHCP server 2.



To configure a DHCP shared subnet:

1. Configure the DHCP servers:

```
config system dhcp server
    edit 1
        set default-gateway 10.18.0.10
        set netmask 255.255.255.0
        set interface "p2_vl3819"
        config ip-range
            edit 1
                set start-ip 10.18.0.110
                set end-ip 10.18.0.111
            next
```

```
        end
        set shared-subnet enable
        set relay-agent 10.18.0.10
        set dns-server1 8.8.8.8
    next
    edit 2
        set default-gateway 10.18.1.130
        set netmask 255.255.255.128
        set interface "p2_vl3819"
        config ip-range
            edit 1
                set start-ip 10.18.1.200
                set end-ip 10.18.1.201
            next
        end
        set shared-subnet enable
        set relay-agent 10.18.0.10
        set dns-server1 8.8.8.8
    next
end
```

2. Verify the DHCP lease list:

```
# execute dhcp lease-list
port6
  IP           MAC-Address      Hostname    VCI    SSID    AP    SERVER-ID    Expiry
  10.18.0.110  00:50:56:02:92:11                                 1            Fri Jan 13 15:37:35
2023
  10.18.0.111  00:50:56:02:92:12                                 1            Fri Jan 13 15:37:38
2023

Result: PASS
```

Clients 1 and 2 get their IP from the DHCP server 1.

When the IP pool is exhausted, the DHCP daemon assigns the IP from other pools that have the same relay agent.

3. Verify the DHCP lease list:

```
# execute dhcp lease-list
port6
  IP           MAC-Address      Hostname    VCI    SSID    AP    SERVER-ID    Expiry
  10.18.0.110  00:50:56:02:92:11                                 1            Fri Jan 13 15:37:35
2023
  10.18.0.111  00:50:56:02:92:12                                 1            Fri Jan 13 15:37:38
2023
  10.18.1.200  00:50:56:02:92:13                                 2            Fri Jan 13 15:38:05
2023
  10.18.1.201  00:50:56:02:92:14                                 2            Fri Jan 13 15:38:06
2023
```

Clients 3 and 4 get their IP from DHCP server 2, since the server 1 IP pool is exhausted.

Multiple DHCP relay servers

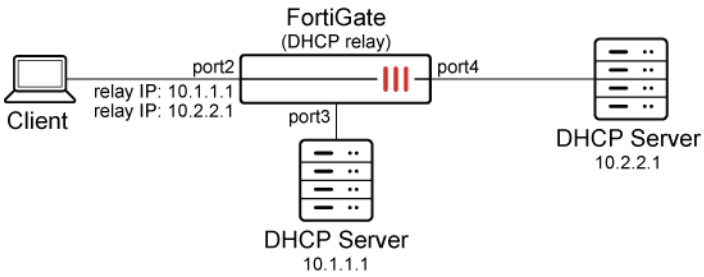
Multiple DHCP relays can be configured on an interface. After receiving a DHCP request from a client, the FortiGate forwards it to all configured servers simultaneously without waiting for any response. Each server sends back an IP address for the client, but the client usually uses the IP address from the first response that is receives.

This allows the FortiGate to forward DHCP requests to all configured servers simultaneously, reducing wait times and potential bottlenecks.

```
config system interface
    edit <name>
        set dhcp-relay-service {enable | disable}
        set dhcp-relay-ip <ip-address>
    next
end
```

Example

In this example, two DHCP relay servers are configured on port2, with DHCP relay IP addresses 10.1.1.1 and 10.2.2.1.



To configure the DHCP relay servers:

```
config system interface
    edit "port2"
        set dhcp-relay-service enable
        set dhcp-relay-ip 10.1.1.1 10.2.2.1
    next
end
```

To check the debug messages to verify that the DHCP relay is working:

```
# diagnose debug application dhcprelay -1
```

```
Debug messages will be on for 30 minutes.
# (xid:d7d00b58) L2 socket: received request message from 0.0.0.0:68 to 255.255.255.255 at port2
(xid:d7d00b58) got a DHCPDISCOVER
(xid:d7d00b58) Warning! can't get server id from client message
```

```
Insert option(82), len(7)

(xid:d7d00b58) forwarding dhcp request from 10.10.10.12:67 to 10.1.1.1:67
found route to 10.2.2.1 via 10.2.2.254 iif=6 oif=11/port4, mode=auto, ifname=
(xid:d7d00b58) forwarding dhcp request from 10.10.10.12:67 to 10.2.2.1:67
(xid:d7d00b58) got a DHCPOFFER
(xid:d7d00b58) from server 10.2.2.1
(xid:d7d00b58) sending dhcp reply from 10.10.10.12:67 to 255.255.255.255:68
(xid:d7d00b58) got a DHCPACK
(xid:d7d00b58) from server 10.1.1.1
(xid:d7d00b58) sending dhcp reply from 10.10.10.12:67 to 255.255.255.255:68
```

The debug output shows the following information:

`got a DHCPDISCOVER`
`forwarding dhcp request from 10.10.10.12:67 to 10.1.1.1:67`
`forwarding dhcp request from 10.10.10.12:67 to 10.2.2.1:67`
	FortiGate received a DHCPDISCOVER message from the DHCP client and forwarded it to both DHCP servers.

`got a DHCPOFFER` `from server 10.1.1.1`	FortiGate received a DHCPOFFER message from server 10.1.1.1.

`got a DHCPREQUEST`
`forwarding dhcp request from 10.10.10.12:67 to 10.1.1.1:67`
`forwarding dhcp request from 10.10.10.12:67 to 10.2.2.1:67`
	FortiGate received a DHCPREQUEST message from the client and forwarded it to both servers again.

`got a DHCPOFFER` `from server 10.2.2.1`	FortiGate received another DHCPOFFER message from server 10.2.2.1.
`got a DHCPACK` `from server 10.1.1.1`	FortiGate received a DHCPACK message from server 10.1.1.1. Because the DHCP server 10.1.1.1 was the first to send response, the client accepts the DHCP configuration from this server.

DHCP smart relay on interfaces with a secondary IP

DHCP relays can be configured on interfaces with secondary IP addresses. The FortiGate will track the number of unanswered DHCP requests for a client on the interface's primary IP. After three unanswered DHCP requests,

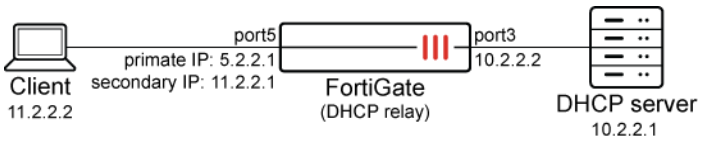
the FortiGate will forward DHCP requests to DHCP relays configured under the secondary IP using the secondary IP address as the source. After three unanswered DHCP requests, the FortiGate will return to using the primary IP and restart the process.

```
config system interface
    edit <name>
        set dhcp-smart-relay {enable | disable}
        config secondaryip
            edit <id>
                set secip-relay-ip <secondary_dhcp_relay_IP_1> <secondary_dhcp_relay_IP_2>
            next
        end
    next
end
```

DHCP relay targets under both the primary and secondary IP may be the same or unique. If smart relay is not configured, all requests are forwarded using the primary IP address on the interface.

Example

In this example, DHCP smart relay is configured on port5 with a DHCP relay IP address of 10.2.2.1.



To configure DHCP smart relay on interfaces with a secondary IP:

1. Configure DHCP relay on the interfaces:

```
config system interface
    edit "port3"
        set vdom "vdom1"
        set ip 10.2.2.2 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set snmp-index 5
    next
    edit "port5"
        set vdom "vdom1"
        set dhcp-relay-service enable
        set dhcp-smart-relay enable
        set ip 5.2.2.1 255.255.255.0
        set allowaccess ping https ssh snmp http
        set type physical
        set snmp-index 7
        set secondary-IP enable
        set dhcp-relay-ip "10.2.2.1"
        config secondaryip
            edit 1
```

```
                set ip 11.2.2.1 255.255.255.0
                set secip-relay-ip "10.2.2.1"
                set allowaccess ping https ssh snmp http
            next
        end
    next
end
```

2. Verify the debug messages to check that the DHCP relay is working. After three unanswered DHCP requests, the request is forwarded to the secondary IP DHCP relay target:

```
# diagnose debug application dhcprelay -1
Debug messages will be on for 30 minutes.

(xid:7ea80e4b) received request message from 0.0.0.0:68 to 255.255.255.255 at port5

(xid:7ea80e4b) forwarding dhcp request from 11.2.2.1:67 to 10.2.2.1:67
(xid:7ea80e4b) received request message from 10.2.2.1:67 to 11.2.2.1 at port3
(xid:7ea80e4b) got a DHCPACK
(xid:7ea80e4b) from server 10.2.2.1
(xid:7ea80e4b) sending dhcp reply from 11.2.2.1:67 to 255.255.255.255:68
```

FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses

As clients are assigned IP addresses, they send back information that would be found in an A record to the FortiGate DHCP server, which can take this information and pass it back to a corporate DNS server so that even devices using leased IP address can be reached using FQDNs. You can configure the settings for this feature using the `ddns-update` CLI command and some other DDNS related options. Please refer to *DDNS update override* in the DDNS on page 313 topic for further details.

Static routing

Static routing is one of the foundations of firewall configuration. It is a form of routing in which a device uses manually-configured routes. In the most basic setup, a firewall will have a default route to its gateway to provide network access. In a more complex setup with dynamic routing, ADVPN, or SD-WAN involved, you would still likely find static routes being deployed.

This section explores concepts in using static routing and provides examples in common use cases:

- Routing concepts on page 470
- Policy routes on page 484
- Equal cost multi-path on page 487
- Dual internet connections on page 492

The following topics include additional information about static routes:

- Deploying the Security Fabric on page 3809
- Security Fabric over IPsec VPN on page 3833
- Adding a static route on page 899
- IPsec VPN in an HA environment on page 2589
- IPsec VPN to Azure with virtual network gateway on page 2473
- FortiGate as dialup client on page 2492
- ADVPN with BGP as the routing protocol on page 2628
- ADVPN with OSPF as the routing protocol on page 2638
- ADVPN with RIP as the routing protocol on page 2648
- Basic site-to-site VPN with pre-shared key on page 2414

Routing concepts

This section contains the following topics:

- Default route on page 470
- Adding or editing a static route on page 470
- Configuring FQDNs as a destination address in static routes on page 471
- Routing table on page 472
- Viewing the routing database on page 475
- Kernel routing table on page 475
- Route look-up on page 477
- Blackhole routes on page 477
- Reverse path look-up on page 478
- Asymmetric routing on page 479
- Routing changes on page 481
- Static route tags on page 482
- Defining a preferred source IP for local-out egress interfaces on page 483

Default route

The default route has a destination of `0.0.0.0/0.0.0.0`, representing the least specific route in the routing table. It is a catch all route in the routing table when traffic cannot match a more specific route. Typically this is configured with a static route with an administrative distance of `10`. In most instances, you will configure the next hop interface and the gateway address pointing to your next hop. If your FortiGate is sitting at the edge of the network, your next hop will be your ISP gateway. This provides internet access for your network.

Sometimes the default route is configured through DHCP. On some entry-level models, the WAN interface is preconfigured in DHCP mode. Once the WAN interface is plugged into the network modem, it will receive an IP address, default gateway, and DNS server. FortiGate will add this default route to the routing table with a distance of `5`, by default. This will take precedence over any default static route with a distance of `10`. Therefore, take caution when you are configuring an interface in DHCP mode, where *Retrieve default gateway from server* is enabled. You may disable it and/or change the distance from the *Network* > *Interfaces* page when you edit an interface.

Adding or editing a static route

To add a static route using the GUI:

1. Go to *Network* > *Static Routes* and click *Create New*.
2. Enter the following information:

Destination	• Subnet Enter the destination IP address and netmask. A value of `0.0.0.0/0.0.0.0` creates a default route. • Named Address

	Select an address or address group object. Only addresses with static route configuration enabled will appear on the list. This means a geography type address cannot be used. • Internet Service Select an Internet Service. These are known IP addresses of popular services across the Internet.
Interface	Select the name of the interface that the static route will connect through.
Gateway Address	Enter the gateway IP address. If a DHCP/PPPoE interface is selected, select *Dynamic* to automatically retrieve the interface's dynamic gateway, or select *Specify* to manually enter the gateway IP address. If an IPsec VPN interface or SD-WAN creating a blackhole route is selected, the gateway cannot be specified.
Administrative Distance	Enter the distance value, which will affect which routes are selected first by different protocols for route management or load balancing. The default is 10.
Advanced Options	Optionally, expand *Advanced Options* and enter a *Priority*. When two routes have an equal distance, the route with a lower priority number will take precedence. The default is 1.

3. Click *OK*.

Configuring FQDNs as a destination address in static routes

You can configure FQDN firewall addresses as destination addresses in a static route, using either the GUI or the CLI.

In the GUI, to add an FQDN firewall address to a static route in the firewall address configuration, enable the *Static Route Configuration* option. Then, when you configure the static route, set *Destination* to *Named Address*.

To configure an FQDN as a destination address in a static route using the CLI:

```
config firewall address
    edit 'Fortinet-Documentation-Website'
        set type fqdn
        set fqdn docs.fortinet.com
        set allow-routing enable
    next
end
```

```
config router static
    edit 0
        set dstaddr Fortinet-Documentation-Website
        ...
```

```
    next
end
```

Routing table

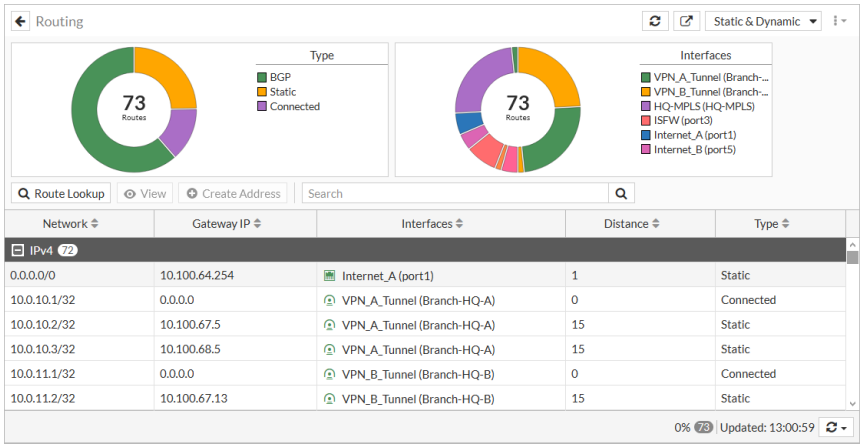
A routing table consists of only the best routes learned from the different routing protocols. The most specific route always takes precedence. If there is a tie, then the route with a lower administrative distance will be injected into the routing table. If administrative distances are also equal, then all the routes are injected into the routing table, and *Cost* and *Priority* become the deciding factors on which a route is preferred. If these are also equal, then FortiGate will use Equal cost multi-path on page 487 to distribute traffic between these routes.

Viewing the routing table in the GUI

You can view routing tables in the FortiGate GUI under *Dashboard* > *Network* > *Static & Dynamic Routing* by default. Expand the widget to see the full page. Additionally, if you want to convert the widget into a dashboard, click on the *Save as Monitor* icon on the top right of the page.

You can also monitor policy routes by toggling from *Static & Dynamic* to *Policy* on the top right corner of the page. The active policy routes include policy routes that you created, SD-WAN rules, and Internet Service static routes. It also supports downstream devices in the Security Fabric.

The following figure show an example of the static and dynamic routes in the Routing Monitor:



To view more columns, right-click on the column header to select the columns to be displayed:

Field	Description
IP Version	Shows whether the route is IPv4 or IPv6.
Network	The IP addresses and network masks of destination networks that the FortiGate can reach.
Gateway IP	The IP addresses of gateways to the destination networks.
Interfaces	The interface through which packets are forwarded to the gateway of the destination network.

Field	Description
Distance	The administrative distance associated with the route. A lower value means the route is preferable compared to other routes to the same destination.
Type	The type values assigned to FortiGate routes (Static, Connected, RIP, OSPF, or BGP): • *Connected*: All routes associated with direct connections to FortiGate interfaces • *Static*: The static routes that have been added to the routing table manually • *RIP*: All routes learned through RIP • *RIPNG*: All routes learned through RIP version 6 (which enables the sharing of routes through IPv6 networks) • *BGP*: All routes learned through BGP • *OSPF*: All routes learned through OSPF • *OSPF6*: All routes learned through OSPF version 6 (which enables the sharing of routes through IPv6 networks) • *IS-IS*: All routes learned through IS-IS • *HA*: RIP, OSPF, and BGP routes synchronized between the primary unit and the subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you're viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster.
Metric	The metric associated with the route type. The metric of a route influences how the FortiGate dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to: • *Hop count*: Routes learned through RIP • *Relative cost*: Routes learned through OSPF • *Multi-Exit Discriminator (MED)*: Routes learned through BGP. By default, the MED value associated with a BGP route is zero. However, the MED value can be modified dynamically. If the value was changed from the default, the Metric column displays a non-zero value.
Priority	In static routes, priorities are 1 by default. When two routes have an equal distance, the route with the lower priority number will take precedence.
VRF	Virtual routing and forwarding (VRF) allows multiple routing table instances to co-exist. VRF can be assigned to an Interface. Packets are only forwarded between interfaces with the same VRF.
Up Since	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable.

Viewing the routing table in the CLI

Viewing the routing table using the CLI displays the same routes as you would see in the GUI.

If VDOMs are enabled on the FortiGate, all routing-related CLI commands must be run within a VDOM and not in the global context.

To view the routing table using the CLI:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

E1 - OSPF external type 1, E2 - OSPF external type 2
 i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
 * - candidate default
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 172.31.0.1, MPLS [1/0]via 192.168.2.1, port1 [1/0] via 192.168.122.1,
port2
S       1.2.3.4/32 [10/0] via 172.16.100.81, VLAN100
C       10.10.2.0/24 is directly connected, hub
C       10.10.2.1/32 is directly connected, hub
O       10.10.10.0/24 [110/101] via 192.168.2.1, port1, 01:54:18
C       10.253.240.0/20 is directly connected, wqt.root
S       110.2.2.122/32 [22/0] via 2.2.2.2, port2, [3/3]
C       172.16.50.0/24 is directly connected, WAN1-VLAN50
C       172.16.60.0/24 is directly connected, WAN2-VLAN60
C       172.16.100.0/24 is directly connected, VLAN100
C       172.31.0.0/30 is directly connected, MPLS
C       172.31.0.2/32 is directly connected, MPLS
B       192.168.0.0/24 [20/0] via 172.31.0.1, MPLS, 00:31:43
C       192.168.2.0/24 is directly connected, port1
C       192.168.20.0/24 is directly connected, port3
C       192.168.99.0/24 is directly connected, Port1-VLAN99
C       192.168.122.0/24 is directly connected, port2
Routing table for VRF=10
C       172.16.101.0/24 is directly connected, VLAN101
```

Examining an entry:

```
B       192.168.0.0/24 [20/0] via 172.31.0.1, MPLS, 00:31:43
```

Value	Description
`B`	BGP. The routing protocol used.
`192.168.0.0/24`	The destination of this route, including netmask.
`[20/0]`	`20` indicates an administrative distance of `20` out of a range of `0` to `255`. `0` is an additional metric associated with this route, such as in OSPF.
`172.31.0.1`	The gateway or next hop.
`MPLS`	The interface that the route uses.
`00:31:43`	The age of the route in `HH:MM:SS`.

Viewing the routing database

The routing database consists of all learned routes from all routing protocols before they are injected into the routing table. This likely lists more routes than the routing table as it consists of routes to the same destinations with different distances. Only the best routes are injected into the routing table. However, it is useful to see all learned routes for troubleshooting purposes.

To view the routing database using the CLI:

```
# get router info routing-table database
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
     E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       > - selected route, * - FIB route, p - stale info
Routing table for VRF=0
S    *> 0.0.0.0/0 [1/0] via 172.31.0.1, MPLS
     *>           [1/0] via 192.168.2.1, port1
     *>           [1/0] via 192.168.122.1, port2
S    *> 1.2.3.4/32 [10/0] via 172.16.100.81, VLAN100
C    *> 10.10.2.0/24 is directly connected, hub
C    *> 10.10.2.1/32 is directly connected, hub
O    *> 10.10.10.0/24 [110/101] via 192.168.2.1, port1, 02:10:17
C    *> 10.253.240.0/20 is directly connected, wqt.root
S    *> 110.2.2.122/32 [22/0] via 2.2.2.2, port2, [3/3]
C    *> 172.16.50.0/24 is directly connected, WAN1-VLAN50
C    *> 172.16.60.0/24 is directly connected, WAN2-VLAN60
C    *> 172.16.100.0/24 is directly connected, VLAN100
O       172.31.0.0/30 [110/201] via 192.168.2.1, port1, 00:47:36
C    *> 172.31.0.0/30 is directly connected, MPLS
```

Selected routes are marked by the > symbol. In the above example, the OSPF route to destination `172.31.0.0/30` is not selected.

Kernel routing table

The kernel routing table makes up the actual Forwarding Information Base (FIB) that used to make forwarding decisions for each packet. The routes here are often referred to as kernel routes. Parts of this table are derived from the routing table that is generated by the routing daemon.

To view the kernel routing table using the CLI:

```
# get router info kernel
tab=254 vf=0 scope=0 type=1 proto=11 prio=0 0.0.0.0/0.0.0.0/0->0.0.0.0/0 pref=0.0.0.0
        gwy=172.31.0.1 flag=04 hops=0 oif=31(MPLS)
        gwy=192.168.2.1 flag=04 hops=0 oif=3(port1)
        gwy=192.168.122.1 flag=04 hops=0 oif=4(port2)
```

```
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.122.98/255.255.255.255/0->1.1.1.1/32
pref=0.0.0.0 gwy=192.168.122.1 dev=4(port2)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 172.31.0.2/255.255.255.255/0->1.1.1.1/32 pref=0.0.0.0
gwy=172.31.0.1 dev=31(MPLS)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.2.5/255.255.255.255/0->1.1.1.1/32 pref=0.0.0.0
gwy=192.168.2.1 dev=3(port1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=0 0.0.0.0/0.0.0.0/0->1.2.3.4/32 pref=0.0.0.0
gwy=172.16.100.81 dev=20(VLAN100)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.122.98/255.255.255.255/0->8.8.8.8/32
pref=0.0.0.0 gwy=192.168.122.1 dev=4(port2)
```

The kernel routing table entries are:

Value	Description
`tab`	Table number: It will either be `254` (unicast) or `255` (multicast).
`vf`	Virtual domain of the firewall: It is the VDOM index number. If VDOMs are not enabled, this number is `0`.
`type`	Type of routing connection. Valid values include: • `0` - unspecific • `1` - unicast • `2` - local • `3` - broadcast • `4` - anycast • `5` - multicast • `6` - blackhole • `7` - unreachable • `8` - prohibited
`proto`	Type of installation that indicates where the route came from. Valid values include: • `0` - unspecific • `2` - kernel • `11` - ZebOS routing module • `14` - FortiOS • `15` - HA • `16` - authentication based • `17` - HA1
`prio`	Priority of the route. Lower priorities are preferred.
`->0.0.0.0/0 (->x.x.x.x/mask)`	The IP address and subnet mask of the destination.
`pref`	Preferred next hop along this route.
`gwy`	Gateway: The address of the gateway this route will use.

Value	Description
dev	Outgoing interface index: This number is associated with the interface for this route. If VDOMs are enabled, the VDOM is also included here. If an interface alias is set for this interface, it is also displayed here.

Route look-up

Route look-up typically occurs twice in the life of a session. Once when the first packet is sent by the originator and once more when the first reply packet is sent from the responder. When a route look-up occurs, the routing information is written to the session table. If routing changes occur during the life of a session, additional routing look-ups may occur.

FortiGate performs a route look-up in the following order:

1. Policy-based routes: If a match occurs and the action is to forward, traffic is forwarded based on the policy route.
2. Forwarding Information Base, otherwise known as the kernel routing table.
3. If no match occurs, the packet is dropped.

Searching the routing table

When there are many routes in your routing table, you can perform a quick search by using the search bar to specify your criteria, or apply filters on the column header to display only certain routes. For example, if you want to only display static routes, you may use "static" as the search term, or filter by the *Type* field with value *Static*.

Route look-up on the other hand provides a utility for you to enter criteria such as *Destination*, *Destination Port*, *Source*, *Protocol* and/or *Source Interface*, in order to determine the route that a packet will take. Once you click *Search*, the corresponding route will be highlighted.

You can also use the CLI for a route look-up. The CLI provides a basic route look-up tool.

To look-up a route in the CLI:

```
# get router info routing-table details 4.4.4.4
Routing table for VRF=0
Routing entry for 0.0.0.0/0
      Known via "static", distance 1, metric 0, best
      * 172.31.0.1, via MPLS distance 0
      * 192.168.2.1, via port1 distance 0
      * 192.168.122.1, via port2 distance 0
```

Blackhole routes

Sometimes upon routing table changes, it is not desirable for traffic to be routed to a different gateway. For example, you may have traffic destined for a remote office routed through your IPsec VPN interface. When the VPN is down, traffic will try to re-route to another interface. However, this may not be viable and traffic will

instead be routed to your default route through your WAN, which is not desirable. Traffic may also be routed to another VPN, which you do not want. For such scenarios, it is good to define a blackhole route so that traffic is dropped when your desired route is down. Upon reconnection, your desired route is once again added to the routing table and your traffic will resume routing to your desired interface. For this reason, blackhole routes are created when you configure an IPsec VPN using the IPsec wizard.

For FortiOS 7.4.0, SSL VPN web mode, explicit web proxy, and interface mode IPsec VPN features will not work with the following configuration:

1. An IP pool with ARP reply enabled is configured.
2. This IP pool is configured as the source IP address in a firewall policy for SSL VPN web mode, in a proxy policy for explicit web proxy, or as the local gateway in the Phase 1 settings for an interface mode IPsec VPN.
3. A matching blackhole route is configured for IP pool reply traffic.

Configuring an IP pool as the source NAT IP address in a regular firewall policy works as before.

For details, see Technical Tip: IP pool and virtual IP behaviour changes in FortiOS 6.4, 7.0, 7.2, and 7.4.

To create a blackhole route in the GUI:

1. Go to *Network* > *Static Routes*.
2. Click *Create New*. The *New Static Route* screen appears.
3. Specify a *Destination* type.
4. Select *Blackhole* from the *Interface* field.
5. Type the desired *Administrative Distance*.
6. Click *OK*.

Route priority for a *Blackhole* route can only be configured from the CLI.

Reverse path look-up

Whenever a packet arrives at one of the interfaces on a FortiGate, the FortiGate determines whether the packet was received on a legitimate interface by doing a reverse look-up using the source IP address in the packet header. This protects against IP spoofing attacks. If the FortiGate does not have a route to the source IP address through the interface on which the packet was received, the FortiGate drops the packet as per Reverse Path Forwarding (RPF) check. There are two modes of RPF – feasible path and strict. The default feasible RPF mode checks only for the existence of at least one active route back to the source using the incoming interface. The strict RPF check ensures the best route back to the source is used as the incoming interface.

To configure a strict Reverse Path Forwarding check in the CLI:

```
config system settings
    set strict-src-check enable
```

```
end
```

You can remove RPF state checks without needing to enable asymmetric routing by disabling state checks for traffic received on specific interfaces. Disabling state checks makes a FortiGate less secure and should only be done with caution for troubleshooting purposes.

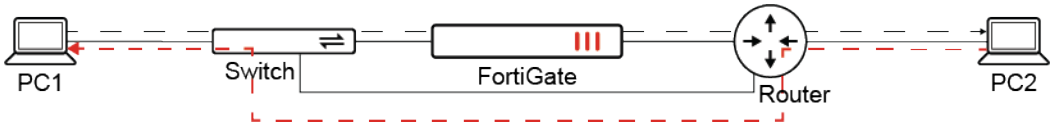
To remove Reverse Path Forwarding checks from the state evaluation process in the CLI:

```
config system interface
    edit <interface_name>
        set src-check disable
    next
end
```

Asymmetric routing

Asymmetric routing occurs when request and response packets follow different paths that do not cross the same firewall.

In the following topology, traffic between PC1 and PC2 takes two different paths.



Traffic from PC1 to PC2 goes through the FortiGate, while traffic from PC2 to PC1 does not.

In TCP, if the packets in the request and response directions follow different paths, the FortiGate will block the packets, since the TCP three-way handshake is not established through the FortiGate.

Scenario 1: PC1 starts a TCP connection with PC2

1. The TCP SYN is allowed by the FortiGate.
2. The TCP SYN/ACK bypasses the FortiGate.
3. The TCP ACK is blocked by the FortiGate.
4. Subsequent TCP packets are blocked by the FortiGate.

Scenario 2: PC2 starts a TCP connection with PC1

1. The TCP SYN bypasses the FortiGate.
2. The TCP SYN/ACK is blocked by the FortiGate.
3. Subsequent TCP packets are blocked by the FortiGate.

In ICMP, consider the following scenarios.

Scenario 1: PC1 pings PC2

1. The ICMP request passes through the FortiGate. A session is created.
2. The ICMP reply bypasses the FortiGate, but reaches PC1. The ping is successful.

3. The ICMP request passes through the FortiGate, and it matches the previous session.
4. The ICMP reply bypasses the FortiGate, but it reaches PC1. The ping is successful.
5. Subsequent ICMP requests are allowed by the FortiGate.

Scenario 2: PC2 pings PC1

1. The ICMP request bypasses the FortiGate, but it reaches PC1.
2. The ICMP reply passes through the FortiGate. No session is matched, and the packet is dropped.
3. Subsequent ICMP replies are blocked by the FortiGate.

If an ICMP request does not pass through the FortiGate, but the response passes through the FortiGate, then by default it blocks the packet as invalid.

Permitting asymmetric routing

If required, the FortiGate can be configured to permit asymmetric routing.

To permit asymmetric routing:

```
config system settings
    set asymroute enable
end
```

This setting should be used only when the asymmetric routing issue cannot be resolved by ensuring both directions of traffic pass through the FortiGate.

When asymmetric routing is enabled and occurs, the FortiGate cannot inspect all traffic. Potentially malicious traffic may pass through and compromise the security of the network.

Asymmetric routing behaves as follows when it is permitted by the FortiGate:

TCP packets

Scenario 1: PC1 starts a TCP connection with PC2

1. The TCP SYN is allowed by the FortiGate. The FortiGate creates a session, checks the firewall policies, and applies the configuration from the matching policy (UTM inspection, NAT, traffic shaping, and so on).
2. The TCP SYN/ACK bypasses the FortiGate.
3. The TCP ACK is allowed by the FortiGate. The packet matches the previously created session.
4. Subsequent TCP packets are allowed by the FortiGate. The packets in the session can also be offloaded where applicable.

Scenario 2: PC2 starts a TCP connection with PC1

1. The TCP SYN bypasses the FortiGate.
2. The TCP SYN/ACK is allowed by the FortiGate. No session is matched. The packet passes to the CPU and is forwarded based on the routing table.
3. The TCP ACK bypasses the FortiGate.

4. Subsequent TCP packets are allowed by the FortiGate. The FortiGate acts as a router that only makes routing decisions. No security inspection is performed.

ICMP packets

Scenario 1: PC1 pings PC2

1. There is no difference from when asymmetric routing is disabled.

Scenario 2: PC2 pings PC1

1. The ICMP request bypasses the FortiGate, but it reaches PC1.
2. The ICMP reply passes through the FortiGate. No session is matched. The packet passes to the CPU and is forwarded based on the routing table.
3. Subsequent ICMP replies are allowed by the FortiGate. The FortiGate acts as a router that only makes routing decisions. No security inspection is performed.

UDP packets

Asymmetric routing does not affect UDP packets. UDP packets are checked by the session table regardless of asymmetric routing. A policy is required to allow UDP.

Routing changes

When routing changes occur, routing look-up may occur on an existing session depending on certain configurations.

Routing changes without SNAT

When a routing change occurs, FortiGate flushes all routing information from the session table and performs new routing look-up for all new packets on arrival by default. You can modify the default behavior using the following commands:

```
config system interface
    edit <interface>
        set preserve-session-route enable
    next
end
```

By enabling `preserve-session-route`, the FortiGate marks existing session routing information as persistent. Therefore, routing look-up only occurs on new sessions.

Routing changes with SNAT

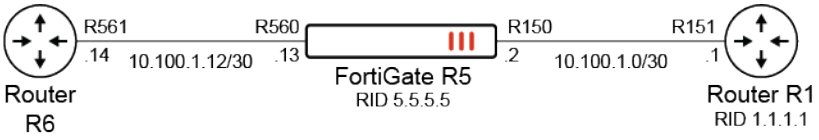
When SNAT is enabled, the default behavior is opposite to that of when SNAT is not enabled. After a routing change occurs, sessions with SNAT keep using the same outbound interface as long as the old route is still active. This may be the case if the priority of the static route was changed. You can modify this default behavior using the following commands:

```
config system global
    set snat-route-change enable
end
```

By enabling `snat-route-change`, sessions with SNAT will require new route look-up when a routing change occurs. This will apply a new SNAT to the session.

Static route tags

When a static route is configured with a route tag, it is matched in the route map, and then used to set the route's metric and advertise to the BGP neighbor. In the following example, route tag 565 is used, and router R1 receives the advertised route from the FortiGate router R5.



To configure the FortiGate:

1. Configure the static route:

```
config router static
    edit 1
        set dst 77.7.7.7 255.255.255.255
        set distance 2
        set device "R560"
        set tag 565
    next
end
```

2. Configure the route map:

```
config router route-map
    edit "map1"
        config rule
            edit 2
                set match-tag 565
                set set-metric 2301
            next
        end
    next
end
```

3. Configure the BGP neighbor:

```
config router bgp
    config neighbor
        edit "10.100.1.2"
            set route-map-out "map1"
        next
```

```
    end
end
```

On its neighbor side, router R1 receives the advertised route from the FortiGate router R5.

4. Verify the BGP routing table:

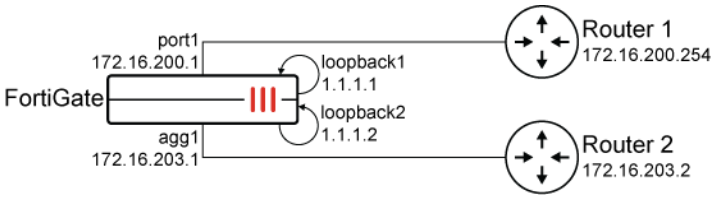
```
# get router info routing-table bgp
Routing table for VRF=0
B       77.7.7.7/32 [20/2301] via 10.100.1.1 (recursive is directly connected, R150),
03:18:53, [1/0]
```

5. Verify the network community:

```
# get router info bgp network 77.7.7.7/32
VRF 0 BGP routing table entry for 77.7.7.7/32
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Advertised to non peer-group peers:
   2.2.2.2 3.3.3.3 10.100.1.5 2000::2:2:2:2
  Original VRF 0
  20
    10.100.1.1 from 10.100.1.1 (5.5.5.5)
      Origin incomplete metric 2301, localpref 200, valid, external, best
      Last update: Wed Oct  5 16:48:28 2022
```

Defining a preferred source IP for local-out egress interfaces

The preferred source IP can be configured on a static route so that local-out traffic is sourced from that IP. In the following example, a source IP is defined per static route. Local traffic that uses the static route will use the source IP instead of the interface IP associated with the route.



To configure preferred source IPs for static routes:

1. Configure the static routes:

```
config router static
    edit 22
        set dst 172.17.254.0 255.255.255.0
        set gateway 172.16.200.254
        set preferred-source 1.1.1.1
        set distance 2
        set device "port1"
    next
    edit 23
        set dst 172.17.254.0 255.255.255.0
```

```
        set gateway 172.16.203.2
        set preferred-source 1.1.1.2
        set distance 2
        set device "agg1"
    next
end
```

2. Configure the primary DNS server IP address:

```
config system dns
    set primary 172.17.254.148
end
```

To verify the configuration:

1. Verify the kernel routing table:

```
# get router info kernel
...
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.17.254.0/24 pref=0.0.0.0
        gwy=172.16.200.254 flag=14 hops=0 oif=9(port1) pref=1.1.1.1
        gwy=172.16.203.2 flag=14 hops=0 oif=33(agg1) pref=1.1.1.2
```

2. Verify the routing table for 172.17.254.148:

```
# get router info routing-table details 172.17.254.148
Routing table for VRF=0
Routing entry for 172.17.254.0/24
  Known via "static", distance 2, metric 0, best
  * vrf 0 172.16.200.254, via port1, prefsrc 1.1.1.1
  * vrf 0 172.16.203.2, via agg1, prefsrc 1.1.1.2
```

3. Run a sniffer trace after some traffic passes:

```
# diagnose sniffer packet any "host 172.17.254.148" 4
interfaces=[any]
filters=[host 172.17.254.148]
1.319811 port1 out 1.1.1.1.1371 -> 172.17.254.148.53: udp 43
1.320095 port1 in 172.17.254.148.53 -> 1.1.1.1.1371: udp 310
1.921718 port1 out 1.1.1.1.1371 -> 172.17.254.148.53: udp 27
2.031520 port1 in 172.17.254.148.53 -> 1.1.1.1.1371: udp 213
```

When DNS traffic leaves the FortiGate and is routed through port1, the source address 1.1.1.1 is used.

Policy routes

Policy routing allows you to specify an interface to route traffic. This is useful when you need to route certain types of network traffic differently than you would if you were using the routing table. You can use the incoming traffic's protocol, source or destination address, source interface, or port number to determine where to send the traffic.

When a packet arrives, the FortiGate starts at the top of the policy route list and attempts to match the packet with a policy. For a match to be found, the policy must contain enough information to route the packet. At a minimum, this requires either the outgoing interface to forward the traffic, or the gateway to route the traffic to, or both.

If one or both of these are not specified in the policy route, then the FortiGate searches the routing table to find the best active route that corresponds to the policy route:

- If only the outgoing interface is specified, FortiGate will look up the routing table to find the gateway, filtered by the outgoing interface.
- If only the gateway is specified, FortiGate will look up the routing table to find the outgoing interface, filtered by the gateway

If either of these cannot be found, then the policy route does not match the packet.

When both the outgoing interface and gateway are specified, the FortiGate must still find a route in the routing table ensuring that the gateway is routable over the outgoing interface. If a route cannot be found, then the policy route again does not match the packet.

In any of these scenarios, the FortiGate continues down the policy route list until it reaches the end. If no matches are found, then the FortiGate does a route lookup using the routing table.

Policy routes are sometimes referred to as Policy-based routes (PBR).

Configuring a policy route

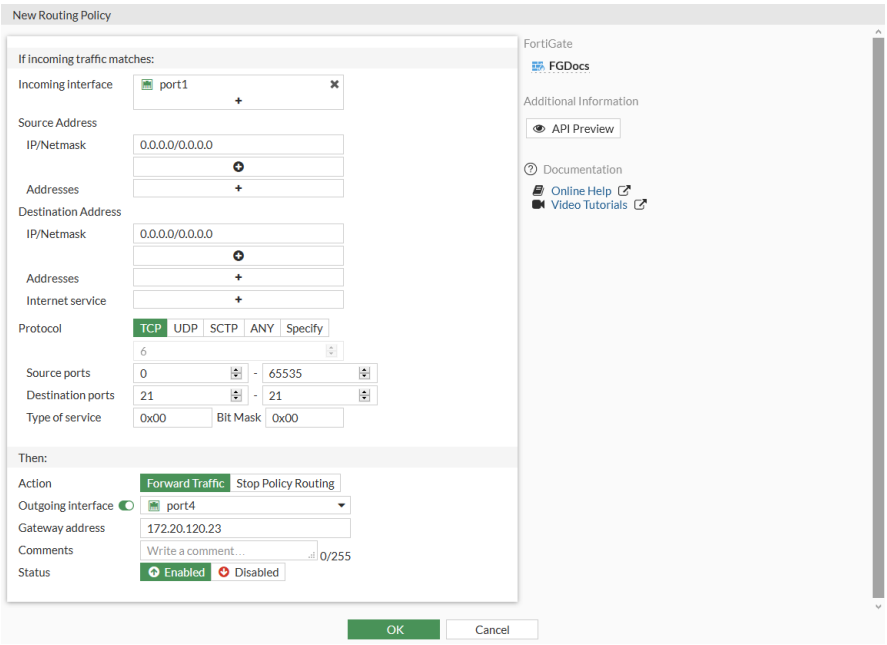
In this example, a policy route is configured to send all FTP traffic received at port1 out through port4 and to a next hop router at 172.20.120.23. To route FTP traffic, the protocol is set to TCP (6) and the destination ports are set to 21 (the FTP port).

To configure a policy route in the GUI:

1. Go to *Network* > *Policy Routes*.
2. Click *Create New* > *Policy Route*.
3. Configure the following fields:

Incoming interface	port1
Source Address	0.0.0.0/0.0.0.0
Destination Address	0.0.0.0/0.0.0.0
Protocol	TCP
Destination ports	21 - 21
Type of service	0x00
Bit Mask	0x00

Outgoing interface	Enable and select port4
Gateway address	172.20.120.23



4. Click *OK*.

To configure a policy route in the CLI:

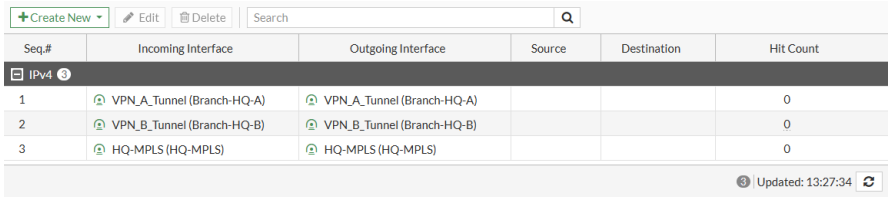
```
config router policy
    edit 1
        set input-device "port1"
        set src "0.0.0.0/0.0.0.0"
        set dst "0.0.0.0/0.0.0.0"
        set protocol 6
        set start-port 21
        set end-port 21
        set gateway 172.20.120.23
        set output-device "port4"
        set tos 0x00
        set tos-mask 0x00
    next
end
```

Moving a policy route

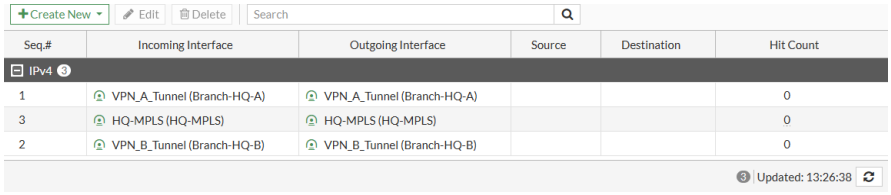
A routing policy is added to the bottom of the table when it is created. Routing policies can be moved to a different location in the table to change the order of preference. In this example, routing policy 3 will be moved before routing policy 2.

To move a policy route in the GUI:

1. Go to *Network* > *Policy Routes*.
2. In the table, select the policy route.



3. Drag the selected policy route to the desired position.



To move a policy route in the CLI:

```
config router policy
    move 3 after 1
end
```

Equal cost multi-path

Equal cost multi-path (ECMP) is a mechanism that allows a FortiGate to load-balance routed traffic over multiple gateways. Just like routes in a routing table, ECMP is considered after policy routing, so any matching policy routes will take precedence over ECMP.

ECMP pre-requisites are as follows:

- Routes must have the same destination and costs. In the case of static routes, costs include distance and priority
- Routes are sourced from the same routing protocol. Supported protocols include static routing, OSPF, and BGP

ECMP and SD-WAN implicit rule

ECMP and SD-WAN implicit rule are essentially similar in the sense that an SD-WAN implicit rule is processed after SD-WAN service rules are processed. See Implicit rule on page 1026 to learn more.

The following table summarizes the different load-balancing algorithms supported by each:

ECMP	SD-WAN		Description
	GUI	CLI	
source-ip-based	Source IP	source-ip-based	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address use the same path. This is the default selection.
weight-based	Sessions	weight-based	The workload is distributed based on the number of sessions that are connected through the interface. The weight that you assign to each interface is used to calculate the percentage of the total sessions allowed to connect through an interface, and the sessions are distributed to the interfaces accordingly.
usage-based	Spillover	usage-based	The interface is used until the traffic bandwidth exceeds the ingress and egress thresholds that you set for that interface. Additional traffic is then sent through the next interface member.
source-dest-ip-based	Source-Destination IP	source-dest-ip-based	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address and go to the same destination IP address use the same path.
Not supported	Volume	measured-volume-based	This mode is supported in SD-WAN only. The workload is distributed based on the number of packets that are going through the interface.

To configure the ECMP algorithm from the CLI:

- At the VDOM level:

```
config system settings
    set v4-ecmp-mode {source-ip-based* | weight-based | usage-based | source-dest-ip-based}
end
```

- If SD-WAN is enabled, the above option is not available and ECMP is configured under the SD-WAN settings:

```
config system sdwan
    set status enable
    set load-balance-mode {source-ip-based* | weight-based | usage-based | source-dest-ip-
based | measured-volume-based}
end
```

For ECMP in IPv6, the mode must also be configured under SD-WAN:

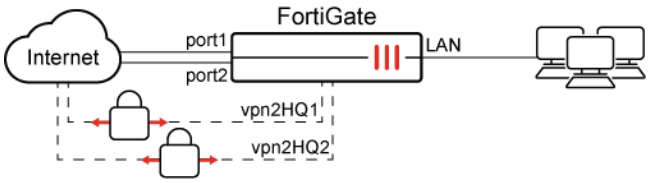
```
# diagnose sys vd list
system fib version=63
list virtual firewall info:
name=root/root index=0 enabled fib_ver=40 use=168 rt_num=46 asym_rt=0 sip_helper=0, sip_nat_
trace=1, mc_fwd=0, mc_ttl_nc=0, tpmc_sk_pl=0
ecmp=source-ip-based, ecmp6=source-ip-based asym_rt6=0 rt6_num=55 strict_src_check=0 dns_log=1
ses_num=20 ses6_num=0 pkt_num=19154477
```

To change the number of paths allowed by ECMP:

```
config system settings
    set ecmp-max-paths <number of paths>
end
```

Setting `ecmp-max-paths` to the lowest value of `1` is equivalent to disabling ECMP.

ECMP configuration examples



The following examples demonstrate the behavior of ECMP in different scenarios:

- Example 1: Default ECMP on page 489
- Example 2: Same distance, different priority on page 490
- Example 3: Weight-based ECMP on page 490
- Example 4: Load-balancing BGP routes on page 491

Example 1: Default ECMP

```
config router static
    edit 1
        set gateway 172.16.151.1
        set device "port1"
    next
    edit 2
        set gateway 192.168.2.1
        set device "port2"
    next
end
```

```
# get router info routing-table all
Routing table for VRF=0
S*    0.0.0.0/0 [10/0] via 172.16.151.1, port1
                [10/0] via 192.168.2.1, port2
C    172.16.151.0/24 is directly connected, port1
C    192.168.2.0/24 is directly connected, port2
```

Result:

Both routes are added to the routing table and load-balanced based on the source IP.

Example 2: Same distance, different priority

```
config router static
    edit 1
        set gateway 172.16.151.1
        set priority 5
        set device "port1"
    next
    edit 2
        set gateway 192.168.2.1
        set device "port2"
    next
end
```

```
# get router info routing-table all
Routing table for VRF=0
S*    0.0.0.0/0 [10/0] via 192.168.2.1, port2
                [10/0] via 172.16.151.1, port1, [5/0]
C    172.16.151.0/24 is directly connected, port1
C    192.168.2.0/24 is directly connected, port2
```

Result:

Both routes are added to the routing table, but traffic is routed to `port2` which has a lower priority value with a default of `0`.

Example 3: Weight-based ECMP

```
config router static
    edit 3
        set dst 10.10.30.0 255.255.255.0
        set weight 80
        set device "vpn2HQ1"
    next
    edit 5
        set dst 10.10.30.0 255.255.255.0
        set weight 20
        set device "vpn2HQ2"
```

```
   next
end
```

```
# get router info routing-table all
Routing table for VRF=0
...
S    10.10.30.0/24 [10/0] is directly connected, vpn2HQ1, [0/80]
                   [10/0] is directly connected, vpn2HQ2, [0/20]
C    172.16.151.0/24 is directly connected, port1
C    192.168.0.0/24 is directly connected, port3
C    192.168.2.0/24 is directly connected, port2
```

Result:

Both routes are added to the routing table, but 80% of the sessions to `10.10.30.0/24` are routed to `vpn2HQ1`, and 20% are routed to `vpn2HQ2`.

Example 4: Load-balancing BGP routes

eBGP routes that are advertised to iBGP neighbors by multiple paths may be aggregated if the tie breakers specified in RFC 4271 > 9.1.2.2 have the same attribute. This includes having equal cost IGP metric. RFC conditions f) and g) are not evaluated when forming ECMP this way.

```
config router bgp
    set as 64511
    set router-id 192.168.2.86
    set ebgp-multipath enable
    config neighbor
        edit "192.168.2.84"
            set remote-as 64512
        next
        edit "192.168.2.87"
            set remote-as 64512
        next
   end
end
# get router info routing-table all
Routing table for VRF=0
...
C    172.16.151.0/24 is directly connected, port1
C    192.168.0.0/24 is directly connected, port3
C    192.168.2.0/24 is directly connected, port2
B    192.168.80.0/24 [20/0] via 192.168.2.84, port2, 00:00:33
                     [20/0] via 192.168.2.87, port2, 00:00:33
```

Result:

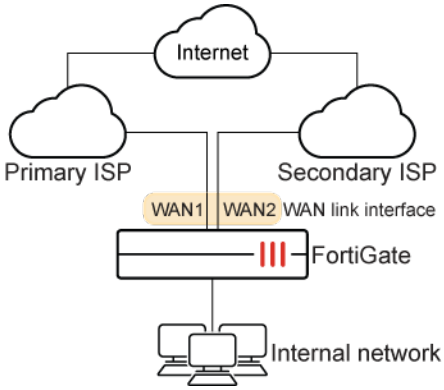
The network `192.168.80.0/24` is advertised by two BGP neighbors. Both routes are added to the routing table, and traffic is load-balanced based on Source IP.

For multiple BGP paths to be added to the routing table, you must enable `ebgp-multipath` for eBGP or `ibgp-multipath` for iBGP. These settings are disabled by default.

Dual internet connections

Dual internet connections, also referred to as dual WAN or redundant internet connections, refers to using two FortiGate interfaces to connect to the Internet. This is generally accomplished with SD-WAN, but this legacy solution provides the means to configure dual WAN without using SD-WAN. You can use dual internet connections in several ways:

- Link redundancy: If one interface goes down, the second interface automatically becomes the main connection.
- Load sharing: This ensures better throughput.
- Use a combination of link redundancy and load sharing.



This section describes the following dual internet connection scenarios:

- Scenario 1: Link redundancy and no load-sharing on page 492
- Scenario 2: Load-sharing and no link redundancy on page 494
- Scenario 3: Link redundancy and load-sharing on page 496

Scenario 1: Link redundancy and no load-sharing

Link redundancy ensures that if your Internet access is no longer available through a certain port, the FortiGate uses an alternate port to connect to the Internet.

In this scenario, two interfaces, WAN1 and WAN2, are connected to the Internet using two different ISPs. WAN1 is the primary connection. In the event of a failure of WAN1, WAN2 automatically becomes the connection to the Internet. For this configuration to function correctly, you must configure the following settings:

- Link health monitor on page 493: To determine when the primary interface (WAN1) is down and when the connection returns.
- Routing on page 493: Configure a default route for each interface.
- Security policies on page 494: Configure security policies to allow traffic through each interface to the internal network.

Link health monitor

Adding a link health monitor is required for routing failover traffic. A link health monitor confirms the device interface connectivity by probing a gateway or server at regular intervals to ensure it is online and working. When the server is not accessible, that interface is marked as down.

Set the `interval` (how often to send a ping) and `failtime` (how many lost pings are considered a failure). A smaller interval value and smaller number of lost pings results in faster detection, but creates more traffic on your network.

The link health monitor supports both IPv4 and IPv6, and various other protocols including ping, tcp-echo, udp-echo, http, and twamp.

To add a link health monitor (IPv4) using the CLI:

```
config system link-monitor
    edit <link-monitor-name>
        set addr-mode ipv4
        set srcintf <interface-name>
        set server <server-IP-address>
        set protocol {ping tcp-echo udp-echo http twamp}
        set gateway-ip <gateway-IP-address>
        set interval <seconds>
        set failtime <retry-attempts>
        set recoverytime <number-of-successful-responses>
        set status enable
    next
end
```

Option	Description
`set update-cascade-interface {enable | disable}`	This option is used in conjunction with fail-detect and fail-alert options in interface settings to cascade the link failure down to another interface. See the Bring other interfaces down when link monitor fails KB article for details.
`set update-static-route {enable | disable}`	When the link fails, all static routes associated with the interface will be removed.

Routing

You must configure a default route for each interface and indicate your preferred route as follows:

- Specify different distances for the two routes. The lower of the two distance values is declared active and placed in the routing table.

  Or

- Specify the same distance for the two routes, but give a higher priority to the route you prefer by defining a lower value. Both routes will be added to the routing table, but the route with a higher priority will be chosen as the best route

In the following example, we will use the first method to configure different distances for the two routes. You might not be able to connect to the backup WAN interface because the FortiGate does not route traffic out of the backup interface. The FortiGate performs a reverse path look-up to prevent spoofed traffic. If an entry cannot be found in the routing table that sends the return traffic out through the same interface, the incoming traffic is dropped.

To configure the routing of the two interfaces using the GUI:

1. Go to *Network* > *Static Routes*, and click *Create New*.
2. Enter the following information:

Destination	For an IPv4 route, enter a subnet of `0.0.0.0/0.0.0.0`. For an IPv6 route, enter a subnet of `::/0`.
Interface	Select the primary connection. For example, `wan1`.
Gateway Address	Enter the gateway address.
Administrative Distance	Leave as the default of `10`.

3. Click *OK*.
4. Repeat the above steps to set *Interface* to `wan2` and *Administrative Distance* to `20`.

To configure the routing of the two interfaces using the CLI:

```
config router {static | static6}
    edit 1
        set dst 0.0.0.0 0.0.0.0
        set device wan1
        set gateway <gateway_address>
        set distance 10
    next
    edit 2
        set dst 0.0.0.0 0.0.0.0
        set device wan2
        set gateway <gateway_address>
        set distance 20
    next
end
```

Security policies

When you create security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic is allowed to pass through WAN2, as it did with WAN1. This ensures that failover occurs with minimal effect to users.

Scenario 2: Load-sharing and no link redundancy

Load sharing may be accomplished in a few of the following ways of the many possible ways:

- By defining a preferred route with a lower distance, and specifying policy routes to route certain traffic to the secondary interface.
- By defining routes with same distance values but different priorities, and specifying policy routes to route certain traffic to the secondary interface.
- By defining routes with same distance values and priorities, and use equal-cost multi-path (ECMP) routing to equally distribute traffic between the WAN interfaces.

In our example, we will use the first option for our configuration. In this scenario, because link redundancy is not required, you do not have to configure a link monitor.

Traffic behaviour without a link monitor is as follows:

- If the remote gateway is down but the primary WAN interface of a FortiGate is still up, the FortiGate will continue to route traffic to the primary WAN. This results in traffic interruptions.
- If the primary WAN interface of a FortiGate is down due to physical link issues, the FortiGate will remove routes to it and the secondary WAN routes will become active. Traffic will failover to the secondary WAN.

Routing

Configure routing as you did in Scenario 1: Link redundancy and no load-sharing on page 492 above.

Policy routes

By configuring policy routes, you can redirect specific traffic to the secondary WAN interface. This works in this case because policy routes are checked before static routes. Therefore, even though the static route for the secondary WAN is not in the routing table, traffic can still be routed using the policy route.

In this example, we will create a policy route to route traffic from one address group to the secondary WAN interface.

To configure a policy route from the GUI:

1. Go to *Network* > *Policy Routes*, and click *Create New*.
2. Enter the following information:

Incoming interface	Define the source of the traffic. For example, `internal`.
Source Address	If we prefer to route traffic only from a group of addresses, define an address or address group, and add here.
Destination Address	Because we want to route all traffic from the address group here, we do not specify a destination address.
Protocol	Specify any protocol.
Action	Forward traffic.
Outgoing interface	Select the secondary WAN as the outbound interface. For example, `wan2`.
Gateway address	Input the gateway address for your secondary WAN.

	Because its default route has a higher distance value and is not added to the routing table, the gateway address must be added here.

3. Click OK.

To configure a policy route from the CLI:

```
config router policy
    edit 1
        set input-device "internal"
        set srcaddr "Laptops"
        set gateway <gateway_address>
        set output-device "wan2"
    next
end
```

Security policies

Your security policies should allow all traffic from `internal` to WAN1. Because link redundancy is not needed, you do not need to duplicate all WAN1 policies to WAN2. You will only need to define policies used in your policy route.

Scenario 3: Link redundancy and load-sharing

In this scenario, both the links are available to distribute Internet traffic with the primary WAN being preferred more. Should one of the interfaces fail, the FortiGate will continue to send traffic over the other active interface. The configuration is a combination of both the link redundancy and the load-sharing scenarios. The main difference is that the configured routes have equal distance values, with the route with a higher priority being preferred more. This ensures both routes are active in the routing table, but the route with a higher priority will be the best route.

Link health monitor

Link monitor must be configured for both the primary and the secondary WAN interfaces. This ensures that if the primary or the secondary WAN fails, the corresponding route is removed from the routing table and traffic re-routed to the other WAN interface.

For configuration details, see sample configurations in Scenario 1: Link redundancy and no load-sharing on page 492.

Routing

Both WAN interfaces must have default routes with the same distance. However, preference is given to the primary WAN by giving it a higher priority.

To configure the routing of the two interfaces using the CLI:

```
config router {static | static6}
    edit 1
        set dst 0.0.0.0 0.0.0.0
        set device wan1
        set gateway <gateway_address>
        set distance 10
        set priority 1
    next
    edit 2
        set dst 0.0.0.0 0.0.0.0
        set device wan2
        set gateway <gateway_address>
        set distance 10
        set priority 10
    next
end
```

Policy routes

The policy routes configuration is very similar to that of the policy routes in Scenario 2: Load-sharing and no link redundancy on page 494, except that the gateway address should not be specified. When a policy route is matched and the gateway address is not specified, the FortiGate looks at the routing table to obtain the gateway. In case the secondary WAN fails, traffic may hit the policy route. Because there is no gateway specified and the route to the secondary WAN is removed by the link monitor, the policy route will by bypassed and traffic will continue through the primary WAN. This ensures that the policy route is not active when the link is down.

Security policies

When you create security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic is allowed to pass through WAN2, as it was with WAN1. This ensures that failover occurs with minimal effect to users.

Dynamic routing

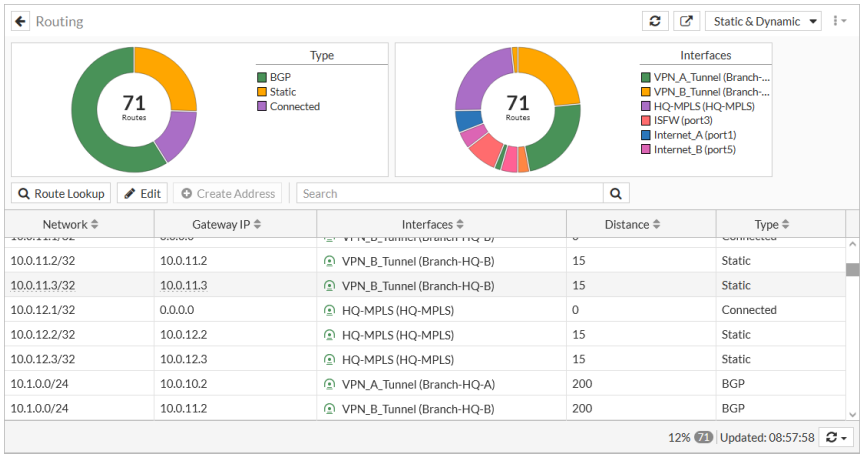
Dynamic routing protocols attempt to build a map of the network topology to identify the best routes to reach different destinations. Instead of manually defining static routes, which is not scalable, dynamic routing typically involves defining neighbors and peer routers that share their network topology and routing updates with each other. Protocols like distance vector, link state, and path vector are used by popular routing protocols. FortiGate supports RIP, OSPF, BGP, and IS-IS, which are interoperable with other vendors. When different dynamic routing protocols are used, the administrative distance of each protocol helps the FortiGate decide which route to pick.

Go to *System > Feature Visibility* and enable *Advanced Routing* to configure dynamic routing options in the GUI. See Feature visibility on page 3595 for more information.

This section includes:

- RIP on page 498
- OSPF on page 520
- BGP on page 538
- BFD on page 597
- Routing objects on page 607

To view the routing table and perform route look-ups in the GUI, go to *Dashboard* > *Network* and expand the *Routing* widget.



To view the routing table in the CLI:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
 Routing table for VRF=0
S*   0.0.0.0/0 [5/0] via 192.168.0.1, wan1
C    10.10.10.0/24 is directly connected, internal
C    169.254.2.1/32 is directly connected, Dialup-test
C    172.31.0.0/30 is directly connected, toKVM-MPLS
C    172.31.0.1/32 is directly connected, toKVM-MPLS
C    192.168.0.0/24 is directly connected, wan1
O    192.168.2.0/24 [110/101] via 10.10.10.11, internal, 00:00:26
S    192.168.20.0/24 [10/0] via 172.31.0.2, toKVM-MPLS
      [10/0] via 10.10.10.11, internal
```

RIP

Routing Information Protocol (RIP) is a distance-vector routing protocol that is intended for small and relatively homogeneous networks. It works well when there are minimal redundant paths and limited hop counts. FortiGate supports RIP version 1 (RFC 1058), RIP version 2 (RFC 2453), and RIPng (RFC 2080).

Basic configuration

To configure the FortiGate to participate in RIP using the most basic configurations in the GUI:

1. Go to *Network* > *RIP*.
2. Set the *Version*.
3. Add the networks that the FortiGate will advertise in and that will participate in RIP.
4. If the interface settings, such as passive interface, authentication, or enabling send/receive updates, must be edited, add the interfaces to the *Interface* table.
5. Click *Apply*.

To configure the FortiGate to participate in RIP using the most basic configurations in the CLI:

```
config router rip
    config network
        edit 1
            set prefix <subnet> <netmask>
        next
    end
    config interface
        edit <interface>
            set receive-version 2
            set send-version 2
        next
    end
end
```

Default route injection

Enabling *Inject default route* (`default-information-originate`) advertises a default route into the FortiGate's RIP network.

To enable/disable default route injection in the GUI:

1. Go to *Network* > *RIP*.
2. Expand the *Advanced Options*.
3. Enable/disable *Inject Default Route*.
4. Click *OK*.

To enable/disable default route injection in the CLI:

```
config router rip
    set default-information-originate {enable | disable}
end
```

Default metric

The default metric setting sets the default metric for all redistributed routes. If the default metric is set to five, and static routes are redistributed, then static routes have a metric of five. This value can be overridden by setting a specific metric value for a protocol. For example, the static route metric can be set to two, overriding the default metric.

```
config router rip
    set default-metric 5
    config redistribute "static"
        set status enable
        set metric 2
    end
end
```

The default metric is five, but redistributed static routes have a metric of two. So, the default metric is overridden and the metric for redistributed static routes is two.

Timers

RIP uses the update, timeout, and garbage timers to regulate its performance. The default timer settings are effective in most configurations. When customizing the settings, you must ensure that the new settings are compatible with your local routers and access servers.

Go to *Network* > *RIP* and expand the *Advanced Options* to configure the timers in the GUI, or use the CLI:

```
config router rip
    set timeout-timer <seconds>
    set update-timer <seconds>
    set garbage-timer <seconds>
end
```

Update timer

The update timer sets the interval between routing updates. The default value is 30 seconds. Randomness is added to help prevent network congestion due to multiple routers trying to update their neighbors simultaneously. The update timer must be at least three times shorter than the timeout timer.

If there is significant RIP traffic on the network, you can increase the update timer to send fewer updates. You must apply the same increase to all routers on the network to avoid timeouts that degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time that a reachable route is kept in the routing table since its last update. The default value is 180 seconds. If an update for the route is received before the timeout period elapses, then the timer is reset. The timeout timer should be at least three times longer than the update timer.

If routers are not responding to updates in time, increasing the timeout timer can help. A longer timeout timer results in longer update periods, and the FortiGate could wait a considerable amount of time for all of the timers to expire on an unresponsive route.

Garbage timer

The garbage timer is the amount of time that the FortiGate advertises a route as unreachable before deleting the route from the routing table. The default value is 120 seconds.

If the timer is short, older routes are removed from the routing table more quickly, resulting in a smaller routing table. This can be useful for large networks, or if the network changes frequently.

Authentication and key chain

RIP version 1 (RIPv1) has no authentication. RIP version 2 (RIPv2) uses text passwords or authentication keys to ensure that the routing information exchanged between routers is reliable. For authentication to work, both the sending and receiving routers must be set to use authentication and must be configured with the same password or keys. An authentication key that uses authentication key chains is more secure than a text password because the intervals when the key is valid can be configured.

A key chain is a list of one or more authentication keys that each have send and receive lifetimes. Keys are used to authenticate routing packets only during the keys specified lifetimes. The FortiGate migrates from one key to the next according to the scheduled lifetimes. The sending and receiving routers should have synchronized system dates and times to ensure that both ends are using the same keys at the same times. You can overlap the key lifetimes to make sure that a key is always available, even if there is some difference in the system times.

To configure a text password in the GUI:

1. Go to *Network* > *RIP*.
2. In the *Interfaces* table, click *Create New*, or edit an existing interface.
3. Enable *Authentication* and select *Text* or *MD5*.
4. Click *Change*, and enter the password.
5. Configure the remaining settings as needed.
6. Click *OK*.
7. Click *Apply*.

To configure a text password in the CLI:

```
config router rip
    config interface
        edit <interface>
            set auth-mode {text | md5}
            set auth-string **********
        next
    end
end
```

To configure a key chain with two sequentially valid keys and use it in a RIP interface:

```
config router key-chain
    edit rip_key
```

```
        config key
            edit 1
                set accept-lifetime 09:00:00 23 02 2020 09:00:00 17 03 2020
                set send-lifetime 09:00:00 23 02 2020 09:00:00 17 03 2020
                set key-string **********
            next
            edit 2
                set accept-lifetime 09:01:00 17 03 2020 09:00:00 1 04 2020
                set send-lifetime 09:01:00 17 03 2020 09:00:00 1 04 2020
                set key-string **********
            next
        end
    next
end
```

```
config router rip
    config interface
        edit port1
            set auth-keychain "rip_key"
        next
    end
end
```

Passive RIP interfaces

By default, an active RIP interface keeps the FortiGate routing table current by periodically asking neighbors for routes and sending out route updates. This can generate a significant amount of extra traffic in a large network.

A passive RIP interface listens to updates from other routers, but does not send out route updates. This can reduce network traffic when there are redundant routers in the network that would always send out essentially the same updates.

This example shows how to configure a passive RIPv2 interface on port1 using MD5 authentication.

To configure a passive RIP interface in the GUI:

1. Go to *Network* > *RIP*.
2. In the *Interfaces* table, click *Create New*.
3. Set *Interface* to the required interface.
4. Enable *Passive*.
5. Enable *Authentication* and set it to *MD5*.
6. Click *Change* and enter a password.
7. Set *Receive Version* to *2*.
8. Click *OK*.

To configure a passive RIP interface in the CLI:

```
config router rip
    set passive-interface "port1"
```

```
    config interface
        edit "port1"
            set auth-mode md5
            set auth-string **********
            set receive-version 2
            set send-version 2
        next
    end
end
```

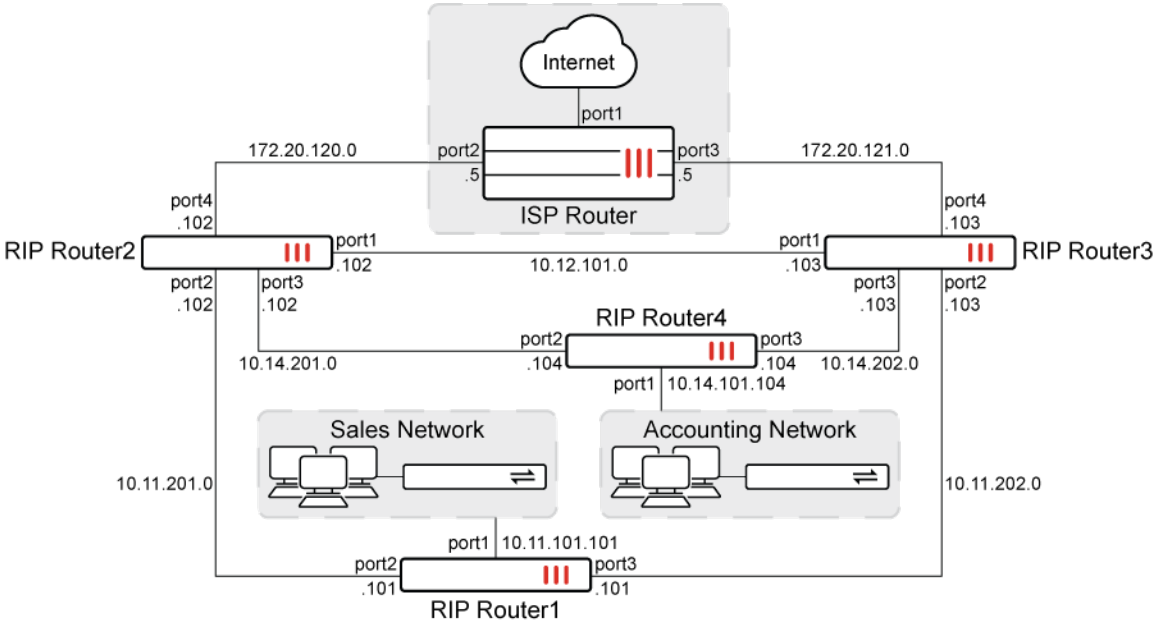
RIP and IPv6

RIP next generation (RIPng) is an extension of RIPv2 that includes support for IPv6. See Basic RIPng example on page 517 and IPv6 tunneling on page 782 for more information.

Basic RIP example

In this example, a medium-sized network is configured using RIPv2.

- Two core routers, RIP Router2 and RIP Router3, connect to the ISP router for two redundant paths to the internet.
- Two other routers, RIP Router1 and RIP Router4, connect to the two core routers and to different local networks.
- The ISP router is using RIP for its connections to the core routers, and redistributes its default route to the network - that is, default route injection is enabled.
- The ISP router uses NAT and has a static route to the internet. None of the other routers use NAT or static routes.



All of the FortiGate routers are configured as shown, using netmask 255.255.255.0. Firewall policies have been configured to allow the required traffic to flow across the interfaces.

Router	Interface	Interface name	IP address
Router1	port1	LoSales	10.11.101.101
	port2	vd12link0	10.11.201.101
	port3	vd13link0	10.11.202.101
Router2	port1	vd23link0	10.12.101.102
	port2	vd12link1	10.11.201.102
	port3	vd42link1	10.14.201.102
	port4	vdr2link1	172.20.120.102
Router3	port1	vd23link1	10.12.101.103
	port2	vd13link1	10.11.202.103
	port3	vd43link1	10.14.202.103
	port4	vdr3link1	172.20.121.103
Router4	port1	LoAccounting	10.14.101.104
	port2	vd42link0	10.14.201.104
	port3	vd43link0	10.14.202.104
ISP Router	port1	port1	To internet
	port2	vdr2link0	172.20.120.5
	port3	vdr3link0	172.20.121.5

After configuring each router, you can check the status of the connections by viewing the RIP database, RIP interfaces, and routing table. See Verifying the configuration on page 509.

After the network is configured, you can test it to ensure that when network events occur, such as a downed link, routing updates are triggered and converge as expected. See Testing the configuration and routing changes on page 514.

ISP router

To configure the ISP Router in the GUI:

1. Go to *Network* > *RIP*.
2. Set the *Version* to *2*.
3. Under *Networks*, add two networks:
   - *172.20.120.0/255.255.255.0*
   - *172.20.121.0/255.255.255.0*
4. Add the interfaces:

   a. In the *Interfaces* table, click *Create New*.
   b. Set *Interface* to *port2*.
   c. Leave the remaining settings as their default values.
   d. Click *OK*.
   e. Repeat these steps for *port3*.
5. Under *Advanced Options*, enable *Inject Default Route*.
   This setting allows the ISP router to share its default 0.0.0.0 routes with other routers in the RIP network.
6. Click *Apply*.

To configure the ISP Router in the CLI:

```
config router rip
    set default-information-originate enable
    config network
        edit 1
            set prefix 172.20.121.0 255.255.255.0
        next
        edit 2
            set prefix 172.20.120.0 255.255.255.0
        next
    end
    config interface
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
            set receive-version 2
            set send-version 2
        next
    end
end
```

Router2 and Router3

Router2 and Router3 RIP configurations have different IP addresses, but are otherwise the same.

To configure Router2 and Router3 in the GUI:

1. Go to *Network* > *RIP*.
2. Set the *Version* to *2*.
3. Under *Networks*, add the IP addresses for each port:

Router2	10.12.101.0/255.255.255.0
	10.11.201.0/255.255.255.0
	10.14.201.0/255.255.255.0
	172.20.120.0/255.255.255.0
Router3	10.12.101.0/255.255.255.0
	10.11.202.0/255.255.255.0
	10.14.202.0/255.255.255.0
	172.20.121.0/255.255.255.0

4. Add the interfaces:
   a. In the *Interfaces* table, click *Create New*.
   b. Set *Interface* to *port1*.
   c. Leave the remaining settings as their default values.
   d. Click *OK*.
   e. Repeat these steps for *port2*, *port3*, and *port4*.
5. Click *Apply*.

To configure Router2 in the CLI:

```
config router rip
    config network
        edit 1
            set prefix 10.12.101.0 255.255.255.0
        next
        edit 2
            set prefix 10.11.201.0 255.255.255.0
        next
        edit 3
            set prefix 10.14.201.0 255.255.255.0
        next
        edit 4
            set prefix 172.20.120.0 255.255.255.0
        next
    end
    config interface
        edit "port1"
            set receive-version 2
            set send-version 2
        next
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
            set receive-version 2
```

```
            set send-version 2
        next
        edit "port4"
            set receive-version 2
            set send-version 2
        next
    end
end
```

To configure Router3 in the CLI:

```
config router rip
    config network
        edit 1
            set prefix 10.12.101.0 255.255.255.0
        next
        edit 2
            set prefix 10.11.202.0 255.255.255.0
        next
        edit 3
            set prefix 10.14.202.0 255.255.255.0
        next
        edit 4
            set prefix 172.20.121.0 255.255.255.0
        next
    end
    config interface
        edit "port1"
            set receive-version 2
            set send-version 2
        next
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
            set receive-version 2
            set send-version 2
        next
        edit "port4"
            set receive-version 2
            set send-version 2
        next
    end
end
```

Router1 and Router4

Router1 and Router4 RIP configurations have different IP addresses, but are otherwise the same.

To configure Router1 and Router4 in the GUI:

1. Go to *Network* > *RIP*.
2. Set the *Version* to *2*.
3. Under *Networks*, add the IP addresses for each port:

Router1	10.11.101.0/255.255.255.0
	10.11.201.0/255.255.255.0
	10.11.202.0/255.255.255.0
Router4	10.14.101.0/255.255.255.0
	10.14.201.0/255.255.255.0
	10.14.202.0/255.255.255.0

4. Add the interfaces:
   a. In the *Interfaces* table, click *Create New*.
   b. Set *Interface* to *port1*.
   c. For port1 only, enable *Passive*.
   d. Leave the remaining settings as their default values.
   e. Click *OK*.
   f. Repeat these steps for *port2* and *port3*, making sure that *Passive* is disabled.
5. Click *Apply*.

To configure Router1 in the CLI:

```
config router rip
    config network
        edit 1
            set prefix 10.11.101.0 255.255.255.0
        next
        edit 2
            set prefix 10.11.201.0 255.255.255.0
        next
        edit 3
            set prefix 10.11.202.0 255.255.255.0
        next
    end
    set passive-interface "port1"
    config interface
        edit "port1"
            set receive-version 2
            set send-version 2
        next
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
```

```
            set receive-version 2
            set send-version 2
        next
    end
end
```

To configure Router4 in the CLI:

```
config router rip
    config network
        edit 1
            set prefix 10.14.101.0 255.255.255.0
        next
        edit 2
            set prefix 10.14.201.0 255.255.255.0
        next
        edit 3
            set prefix 10.14.202.0 255.255.255.0
        next
    end
    set passive-interface "port1"
    config interface
        edit "port1"
            set receive-version 2
            set send-version 2
        next
        edit "port2"
            set receive-version 2
            set send-version 2
        next
        edit "port3"
            set receive-version 2
            set send-version 2
        next
    end
end
```

Verifying the configuration

The interface's names are shown in the debugs. The same commands should also be run on the other routers.

To verify the configuration after the ISP router, Router2, and Route3 have been configured:

This verification can be done after the ISP router, Router2, and Router3 have been configured. Only Router2's debugs are shown.

1. Check the RIP interface information:

```
# get router info rip interface
Router2 is up, line protocol is up
  RIP is not enabled on this interface
```

```
ssl.Router2 is up, line protocol is up
  RIP is not enabled on this interface
vdr2link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      172.20.120.102/24
vd12link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.201.102/24
vd42link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.14.201.102/24
vd23link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.12.101.102/24
```

RIP starts exchanging routes as soon as the networks are added to the Router2 and Router3 configurations because the RIP interfaces are active by default, and start sending and receiving RIP updates when a matching interface on the subnet is found. The interface configuration allows the interface settings to be fine tuned, in this case to specify only RIPv2 support.

2. Check the RIP database:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          172.20.120.5          2 172.20.120.5    vdr2link1 02:55
Rc 10.11.201.0/24                           1                 vd12link1
R  10.11.202.0/24     10.12.101.103         2 10.12.101.103   vd23link0 02:33
Rc 10.12.101.0/24                           1                 vd23link0
Rc 10.14.201.0/24                           1                 vd42link1
R  10.14.202.0/24     10.12.101.103         2 10.12.101.103   vd23link0 02:33
```

```
Rc 172.20.120.0/24                          1                 vdr2link1
R  172.20.121.0/24    10.12.101.103         2 10.12.101.103   vd23link0 02:33
```

3. Check the routing table:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
R*      0.0.0.0/0 [120/2] via 172.20.120.5, vdr2link1, 13:37:23
C       10.11.201.0/24 is directly connected, vd12link1
R       10.11.202.0/24 [120/2] via 10.12.101.103, vd23link0, 14:10:01
C       10.12.101.0/24 is directly connected, vd23link0
C       10.14.201.0/24 is directly connected, vd42link1
R       10.14.202.0/24 [120/2] via 10.12.101.103, vd23link0, 14:10:01
C       172.20.120.0/24 is directly connected, vdr2link1
R       172.20.121.0/24 [120/2] via 10.12.101.103, vd23link0, 13:20:36
```

Router2 has learned the default gateway from the ISP router, and has learned of other networks from Router3.

4. If firewall policies are correctly configured, the outside network can be reached:

```
# execute ping-options source 10.11.201.102
# execute ping 8.8.8.8
PING 8.8.8.8 (8.8.8.8): 56 data bytes
64 bytes from 8.8.8.8: icmp_seq=0 ttl=115 time=4.5 ms
64 bytes from 8.8.8.8: icmp_seq=1 ttl=115 time=4.2 ms
64 bytes from 8.8.8.8: icmp_seq=2 ttl=115 time=4.2 ms
64 bytes from 8.8.8.8: icmp_seq=3 ttl=115 time=4.2 ms
64 bytes from 8.8.8.8: icmp_seq=4 ttl=115 time=4.1 ms
--- 8.8.8.8 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 4.1/4.2/4.5 ms
```

```
# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  172.20.120.5  0.101 ms  0.030 ms  0.014 ms
 2  172.16.151.1  0.169 ms  0.144 ms  0.131 ms
 3  * * *
```

To verify the configuration after Router1 and Router4 have also been configured:

This verification can be done after Router1 and Router4 have been configured. Only Router1's debugs are shown.

1. Check the RIP interface information:

```
# get router info rip interface
Router1 is up, line protocol is up
  RIP is not enabled on this interface
ssl.Router1 is up, line protocol is up
  RIP is not enabled on this interface
vd12link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.201.101/24
vd13link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.202.101/24
LoSales is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Enabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.101.101/24
      127.0.0.1/8
```

2. Check the RIP database:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          10.11.202.103         3 10.11.202.103   vd13link0 02:35
Rc 10.11.101.0/24                           1                 LoSales
Rc 10.11.201.0/24                           1                 vd12link0
Rc 10.11.202.0/24                           1                 vd13link0
R  10.12.101.0/24     10.11.202.103         2 10.11.202.103   vd13link0 02:35
R  10.14.101.0/24     10.11.202.103         3 10.11.202.103   vd13link0 02:35
R  10.14.201.0/24     10.11.201.102         2 10.11.201.102   vd12link0 02:30
R  10.14.202.0/24     10.11.202.103         2 10.11.202.103   vd13link0 02:35
R  172.20.120.0/24    10.11.201.102         2 10.11.201.102   vd12link0 02:30
R  172.20.121.0/24    10.11.202.103         2 10.11.202.103   vd13link0 02:35
```

3. Check the routing table:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
R*      0.0.0.0/0 [120/3] via 10.11.202.103, vd13link0, 00:09:42
C       10.11.101.0/24 is directly connected, LoSales
C       10.11.201.0/24 is directly connected, vd12link0
C       10.11.202.0/24 is directly connected, vd13link0
R       10.12.101.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
R       10.14.101.0/24 [120/3] via 10.11.202.103, vd13link0, 00:09:42
R       10.14.201.0/24 [120/2] via 10.11.201.102, vd12link0, 00:09:42
R       10.14.202.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
R       172.20.120.0/24 [120/2] via 10.11.201.102, vd12link0, 00:09:42
R       172.20.121.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
```

4. If firewall policies are correctly configured, the accounting network and the internet are reachable from the sales network:

```
# execute ping-options source 10.11.101.101
# execute ping 10.14.101.104
PING 10.14.101.104 (10.14.101.104): 56 data bytes
64 bytes from 10.14.101.104: icmp_seq=0 ttl=254 time=0.1 ms
64 bytes from 10.14.101.104: icmp_seq=1 ttl=254 time=0.0 ms
64 bytes from 10.14.101.104: icmp_seq=2 ttl=254 time=0.0 ms
64 bytes from 10.14.101.104: icmp_seq=3 ttl=254 time=0.0 ms
64 bytes from 10.14.101.104: icmp_seq=4 ttl=254 time=0.0 ms
--- 10.14.101.104 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.0/0.0/0.1 ms
```

```
# execute traceroute 10.14.101.104
traceroute to 10.14.101.104 (10.14.101.104), 32 hops max, 3 probe packets per hop, 84 byte
packets
 1  10.11.202.103  0.079 ms  0.029 ms  0.013 ms
 2  10.14.101.104  0.043 ms  0.020 ms  0.010 ms
```

```
# execute ping 8.8.8.8
PING 8.8.8.8 (8.8.8.8): 56 data bytes
64 bytes from 8.8.8.8: icmp_seq=0 ttl=114 time=4.3 ms
64 bytes from 8.8.8.8: icmp_seq=1 ttl=114 time=4.1 ms
--- 8.8.8.8 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max = 4.1/4.2/4.3 ms
```

```
# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
```

```
1  10.11.202.103  0.094 ms  0.036 ms  0.030 ms
2  172.20.121.5  0.216 ms  0.045 ms  0.038 ms
```

Testing the configuration and routing changes

After the network is configured, test it to ensure that when network events occur, such as a downed link, routing updates are triggered and converge as expected.

In the following examples, we disable certain links to simulate network outages, then verify that routing and connectivity is restored after the updates have converged.

Example 1 - ISP router port3 interface goes down

In this example, a link outage occurs on port3 of the ISP router. Consequently, all routers must use Router2, and not Router3, to reach the internet. Note the RIP database before and after the link failure, and the time taken for the route updates to propagate and return to a functioning state.

Router4's debugs are shown.

Before:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          10.14.202.103         3 10.14.202.103   vd43link0 02:31
R  10.11.101.0/24     10.14.202.103         3 10.14.202.103   vd43link0 02:31
R  10.11.201.0/24     10.14.201.102         2 10.14.201.102   vd42link0 02:47
R  10.11.202.0/24     10.14.202.103         2 10.14.202.103   vd43link0 02:31

```

```
R       172.20.120.0/24 [120/2] via 10.14.201.102, vd42link0, 02:45:15
R       172.20.121.0/24 [120/2] via 10.14.202.103, vd43link0, 02:45:15
```

```
# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.14.202.103  0.187 ms  0.054 ms  0.030 ms
 2  172.20.121.5  0.117 ms  0.062 ms  0.040 ms
 3  * * *
```

After:

- You might see different routes, and the routes might change, while convergence is occurring. During convergence, the metric for your default route increases to 16.

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          10.14.202.103        16 10.14.202.103   vd43link0 01:50
```

- After convergence is complete, the RIP database will look similar to the following:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          10.14.201.102         3 10.14.201.102   vd42link0 02:53
R  10.11.101.0/24     10.14.202.103         3 10.14.202.103   vd43link0 03:00
R  10.11.201.0/24     10.14.201.102         2 10.14.201.102   vd42link0 02:53
R  10.11.202.0/24     10.14.202.103         2 10.14.202.103   vd43link0 03:00
R  10.12.101.0/24     10.14.202.103         2 10.14.202.103   vd43link0 03:00
Rc 10.14.101.0/24                           1                 LoAccounting
Rc 10.14.201.0/24                           1                 vd42link0
Rc 10.14.202.0/24                           1                 vd43link0

```

```
# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.14.201.102  0.167 ms  0.063 ms  0.029 ms
 2  172.20.120.5  0.117 ms  0.073 ms  0.041 ms
 3  172.16.151.1  0.303 ms  0.273 ms  0.253 ms
```

Example 2- Additional link failures on Router2

In addition to the link failure on the ISP router in example, port1 and port3 on Router2 have also failed. This means that Router4 must go through Router3, Router1, Router2, then the ISP router to reach the internet. Note that, for a period of time, some routes' metrics increase to 16. If no better routes are found for these networks, then they eventually disappear.

After the convergence completes, the RIP database and routing table on Router4 should resemble the following:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network            Next Hop         Metric From            If     Time
R  0.0.0.0/0          10.14.202.103         5 10.14.202.103   vd43link0 02:54
R  10.11.101.0/24     10.14.202.103         3 10.14.202.103   vd43link0 02:54
R  10.11.201.0/24     10.14.202.103         3 10.14.202.103   vd43link0 02:54
R  10.11.202.0/24     10.14.202.103         2 10.14.202.103   vd43link0 02:54
Rc 10.14.101.0/24                           1                 LoAccounting
Rc 10.14.202.0/24                           1                 vd43link0
R  172.20.120.0/24    10.14.202.103         4 10.14.202.103   vd43link0 02:54
```

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
R*      0.0.0.0/0 [120/5] via 10.14.202.103, vd43link0, 00:03:54
R       10.11.101.0/24 [120/3] via 10.14.202.103, vd43link0, 03:10:12
R       10.11.201.0/24 [120/3] via 10.14.202.103, vd43link0, 00:03:54
R       10.11.202.0/24 [120/2] via 10.14.202.103, vd43link0, 03:10:38
C       10.14.101.0/24 is directly connected, LoAccounting
C       10.14.202.0/24 is directly connected, vd43link0
R       172.20.120.0/24 [120/4] via 10.14.202.103, vd43link0, 00:03:54
```

Reaching the internet on the default gateway now requires five hops from Router4:

```
# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.14.202.103  0.087 ms  0.026 ms  0.012 ms
 2  10.11.202.101  0.045 ms  0.024 ms  0.025 ms
```

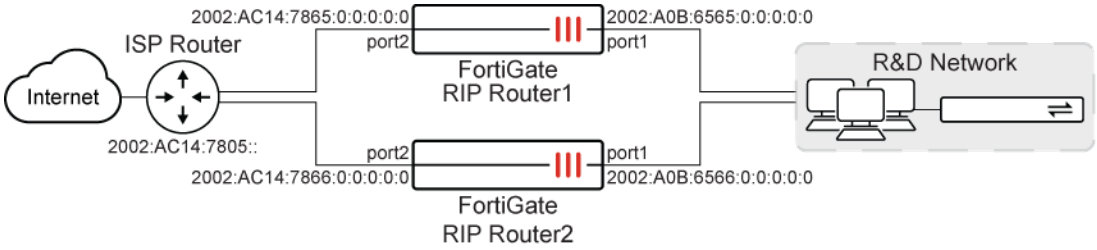
```
3  10.11.201.102  0.048 ms  0.024 ms  0.015 ms
4  172.20.120.5  0.050 ms  0.028 ms  0.019 ms
5  * * *
```

Basic RIPng example

In this example, a small network is configured with RIP next generation (RIPng). Two FortiGates are connected to the internal network and the ISP, providing some redundancy to help ensure that the internal network can always reach the internet.

The FortiGates are running in NAT mode with VDOMs disabled, and firewall policies have already been configured to allow traffic to flow across the interfaces.

All of the internal computers and other network devices support IPv6 addressing and are running RIPng (where applicable), so no static routing is required. Internal network devices only need to know the FortiGate's internal interface network addresses.



Router	Interface (alias)	IPv6 address
Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
	port2 (ISP)	2002:AC14:7865:0:0:0:0:0
Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
	port2 (ISP)	2002:AC14:7866:0:0:0:0:0

On each FortiGate, the interfaces are configured first, and then RIPng. No redistribution or authentication is configured.

In the RIPng configuration, only the interface names are required. The ISP router and the other FortiGate are configured as neighbors. Declaring the neighbors reduces the discovery traffic when the routers start. There is no specific command to include a subnet in the RIP broadcast, and RIPng can only be configured using the CLI.

To configure Router1:

1. Configure the interfaces:

```
config system interface
    edit port1
        set allowaccess ping https ssh
        set type physical
        set description "Internal RnD network"
        set alias "internal"
```

```
        config ipv6
            set ip6-address 2002:a0b:6565::/0
        end
    next
    edit port2
        set allowaccess ping https ssh
        set type physical
        set description "ISP and Internet"
        set alias "ISP"
        config ipv6
            set ip6-address 2002:ac14:7865::/0
        end
    next
end
```

2. Configure RIPng:

```
config router ripng
    config neighbor
        edit 1
            set ip6 2002:a0b:6566::
            set interface port1
        next
        edit 2
            set ip6 2002:ac14:7805::
            set interface port2
        next
    end
    config interface
        edit port1
        next
        edit port2
        next
    end
end
```

To configure Router2:

1. Configure the interfaces:

```
config system interface
    edit port1
        set allowaccess ping https ssh
        set type physical
        set description "Internal RnD network"
        set alias "internal"
        config ipv6
            set ip6-address 2002:a0b:6566::/0
        end
    next
    edit port2
        set allowaccess ping https ssh
```

```
        set type physical
        set description "ISP and Internet"
        set alias "ISP"
        config ipv6
            set ip6-address 2002:ac14:7866::/0
        end
    next
end
```

2. Configure RIPng:

```
config router ripng
    config neighbor
        edit 1
            set ip6 2002:a0b:6565::
            set interface port1
        next
        edit 2
            set ip6 2002:ac14:7805::
            set interface port2
        next
    end
    config interface
        edit port1
        next
        edit port2
        next
    end
end
```

Testing the configuration

The following commands can be used to check the RIPng information on the FortiGates, and can help track down issues:

To view the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate:

```
# diagnose ipv6 address list
```

To view IPv6 addresses that are installed in the routing table:

```
# diagnose ipv6 route list
```

To view the IPv6 routing table:

```
# get router info6 routing-table
```

This information is similar to the `diagnose ipv6 route list` command, but it is presented in an easier to read format.

To view the brief output on the RIP information for the interface listed:

```
# get router info6 rip interface external
```

This includes information such as, if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon is enabled.

OSPF

Open Shortest Path First (OSPF) is a link state routing protocol that is commonly used in large enterprise networks with L3 switches, routers, and firewalls from multiple vendors. It can quickly detect link failures, and converge network traffic without networking loops. It also has features to control which routes are propagated, allowing for smaller routing tables, and provides better load balancing on external links when compared to other routing protocols.

To configure OSPF in the GUI, go to *Network* > *OSPF*:

Option	Description
Router ID	A unique ID to identify your router in the network, typically in the format x.x.x.x.
Areas	The areas that the router is part of. For each are area, define the *Area ID*, *Type*, and *Authentication* method.
Networks	The networks that OSPF is enabled in, and the area that they belong to.
Interfaces	OSPF interfaces for transmitting and receiving packets. Configure interface properties, such as *Network Type*, *Cost*, *Hello interval*, and others.
Advanced Options	Settings for *Inject Default Route*, *Passive Interfaces*, and *Redistribute*. Redistribution can be enabled by protocol and the metric for each protocol can be configured.

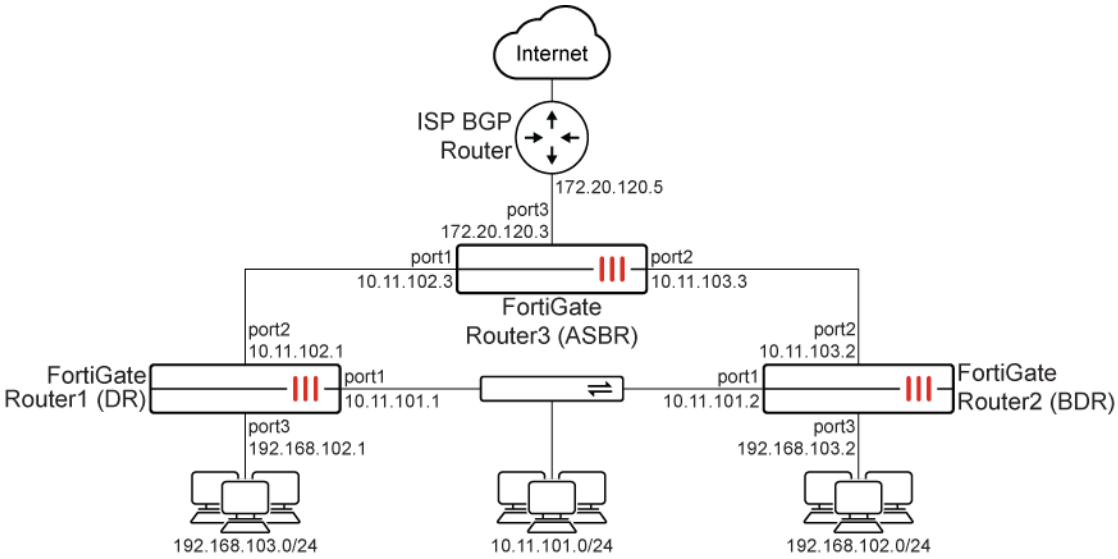
This section includes the following topics:

- Basic OSPF example on page 520
- OSPFv3 neighbor authentication on page 531
- OSPF graceful restart upon a topology change on page 534
- OSPF link detection customization on page 537

Basic OSPF example

In this example, three FortiGate devices are configured in an OSPF network.

- Router1 is the Designated Router (DR). It has the highest priority and the lowest IP address, to ensure that it becomes the DR.
- Router2 is the Backup Designated Router (BDR). It has a high priority to ensure that it becomes the BDR.
- Router3 is the Autonomous System Border Router (ASBR). It routes all traffic to the ISP BGP router for internet access. It redistributes routes from BGP and advertises a default route to its neighbors. It can allow different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics can be assigned to these routes to make them more or less preferred than regular OSPF routes. Route maps could be used to further control what prefixes are advertised or received from the ISP.



FortiGate	Interface	IP address
Router1 (DR)	port1	10.11.101.1
	port2	10.11.102.1
	port3	192.168.102.1
Router2 (BDR)	port1	10.11.101.2
	port2	10.11.103.2
	port3	192.168.103.2
Router3 (ASBR)	port1	10.11.102.3
	port2	10.11.103.3
	port3	172.20.120.3

- Firewall policies are already configured to allow unfiltered traffic in both directions between all of the connected interfaces.
- The interfaces are already configured, and NAT is only used for connections to public networks. The costs for all of the interfaces is left at 0.
- The OSPF network belongs to Area 0, and is not connected to any other OSPF networks. All of the routers are part of the backbone 0.0.0.0 area, so no inter-area communications are needed.
- Router3 redistributes BGP routes into the OSPF AS and peers with the ISP BGP Router over eBGP. For information about configuring BGP, see BGP on page 538.
- The advertised networks - 10.11.101.0, 10.11.102.0, and 10.11.103.0 - are summarized by 10.11.0.0/16. Additional networks are advertised individually by the /24 subnet.

Router1

To configure Router1 in the GUI:

1. Go to *Network* > *OSPF*.
2. Set *Router ID* to *10.11.101.1*.
3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.
5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

6. Click *OK*.
7. In the *Networks* table, click *Create New* again and set the following:

Area	0.0.0.0
IP/Netmask	192.168.102.0 255.255.255.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router1-Internal-DR
Interface	port1
Cost	0
Priority	255
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router1-External
Interface	port2
Cost	0
Authentication	None
Timers	• Hello Interval: 10

• Dead Interval: 40

12. Click *OK*.
13. Click *Apply*.

To configure Router1 in the CLI:

```
config router ospf
    set router-id 10.11.101.1
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit "Router1-Internal-DR"
            set interface "port1"
            set priority 255
            set dead-interval 40
            set hello-interval 10
        next
        edit "Router1-External"
            set interface "port2"
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 1
            set prefix 10.11.0.0 255.255.0.0
        next
        edit 2
            set prefix 192.168.102.0 255.255.255.0
        next
    end
end
```

Router2

To configure Router2 in the GUI:

1. Go to *Network* > *OSPF*.
2. Set *Router ID* to *10.11.101.2*.
3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.

5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

6. Click *OK*.
7. In the *Networks* table, click *Create New* again and set the following:

Area	0.0.0.0
IP/Netmask	192.168.103.0 255.255.255.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router2-Internal
Interface	port1
Cost	0
Priority	250
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router2-External
Interface	port2
Cost	0
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

12. Click *OK*.
13. Click *Apply*.

To configure Router2 in the CLI:

```
config router ospf
    set router-id 10.11.101.2
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit "Router2-Internal"
```

```
            set interface "port1"
            set priority 250
            set dead-interval 40
            set hello-interval 10
        next
        edit "Router2-External"
            set interface "port2"
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 1
            set prefix 10.11.0.0 255.255.0.0
        next
        edit 2
            set prefix 192.168.103.0 255.255.255.0
        next
    end
end
```

Router3

To configure Router3 in the GUI:

1. Go to *Network* > *OSPF*.
2. Set *Router ID* to *10.11.103.3*.
3. Under *Default Settings*, set *Inject default route* to *Regular Areas*.
   A default route must be present on Router3 to advertise it to other routers.
4. Enable *Redistribute BGP* and use the default settings.
5. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

6. Click *OK*.
7. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router3-Internal
Interface	port1

Cost	0
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router3-Internal2
Interface	port2
Cost	0
Authentication	None
Timers	• Hello Interval: 10 • Dead Interval: 40

12. Click *OK*.
13. Click *Apply*.

To configure Router3 in the CLI:

```
config router ospf
    set default-information-originate enable
    set router-id 10.11.103.3
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit "Router3-Internal"
            set interface "port1"
            set dead-interval 40
            set hello-interval 10
        next
        edit "Router3-Internal2"
            set interface "port2"
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 1
            set prefix 10.11.0.0 255.255.0.0
        next
    end
    config redistribute "bgp"
        set status enable
```

```
    end
end
```

To configure BGP on Router3 in the CLI:

```
config router bgp
    set as 64511
    set router-id 1.1.1.1
    config neighbor
        edit "172.20.120.5"
            set remote-as 64512
        next
    end
    config network
        edit 1
            set prefix 172.20.120.0 255.255.255.0
        next
    end
end
```

For more information on configuring BGP, see BGP on page 538.

Testing the configuration

Both the network connectivity and OSPF routing are tested. When a link goes down, routes should converge as expected.

Working state

- Router3:

```
Router3 # get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
10.11.101.1       1   Full/Backup     00:00:34    10.11.102.1     port1
10.11.101.2       1   Full/Backup     00:00:38    10.11.103.2     port2
```

```
Router3 # get router info ospf status
 Routing Process "ospf 0" with ID 10.11.103.3
 Process uptime is 18 hours 52 minutes
 Process bound to VRF default
 Conforms to RFC2328, and RFC1583Compatibility flag is disabled
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 Do not support Restarting
 This router is an ASBR (injecting external routing information)
 SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
 Refresh timer 10 secs
 Number of incomming current DD exchange neighbors 0/5
 Number of outgoing current DD exchange neighbors 0/5
```

```
 Number of external LSA 3. Checksum 0x021B78
 Number of opaque AS LSA 0. Checksum 0x000000
 Number of non-default external LSA 2
 External LSA database is unlimited.
 Number of LSA originated 16
 Number of LSA received 100
 Number of areas attached to this router: 1
    Area 0.0.0.0 (BACKBONE)
        Number of interfaces in this area is 2(2)
        Number of fully adjacent neighbors in this area is 2
        Area has no authentication
        SPF algorithm last executed 00:37:36.690 ago
        SPF algorithm executed 13 times
        Number of LSA 6. Checksum 0x03eafa
```

```
Router3 # get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
B*      0.0.0.0/0 [20/0] via 172.20.120.5, port3, 01:10:12
O       10.11.101.0/24 [110/2] via 10.11.103.2, port2, 00:39:34
                       [110/2] via 10.11.102.1, port1, 00:39:34
C       10.11.102.0/24 is directly connected, port1

```

OSPFv3 neighbor authentication

OSPFv3 neighbor authentication is available for enhanced IPv6 security.

To configure an OSPF6 interface:

```
config router ospf6
    config ospf6-interface
        edit <name>
            set authentication {none | ah | esp | area}
            set key-rollover-interval <integer>
            set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
            set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
            config ipsec-keys
                edit <spi>
                    set auth-key <string>
                    set enc-key <string>
                next
            end
        next
    end
end
```

To configure an OSPF6 virtual link:

```
config router ospf6
    config area
        edit <id>
            config virtual-link
                edit <name>
                    set authentication {none | ah | esp | area}
                    set key-rollover-interval <integer>
                    set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
                    set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
                    config ipsec-keys
                        edit <spi>
                            set auth-key <string>
                            set enc-key <string>
                        next
                    end
                next
            end
        next
    end
end
```

To configure an OSPF6 area:

```
config router ospf6
    config area
        edit <id>
            set authentication {none | ah | esp}
            set key-rollover-interval <integer>
            set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
            set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
```

```
            config ipsec-keys
                edit <spi>
                    set auth-key <string>
                    set enc-key <string>
                next
            end
        next
    end
end
```

CLI command descriptions

Command	Description
<id>	Area entry IP address.
authentication {none | ah | esp | area}	Authentication mode: • none: Disable authentication • ah: Authentication Header • esp: Encapsulating Security Payload • area: Use the routing area authentication configuration
key-rollover-interval <integer>	Enter an integer value (300 - 216000, default = 300).
ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}	Authentication algorithm.
ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}	Encryption algorithm.
<spi>	Security Parameters Index.
auth-key <string>	Authentication key should be hexadecimal numbers. Key length for each algorithm: • MD5: 16 bytes • SHA1: 20 bytes • SHA256: 32 bytes • SHA384:48 bytes • SHA512:84 bytes If the key is shorter than the required length, it will be padded with zeroes.
enc-key <string>	Encryption key should be hexadecimal numbers. Key length for each algorithm: • DES: 8 bytes • 3DES: 24 bytes • AES128: 16 bytes • AES192: 24 bytes • AES256: 32 bytes If the key is shorter than the required length, it will be padded with zeroes.

OSPF graceful restart upon a topology change

In OSPF graceful restart mode, the `restart-on-topology-change` option can be used to keep restarting the router in graceful restart mode when a topology change is detected during a restart.

```
config router ospf
    set restart-on-topology-change {enable | disable}
end
```

OSPFv3 graceful restart mode upon a topology change can be used in OSPF6:

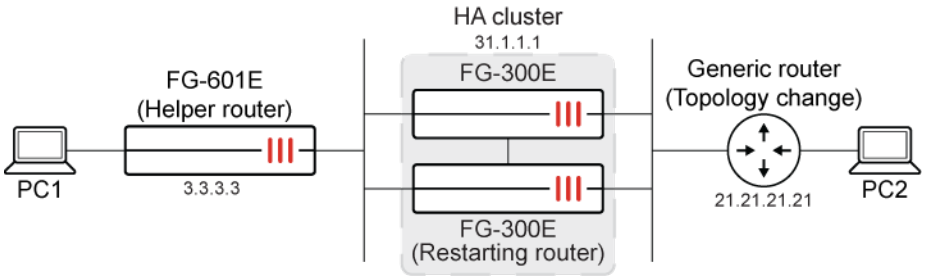
```
config router ospf6
    set restart-on-topology-change {enable | disable}
end
```

Example

In this example, a restarting router (one of the FG-300Es in the HA cluster) informs its neighbors using grace LSAs before restarting its OSPF process. When the helper router (the FG-601E) receives the grace LSAs, it enters helper mode to help with the graceful restart until the graceful period expires. It will act as though there are no changes on the restarting router (FG-300E). A generic router simulates a topology change during the restart event.

If `restart-on-topology-change` is enabled on the restarting router, it will not exit the graceful restart mode even when a topology change is detected.

If `restart-on-topology-change` is disabled on the restarting router, it will exit graceful restart mode when a topology change is detected.



To configure the restarting router:

```
config router ospf
    set router-id 31.1.1.1
    set restart-mode graceful-restart
    set restart-period 180
    set restart-on-topology-change enable
    config area
        edit 0.0.0.0
        next
    end
    config network
```

```
        edit 1
            set prefix 172.16.200.0 255.255.255.0
        next
        edit 2
            set prefix 31.1.1.1 255.255.255.255
        next
    end
end
```

To configure the restarting helper router:

```
config router ospf
    set router-id 3.3.3.3
    set restart-mode graceful-restart
    config area
        edit 0.0.0.0
        next
    end
    config network
        edit 1
            set prefix 172.16.200.0 255.255.255.0
        next
        edit 2
            set prefix 3.3.3.3 255.255.255.255
        next
    end
end
```

Testing the configuration

Topology change with continuing graceful restart enabled:

When `restart-on-topology-change` is enabled and there is a topology change during the HA OSPF graceful restart, the graceful restart will continue. The routes on the helper router (FG-601E) are still there and no traffic will drop.

```
# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:47*   172.16.200.31   port1
```

```

O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:10:37
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:56:13
O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:13:13
```

Topology change with continuing graceful restart disabled:

When `restart-on-topology-change` is disabled and there is a topology change during the HA OSPF graceful restart, the graceful restart will exit. The routes on the helper router (FG-601E) are lost and traffic will drop.

```
# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:57*   172.16.200.31   port1
```

```
# get router info routing-table ospf
Routing table for VRF=0
O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:11:16
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:56:52
O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:13:52
```

```
# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:42*   172.16.200.31   port1
```

```
# get router info routing-table ospf
Routing table for VRF=0
O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:11:31
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:57:07
O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:14:07
```

```
# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:40*   172.16.200.31   port1
```

No routes are lost:

```
# get router info routing-table ospf
Routing table for VRF=0
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:57:09
```

```
# get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID     Pri   State           Dead Time   Address         Interface
31.1.1.1          1   Full/DR         00:14:38*   172.16.200.31   port1
```

No routes are lost:

```
# get router info routing-table ospf
Routing table for VRF=0
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 00:57:11
```

No routes are lost:

```
# get router info routing-table ospf
Routing table for VRF=0
O       21.21.21.21/32 [110/300] via 172.16.200.31, port1, 00:04:42
O       31.1.1.1/32 [110/200] via 172.16.200.31, port1, 01:01:59
O       100.21.1.0/24 [110/200] via 172.16.200.31, port1, 00:04:42
```

OSPF link detection customization

OSPF route detection and interface-down detection can be customized by customizing the Link State Advertisement (LSA) refresh intervals and enabling fast-link failover using the `config router ospf` command:

```
config router ospf
    set lsa-refresh-interval <integer>
    config ospf-interface
        edit <name>
            set interface <string>
            set linkdown-fast-failover {enable | disable}
        next
```

```
    end
end
```

`set lsa-refresh-interval <integer>`	How often LSA refreshes for OSPF, in seconds (0 to 5, default = 5).
`set linkdown-fast-failover {enable | disable}`	Enable/disable fast link failover. • `enable`: OSPF updates the link status from `up` to `down` and advertises the LSA update as soon as the underlying physical interface goes down. • `disable`: Disable the use of OSPF and use the kernal detection and notification instead. Used when the `ospf-interface` interface attribute is configured, and the type of the underlying interface is VLAN.

BGP

Border Gateway Protocol (BGP) is a standardized routing protocol that is used to route traffic across the internet. It exchanges routing information between Autonomous Systems (AS) on the internet and makes routing decisions based on path, network policies, and rule sets. BGP contains two distinct subsets: internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect different networks together and is the main routing protocol for the internet backbone.

To configure BGP in the GUI, go to *Network > BGP*:

Option	Description
Local AS	The AS number for the local router.
Router ID	A unique ID to identify your router in the network, typically in the format x.x.x.x.
Neighbors	The neighbors that the FortiGate will be peering with. Configure the remote router's AS number, any other properties used for peering with the neighbor, and IPv4 and IPv6 filtering.
Neighbor Groups	The neighbor groups that share the same outbound policy configurations.
Neighbor Ranges	The source address range of BGP neighbors that will be automatically assigned to a neighbor group.
Networks	The IPv4 networks to be advertised to other BGP routers. Choose from: • *IP/Netmask*: Specify the IPv4 address and netmask. • *Firewall Address*: Select an existing firewall address or group with `allow-routing` enabled. See Using firewall addresses and groups for BGP network prefixes on page 591.
IPv6 Networks	The IPv6 networks to be advertised to other BGP routers.
IPv4 & IPv6 Redistribute	Enable redistribution by protocol. Specify either *All* routes, or *Filter* by route map.

Option	Description
Dampening	Enable route flap dampening to reduce the propagation of flapping routes.
Graceful Restart	Enable BGP graceful restart, which causes the adjacent routers to keep routes active while the BGP peering is restarted on the FortiGate. This is useful in HA instances when failover occurs.
Advanced Options	Various advanced settings, such as *Local Preference*, *Distance internal*, *Keepalive*, *Holdtime*, and others
Best Path Selection	Configure path selection attributes on this router.

This section includes the following topics:

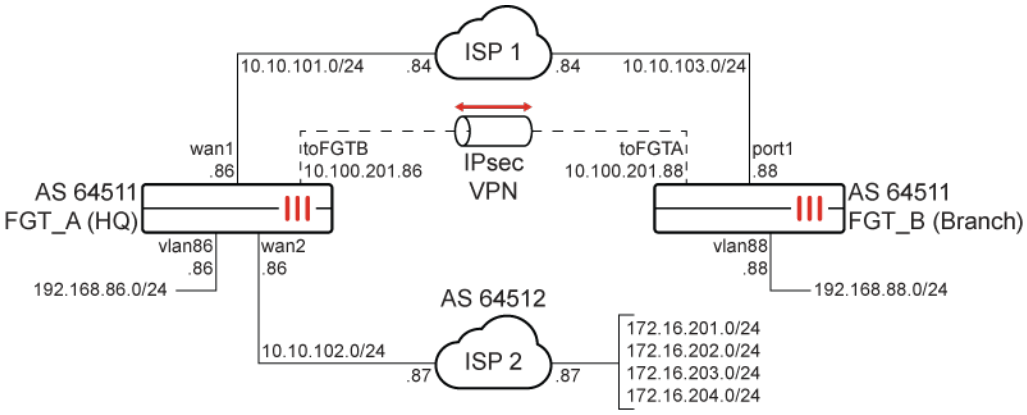
- Basic BGP example on page 539
- Route filtering with a distribution list on page 549
- Next hop recursive resolution using other BGP routes on page 553
- Next hop recursive resolution using ECMP routes on page 554
- Next hop recursive resolution using IPv6 prefix with on-link flag from route aggregation New on page 555
- BGP conditional advertisement on page 557
- BGP error handling per RFC 7606 on page 573
- BGP next hop tag-match mode on page 574
- BGP neighbor password on page 580
- Defining a preferred source IP for local-out egress interfaces on BGP routes on page 581
- BGP multi-exit discriminator on page 584
- TCP Authentication Option advanced security measures on page 588
- Assigning multiple remote Autonomous Systems to a single BGP neighbor group on page 590
- Using firewall addresses and groups for BGP network prefixes on page 591
- Troubleshooting BGP on page 593

Basic BGP example

In this example, BGP is configured on two FortiGate devices. The FortiGates are geographically separated, and form iBGP peering over a VPN connection. FGT_A also forms eBGP peering with ISP2.

FGT_A learns routes from ISP2 and redistributes them to FGT_B while preventing any iBGP routes from being advertised.

The internal networks behind the FortiGates can communicate with each other, and the internal networks behind FGT_B can traverse FGT_A to reach networks that are advertised by ISP2.



- FGT_A and FGT_B have static routes to each other through ISP1. ISP1 does not participate in BGP.
- The IPsec VPN tunnel between FGT_A and FGT_B is configured with wildcard 0.0.0.0/0 networks for phase2 local and remote selectors. The VPN interfaces have IP addresses already configured and are used for peering between FGT_A and FGT_B.
- FGT_A is configure to peer with ISP2 on 10.10.108.86.
- The firewall policies between FGT_A and FGT_B are not NATed. The firewall policies egressing on wan2 are NATed.

Configuring iBGP peering

To configure FGT_A to establish iBGP peering with FGT_B in the GUI:

1. Go to *Network* > *BGP*.
2. Set *Local AS* to *64511*
3. Set *Router ID* to *1.1.1.1*.
4. In the *Neighbors* table, click *Create New* and set the following:

IP	10.100.201.88
Remote AS	64511

5. Click *OK*.
6. Under *Networks*, set *IP/Netmask* to *192.168.86.0/24*.
7. Click *Apply*.
8. In the CLI, set the interface used as the source IP address of the TCP connection (where the BGP session, TCP/179, is connecting from) for the neighbor (`update-source`) to `toFGTB`.

To configure FGT_A to establish iBGP peering with FGT_B in the CLI:

```
config router bgp
    set as 64511
    set router-id 1.1.1.1
    config neighbor
        edit "10.100.201.88"
            set remote-as 64511
            set update-source "toFGTB"
```

```
        next
    end
    config network
        edit 1
            set prefix 192.168.86.0 255.255.255.0
        next
    end
end
```

To configure FGT_B to establish iBGP peering with FGT_A in the GUI:

1. Go to *Network > BGP*.
2. Set *Local AS* to *64511*
3. Set *Router ID* to *2.2.2.2*.
4. In the *Neighbors* table, click *Create New* and set the following:

IP	10.100.201.86
Remote AS	64511

5. Click *OK*.
6. Under *Networks*, set *IP/Netmask* to *192.168.88.0/24*.
7. Click *Apply*.
8. In the CLI, set the interface used as the source IP address of the TCP connection (where the BGP session, TCP/179, is connecting from) for the neighbor (`update-source`) to `toFGTA`.

To configure FGT_B to establish iBGP peering with FGT_A in the CLI:

```
config router bgp
    set as 64511
    set router-id 2.2.2.2
    config neighbor
        edit "10.100.201.86"
            set remote-as 64511
            set update-source "toFGTA"
        next
    end
    config network
        edit 1
            set prefix 192.168.88.0 255.255.255.0
        next
    end
end
```

To check the FGT_A and FGT_B peering:

1. Check the BGP neighbors:

```
# get router info bgp neighbors
```

2. Check the networks learned from neighbors:

```
# get router info bgp network
```

3. Check that the routes are added to the routing table:

```
# get router info routing-table all
```

To see the neighborship status, network, and routing table command outputs for the completed example, see Troubleshooting and debugging on page 544.

Configuring eBGP peering

By establishing eBGP peering with ISP2, learned routes will have a distance of 20 and will automatically be propagated to iBGP peers. iBGP peers do not change the next hop when they advertise a route. To make FGT_B receive a route with FGT_A as the next hop, and not ISP 2's network, *Next hop self* (`next-hop-self`) is enabled for routes advertised to FGT_B.

Additionally, to peer with another router that is multiple hops away, enable `ebg-enforce-multihop` in the neighbor configuration.

In this example, the iBGP routes are automatically advertised to the eBGP neighbor, so a route map is created to deny iBGP routes from being advertised to ISP 2. Prefixes from ISP 2 are advertised to FGT_A and FGT_B, but no prefixes are advertised from FGT_A to ISP 2.

To configure FGT_A to establish eBGP peering with ISP 2 in the GUI:

1. Configure a route map to prevent advertisement of iBGP routes to ISP 2:
   a. Go to *Network* > *Routing Objects* and click *Create New* > *Route Map*.
   b. Set *Name* to *exclude1*.
   c. In the *Rules* table, click *Create New*.
   d. Set *Action* to *Deny*.
   e. Under *Other Rule Variables*, enable *Match origin* and set it to *IGP*.
   f. Click *OK*.
   g. Click *OK*.
2. Update the BGP configuration:
   a. Go to *Network* > *BGP*.
   b. In the *Neighbors* table, click *Create New* and set the following:

IP	10.10.102.87
Remote AS	64512
Route map out	exclude1

   c. Click *OK*.
   d. In the *Neighbors* table, edit the previously created entry, *10.100.201.88*.
   e. Under *IPv4 Filtering*, select *Next hop self*.
   f. Click *OK*.
   g. Click *Apply*.

To configure FGT_A to establish eBGP peering with ISP 2 in the CLI:

1. Configure a route map to prevent advertisement of iBGP routes to ISP 2:

```
config router route-map
    edit "exclude1"
        config rule
            edit 1
                set action deny
                set match-origin igp
            next
        end
    next
end
```

2. Update the BGP configuration:

```
config router bgp
    config neighbor
        edit "10.10.102.87"
            set remote-as 64512
            set route-map-out "exclude1"
        next
        edit "10.100.201.88"
            set next-hop-self enable
        next
    end
end
```

To see the neighborship status, network, and routing table command outputs for the completed example, see Troubleshooting and debugging on page 544.

Firewall policies

On FGT_A configure the following policies:

- Allow the internal subnet to the VPN interface. Do not enable NAT. Enable security profiles as required.
- Allow the VPN interface to the internal subnet. Do not enable NAT. Enable security profiles as required.
- Allow the internal subnet to wan2. Enable NAT and security profiles as required.
- Allow VPN traffic from toFGTA to wan2. Enable NAT and security profiles as required.

On FGT_B configure the following policies:

- Allow the internal subnet to the VPN interface. Do not enable NAT. Enable security profiles as required.
- Allow the VPN interface to the internal subnet. Do not enable NAT. Enable security profiles as required.

To verify that pinging from FGT_B to FGT_A is successful:

```
FGT_B # execute ping-options source 192.168.88.88
FGT_B # execute ping 192.168.86.86
PING 192.168.86.86 (192.168.86.86): 56 data bytes
64 bytes from 192.168.86.86: icmp_seq=0 ttl=255 time=0.5 ms
```

```
...
--- 192.168.86.86 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.3/0.3/0.5 ms
```

To verify that pinging from FGT_B to a subnet in ISP 2 is successful:

```
FGT_B # execute ping-options source 192.168.88.88
FGT_B # execute ping 172.16.201.87
PING 172.16.201.87 (172.16.201.87): 56 data bytes
64 bytes from 172.16.201.87: icmp_seq=0 ttl=254 time=0.6 ms
...
--- 172.16.201.87 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.4/0.4/0.6 ms

FGT_B # execute traceroute-options source 192.168.88.88
FGT_B # execute traceroute 172.16.201.87
traceroute to 172.16.201.87 (172.16.201.87), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.100.201.86  0.315 ms  0.143 ms  0.110 ms
 2  172.16.201.87  0.258 ms  0.144 ms  0.222 ms
```

Troubleshooting and debugging

When troubleshooting issues, logically step through the debugs. For example, if peering cannot be established between FGT_A and FGT_B:

1. Verify the basic connectivity between the FGT_A wan1 interface and the FGT_B port1 interface.
2. Verify that the VPN between FGT_A and FGT_B is established.
3. Verify the connectivity between the VPN interfaces.
4. Check the neighborship status on each peer. Use the BGP state to help determine the possible issue, for example:

Idle state	The local FortiGate has not started the BGP process with the neighbor. This could be because the eBGP peer is multiple hops away, but multihop is not enabled.
Connect	The local FortiGate has started the BGP process, but has not initiated a TCP connection, possibly due to improper routing.
Active	The local FortiGate has initiated a TCP connection, but there is no response. This might indicate issues with the delivery or the response from the remote peer.

5. If there are issues establishing the TCP connection, use the command `diagnose sniffer packet any 'tcp and port 179'` to identify the problem at the packet level.

The following outputs show instances where all of the configurations are completed, peering has formed, and routes have been exchanged. The debug output during each configuration step might differ from these outputs. These debug outputs can be used to help identify what might be missing or misconfigured on your device.

To verify the status of the neighbors:

```
FGT_A # get router info bgp neighbors
VRF 0 neighbor table:
BGP neighbor is 10.10.102.87, remote AS 64512, local AS 64511, external link

```

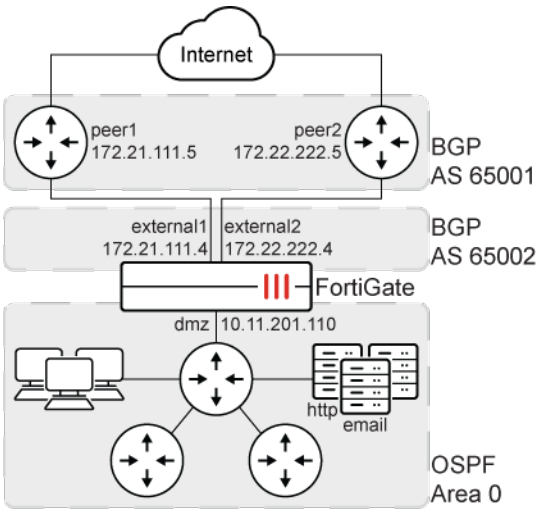
Route filtering with a distribution list

During BGP operations, routes can be propagated between BGP peers and redistributed from other routing protocols. In some situations, advertising routes from one peer to another might need to be prevented.

The Basic BGP example on page 539 explains using a route map to filter routes that are learned from iBGP to prevent them from propagating to an eBGP peer. In this example, a distribution list is used to prevent certain routes from one peer from being advertised to another peer.



- A company has its own web and email servers in an OSPF area, and needs to advertise routes to these resources to external peers. Users, routers, and other server all reside in the OSPF area.
- The FortiGate acts as the BGP border router, redistributing routes from the company's network to its BGP peers. It is connected to the OSPF area using its DMZ interface.
- Two ISP managed BGP peers in an AS (Peer 1 and Peer 2) are used to access the internet, and routes must not to be advertised from Peer 1 to Peer 2. The manufacturers of these routers, and information about other devices on the external BGP AS, are not known.
- Routes to the BGP peers are redistributed so that external locations can access the web and email servers in the OSPF area. The FortiGate device's external interfaces and the BGP peers are in different ASs, and form eBGP peers.
- Other networking devices must be configured for BGP. The peer routers must be updated with the FortiGate device's BGP information, including IP addresses, AS number, and any specific capabilities that are used, such as IPv6, graceful restart, BFD, and so on.
- It is assumed that security policies have been configured to allow traffic between the networks and NAT is not used. To tighten security, only the required services should be allowed inbound to the various servers.
- In a real life scenario, public IP addresses would be used in place of private IP addresses.

Configuring BGP

In this example, Peer 1 routes are blocked from being advertised to Peer 2 using an access list. All incoming routes from Peer 1 are blocked when updates are sent to Peer 2.

Routes learned from OSPF are redistributed into BGP. EBGP multi path is enabled to load-balance traffic between the peers using ECMP. See Equal cost multi-path on page 487 for more information.

To configure BGP in the GUI:

1. Configure an access list to block Peer 1 routes:
   a. Go to *Network* > *Routing Objects* and click *Create New* > *Access List*.
   b. Set *Name* to *block_peer1*.
   c. In the *Rules* table, click *Create New*.
   d. Set *Action* to *Deny*.
   e. Enable *Exact Match* and specify the prefix *172.21.111.0 255.255.255.0*.
   f. Click *OK*.
   g. Click *OK*.
2. Configure BGP:
   a. Go to *Network* > *BGP*.
   b. Set *Local AS* to *65001*
   c. Set *Router ID* to *10.11.201.110*.
   d. In the *Neighbors* table, click *Create New* and set the following:

IP	172.21.111.5
Remote AS	65001

   e. Click *OK*.
   f. In the *Neighbors* table, click *Create New* again and set the following:

IP	172.22.222.5
Remote AS	65001
Distribute list out	Enable, and select the *block_peer1* access list.

   g. Click *OK*.
   h. Under *IPv4 Redistribute*, enable *OSPF* and select *ALL*.
   i. Expand *Best Path Selection* and enable *EBGP multi path*.
   j. Click *Apply*.

To configure BGP in the CLI:

1. Configure an access list to block Peer 1 routes:

```
config router access-list
    edit "block_peer1"
        config rule
            edit 1
```

```
                set action deny
                set prefix 172.21.111.0 255.255.255.0
                set exact-match enable
            next
        end
    next
end
```

2. Configure BGP:

```
config router bgp
    set as 65001
    set router-id 10.11.201.110
    set ebgp-multipath enable
    config neighbor
        edit "172.21.111.5"
            set remote-as 65001
        next
        edit "172.22.222.5"
            set distribute-list-out "block_peer1"
            set remote-as 65001
        next
    end
    config redistribute "ospf"
        set status enable
    end
end
```

Configuring OSPF

In this example, all of the traffic is within the one OSPF area, and there are other OSPF routers in the network. When adjacencies are formed, other routers receive the routes advertised from the FortiGate that are redistributed from BGP.

To configure OSPF in the GUI:

1. Go to *Network* > *OSPF*.
2. Set *Router ID* to *10.11.201.110*.
3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.
5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.201.0 255.255.255.0

6. Click *OK*.
7. In the *Interfaces* table, click *Create New* and set the following:

Name	OSPF_dmz_network
Interface	dmz

8. Click *OK*.
9. Enable *Redistribute BGP* and set *Metric value* to *1*.
10. Click *Apply*.

To configure OSPF in the CLI:

```
config router ospf
    set router-id 10.11.201.110
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit "OSPF_dmz_network"
            set interface "dmz"
        next
    end
    config network
        edit 1
            set prefix 10.11.201.0 255.255.255.0
        next
    end
    config redistribute "bgp"
        set status enable
        set metric 1
    end
end
```

Testing the configuration

To test this configuration, run the standard connectivity checks, and also make sure that routes are being passed between protocols as expected. Use the following checklist to help verify that the FortiGate is configured successfully:

1. Check that the FortiGate has established peering with BGP Peer 1 and Peer 2:

```
# get router info bgp summary
```

```
# get router info bgp neighbors
```

2. Check that the FortiGate has formed adjacency with OSPF neighbors:

```
# get router info ospf status
```

```
# get router info ospf neighbors
```

3. Check the routing table on the FortiGate to make sure that routes from both OSPF and BGP are included:

```
# get router info routing-table all
```

4. Check devices in the OSPF network for internet connectivity and to confirm that routes redistributed from BGP are in their routing tables.
5. Check the routing table on Peer 2 to confirm that no routes from Peer 1 are included.
6. Check that the routes from the internal OSPF network are redistributed to Peer 1 and Peer 2.
7. Verify connectivity to the HTTP and email servers.

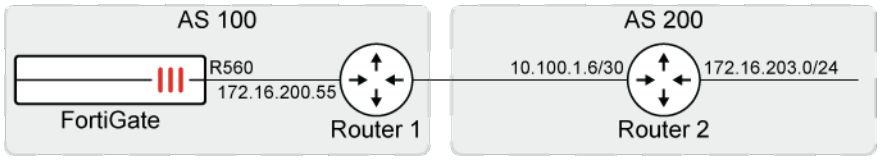
Next hop recursive resolution using other BGP routes

By default, BGP routes are not considered when a BGP next hop requires recursive resolution. They are considered when `recursive-next-hop` is enabled. Recursive resolution will resolve to one level.

To consider BGP routes for recursive resolution of next hops:

```
config router bgp
    set recursive-next-hop enable
end
```

Example



To see the change in the routing table when the option is enabled:

1. Check the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B       10.100.1.4/30 [200/0] via 10.100.1.14 (recursive is directly connected, R560),
00:02:06
```

2. Enable BGP routes for recursive resolution of next hops:

```
config router bgp
    set recursive-next-hop enable
end
```

3. Check the BGP routing table again:

```
# get router info routing-table bgp
Routing table for VRF=0
B       10.100.1.4/30 [200/0] via 10.100.1.14 (recursive is directly connected, R560),
```

```
00:02:15
B       172.16.203.0/24 [200/0] via 10.100.1.6 (recursive via 10.100.1.14, R560), 00:00:06
```

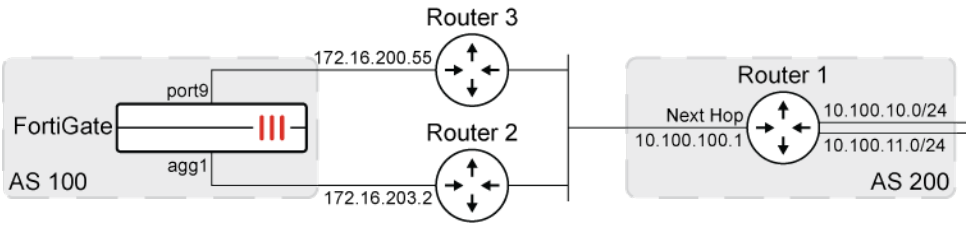
The second BGP route's next hop is now recursively resolved by another BGP route.

Next hop recursive resolution using ECMP routes

When there are multiple ECMP routes to a BGP next hop, all of them are considered for the next hop recursive resolution. This ensures that the outgoing traffic can be load balanced.

To support multipath, either EGBP or IGBP multipath must be enabled:

```
config router bgp
    set ebgp-multipath enable
    set ibgp-multipath enable
end
```



In this example, there are two static routes. The FortiGate has learned two BGP routes from Router 1 that have the same next hop at 10.100.100.1. The next hop is resolved by the two static routes.

To verify that the routes are added to the BGP routing table:

1. Check the two static routes:

```
# get router info routing-table static
Routing table for VRF=0
S       10.100.100.0/24 [10/0] via 172.16.200.55, port9
                        [10/0] via 172.16.203.2, agg1
```

2. Confirm that both routes are in the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B       10.100.10.0/24 [20/200] via 10.100.100.1 (recursive via 172.16.200.55, port9),
00:00:07
                                                 (recursive via 172.16.203.2, agg1), 00:00:07
B       10.100.11.0/24 [20/200] via 10.100.100.1 (recursive via 172.16.200.55, port9),
00:00:07
                                                 (recursive via 172.16.203.2, agg1), 00:00:07
```

Next hop recursive resolution using IPv6 prefix with on-link flag from route aggregation NEW

When a FortiGate is acting as an IPv4 BGP neighbor and using stateful DHCPv6, it learns BGP routes with the IPv6 next hop belonging to an on-link prefix that is advertised through route aggregation (RA).

By default, the administrative distance for routes learned from the kernel is 255, and the routes do not interfere with the current route selection. To make the RA route usable by BGP, the distance must be set to less than 255 using the new `kernel-route-distance` command.

```
config router setting
    set kernel-route-distance <0-255>
end
```

If there are other user space routes with the same prefix, the best route is selected based on the distance.

To check the effect of changing the administrative distance:

1. Configure FGT_A:

```
config system interface
    edit "agg1"
        set vdom "root"
        set ip 172.16.203.1 255.255.255.0
        set allowaccess ping https http
        set type aggregate
        set member "port4"
        set alias "To_FGT_B_agg1"
        set lldp-transmission enable
        set snmp-index 40
        config ipv6
            set ip6-mode dhcp
            set ip6-allowaccess ping
        end
    next
end
```

2. Configure FGT_B (RA):

```
config system interface
    edit "agg2"
        set vdom "root"
        set ip 172.16.203.2 255.255.255.0
        set allowaccess ping https http
        set bfd disable
        set type aggregate
        set member "port4"
        set alias "To_FGT_A_agg1"
        set lldp-transmission enable
        set snmp-index 28
        config ipv6
```

```
            set ip6-address 2001:4::133/64
            set ip6-allowaccess ping
            set ip6-send-adv enable
            set ip6-manage-flag enable
            set ip6-other-flag enable
            set ip6-max-interval 10
            set ip6-min-interval 5
            config ip6-prefix-list
                edit 2001:4::/64
                next
            end
        end
    next
end
```

```
config system dhcp6 server
    edit 1
        set subnet 2001:4::/64
        set interface "agg2"
        config ip-range
            edit 1
                set start-ip 2001:4::11
                set end-ip 2001:4::20
            next
        end
    next
end
```

3. By default, the learned kernel route has a distance of 255 and does not interfere with the current route selection:

```
FGT_A (root)# get router info6 routing-table database
IPv6 Routing Table
Codes: K - kernel route, C - connected, S - static, R - RIP, O - OSPF,
       IA - OSPF inter area

[1024/0]
R    *> 2000:172:16:210::/64 [120/2] via fe80::96f3:92ff:fe15:f7b, vlan100, 00:03:10, [1024/0]
C    *> 2000:172:16:211::/64 via ::, sit_A_D, 00:03:33
B    *> 2000:172:27:1::/64 [200/0] via 2000::2:2:2:2 (recursive via fe80::96f3:92ff:fe15:f7b,
agg1), 00:01:25, [1024/0]
K    *  2001:4::/64 via ::, agg1, 00:00:20
O    *> 2001:4::/64 [110/100] via ::, agg1, 00:00:24, [1024/0]
```

```
FGT_A (root)# get router info6 routing-table kernel
No route available
```

4. Change the distance to 254:

```
FGT_A (root)# config router setting
    set kernel-route-distance 254
end
```

5. Now there is a kernel route:

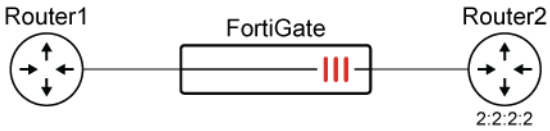
```
FGT_A (root)# get router info6 routing-table kernel
Routing table for VRF=0
K*      ::/0 [254/1024] via fe80::96f3:92ff:fe15:f7b, agg1, 00:01:04
...
```

BGP conditional advertisement

BGP conditional advertisement allows the router to advertise a route only when certain conditions are met. Multiple conditions can be used together, with conditional route map entries treated as an AND operator, and IPv6 is supported.

Multiple conditions example

In this example, the FortiGate only advertises routes to its neighbor 2.2.2.2 if it learns multiple BGP routes defined in its conditional route map entry. All conditionals must be met.



To configure multiple conditions in BGP conditional advertisements:

1. Configure the IPv4 prefix list:

```
config router prefix-list
    edit "281"
        config rule
            edit 1
                set prefix 172.28.1.0 255.255.255.0
                unset ge
                unset le
            next
        end
    next
    edit "282"
        config rule
            edit 1
                set prefix 172.28.2.0 255.255.255.0
                unset ge
                unset le
            next
        end
    next
    edit "222"
        config rule
            edit 1
                set prefix 172.22.2.0 255.255.255.0
                unset ge
                unset le
            next
        end
    next
end
```

2. Configure the IPv4 route maps:

```
config router route-map
    edit "2814"
        config rule
            edit 1
                set match-ip-address "281"
            next
```

```
        end
    next
    edit "2224"
        config rule
            edit 1
                set match-ip-address "222"
            next
        end
    next
    edit "2824"
        config rule
            edit 1
                set match-ip-address "282"
            next
        end
    next
end
```

3. Configure the IPv6 prefix list:

```
config router prefix-list6
    edit "adv-2226"
        config rule
            edit 1
                set prefix6 2003:172:22:1::/64
                unset ge
                unset le
            next
        end
    next
    edit "list6-1"
        config rule
            edit 1
                set prefix6 2003:172:28:1::/64
                unset ge
                unset le
            next
        end
    next
    edit "list6-2"
        config rule
            edit 1
                set prefix6 2003:172:28:2::/64
                unset ge
                unset le
            next
        end
    next
end
```

4. Configure the IPv6 route maps:

```
config router route-map
    edit "map-2226"
        config rule
            edit 1
                set match-ip6-address "adv-2226"
            next
        end
    next
    edit "map-2816"
        config rule
            edit 1
                set match-ip6-address "list6-1"
            next
        end
    next
    edit "map-2826"
        config rule
            edit 1
                set match-ip6-address "list6-2"
            next
        end
    next
end
```

5. Configure the BGP settings:

```
config router bgp
    config neighbor
        edit "2.2.2.2"
            config conditional-advertise
                edit "2224"
                    set condition-routemap "2814" "2824"
                    set condition-type non-exist
                next
            end
        next
        edit "2003::2:2:2:2"
            config conditional-advertise6
                edit "map-2226"
                    set condition-routemap "map-2816" "map-2826"
                next
            end
            set route-reflector-client6 enable
        next
    end
end
```

To verify the IPv4 conditional advertisements:

```
# get router info bgp neighbors 2.2.2.2
...
  Conditional advertise-map:
        Adv-map 2224root 2814root, cond-state 0-1
                         2824root, cond-state 0-1
...
```

In this output, the condition is that the routes in route maps 2814 and 2824 do not exist. However, routes for 2814 and 2224 exist, so the conditions are not met.

To verify the IPv6 conditional advertisements:

```
# get router info6 bgp neighbors 2003::2:2:2:2
...
  Conditional advertise-map:
        Adv-map map-2226root map-2816root, cond-state 1-1
                            map-2826root, cond-state 1-0
...
```

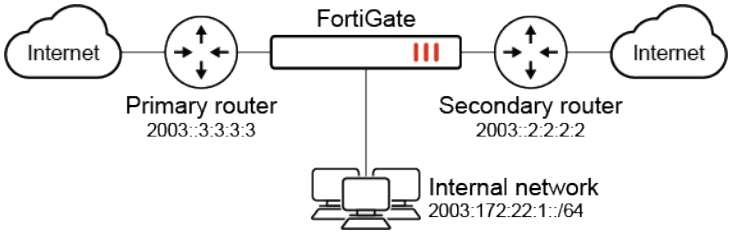
In this output, the condition is that the routes in route maps map-2816 and map-2826 exist. However, routes for map-2816 exist, but map-2826 does not, so the conditions are not met.

To view the conditional route maps:

```
# diagnose ip router command show-vrf root show running router bgp
...
 neighbor 2.2.2.2 advertise-map 2224root exist-map 2814root
 neighbor 2.2.2.2 advertise-map 2224root exist-map 2824root
... ...
 !
 address-family ipv6
 neighbor 2003::2:2:2:2 advertise-map map-2226root non-exist-map map-2816root
 neighbor 2003::2:2:2:2 advertise-map map-2226root non-exist-map map-2826root
!
```

IPv6 example 1

In this example, the FortiGate advertises its local network to the secondary router when the primary router is down. The FortiGate detects the primary router is down in the absence of a learned route.



- When the FortiGate learns route 2003:172:28:1::/64 from the primary router, it does not advertise its local route (2003:172:22:1::/64) to the secondary router.
- When the FortiGate does not learn route 2003:17:28:1::/64 from the primary router, advertises its local route (2003:172:22:1::/64) to the secondary router.
- The BGP conditional advertisement condition is set to be true if the condition route map (2003:172:28:1::/64) is not matched (`non-exist`).

To configure BGP conditional advertisement with IPv6:

1. Configure the IPv6 prefix lists:

```
config router prefix-list6
    edit "adv-222"
        config rule
            edit 1
                set prefix6 2003:172:22:1::/64
                unset ge
                unset le
            next
        end
    next
    edit "lrn-281"
        config rule
            edit 1
                set prefix6 2003:172:28:1::/64
                unset ge
                unset le
            next
        end
    next
end
```

2. Configure the route maps:

```
config router route-map
    edit "map-221"
        config rule
            edit 1
                set match-ip6-address "adv-222"
            next
        end
    next
    edit "map-281"
        config rule
            edit 1
                set match-ip6-address "lrn-281"
            next
        end
    next
end
```

3. Configure BGP:

```
config router bgp
    set as 65412
    set router-id 1.1.1.1
    set ibgp-multipath enable
    set network-import-check disable
    set graceful-restart enable
    config neighbor
        edit "2003::2:2:2:2"
            set soft-reconfiguration6 enable
            set remote-as 65412
            set update-source "loopback1"
            config conditional-advertise6
                edit "map-221"
                    set condition-routemap "map-281"
                    set condition-type non-exist
                next
            end
        next
        edit "2003::3:3:3:3"
            set soft-reconfiguration6 enable
            set remote-as 65412
            set update-source "loopback1"
        next
    end
end
```

In this configuration, if route map `map-281` does not exist, then the FortiGate advertises route map `map-221` to neighbor 2003::2:2:2:2.

4. Verify the routing table:

```
# get router info6 routing-table bgp
B       2003:172:28:1::/64 [200/0] via 2003::3:3:3:3 (recursive via ****::***:***:****:****,
port9), 01:23:45
B       2003:172:28:2::/64 [200/0] via 2003::3:3:3:3 (recursive via ****::***:***:****:****,
port9), 23:09:22
```

When the FortiGate learns 2003:172:28:1::/64, it will not advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2:2. If the FortiGate has not learned 2003:172:28:1::/64, it will advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2:2.

IPv6 example 2

With the same IPv6 prefix lists and route maps, when the FortiGate does learn 2003:172:28:1::/64, it advertises local route 2003:172:22:1::/64 to the secondary router. The BGP conditional advertisement condition is set to be true if the condition route map is matched (`exist`).

To configure BGP conditional advertisement with IPv6:

1. Configure BGP:

```
config router bgp
    config neighbor
        edit "2003::2:2:2:2"
            config conditional-advertise6
                edit "map-221"
                    set condition-routemap "map-281"
                    set condition-type exist
                next
            end
        next
    end
end
```

2. Verify the routing table:

```
# get router info6 routing-table bgp
B       2003:172:28:1::/64 [200/0] via 2003::3:3:3:3 (recursive via ****::***:***:****:****,
port9), 01:23:45
B       2003:172:28:2::/64 [200/0] via 2003::3:3:3:3 (recursive via ****::***:***:****:****,
port9), 23:09:22
```

When the FortiGate learns 2003:172:28:1::/64, it will advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2:2. If the FortiGate has not learned route 2003:172:28:1::/64, it will not advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2:2.

BGP conditional advertisements for IPv6 prefix when IPv4 prefix conditions are met and vice-versa

The FortiGate supports conditional advertisement of IPv4 and IPv6 route maps with `edit <advertise-routemap>` under `config conditional-advertise`, and supports configuring IPv4 and IPv6 route maps as conditions with the `condition-routemap` setting.

The FortiGate can cross-check conditions involving IPv4 and IPv6 route maps and perform conditional advertisements accordingly when those conditions are met. The global option, `cross-family-conditional-adv` in the BGP configuration settings allows this cross-checking to occur.

```
config router bgp
    set cross-family-conditional-adv {enable | disable}
    config conditional-advertise
        edit <advertise-routemap>
            set advertise-routemap <string>
            set condition-routemap <name1>, <name2>, ...
            set condition-type {exist | non-exist}
        next
    end
end
```

By default, the `cross-family-conditional-adv` setting is disabled. When disabled, the FortiGate will only check conditional route maps against the routing information base (RIB) of the IP address family (IPv4 or IPv6) that corresponds to the IP address family of the route map to be advertised conditionally.

For example, for an IPv6 conditional advertisement, if IPv4 conditional route maps have been configured, then the FortiGate will not meet any of these conditions because IPv4 routes will not exist in the IPv6 RIB. The same behavior applies for an IPv4 conditional advertisement, namely, that the FortiGate will not meet any configured IPv6 conditions since these routes will not exist in the IPv4 RIB. If routes do not match a conditional route map, then the condition is considered non-existent.

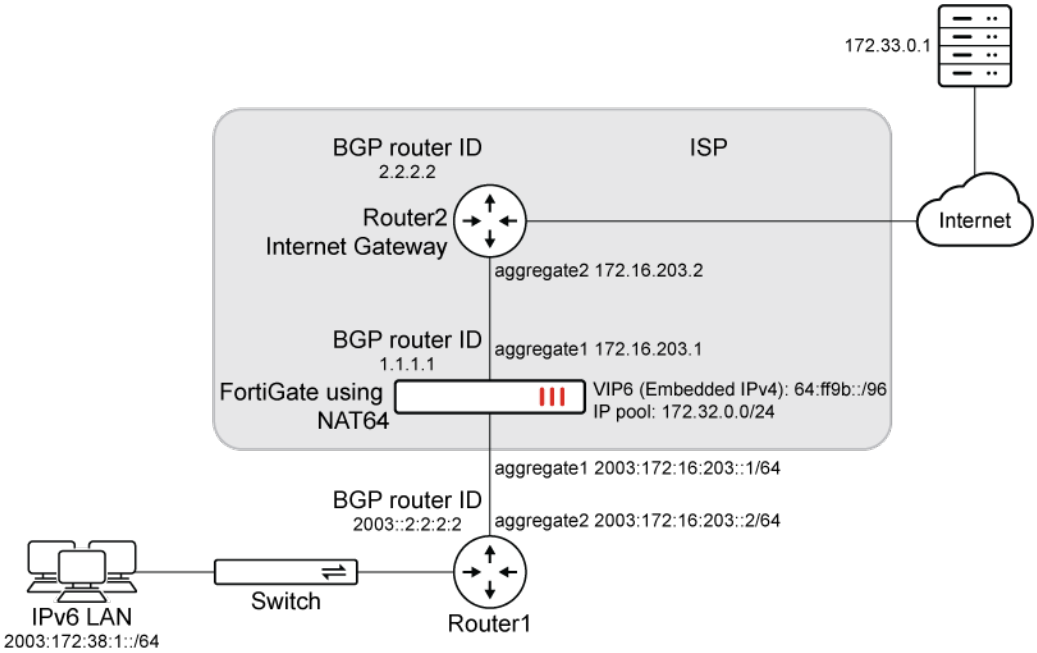
IPv4 and IPv6 BGP conditional advertisements using advertising and conditional route maps of the same IP address family are already supported in previous versions of FortiOS.

NAT64 example

In this example, the FortiGate uses NAT64 where the LAN via Router1 uses IPv6 and where Router2 is the internet gateway using IPv4.

This example assumes a pure NAT64 design with the following expectations:

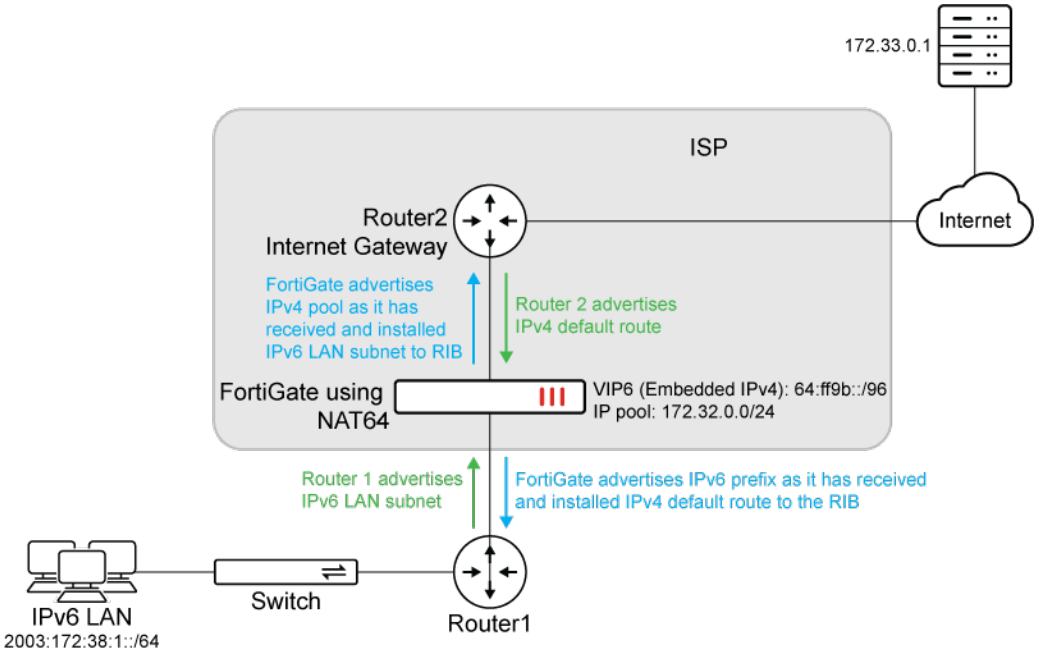
- IPv4 IP pools would be announced to Internet gateway when IPv6 client subnets learned from IPv6 route.
- IPv6 virtual IP addresses (VIPs) (default = 64:ff9b::/96) would be announced to Router 1 when IPv4 default route learned from Internet gateway.



The administrator of the FortiGate has the following requirements, which are implemented using IPv4 and IPv6 conditional advertisements:

- The FortiGate needs to announce IPv4 pools for NAT translation towards the internet gateway only if the IPv6 prefix exists in the routing table.
- The FortiGate needs to advertise the IPv6 address towards the LAN only if the IPv4 default route exists on the FortiGate.

The below diagram details the flow of routing advertisements:



The prefixes defined in IPv4 route map 2814 and IPv6 route map `map-281` both exist, so the FortiGate advertises the route map prefix in route-map `2224` (172.22.2.0/255.255.255.0) to its BGP neighbor 2.2.2.2.

For IPv6 neighbor 2003::2:2:2:2, the prefixes defined in IPv4 route map 2874 and IPv6 route map `map-38` both do not exist, and the `condition-type` is set to `non-exist`, so the FortiGate advertises the route map prefix in route map `map-222` (2003:172:22:1::/64) to its BGP neighbor 2003::2:2:2:2.

When the global `cross-family-conditional-adv` enabled, this is the only time the FortiGate will cross-check the address family; otherwise, it only checks the corresponding conditional map and treats the cross-family addresses as non-existent.

To configure the conditional advertisement to BGP neighbor 2.2.2.2 and its conditional route maps:

1. Configure the IPv4 prefix lists:

```
config router prefix-list
    edit "281"
        config rule
            edit 1
                set prefix 172.28.1.0 255.255.255.0
                unset ge
                unset le
            next
        end
    next
    edit "222"
        config rule
            edit 1
                set prefix 172.22.2.0 255.255.255.0
                unset ge
```

```
                unset le
            next
        end
    next
end
```

2. Configure the IPv6 prefix list:

```
config router prefix-list6
    edit "list6-1"
        config rule
            edit 1
                set prefix6 2003:172:28:1::/64
                unset ge
                unset le
            next
        end
    next
end
```

3. Configure the route maps:

```
config router route-map
    edit "2814"
        config rule
            edit 1
                set match-ip-address "281"
            next
        end
    next
    edit "map-281"
        config rule
            edit 1
                set match-ip6-address "list6-1"
            next
        end
    next
    edit "2224"
        config rule
            edit 1
                set match-ip-address "222"
            next
        end
    next
end
```

To configure the conditional advertisement to BGP neighbor 2003::2.2.2.2 and its conditional route maps:

1. Configure the IPv4 prefix list:

```
config router prefix-list
    edit "287"
        config rule
            edit 1
                set prefix 172.28.7.0 255.255.255.0
                unset ge
                unset le
            next
        end
    next
end
```

2. Configure the IPv6 prefix lists:

```
config router prefix-list6
    edit "list6-38"
        config rule
            edit 1
                set prefix6 2003:172:38:1::/64
                unset ge
                unset le
            next
        end
    next
    edit "adv-222"
        config rule
            edit 1
                set prefix6 2003:172:22:1::/64
                unset ge
                unset le
            next
        end
    next
end
```

3. Configure the route maps:

```
config router route-map
    edit "2874"
        config rule
            edit 1
                set match-ip-address “287”
            next
        end
    next
    edit "map-38"
        config rule
            edit 1
```

```
                set match-ip6-address "list6-38"
            next
        end
    next
    edit "map-222"
        config rule
            edit 1
                set match-ip6-address "adv-222"
            next
        end
    next
end
```

To configure the BGP settings with address family cross-checking:

```
config router bgp
    set as 65412
    set router-id 1.1.1.1
    set ibgp-multipath enable
    set network-import-check disable
    set cluster-id 1.1.1.1
    set graceful-restart enable
    set cross-family-conditional-adv enable
    config neighbor
        edit "3.3.3.3"
            set activate6 disable
            set capability-graceful-restart enable
            set soft-reconfiguration enable
            set prefix-list-out "local-out"
            set remote-as 65412
            set route-map-out "as-prepend"
            set keep-alive-timer 30
            set holdtime-timer 90
            set update-source "loopback1"
            set route-reflector-client enable
        next
        edit "2.2.2.2"
            set advertisement-interval 5
            set activate6 disable
            set capability-graceful-restart enable
            set soft-reconfiguration enable
            set remote-as 65412
            set keep-alive-timer 34
            set holdtime-timer 90
            set update-source "loopback1"
            config conditional-advertise
                edit "2224"
                    set condition-routemap "2814" "map-281"
                next
            end
            set route-reflector-client enable
        next
```

```
        edit "2003::2:2:2:2"
            set advertisement-interval 5
            set activate disable
            set capability-graceful-restart6 enable
            set soft-reconfiguration enable
            set soft-reconfiguration6 enable
            set remote-as 65412
            set keep-alive-timer 30
            set holdtime-timer 90
            set update-source "loopback1"
            config conditional-advertise6
                edit "map-222"
                    set condition-routemap "map-38" "2874"
                    set condition-type non-exist
                next
            end
            set route-reflector-client6 enable
        next
        edit "2003::3:3:3:3"
            set advertisement-interval 5
            set activate disable
            set capability-graceful-restart6 enable
            set soft-reconfiguration6 enable
            set remote-as 65412
            set route-map-in6 "community-del777"
            set keep-alive-timer 30
            set holdtime-timer 90
            set update-source "loopback1"
        next
    end
    config network
        edit 1
            set prefix 172.27.1.0 255.255.255.0
        next
        edit 2
            set prefix 172.27.2.0 255.255.255.0
        next
        edit 3
            set prefix 172.22.2.0 255.255.255.0
        next
    end
    config network6
        edit 1
            set prefix6 2003:172:22:1::/64
        next
    end
end
```

To verify the BGP status and the BGP routing table for IPv4:

```
# get router info bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
```

```
BGP table version is 2
6 BGP AS-PATH entries
2 BGP community entries

Neighbor   V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd

```

To verify the BGP routing table for IPv4 and confirm the conditional advertisement occurred:

```
# get router info routing-table bgp
Routing table for VRF=0
B       172.22.2.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:00:03, [1/0]
B       172.27.1.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:37:30, [1/0]
B       172.27.2.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:37:30, [1/0]
B       172.27.5.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:37:30, [1/0]
B       172.27.6.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:37:30, [1/0]
B       172.27.7.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:37:30, [1/0]
B       172.27.8.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:37:30, [1/0]
B       172.29.1.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:37:30, [1/0]
B       172.29.2.0/24 [200/0] via 1.1.1.1 (recursive via 172.16.203.1, agg2), 00:37:30, [1/0]
```

To verify the BGP routing table for IPv6 and confirm the conditional advertisement occurred:

```
# get router info6 routing-table bgp
Routing table for VRF=0
B       2003:172:22:1::/64 [200/0] via 2003::1:1:1:1 (recursive via 2003:172:16:203::1, agg2),
00:00:01, [1024/0]
B       2003:172:28:1::/64 [200/0] via 2003::3:3:3:3 (recursive via fe80::a5b:eff:feeb:ca45,
port1), 00:37:59, [1024/0]
B       2003:172:28:2::/64 [200/0] via 2003::3:3:3:3 (recursive via fe80::a5b:eff:feeb:ca45,
port1), 00:37:59, [1024/0]
```

Behavior when address family cross-checking is disabled

Using a similar BGP configuration with `cross-family-conditional-adv` disabled, note the following behavior based on the condition type.

When the condition type is set to exist:

```
config router bgp
       set cross-family-conditional-adv disable
       config neighbor
        edit "2.2.2.2"
            config conditional-advertise
                edit "222v4"
                    set condition-routemap "4-281" "6-281"
                    set condition-type exist
                next
            end
        next
    end
end
```

The FortiGate will only check the IPv4 RIB table to see if there is a matching IP address for each route map. Any IPv6 address under the route map will not get checked in the corresponding IPv6 RIB table, and the condition result will be non-existent. The `222v4` route map will not advertise to its neighbor because the result is non-existent, while the condition type is existent.

When the condition type is set to non-exist:

```
config router bgp
       set cross-family-conditional-adv disable
       config neighbor
        edit "2003::2:2:2:2"
            config conditional-advertise6
                edit "v6-222"
                    set condition-routemap "v6-238" "v4-287"
                    set condition-type non-exist
                next
            end
        next
```

```
    end
end
```

If the `v6-238` IPv6 prefix does not exist in the IPv6 RIB table, then the FortiGate will only check `v4-287` in the IPv6 RIB table. The FortiGate will not find it because it is an IPv4 address. Since the condition type is also `non-exist`, route `v6-222` will be advertised to its neighbor.

BGP error handling per RFC 7606

The FortiGate uses one of the three approaches to handle malformed attributes in BGP UPDATE messages, in order of decreasing severity:

1. Notification and Session reset
2. Treat-as-withdraw
3. Attribute discard

When a BGP UPDATE message contains multiple malformed attributes, the most severe approach that is triggered by one of the attributes is followed. See RFC 7606 for more information.

The following table lists the BGP attributes, and how FortiGate handles a malformed attribute in the UPDATE message:

BGP attribute	Handling
origin	Handled by the treat-as-withdraw approach.
AS path	Handled by the treat-as-withdraw approach.
AS 4 path	Handled by the attribute discard approach.
aggregator	Handled by the attribute discard approach.
aggregator 4	Handled by the attribute discard approach.
next-hop	Handled by the treat-as-withdraw approach.
multiple exit discriminator	Handled by the treat-as-withdraw approach.
local preference	Handled by the treat-as-withdraw approach.
atomic aggregate	Handled by the attribute discard approach.
community	Handled by the treat-as-withdraw approach.
extended community	Handled by the treat-as-withdraw approach.
originator	Handled by the treat-as-withdraw approach.
cluster	Handled by the treat-as-withdraw approach.
PMSI	Handled by the treat-as-withdraw approach.
MP reach	Handled by the notification message approach.
MP unreach	Handled by the notification message approach.
attribute set	Handled by the treat-as-withdraw approach.

BGP attribute	Handling
AIGP	Handled by the treat-as-withdraw approach.
Unknown	If the BGP flag does not indicate that this is an optional attribute, this malformed attribute is handled by the notification message approach.

BGP next hop tag-match mode

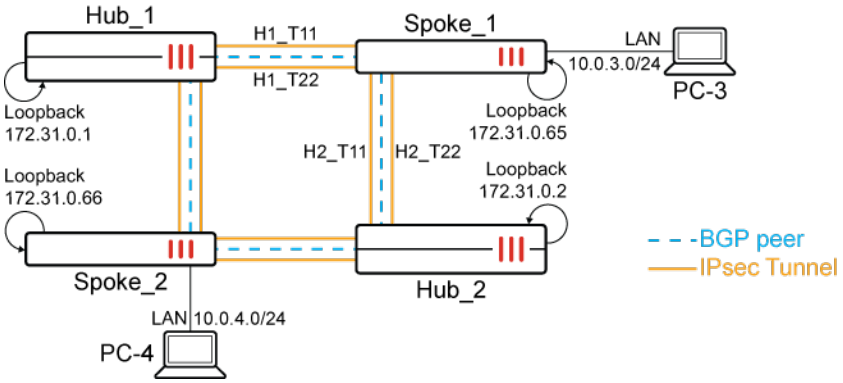
Tag-match mode can be configured to increase flexibility when controlling how BGP routes' next hops are resolved:

```
config router bgp
    set tag-resolve-mode {disable | preferred | merge}
end
```

Best-match (`disable`)	Resolve the BGP route's next hops with best-matched routes. This is the default setting.
Tag-match (`preferred`)	Resolve the BGP route's next hops with routes that have the same tag. If there are no results, resolve the next hops with best-matched routes.
Tag-and-best-match (`merge`)	Merge tag-match with best-match if they are using different routes, then let shortcuts hide their parents. The results exclude the next hops of tag-match whose interfaces have appeared in best-match.

In these examples:

- Each spoke has two IPsec tunnels to each hub, and one BGP peer on loopback interface to each hub (route-reflector).
- The loopbacks are exchanged with IKE between the spokes and hubs. They are installed as static routes that are used to provide reachability for establishing BGP neighbors.
- The summary BGP routes from the loopback IP address ranges that originated on the hubs are advertised to the spokes for resolving the BGP next hop s on the spokes.
- The spokes' PC LAN subnets are reflected by the hubs.
- Spoke_1 receives BGP routes (the LAN subnet and loopback IP summary) from Hub_1 with tag 1 and from Hub_2 with tag 2.
- SD-WAN is enabled on Spoke_1, and all of the tunnels are SD-WAN members.



Example 1: Connection between Hub and Spoke down

If the connections between Hub_1 and Spoke_2 are down, traffic from PC_3 to PC_4 can still go through Hub_1 because of the best-match resolving on Spoke_1, but packets will be dropped on Hub_1. When tag-match is enabled on Spoke_1, the spoke will resolve the PC_4 LAN route to Hub2, and traffic will be forwarded to Hub_2 and reach its destination.

To test the tag-match mode:

1. View the key routes on Spoke_1:

```
Spoke_1(root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11 tunnel 172.31.1.1),
20:09:52
              (recursive via H1_T22 tunnel 10.0.0.2), 20:09:52
              (recursive via H2_T11 tunnel 172.31.1.101), 20:09:52
              (recursive via H2_T22 tunnel 10.0.0.4), 20:09:52
B       172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
23:25:37
              (recursive via H1_T22 tunnel 10.0.0.2), 23:25:37
            [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 23:25:37
              (recursive via H2_T22 tunnel 10.0.0.4), 23:25:37
S       172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
            [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S       172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
            [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C       172.31.0.65/32 is directly connected, Loopback0
...
```

   172.31.0.0/25 is the loopback IP summary originated by both Hub_1 and Hub_2. The next hop of the PC_4 LAN route is resolved to Hub_1 (H1_T11, H1_T22) and Hub_2 (H2_T11, H2_T22) based on the loopback IP summary route.

2. When connections between Spoke_2 and Hub_1 fails due to the BGP neighbor, tunnels, or physical ports going down, the PC_4 LAN route can be still resolved to Hub_1 and Hub_2 because the loopback IP summary can still be received from both Hub_1 and Hub_2:

```
Spoke_1(root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 (recursive via H1_T11 tunnel 172.31.1.1), 00:03:06
              (recursive via H1_T22 tunnel 10.0.0.2), 00:03:06
              (recursive via H2_T11 tunnel 172.31.1.101), 00:03:06
              (recursive via H2_T22 tunnel 10.0.0.4), 00:03:06
B       172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
23:55:34
              (recursive via H1_T22 tunnel 10.0.0.2), 23:55:34
            [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 23:55:34
              (recursive via H2_T22 tunnel 10.0.0.4), 23:55:34
...
```

3. If traffic sent from PC_3 to PC_4 goes through Hub_1, packets are dropped because there is no PC_4 LAN route on Hub_1:

```
Spoke_1 (root) # diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
filters=[host 10.0.4.2]
11.261264 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
11.261349 H1_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request
12.260268 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
12.260291 H1_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request

Hub_1 (root) #  diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
filters=[host 10.0.4.2]
6.966064 EDGE_T1 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.965012 EDGE_T1 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
```

4. If the tag-match mode is set to tag-match (preferred) on Spoke_1, then the PC_4 LAN route can only be resolved to Hub_2 because of tag-match checking:

```
Spoke_1(root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 tag 2 (recursive via H2_T11 tunnel 172.31.1.101),
00:02:35
              (recursive via H2_T22 tunnel 10.0.0.4), 00:02:35
B       172.31.0.0/25 [200/0] via 172.31.0.1 tag 1 (recursive via H1_T11 tunnel 172.31.1.1),
03:18:41
              (recursive via H1_T22 tunnel 10.0.0.2), 03:18:41
            [200/0] via 172.31.0.2 tag 2 (recursive via H2_T11 tunnel 172.31.1.101), 03:18:41
              (recursive via H2_T22 tunnel 10.0.0.4), 03:18:41
...
```

```
Spoke_1 (root) # get router info routing-table details 10.0.4.0/24

Routing table for VRF=0
Routing entry for 10.0.4.0/24
  Known via "bgp", distance 200, metric 0, best
  Last update 00:01:11 ago
  * 172.31.0.66, tag 2 (recursive via H2_T11 tunnel 172.31.1.101), tag-match
              (recursive via H2_T22 tunnel 10.0.0.4), tag-match
```

5. If traffic is again sent from PC_3 to PC_4, it will go through Hub_2 and reach the destination:

```
Spoke_1 (root) # diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
filters=[host 10.0.4.2]
7.216948 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.217035 H2_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.217682 H2_T11 in 10.0.4.2 -> 10.0.3.2: icmp: echo reply
7.217729 port4 out 10.0.4.2 -> 10.0.3.2: icmp: echo reply
```

Example 2: SD-WAN failover when shortcut down

After the shortcut from Spoke_1 to Spoke_2 is established, Spoke_1 will only resolve the PC_4 LAN route to the shortcut, because of best-match resolving, prohibiting SD-WAN failover. When tag-and-best-match is enabled

on Spoke_1, the spoke can resolve the PC_4 LAN route to the shortcut and to other alternative tunnels, allowing SD-WAN failover.

To test the tag-and-best-match mode:

1. Unset `tag-resolve-mode` and resume the connections between Spoke_2 and Hub_1. The routing table on Spoke_1 changes to the initial state:

```
Spoke_1(root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11 tunnel 172.31.1.1),
00:01:54
              (recursive via H1_T22 tunnel 10.0.0.2), 00:01:54
              (recursive via H2_T11 tunnel 172.31.1.101), 00:01:54
              (recursive via H2_T22 tunnel 10.0.0.4), 00:01:54
B       172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
03:30:35
              (recursive via H1_T22 tunnel 10.0.0.2), 03:30:35
            [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 03:30:35
              (recursive via H2_T22 tunnel 10.0.0.4), 03:30:35
S       172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
            [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S       172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
            [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C       172.31.0.65/32 is directly connected, Loopback0

...
```

2. Send traffic from PC_3 to PC_4.

   The shortcut from Spoke_1 o Spoke_2 is established.

   The PC_4 LAN route is only resolved to the shortcut because of best-match resolving. If the shortcut is out of SLA, then the traffic cannot switch over to another, alternative tunnel.

```
Spoke_1 (root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11_0 tunnel 10.0.0.40),
00:09:22
B       172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
03:40:12
              (recursive via H1_T22 tunnel 10.0.0.2), 03:40:12
            [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 03:40:12
              (recursive via H2_T22 tunnel 10.0.0.4), 03:40:12
S       172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
            [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S       172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
            [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C       172.31.0.65/32 is directly connected, Loopback0
S       172.31.0.66/32 [15/0] via H1_T11_0 tunnel 10.0.0.40, [1/0]
...
```

3. If the tag-match mode is set to tag-and-best-match (`merge`) on Spoke_1, then the PC_4 LAN route is resolved to the `H1_T11_0` shortcut based on best-match resolving, and to `H1_T11, H1_T22, H2_T11, H2_`

T22 based on tag-match resolving. It is then resolved to H1_T11, H1_T22, H2_T11, H2_T22 after letting the shortcut hide its parent tunnel.

```
Spoke_1 (root) # get router info routing-table all
C       10.0.3.0/24 is directly connected, port4
B       10.0.4.0/24 [200/0] via 172.31.0.66 tag 1 (recursive via H1_T11_0 tunnel 10.0.0.40),
00:07:36
              (recursive via H1_T22 tunnel 10.0.0.2), 00:07:36
            [200/0] via 172.31.0.66 tag 2 (recursive via H1_T11_0 tunnel 10.0.0.40), 00:07:36
              (recursive via H2_T11 tunnel 172.31.1.101), 00:07:36
              (recursive via H2_T22 tunnel 10.0.0.4), 00:07:36
B       172.31.0.0/25 [200/0] via 172.31.0.1 tag 1 (recursive via H1_T11 tunnel 172.31.1.1),
03:48:26
              (recursive via H1_T22 tunnel 10.0.0.2), 03:48:26
            [200/0] via 172.31.0.2 tag 2 (recursive via H2_T11 tunnel 172.31.1.101), 03:48:26
              (recursive via H2_T22 tunnel 10.0.0.4), 03:48:26
S       172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
            [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S       172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
            [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C       172.31.0.65/32 is directly connected, Loopback0
S       172.31.0.66/32 [15/0] via H1_T11_0 tunnel 10.0.0.40, [1/0]

...
```

```
Spoke_1 (root) # get router info routing-table details 10.0.4.0/24

Routing table for VRF=0
Routing entry for 10.0.4.0/24
  Known via "bgp", distance 200, metric 0, best
  Last update 00:01:02 ago
  * 172.31.0.66, tag 1 (recursive via H1_T11_0 tunnel 10.0.0.42), best-match
              (recursive via H1_T22 tunnel 10.0.0.2), tag-match
  * 172.31.0.66, tag 2 (recursive via H1_T11_0 tunnel 10.0.0.42), best-match

```

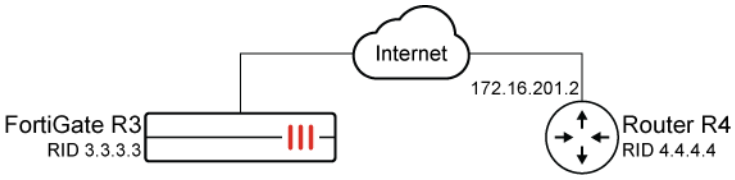
BGP neighbor password

A BGP neighbor password is used for the neighbor range. Once a BGP group is configured, it uses a password to establish the neighborhood.

```
config router bgp
    config neighbor-group
        edit <name>
            set password <password>
        next
    end
end
```



To configure the BGP group:

1. Configure the R3 FortiGate settings:

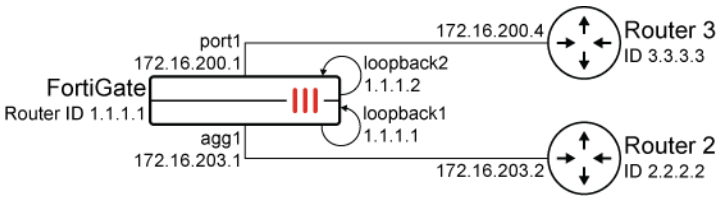
```
config router bgp
    config neighbor-group
        edit "FGT"
            set soft-reconfiguration enable
            set remote-as 65050
            set local-as 65518
            set local-as-no-prepend enable
            set local-as-replace-as enable
            set route-map-in "del-comm"
            set keep-alive-timer 30
            set holdtime-timer 90
            set update-source "npu0_vlink0"
            set weight 1000
            set password ENC ********
        next
    end
    config neighbor-range
        edit 1
            set prefix 172.16.201.0 255.255.255.0
            set max-neighbor-num 10
            set neighbor-group "FGT"
        next
    end
end
```

2. Configure the R4 router settings:

```
config router bgp
    config neighbor
        edit "172.16.201.1"
            set soft-reconfiguration enable
            set remote-as 65518
            set password ********
        next
    end
end
```

Defining a preferred source IP for local-out egress interfaces on BGP routes

The preferred source IP can be configured on BGP routes so that local-out traffic is sourced from that IP. In the following example, a route map is configured to set the preferred source IP so that the BGP route can support the preferred source.



To configure preferred source IPs for BGP routing:

1. Configure the route maps:

```
config router route-map
    edit "map1"
        config rule
            edit 1
                set set-ip-prefsrc 1.1.1.1
            next
        end
    next
    edit "map2"
        config rule
            edit 1
                set set-ip-prefsrc 1.1.1.2
            next
        end
    next
end
```

2. Configure the BGP settings:

```
config router bgp
    set as 65412
    set router-id 1.1.1.1
```

```
    set ibgp-multipath enable
    set cluster-id 1.1.1.1
    set graceful-restart enable
    config aggregate-address
        edit 1
            set prefix 172.28.0.0 255.255.0.0
            set as-set enable
            set summary-only enable
        next
    end
    config neighbor
        edit "3.3.3.3"
            set capability-graceful-restart enable
            set soft-reconfiguration enable
            set prefix-list-out "local-out"
            set remote-as 65412
            set route-map-in "map2"
            set route-map-out "as-prepend"
            set keep-alive-timer 30
            set holdtime-timer 90
            set update-source "loopback1"
            set route-reflector-client enable
        next
        edit "2.2.2.2"
            set advertisement-interval 5
            set activate6 disable
            set capability-graceful-restart enable
            set soft-reconfiguration enable
            set distribute-list-out "local-out-FGTB-deny"
            set remote-as 65412
            set route-map-in "map1"
            set route-map-out "as-rewrite"
            set keep-alive-timer 30
            set holdtime-timer 90
            set update-source "loopback1"
        next
    end
end
```

To verify the configuration:

1. Verify the BGP routing table for 172.25.1.0/24:

```
# get router info bgp network 172.25.1.0/24
VRF 0 BGP routing table entry for 172.25.1.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  Local
    2.2.2.2 (metric 10050) from 2.2.2.2 (2.2.2.2)
      Origin IGP metric 0, localpref 100, valid, internal, best, prefsrc 1.1.1.1
      Last update: Wed Jan 25 15:15:48 2023
```

2. Verify the BGP routing table for 172.28.5.0/24:

```
# get router info bgp network 172.28.5.0/24
VRF 0 BGP routing table entry for 172.28.5.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table, Advertisements suppressed by an
aggregate.)
  Not advertised to any peer
  Original VRF 0
  65050, (Received from a RR-client)
    3.3.3.3 (metric 11000) from 3.3.3.3 (3.3.3.3)
      Origin IGP metric 0, localpref 100, valid, internal, best, prefsrc 1.1.1.2
      Last update: Wed Jan 25 15:15:48 2023
```

3. Verify the kernel routing table for 172.28.5.0/24:

```
# get router info kernel | grep -B 2 172.28.5.0/24
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.28.1.0/24 pref=1.1.1.2
gwy=172.16.200.4 dev=9(port1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.28.2.0/24 pref=1.1.1.2
gwy=172.16.200.4 dev=9(port1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.28.5.0/24 pref=1.1.1.2
gwy=172.16.200.4 dev=9(port1)
```

4. Verify the kernel routing table for 172.25.1.0/24:

```
# get router info kernel | grep -A 2 172.25.1.0/24
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.25.1.0/24 pref=1.1.1.1
gwy=172.16.203.2 dev=33(agg1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.26.1.0/24 pref=1.1.1.1
gwy=172.16.203.2 dev=33(agg1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->172.26.2.0/24 pref=1.1.1.1
gwy=172.16.203.2 dev=33(agg1)
```

The FortiGate learns routes from router 3.3.3.3 and prefers the source IP of 1.1.1.2. It learns routes from router 2.2.2.2 and prefers source IP of 1.1.1.1.

5. Run a sniffer trace after some traffic passes.
   a. When trying to reach a destination in the 172.25.1.0/0 subnet through router 2.2.2.2:

```
# diagnose sniffer packet any "icmp" 4
interfaces=[any]
filters=[icmp]
9.244334 agg1 out 1.1.1.1 -> 172.25.1.2: icmp: echo request
9.244337 port12 out 1.1.1.1 -> 172.25.1.2: icmp: echo request
10.244355 agg1 out 1.1.1.1 -> 172.25.1.2: icmp: echo request
10.244357 port12 out 1.1.1.1 -> 172.25.1.2: icmp: echo request
```

   b. When trying to reach a destination in the 172.28.5.0/24 subnet through router 3.3.3.3:

```
# diagnose sniffer packet any "icmp" 4
interfaces=[any]
filters=[icmp]
```

```
2.434035 port1 out 1.1.1.2 -> 172.28.5.2: icmp: echo request
3.434059 port1 out 1.1.1.2 -> 172.28.5.2: icmp: echo request
```

Traffic destined for the 172.25.1.0/24 subnet uses 1.1.1.1 as source. Traffic destined for the 172.28.5.0/24 subnet uses 1.1.1.2 as source.

BGP multi-exit discriminator

Border Gateway Protocol (BGP) is the routing protocol that governs how internet traffic is efficiently routed between autonomous systems (AS). BGP uses path attributes for its best path calculation to a network.

Multi-Exit Discriminator (MED) is a BGP path attribute that discriminates among multiple exit or entry points to the same neighboring AS. MED is also known as Optional Non-Transitive path attribute. The lower the MED value, the more preferred the path is to the receiving router.

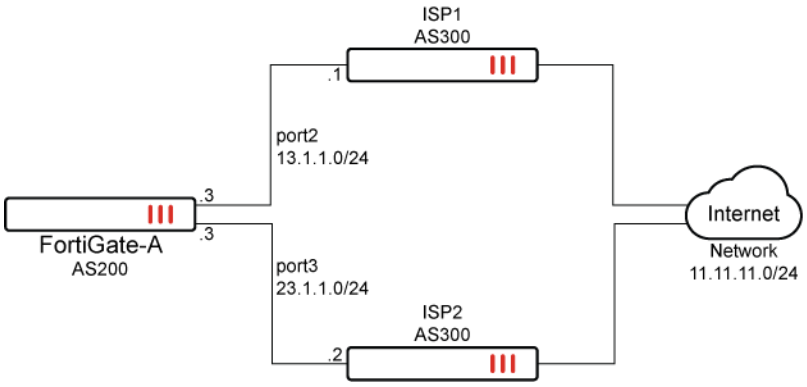
MED is typically utilized when an AS has multiple exit points to another AS. In such cases, the AS may want to influence incoming traffic by advertising different MED values for the same route.

Common use case

A common use case for MED is in the context of a dual-homed AS. In a dual-homed AS scenario, the FortiGate connects to two different ISPs belonging to the same AS for redundancy and load balancing. By manipulating the MED value, the AS can direct traffic to one ISP over the other. For instance, if one link is congested, the AS can advertise a higher MED value for that link, making the other link more suitable to incoming traffic.

MED is a BGP path attribute that discriminates among multiple exit or entry points to the same neighboring AS. If an administrator has two or more eBGP peering to different AS then the local preference can be used to influence the routing decision.

The following example discusses the use of MED in dual-homed AS network and the configuration of MED Path Attribute on FortiOS.



Characteristics of the topology include the following:

- FortiGate-A has two internet service providers: ISP1 and ISP2.
- FortiGate-A belongs to AS 200.
- ISP1 and ISP2 both belong to AS 300.
- FortiGate-A will establish eBGP peering relationships with ISP1 and ISP2.

- Network 11.11.11.0/24 resides on the Internet and is reachable by both ISP1 and ISP2.
- eBGP multipath is enabled on FortiGate-A if FortiGate-A needs to perform equal cost load-balancing of traffic between both ISP1 and ISP2 to reach to 11.11.11.0/24.
- The network 11.11.11.0/24 on the Internet is being advertised by both ISP1 and ISP2 to FortiGate-A through eBGP.

For this example, the traffic originating from behind the FortiGate-A should prefer ISP1 rather than ISP2 to reach 11.11.11.0/24, and needs to use the BGP MED Path Attribute. This is done by configuring `set set-metric` in a route map configuration and ensuring the MED value of ISP1 is less than that of ISP2.

To configure MED in a dual-homed AS network using the CLI:

1. Configure eBGP peering on FortiGate-A by specifying the BGP neighbors:

```
config router bgp
    set as 200
    set router-id 2.2.2.2
    config neighbor
        edit "13.1.1.1"
            set remote-as 300
        next
        edit "23.1.1.2"
            set remote-as 300
        next
    end
end
```

2. Configure eBGP on ISP1 and ISP2, and advertise the 11.11.11.0/24 network:

```
config router bgp
    set as 300
    set router-id 3.3.3.3
    config neighbor
        edit "13.1.1.3"
            set remote-as 200
        next
    end
    config network
        edit 1
            set prefix 11.11.11.0 255.255.255.0
        next
    end
end
```

3. Verify the eBGP neighbors on Fortigate-A with ISP1 and ISP2:

```
# get router info bgp summary
VRF 0 BGP router identifier 2.2.2.2, local AS number 200
BGP table version is 6
1 BGP AS-PATH entries
0 BGP community entries
```

```
Neighbor V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
13.1.1.1 4        300      48      50        0    0    0 00:25:45        1
23.1.1.2 4        300      56      60        6    0    0 00:26:30        1
```

4. Configure the prefix list to filter and select the 11.11.11.0/24 subnet inside the prefix list:
   a. Configure ISP1:

```
config router prefix-list
    edit "ISP1_Prefix_List"
        config rule
            edit 1
                set prefix 11.11.11.0 255.255.255.0
            next
        end
    next
end
```

   b. Configure ISP2:

```
config router prefix-list
    edit "ISP2_Prefix_List"
        config rule
            edit 1
                set prefix 11.11.11.0 255.255.255.0
            next
        end
    next
end
```

5. Configure route maps and configure the MED value:
   a. Configure ISP1:

```
config router route-map
    edit "MED_Route_MAP"
        config rule
            edit 1
                set match-ip-address "ISP1_Prefix_List"
                set set-metric 300
            next
        end
    next
end
```

   b. Configure ISP2:

```
config router route-map
    edit "MED_Route_MAP_2"
        config rule
            edit 1
                set match-ip-address "ISP2_Prefix_List"
                set set-metric 400
            next
```

```
        end
    next
end
```

6. Apply the route map in the outbound direction:

Applying the configuration in the outbound direction ensures that the MED is changed to the respective value for the route 11.11.11.0/24 specified in the prefix list.

a. Configure the ISP1 BGP:

```
config router bgp
    set as 300
    set router-id 3.3.3.3
    config neighbor
        edit "13.1.1.3"
            set remote-as 200
            set route-map-out "MED_Route_MAP"
        next
    end
end
```

b. Configure the ISP2 BGP:

```
config router bgp
    set as 300
    set router-id 4.4.4.4
    config neighbor
        edit "23.1.1.3"
            set remote-as 200
            set route-map-out "MED_Route_MAP_2"
        next
    end
end
```

7. Verify that ISP1 is selected as the best path to reach the 11.11.11.0/24 network:

The neighbor that is considered the best, valid route is marked with a *>.

```
# get router info bgp network
VRF 0 BGP table version is 6, local router ID is 2.2.2.2
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
              S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network          Next Hop            Metric LocPrf Weight RouteTag Path
*> 11.11.11.0/24    13.1.1.1               300             0        0 300 i <-/1>
*                   23.1.1.2               400             0        0 300 i <-/->
```

```
Total number of prefixes 1
```

8. Verify the routing table of FortiGate-A:

The routing table only contains the best and valid paths.

```
# get router info routing-table details
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
B       11.11.11.0/24 [20/300] via 13.1.1.1, port2, 00:37:47
C       13.1.1.0/24 is directly connected, port2
C       23.1.1.0/24 is directly connected, port3
```

TCP Authentication Option advanced security measures

BGP incorporates TCP Authentication Option (TCP-AO) advanced security measures, which supports stronger algorithms, such as AES-128 CMAC and HMAC-SHA1. This integration bolsters the security of and enhances the reliability of BGP connections and contributes to the overall security of the internet.

To set the algorithm to AES-128 CMAC:

```
config router key-chain
    edit <name>
        config key
            edit <id>
                set algorithm cmac-aes128
            next
        end
    next
end
```

To select the key-chain with the TCP-AO in a neighbor or neighbor group:

```
config router bgp
    config {neighbor | neighbor-group}
        edit <ip>
            set auth-options <key-chain>
        end
```

```
    next
end
```

To debug the TCP authentication options:

```
diagnose sys tcp-auth-options
```

Example

In this example, the router BGP neighbor is configured to use the AES-128 CMAC algorithm.

To configure the router BGP to use the AES-128 CMAC algorithm:

1. Configure the router key-chain to use the AES-128 CMAC algorithm:

```
config router key-chain
    edit "11"
        config key
            edit "1"
                set accept-lifetime 01:01:01 01 01 2021 2147483646
                set send-lifetime 01:01:01 01 01 2021 2147483646
                set key-string **********
                set algorithm cmac-aes128
            next
        end
    next
end
```

2. Apply the key-chain to the BGP neighbor or neighbor group:
   The key-chain is applied to the BGP neighbor with IP address 2.2.2.2.

```
config router bgp
    set as 65412
    config neighbor
        edit "2.2.2.2"
            set auth-options "11"
        next
    end
end
```

3. Verify that the router BGP is using the algorithm.
   The command output shows that BGP neighbor 2.2.2.2 is using the AES-128 CMAC algorithm.

```
# diagnose sys tcp-auth-options

VFID=0 send-id=1 recv-id=1 flags=0x784 keylen=6
alg=2(aes128) addr=2.2.2.2
send-begin: Fri Jan  1 01:01:01 2021
send-end: Wed Jan 19 04:15:07 2089
```

```
recv-begin: Fri Jan  1 01:01:01 2021
recv-end: Wed Jan 19 04:15:07 2089
```

Assigning multiple remote Autonomous Systems to a single BGP neighbor group

FortiOS allows the assignment of multiple remote Autonomous Systems (AS) to a single BGP neighbor group using the `remote-as-filter` command. This is achieved through the utilization of AS path lists. This enhancement offers increased flexibility and efficiency in managing BGP configurations, especially in intricate network environments.

```
config router bgp
    set as <local AS>
    config neighbor-group
        edit <name>
            set remote-as-filter <BGP filter for remote AS>
        next
    end
end
```

The `remote-as` and `remote-as-filter` commands are mutually exclusive in the BGP neighbor group. Unset the pre-existing value to use the other command. For example, to change from using `remote-as` to `remote-as-filter`, implement `unset remote-as`.

Example

The following example demonstrates assigning the remote AS of two spokes (AS65505 and AS65006) to a single BGP neighbor group of a hub (AS65505).

To assign multiple remote AS to a single BGP neighbor group in the local hub:

1. Configure the AS path list:

```
config router aspath-list
    edit "aslist1"
        config rule
            edit 1
                set action permit
                set regexp "^6550[1-6]$"
            next
```

```
        end
    next
end
```

2. Configure the BGP neighbor group of the hub to point to the AS path list:

```
config router bgp
    set as 65505
    config neighbor-group
        edit "gr1"
            set remote-as-filter "aslist1"
        next
    end
end
```

3. Configure the BGP neighbor range:

```
config router bgp
    config neighbor-range
        edit 1
            set prefix 10.10.100.0 255.255.255.0
            set neighbor-group "gr1"
        next
    end
end
```

4. Verify that multiple remote AS have been assigned to the BGP neighbor group:

```
# get router info bgp summary

VRF 0 BGP router identifier 11.11.11.11, local AS number 65505
BGP table version is 4
2 BGP AS-PATH entries
0 BGP community entries
Next peer check timer due in 55 seconds

Neighbor    V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
10.10.100.2 4      65505    8240    8229        4    0    0 5d00h03m        2
10.10.100.3 4      65506    8229    8253        4    0    0 4d23h59m        2
Total number of neighbors 2
```

Using firewall addresses and groups for BGP network prefixes

Firewall addresses (`ipmask` and `interface-subnet` types) and groups can be used for BGP prefixes.

```
config firewall address
    edit <address>
        set allow-routing {enable | disable}
    next
end
config firewall addrgrp
```

```
    edit <group>
        set allow-routing {enable | disable}
    next
end
config router bgp
    config network
        edit <id>
            set prefix-name <address or group>
        next
    end
end
```

allow-routing {enable | disable}	Enable/disable use of this address/group in routing configurations.
prefix-name <address or group>	Name of firewall address or address group.

To configure firewall addresses and groups and use them in BGP network prefixes:

1. Configure firewall addresses and groups with allow-routing enabled:

```
config firewall address
    edit "222"
        set allow-routing enable
        set subnet 22.2.3.0 255.255.255.0
    next
    edit "333"
        set allow-routing enable
        set subnet 33.1.1.0 255.255.255.0
    next
    edit "555"
        set type interface-subnet
        set allow-routing enable
        set subnet 66.6.2.0 255.255.255.0
        set interface "port6"
    next
    edit "vlan55 address"
        set type interface-subnet
        set allow-routing enable
        set subnet 55.2.2.0 255.255.255.0
        set interface "vlan55"
    next
end
```

```
config firewall addrgrp
    edit "group1"
        set allow-routing enable
        set member "222" "555"
    next
end
```

2. Configure BGP network prefixes

```
config router bgp
    ...
    config network
        edit 2
            set prefix-name "333"
        next
        edit 20
            set network-import-check disable
            set prefix-name "group1"
        next
        edit 66
            set prefix-name "vlan55 address"
        next
    end
    ...
end
```

Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically, the problems with a BGP network that has been configured involve routes going offline frequently. This is called route flap and causes problems for the routers using that route.

Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the following CLI command:

```
# execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the following CLI command:

```
# execute router clear bgp as 650001
```

Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term that is used if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables. This creates a lot of administration traffic on the network and the same traffic re-occurs when that router comes back online. If the problem is something like a faulty network cable that alternates online and offline every 10 seconds, there could easily be an overwhelming amount of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate devices in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline, resulting in route flap. While this doesn't occur often, or more than once at a time, it can still result in an interruption in

traffic which is disruptive for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they don't expire during the failover process. Also, configuring graceful restart on the HA cluster helps with a smooth failover.

The first method of dealing with route flap is to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either avoid using that interface or swap in a functioning router. If the power source is bad on a router, either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However, if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- Holdtime timer on page 594
- Dampening on page 595
- Graceful restart on page 596
- BFD on page 597

Holdtime timer

The first step to troubleshooting a flapping route is the holdtime timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the holdtime timer won't allow the FortiGate to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate. For the duration of the other outages, there won't be changes because the Fortigate is essentially treating this router as down. If the route is still flapping after the timer expires, it will start again.

If the route isn't flapping (for example, if it goes down, comes up, and stays back up) the timer will still count down and the route is ignored for the duration of the timer. In this situation, the route is seen as down longer than it really is but there will be only the one set of route updates. This isn't a problem in normal operation because updates are not frequent.

The potential for a route to be treated as down when it's really up can be viewed as a robustness feature. Typically, you don't want most of your traffic being routed over an unreliable route. So if there's route flap going on, it's best to avoid that route if you can. This is enforced by the holdtime timer.

How to configure the holdtime timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the holdtime timer.

For example, your network has two routes that you want to set the timer for. One is your main route (to 10.12.101.4) that all of your Internet traffic goes through, and it can't be down for long if it's down. The second is a low speed connection to a custom network that's used infrequently (to 10.13.101.4). The timer for the main route should be fairly short (for example, 60 seconds). The second route timer can be left at the default, since it's rarely used.

To configure the BGP holdtime timer:

```
config router bgp
    config neighbor
        edit 10.12.101.4
            set holdtime-timer 60
            set keepalive-timer 60
        next
        edit 10.13.101.4
            set holdtime-timer 180
            set keepalive-timer 60
        next
    end
end
```

Dampening

Dampening is a method that's used to limit the amount of network problems due to flapping routes. With dampening, the flapping still occurs but the peer routers pay less and less attention to that route as it flaps more often. One flap doesn't start dampening, but the second flap starts a timer where the router won't use that route because it is considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There's a period of time called the reachability half-life, after which a route flap will be suppressed for only half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate device's cache by using one of the `execute router clear bgp` CLI commands:

```
# execute router clear bgp dampening {<ip_address> | <ip_address/netmask>}
```

or

```
# execute router clear bgp flap-statistics {<ip_address> | <ip_address/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the following CLI command:

```
# execute router clear bgp dampening 10.10.0.0/16
```

To configure BGP route dampening:

```
config router bgp
    set dampening {enable | disable}
    set dampening-max-suppress-time <minutes_integer>
    set dampening-reachability-half-life <minutes_integer>
    set dampening-reuse <reuse_integer>
    set dampening-route-map <routemap-name_str>
    set dampening-suppress <limit_integer>
    set dampening-unreachability-half-life <minutes_integer>
end
```

Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded but the hardware can still function normally.

Graceful restart is best used for these situations where routing won't be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart doesn't have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster advertises that it is going offline, and will not appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table. If there is a flap, the HA cluster routing table will be out-of-date.

For example, the FortiGate is one of four BGP routers that send updates to each other. Any of those routers may support graceful starting. When a router plans to go offline, it sends a message to its neighbors stating how long it expects to be offline. This way, its neighboring routers don't remove it from their routing tables. However, if that router isn't back online when expected, the routers will mark it offline. This prevents routing flap and its associated problems.

FortiGate devices support both graceful restart of their own BGP routing software and neighboring BGP routers.

To configure BGP graceful restart:

```
config router bgp
    set graceful-restart {disable | enable}
    set graceful-restart-time <seconds_integer>
    set graceful-stalepath-time <seconds_integer>
    set graceful-update-delay <seconds_integer>
    config neighbor
        edit 10.12.101.4
            set capability-graceful-restart {enable | disable}
        next
    end
end
```

Before the restart, the router sends its peers a message to say it's restarting. The peers mark all the restarting router's routes as stale, but they continue to use the routes. The peers assume the router will restart, check its routes, and take care of them, if needed, after the restart is complete. The peers also know what services the restarting router can maintain during its restart. After the router completes the restart, the router sends its peers a message to say it's done restarting.

To restart the router:

```
# execute router restart
```

Scheduled time offline

Graceful restart is a means for a router to advertise that it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their

routing table until after a set time elapses. During that time, if the router comes back online, everything continues to function as normal. If that router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that the router will be offline for a long time.

The following example demonstrates if you want to configure graceful restart on the FortiGate where you expect the FortiGate to be offline for no more than two minutes, and after three minutes the BGP network should consider the FortiGate to be offline.

To configure graceful restart time settings:

```
config router bgp
    set graceful-restart enable
    set graceful-restart-time 120
    set graceful-stalepath-time 180
end
```

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD communicate with each other and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

For more information about BFD, see BFD on page 597.

BGP path selection process

Sometimes the FortiGate may receive multiple BGP paths from neighbors and must decide which is the best path to take. The following criteria are used to determine the best path.

Consider only routes with no AS loops and a valid next hop, and then:

1. Prefer the highest weight (this attribute is local to the FortiGate).
2. Prefer the highest local preference (applicable within AS).
3. Prefer the route originated by the local router (next hop = 0.0.0.0).
4. Prefer the shortest AS path.
5. Prefer the lowest origin code (IGP > EGP > incomplete).
6. Prefer the lowest MED (exchanged between autonomous systems).
7. Prefer the EBGP path over IBGP path.
8. Prefer the path through the closest IGP neighbor.
9. Prefer the oldest route for EBGP paths.
10. Prefer the path with the lowest neighbor BGP router ID.
11. Prefer the path with the lowest neighbor IP address.

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-enabled

router fail to arrive, that router is declared to be down. BFD communicates this information to the associated routing protocols and the routing information is updated. It helps detect one way device failure and is used for fast convergence of routing protocols.

BFD can run on an entire FortiGate, selected interfaces, or on a protocol, such as BGP, for all configured interfaces. The configuration hierarchy allows each lower level to override the BFD setting of the upper level. For example, if you enable BFD for an entire FortiGate, you can disable BFD for an interface or for BGP.

Echo mode and authentication are not supported for BFD on the FortiGate.

BFD can be enabled per device, VDOM, or interface. Once enabled, a BFD neighbor should be defined. Finally, enable BFD on a route or routing protocol.

To configure BFD for an entire FortiGate:

```
config system settings
    set bfd {enable | disable}
    set bfd-desired-min-tx <ms>
    set bfd-required-min-rx <ms>
    set bfd-detect-mult <multiplier>
    set bfd-dont-enforce-src-port {enable | disable}
end
```

To configure BFD for an interface:

```
config system interface
    edit <interface-name>
        set bfd {global | enable | disable}
        set bfd-desired-min-tx <ms>
        set bfd-required-min-rx <ms>
        set bfd-detect-mult <multiplier>
    next
end
```

To configure BFD neighbors:

```
config router {bfd | bfd6}
    config neighbor
        edit <IP-address>
            set interface <interface-name>
        next
    end
end
```

To show BFD neighbors:

```
# get router {info | info6} bfd neighbor
```

To show BFD requests:

```
# get router {info | info6} bfd requests
```

BFD and static routes

BFD for static routes allows you to configure routing failover based on remote path failure detection. BFD removes a static route from the routing table if the FortiGate can't reach the route's destination and returns the route to the routing table if the route's destination is restored.

For example, you can add two static routes with BFD enabled. If one of the routes has a higher priority, all matching traffic uses that route. If BFD determines that the link to the gateway of the route with the higher priority is down, the higher priority route is removed from the routing table and all matching traffic uses the lower priority route. If the link to the gateway for the higher priority route comes back up, BFD adds the route back into the routing table and all matching traffic switches to use the higher priority route.

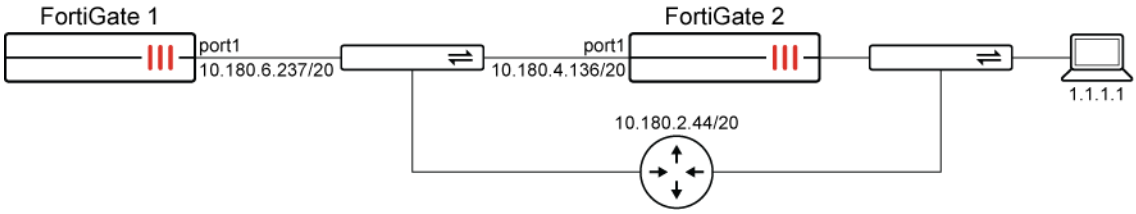
You can configure BFD for IPv4 and IPv6 static routes.

To configure BFD for static routes:

```
config router {static | static6}
    edit <sequence-number>
        set bfd {enable | disable}
        set device <gateway-out-interface>
    next
end
```

Example

The following example demonstrates the configuration of static routes between two FortiGates. There is a host behind FortiGate 2 with an IP address of 1.1.1.1. FortiGate 1 has multiple paths to reach the host.



To configure static routes:

1. Configure FortiGate 1:

```
config system interface
    edit "port1"
        set vdom "root"
        set ip 10.180.6.237 255.255.240.0
        set allowaccess ping
        set bfd enable
```

```
    next
end
config router bfd
    config neighbor
        edit 10.180.4.136
            set interface "port1"
        next
    end
end
```

2. Configure FortiGate 2:

```
config system interface
    edit "port1"
        set vdom "root"
        set ip 10.180.4.136 255.255.240.0
        set allowaccess ping
        set bfd enable
    next
end
config router bfd
    config neighbor
        edit 10.180.6.237
            set interface "port1"
        next
    end
end
```

3. Configure two static routes:

```
config router static
    edit 2
        set dst 1.1.1.1 255.255.255.255
        set gateway 10.180.4.136
        set device "port1"
        set bfd enable
    next
    edit 3
        set dst 1.1.1.1 255.255.255.255
        set gateway 10.180.2.44
        set distance 20
        set device "port1"
    next
end
```

4. Confirm that BFD neighborship is established:

```
# get router info bfd neighbor
OurAddress      NeighAddress    State       Interface       LDesc/RDesc
10.180.6.237    10.180.4.136    UP          port1           1/1
```

5. Review the active route in the routing table:

```
# get router info routing-table all
S       1.1.1.1/32 [10/0] via 10.180.4.136, port1
C       10.180.0.0/20 is directly connected, port1
```

The route with the lower distance is preferred in the routing table.

If port1 on FortiGate 2 goes down or FortiGate 1 is unable to reach 10.180.4.126, the BFD neighborship will go down.

```
# get router info bfd neighbor
OurAddress      NeighAddress    State       Interface       LDesc/RDesc
10.180.6.237    10.180.4.136    DOWN        port1           1/1
```

With BFD neighborship down, the FortiGate is unable to reach 1.1.1.1/32 through gateway 10.180.4.136. The routing table will be updated so that the route through gateway 10.180.2.44 is active in the routing table.

```
# get router info routing-table all
S       1.1.1.1/32 [20/0] via 10.180.2.44, port1
C       10.180.0.0/20 is directly connected, port1
```

BFD removes a static route from the routing table if the FortiGate cannot reach the route's destination. The static route will be returned to the routing table is the route's destination is restored.

BFD and OSPF

You can configure BFD for Open Shortest Path First (OSPF) on a FortiGate. FortiGate supports BFD for OSPF for both IPv4 and IPv6. BFD must be configured globally and per interface.

To configure BFD for OSPF:

```
config router {ospf | ospf6}
    set bfd {enable | disable}
end
```

To enable BFD on a specific OSPF interface:

```
config router {ospf | ospf6}
    set bfd enable
    config {ospf-interface | ospf6-interface}
        edit <ID>
            set bfd {global | enable | disable}
            set area-id <IP address>
        next
    end
end
```

If BFD is configured when OSPF is not, no BFD packets will be sent. When both BFD and OSFP are configured, the neighbors for both will be the same. Use the following commands to confirm that the neighbor IP addresses match:

```
# get router info ospf neighbor
# get router info bfd neighbor
```

BFD and BGP

While BGP can detect route failures, BFD can be configured to detect these failures more quickly, which allows for faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

The `config router bgp` commands allow you to set the addresses of the neighbor units that are also running BFD. Both units must be configured with BFD in order to use it.

To configure BFD for BGP:

```
config router bgp
    config neighbor
        edit <neighbor-IP-address>
            set bfd {enable | disable}
        next
    end
end
```

BFD for Multihop paths

FortiGate BFD can support neighbors connected over multiple hops. When BFD is down, BGP sessions will be reset and will try to re-establish neighbor connection immediately. See BFD for multihop path for BGP on page 603 for more information.

To configure BFD for multihop paths:

```
config router {bfd | bfd6}
    config multihop-template
        edit <ID>
            set src <IP address/netmask>
            set dst <IP address/netmask>
            set bfd-desired-min-tx <integer>
            set bfd-required-min-rx <integer>
            set bfd-detect-mult <integer>
            set auth-mode {none | md5}
            set md5-key <password>
        next
    end
end
```

Troubleshooting BFD

You can troubleshoot BFD using the following commands:

```
# get router {info | info6} bfd neighbor
# get router {info | info6} bfd requests
# diagnose sniffer packet any <filter> <sniffer count>
# diagnose debug application bfdd <debug level>
# diagnose debug enable
```

BFD for multihop path for BGP

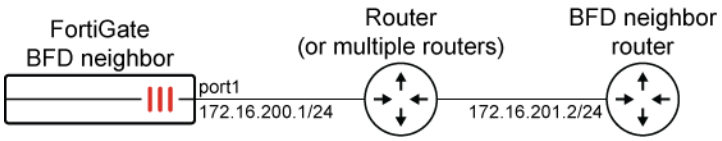
In BFD, a FortiGate can support neighbors connected over multiple hops. When BFD is down, BGP sessions are reset and will try to immediately re-establish neighbor connections. Previously, BFD was only supported when two routers or FortiGates were directly connected on the same network.

```
config router {bfd | bfd6}
    config multihop-template
        edit <ID>
            set src <class_IP/netmask>
            set dst <class_IP/netmask>
            set bfd-desired-min-tx <integer>
            set bfd-required-min-rx <integer>
            set bfd-detect-mult <integer>
            set auth-mode {none | md5}
            set md5-key <password>
        next
    end
end
```

`src <class_IP/netmask>`	Enter the source prefix.
`dst <class_IP/netmask>`	Enter the destination prefix.
`bfd-desired-min-tx <integer>`	Set the BFD desired minimal transmit interval, in milliseconds (100 - 30000, default = 250).
`bfd-required-min-rx <integer>`	Set the BFD required minimal transmit interval, in milliseconds (100 - 30000, default = 250).
`bfd-detect-mult <integer>`	Set the BFD detection multiplier (3 - 50, default = 3).
`auth-mode {none | md5}`	Set the authentication mode (none or meticulous MD5).
`md5-key <password>`	Enter the password.

Example

This example includes IPv4 and IPv6 BFD neighbor configurations. The BFD neighbor is also a BGP neighbor that is in a different AS.



To configure BFD with multihop BGP paths:

1. Enable BFD on all interfaces:

```
config system settings
    set bfd enable
end
```

2. Enable BFD on port1 and ignore the global configuration:

```
config system interface
    edit "port1"
        set bfd enable
    next
end
```

3. Configure the BGP neighbors:

```
config router bgp
    set as 65412
    set router-id 1.1.1.1
    config neighbor
        edit "172.16.201.2"
            set bfd enable
            set ebgp-enforce-multihop enable
            set soft-reconfiguration enable
            set remote-as 65050
        next
        edit "2000:172:16:201::2"
            set bfd enable
            set ebgp-enforce-multihop enable
            set soft-reconfiguration enable
            set remote-as 65050
        next
    end
end
```

4. Configure the IPv4 BFD:

```
config router bfd
    config multihop-template
        edit 1
            set src 172.16.200.0 255.255.255.0
            set dst 172.16.201.0 255.255.255.0
            set auth-mode md5
            set md5-key **********
        next
```

```
    end
end
```

5. Configure the IPv6 BFD:

```
config router bfd6
    config multihop-template
        edit 1
            set src 2000:172:16:200::/64
            set dst 2000:172:16:201::/64
        next
    end
end
```

Testing the connection

1. Verify the BFD status for IPv4 and IPv6:

```
# get router info bfd requests
BFD Peer Requests:
    client types(ct in 0x): 01=external 02=static
        04=ospf 08=bgp 10=pim-sm
src=172.16.200.1     dst=172.16.201.2     ct=08 ifi=9 type=SM
```

```
# get router info bfd neighbor
OurAddress      NeighAddress    State       Interface       LDesc/RDesc
172.16.200.1    172.16.201.2    UP          port1           5/3/M
```

```
# get router info6 bfd requests
BFD Peer Requests:
    client types(ct in 0x): 01=external 02=static
        04=ospf 08=bgp 10=pim-sm
src=2000:172:16:200::1
dst=2000:172:16:201::2
ct=08 ifi=9 type=SM
```

```
# get router info6 bfd neighbor
OurAddress: 2000:172:16:200::1
NeighAddress: 2000:172:16:201::2
State: UP Interface: port1 Desc: 6/4 Multi-hop
```

2. Verify the BGP status and the BGP routing table:

```
# get router info bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 11
3 BGP AS-PATH entries
0 BGP community entries

Neighbor           V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
172.16.201.2       4      65050     185     187       10    0    0 00:54:20        4
```

```
2000:172:16:201::2 4      65050     159     160       10    0    0 00:54:24        4

Total number of neighbors 2
```

```
# get router info routing-table bgp
Routing table for VRF=0
B       172.28.1.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1), 00:54:32
B       172.28.2.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1), 00:54:32
B       172.28.5.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1), 00:54:32
B       172.28.6.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1), 00:54:32
```

```
# get router info6 bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412

0 BGP community entries

Neighbor           V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
172.16.201.2       4      65050     185     187        7    0    0 00:54:24        3
2000:172:16:201::2 4      65050     159     160        7    0    0 00:54:28        3

Total number of neighbors 2
```

```
# get router info6 routing-table bgp
Routing table for VRF=0
B       2000:172:28:1::/64 [20/0] via 2000:172:16:201::2 (recursive via 2000:172:16:200::4,
port1), 00:54:40
B       2000:172:28:2::/64 [20/0] via 2000:172:16:201::2 (recursive via 2000:172:16:200::4,
port1), 00:54:40
B       2000:172:28:3::/64 [20/0] via 2000:172:16:201::2 (recursive via 2000:172:16:200::4,
port1), 00:54:40
```

3. Simulate a disruption to the BFD connection. The BFD neighbor is lost:

```
# get router info bfd neighbor
OurAddress      NeighAddress    State       Interface       LDesc/RDesc
```

```
# get router info6 bfd neighbor
```

4. The BGP neighbor is reset, and the FortiGate attempts to re-establish a connection with the neighbor. The timers are reset once the neighbor connection is re-established:

```
# get router info bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 12
4 BGP AS-PATH entries
0 BGP community entries

Neighbor           V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
172.16.201.2       4      65050     189     192       11    0    0 00:00:11        4
2000:172:16:201::2 4      65050     165     167       12    0    0 00:00:08        4
```

```
Total number of neighbors 2
```

```
# get router info6 bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 10
4 BGP AS-PATH entries
0 BGP community entries

Neighbor           V         AS MsgRcvd MsgSent   TblVer  InQ OutQ Up/Down  State/PfxRcd
172.16.201.2       4      65050     189     192        8    0    0 00:00:15        3
2000:172:16:201::2 4      65050     165     167        9    0    0 00:00:12        3

Total number of neighbors 2
```

5. The BGP routes are learned again, and there are new timers in the route tables:

```
# get router info routing-table bgp
Routing table for VRF=0
B       172.28.1.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1), 00:00:15
B       172.28.2.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1), 00:00:15
B       172.28.5.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1), 00:00:15
B       172.28.6.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1), 00:00:15
```

```
# get router info6 routing-table bgp
Routing table for VRF=0
B       2000:172:28:1::/64 [20/0] via 2000:172:16:201::2 (recursive via 2000:172:16:200::4,
port1), 00:00:13
B       2000:172:28:2::/64 [20/0] via 2000:172:16:201::2 (recursive via 2000:172:16:200::4,
port1), 00:00:13
B       2000:172:28:3::/64 [20/0] via 2000:172:16:201::2 (recursive via 2000:172:16:200::4,
port1), 00:00:13
```

Routing objects

The following objects can be configured from the *Network* > *Routing Objects* page:

- Route maps on page 607
- Access lists on page 611
- Prefix lists on page 613
- AS path lists on page 616
- Community lists on page 617

Route maps

Route maps are a powerful tool to apply custom actions to dynamic routing protocols based on specific conditions. They are used primarily in BGP to manipulate routes advertised by the FortiGate (`route-map-out`) or received routes from other BGP routers (`route-map-in`).

Route maps can be used in OSPF for conditional `default-information-originate`, filtering external routes, or matching specific routes for redistribution. Similarly, route maps can be used by RIP to match routes for redistribution.

A route map may have multiple rules that are processed in the ascending order of their rule ID numbers. The rule ID number determines the order of evaluation, where each rule has an action to permit or deny. If the action is not set, the default action is to permit.

When new are added to an existing route map, they may be shown at the end of the configuration list, regardless of their assigned rule ID. This visual arrangement does not impact functionality; FortiOS processes the rules according to their numerical IDs, and not their position in the route map configuration. For example, if a new rule with ID 15 is added to a route map that already contains rules with IDs 10, 20, 30, and 40, the new rule might appear at the bottom of the list in the configuration. Despite this placement, FortiOS will process the rules in the ascending order of Rule ID number: 10, 15, 20, 30, then 40.

To enhance readability and maintain an organized configuration, it is recommended to arrange the rules sequentially by their IDs. This can be achieved by deleting and re-adding the rules in the desired order during a maintenance window to avoid traffic disruption. Alternatively, using a text editor to reorder the rules before applying them to the FortiOS configuration can streamline this process.

The rules have criteria for matching a route based on various attributes, or setting attributes based on a matched route. For example, a route map can be used to match BGP routes with a certain community string, and then set an AS path to the matching route. This can be applied to a BGP neighbor by configuring the route map in the settings for that neighbor.

To configure a route map that matches criteria based on other routing objects:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set action {permit | deny}
                set match-as-path <string>
                set match-community <string>
                set match-ip-address <string>
                set match-ip6-address <string>
                set match-ip-nexthop <string>
                set match-ip6-nexthop <string>
            next
        end
    next
end
```

`match-as-path <string>`	Match a BGP AS path list.
`match-community <string>`	Match a BGP community list.
`match-ip-address <string>`	Match an IPv4 address permitted by `access-list` or `prefix-list`.
`match-ip6-address <string>`	Match an IPv6 address permitted by `access-list6` or `prefix-list6`.
`match-ip-nexthop <string>`	Match a next hop IPv4 address passed by `access-list` or `prefix-list`.
`match-ip6-nexthop <string>`	Match a next hop IPv6 address passed by `access-list6` or `prefix-list6`.

Route maps can be used by various routing protocols, such as RIP, OSPF, and BGP.

To use a route map with RIP:

```
config router rip
    config redistribute
        edit <name>
            set routemap <string>
        next
    end
end
```

To use a route map with OSPF:

```
config router ospf
    set default-information-route-map <string>
    set distribute-route-map-in <string>
    config redistribute <string>
        set routemap <string>
    end
end
```

`default-information-route-map <string>`	Enter the default information route map.
`distribute-route-map-in <string>`	Enter the route map to filter incoming external routes.
`redistribute <string>`	Configure the redistribute protocol.

To use a route map with BGP:

```
config router bgp
    config neighbor
        edit <ip>
            set route-map-in <string>
            set route-map-in6 <string>
            set route-map-in-vpnv4 <string>
            set route-map-out <string>
            set route-map-out-preferable <string>
            set route-map-out6 <string>
            set route-map-out6-preferable <string>
            set route-map-out-vpnv4 <string>
            set route-map-out-vpnv4-preferable <string>
        next
    end
    config network
        edit <id>
            set prefix <IP/netmask>
            set route-map <string>
        next
```

```
    end
    config redistribute <string>
        set route-map <string>
    end
end
```

route-map-in <string>	Enter the IPv4 inbound route map filter.
route-map-in6 <string>	Enter the IPv6 inbound route map filter.
route-map-in-vpnv4 <string>	Enter the VPNv4 inbound route map filter.
route-map-out <string>	Enter the IPv4 outbound route map filter.
route-map-out-preferable <string>	Enter the IPv4 outbound route map filter if the peer is preferred.
route-map-out6 <string>	Enter the IPv6 outbound route map filter.
route-map-out6-preferable <string>	Enter the IPv6 outbound route map filter if the peer is preferred.
route-map-out-vpnv4 <string>	Enter the VPNv4 outbound route map filter.
route-map-out-vpnv4-preferable <string>	Enter the VPNv4 outbound route map filter if the peer is preferred.
route-map <string>	Enter the route map to modify the generated route.
redistribute <string>	Configure the redistribute protocol.

To use a route map with BGP conditional advertisement:

```
config router bgp
    set as <AS_number>
    config neighbor
        edit <ip>
            set remote-as <AS_number>
            config conditional-advertise
                edit <advertise-routemap>
                    set condition-routemap <name1>, <name2>, ...
                    set condition-type {exist | non-exist}
                next
            end
        next
    end
end
```

<advertise-routemap>	Edit the advertising route map.
condition-routemap <name1>, <name2>, ...	Enter the list of conditional route maps.

Access lists

Access lists are simple lists used for filtering routes based on a prefix consisting of an IPv4 or IPv6 address and netmask.

To configure an IPv4 access list:

```
config router access-list
    edit <name>
        config rule
            edit <id>
                set action {permit | deny}
                set prefix <IPv4_address>
                set wildcard <wildcard_filter>
                set exact-match {enable | disable}
            next
        end
    next
end
```

To configure an IPv6 access list:

```
config router access-list6
    edit <name>
        config rule
            edit <id>
                set action {permit | deny}
                set prefix <IPv6_address>
                set exact-match {enable | disable}
            next
        end
    next
end
```

In RIP, an access list can be used in the `distribute-list` setting to filter received or advertised routes, or in an `offset-list` to offset the hop count metric for a specific prefix.

To use an access list in RIP:

```
config router rip
    config distribute-list
        edit <id>
            set direction {in | out}
            set listname <string>
        next
    end
    config offset-list
        edit <id>
            set direction {in | out}
            set access-list <string>
```

```
            set offset <integer>
        next
    end
end
```

`listname <string>`	Enter the distribute access or prefix list name.
`access-list <string>`	Enter the access list name.

In OSPF, an access list can be used in the `distribute-list-in` setting to act as a filter to prevent a certain route from being inserted into the routing table. An access list can also be used in the `distribute-list` to filter the routes that can be distributed from other protocols.

To use an access list in OSPF:

```
config router ospf
    set distribute-list-in <string>
    config distribute-list
        edit <id>
            set access-list <string>
            set protocol {connected | static | rip}
        next
    end
end
```

`distribute-list-in <string>`	Enter the filter for incoming routes.
`access-list <string>`	Enter the access list name.

In BGP, an access list can be used to filter updates from a neighbor or to a neighbor.

To use an access list in BGP:

```
config router bgp
    config neighbor
        edit <ip>
            set distribute-list-in <string>
            set distribute-list-in6 <string>
            set distribute-list-in-vpnv4 <string>
            set distribute-list-out <string>
            set distribute-list-out6 <string>
            set distribute-list-out-vpnv4 <string>
        next
    end
end
```

`distribute-list-in <string>`	Enter the filter for IPv4 updates from this neighbor.
`distribute-list-in6 <string>`	Enter the filter for IPv6 updates from this neighbor.

`distribute-list-in-vpnv4 <string>`	Enter the filter for VPNv4 updates from this neighbor.
`distribute-list-out <string>`	Enter the filter for IPv4 updates to this neighbor.
`distribute-list-out6 <string>`	Enter the filter for IPv6 updates to this neighbor.
`distribute-list-out-vpnv4 <string>`	Enter the filter for VPNv4 updates to this neighbor.

In a route map, an access list can be used to match IP addresses and next hops.

To use an access list in a route map:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set match-ip-address <string>
                set match-ip6-address <string>
                set match-ip-nexthop <string>
                set match-ip6-nexthop <string>
            next
        end
    next
end
```

`match-ip-address <string>`	Match an IPv4 address permitted by `access-list` or `prefix-list`.
`match-ip6-address <string>`	Match an IPv6 address permitted by `access-list6` or `prefix-list6`.
`match-ip-nexthop <string>`	Match a next hop IPv4 address passed by `access-list` or `prefix-list`.
`match-ip6-nexthop <string>`	Match a next hop IPv6 address passed by `access-list6` or `prefix-list6`.

Prefix lists

Similar to access lists, prefix lists are simple lists used for filtering routes based on a prefix consisting of an IPv4 or IPv6 address and netmask, but they use settings to specify the minimum (`ge`, greater than or equal) and maximum (`le`, less than or equal) prefix length to be matched. For example, a prefix of 10.0.0.0/8 with a `ge` of 16 will match anything in the 10.0.0.0/8 network with /16 or above; 10.10.0.0/16 will match, and 10.10.0.0/12 will not match.

To configure an IPv4 prefix list:

```
config router prefix-list
    edit "prefix-list1"
        config rule
            edit 1
                set action {permit | deny}
                set prefix <IPv4_address>
```

```
                set ge <integer>
                set le <integer>
            next
        end
    next
end
```

To configure an IPv6 prefix list:

```
config router prefix-list6
    edit "prefix-list-IPv6"
        config rule
            edit 1
                set action {permit | deny}
                set prefix6 <IPv6_address>
                set ge <integer>
                set le <integer>
            next
        end
    next
end
```

In RIP, an prefix list can be used in the `distribute-list` setting to filter received or advertised routes.

To use a prefix list in RIP:

```
config router rip
    config distribute-list
        edit <id>
            set listname <string>
        next
    end
end
```

`listname <string>`	Enter the distribute access or prefix list name.

In OSPF, a prefix list can be used in the `distribute-list-in` setting to act as a filter to prevent a certain route from being inserted into the routing table.

To use a prefix list in OSPF:

```
config router ospf
    set distribute-list-in <string>
end
```

`distribute-list-in <string>`	Enter the filter for incoming routes.

In BGP, a prefix list can be used to filter updates from a neighbor or to a neighbor.

To use a prefix list in BGP:

```
config router bgp
    config neighbor
        edit <ip>
            set prefix-list-in <string>
            set prefix-list-in6 <string>
            set prefix-list-in-vpnv4 <string>
            set prefix-list-out <string>
            set prefix-list-out6 <string>
            set prefix-list-out-vpnv4 <string>
        next
    end
end
```

`prefix-list-in <string>`	Enter the IPv4 inbound filter for updates from this neighbor.
`prefix-list-in6 <string>`	Enter the IPv6 inbound filter for updates from this neighbor.
`prefix-list-in-vpnv4 <string>`	Enter the inbound filter for VPNv4 updates from this neighbor.
`prefix-list-out <string>`	Enter the IPv4 outbound filter for updates to this neighbor.
`prefix-list-out6 <string>`	Enter the IPv6 outbound filter for updates to this neighbor.
`prefix-list-out-vpnv4 <string>`	Enter the outbound filter for VPNv4 updates to this neighbor.

In a route map, a prefix list can be used to match IP addresses and next hops.

To use a prefix list in a route map:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set match-ip-address <string>
                set match-ip6-address <string>
                set match-ip-nexthop <string>
                set match-ip6-nexthop <string>
            next
        end
    next
end
```

`match-ip-address <string>`	Match an IPv4 address permitted by `access-list` or `prefix-list`.
`match-ip6-address <string>`	Match an IPv6 address permitted by `access-list6` or `prefix-list6`.
`match-ip-nexthop <string>`	Match a next hop IPv4 address passed by `access-list` or `prefix-list`.
`match-ip6-nexthop <string>`	Match a next hop IPv6 address passed by `access-list6` or `prefix-list6`.

AS path lists

AS path lists use regular expressions to compare and match the AS_PATH attribute for a BGP route. They can be used to filter inbound or outbound routes from a BGP neighbor, or as matching criteria in a route map to match an AS_PATH in a BGP route.

To configure an AS path list:

```
config router aspath-list
    edit <name>
        config rule
            edit <id>
                set action {deny | permit}
                set regexp <string>
            next
        end
    next
end
```

To use an AS path list in BGP:

```
config router bgp
    config neighbor
        edit <ip>
            set filter-list-in <string>
            set filter-list-in6 <string>
            set filter-list-out <string>
            set filter-list-out6 <string>
        next
    end
end
```

`filter-list-in <string>`	Enter the BGP filter for IPv4 inbound routes.
`filter-list-in6 <string>`	Enter the BGP filter for IPv6 inbound routes.
`filter-list-out <string>`	Enter the BGP filter for IPv4 outbound routes.
`filter-list-out6 <string>`	Enter the BGP filter for IPv6 outbound routes.

To use an AS path list in a route map:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set match-as-path <string>
            next
        end
```

```
    next
end
```

`match-as-path <string>`	Match a BGP AS path list.

Community lists

Community lists provide a means to filter BGP routes using a community string. They can be applied in a route map to match routes that have the community string defined in the community list.

To configure a community list:

```
config router community-list
    edit <name>
        set type {standard | expanded}
        config rule
            edit <id>
                set action {deny | permit}
                set regexp <string>
                set match <string>
            next
        end
    next
end
```

To use a community list in a route map to match a BGP community:

```
config router route-map
    edit <name>
        config rule
            edit <id>
                set match-community <string>
            next
        end
    next
end
```

`match-community <string>`	Match a BGP community list.

In an SD-WAN deployment, a remote BGP router or spoke may communicate a preferred interface or path to route traffic using a community string. See Using BGP tags with SD-WAN rules on page 1132 and Controlling traffic with BGP route mapping and service rules on page 1138 for examples.

Multicast

The following topics include information about multicast:

- Multicast routing and PIM support on page 618
- Configuring multicast forwarding on page 620
- Using IPS inspection for multicast UDP traffic on page 627
- Including denied multicast sessions in the session table on page 630

Multicast routing and PIM support

Multicasting (also called IP multicasting) consists of using a single multicast source to send data to many receivers. Multicasting can be used to send data to many receivers simultaneously while conserving bandwidth and reducing network traffic. Multicasting can be used for one-way delivery of media streams to multiple receivers and for one-way data transmission for news feeds, financial information, and so on. Many dynamic routing protocols such as RIPv2, OSPF, and EIGRP use multicasting to share hello packets and routing information.

A FortiGate can operate as a Protocol Independent Multicast (PIM) version 2 router. FortiGates support PIM sparse mode (RFC 4601) and PIM dense mode (RFC 3973), and can service multicast servers or receivers on the network segment to which a FortiGate interface is connected. Groups are supported in the PIM join/prune messages. Multicast routing is not supported in transparent mode.

To support PIM communications, the sending and receiving applications, and all connecting PIM routers in between, must be enabled with PIM version 2. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations. To enable source-to-destination packet delivery, sparse mode or dense mode must be enabled on the PIM router interfaces. Sparse mode routers cannot send multicast messages to dense mode routers. If the FortiGate is located between a source and a PIM router, between two PIM routers, or is connected directly to a receiver, you must manually create a multicast policy to pass encapsulated (multicast) packets or decapsulated data (IP traffic) between the source and destination.

PIM domains

A PIM domain is a logical area comprising a number of contiguous networks. The domain contains at least one bootstrap router (BSR), and if sparse mode is enabled, a number of rendezvous points (RPs) and designated routers (DRs). When PIM is enabled, the FortiGate can perform any of these functions at any time as configured.

A PIM domain can be configured in the GUI by going to *Network* > *Multicast*, or in the CLI using `config router multicast`. Note that PIM version 2 must be enabled on all participating routers between the source and receivers. Use `config router multicast` to set the global operating parameters.

When PIM is enabled, the FortiGate allocates memory to manage mapping information. The FortiGate communicates with neighboring PIM routers to acquire mapping information and, if required, processes the multicast traffic associated with specific multicast groups.

Instead of sending multiple copies of generated IP traffic to more than one specific IP destination address, PIM-enabled routers encapsulate the data and use a Class D multicast group address (224.0.0.0 to 239.255.255.255) to forward multicast packets to multiple destinations. A single stream of data can be sent

because one destination address is used. Client applications receive multicast data by requesting that the traffic destined for a certain multicast group address be delivered to them.

PIM support for virtual routing and forwarding (VRF)

PIM supports all VRFs and is aware of IPv4 multicast routing and forwarding over a single overlay, enhancing network scalability and flexibility compared to the previous VRF 0-only support. See Virtual routing and forwarding on page 656 for more information.

Per-VRF commands are included for multicast routing, as follows:

```
config router multicast
    config pim-sm-global-vrf
        edit <vrf>
            set bsr-candidate {enable | disable}
            set bsr-interface <interface>
            set bsr-priority <0-255, default = 0>
            set bsr-hash <0-32, default = 10>
            set bsr-allow-quick-refresh {enable | disable}
            set cisco-crp-prefix {enable | disable}
            config rp-address
                edit <id>
                    set ip-address <RP router IP address>
                    set group <access list name>
                next
            end
        next
    end
end
```

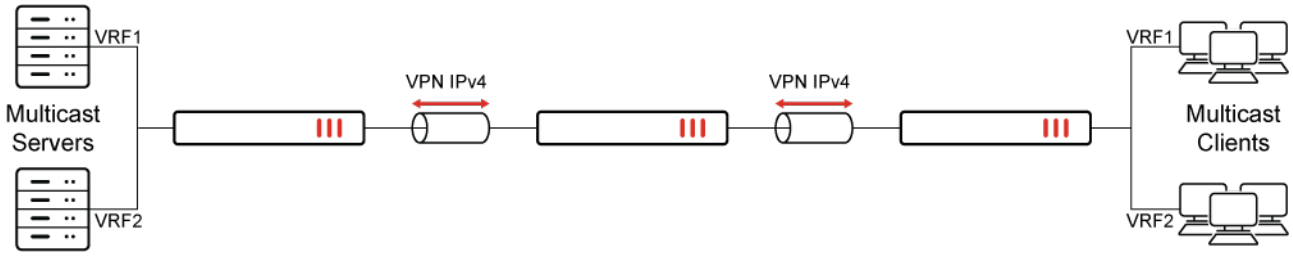
VRF support is also included in the following `diagnose`, `get`, and `execute` commands:

```
diagnose ip multicast mfc-add
diagnose ip multicast mfc-del
diagnose vpn mr|mr6 add
diagnose vpn mr|mr6 del
get router info multicast igmp groups
get router info multicast igmp groups-detail
get router info multicast table
get router info multicast table-count
get router info multicast pim sparse-mode bsr-info
get router info multicast pim sparse-mode rp-mapping
get router info multicast pim sparse-mode next-hop
get router info multicast pim sparse-mode table
execute mrouter clear multicast-routes
execute mrouter clear sparse-mode-bsr
execute mrouter clear sparse-routes
execute mrouter clear statistics
```

NPU offloading of VRF multicast traffic on a dynamic IPsec tunnel is not supported.

Example

This example uses the following topology:



In this example, the multicast server:

- Sends out multicast traffic 225.1.1.1 from 22.1.1.22 in VRF1.
- Sends out multicast traffic 225.1.1.2 from 22.1.1.55 in VRF2.

To verify VRF in IPv4 multicast routing:

1. Review the sniffer information:
   - The VRF1 client can receive 225.1.1.1 and cannot receive 225.1.1.2:

     ```
     24.872130 vd33-vlan33 in 22.1.1.22 -> 225.1.1.1: icmp: echo request
     25.872117 vd3-vlan33 out 22.1.1.22 -> 225.1.1.1: icmp: echo request
     25.872123 vd33-vlan33 in 22.1.1.22 -> 225.1.1.1: icmp: echo request
     26.872131 vd3-vlan33 out 22.1.1.22 -> 225.1.1.1: icmp: echo request
     26.872137 vd33-vlan33 in 22.1.1.22 -> 225.1.1.1: icmp: echo request
     ```

   - The VRF2 client can receive 225.1.1.2 and cannot receive 225.1.1.1:

     ```
     4.320988 vd3-vlan331 out 22.1.1.55 -> 225.1.1.2: icmp: echo request
     4.320996 vd4-vlan331 in 22.1.1.55 -> 225.1.1.2: icmp: echo request
     5.320703 vd3-vlan331 out 22.1.1.55 -> 225.1.1.2: icmp: echo request
     5.320717 vd4-vlan331 in 22.1.1.55 -> 225.1.1.2: icmp: echo request
     6.320671 vd3-vlan331 out 22.1.1.55 -> 225.1.1.2: icmp: echo request
     6.320678 vd4-vlan331 in 22.1.1.55 -> 225.1.1.2: icmp: echo request
     ```

2. Review the group information:

   ```
   # get router info multicast igmp groups
   IGMP Connected Group Membership
   VRF Group Address    Interface            Uptime   Expires          Last Reporter
   1   225.1.1.1        vd3-vlan33           00:15:16 stopped(static)  0.0.0.0
   2   225.1.1.2        vd3-vlan331          00:14:49 stopped(static)  0.0.0.0
   ```

Configuring multicast forwarding

There is sometimes confusion between the terms forwarding and routing. These two functions should not take place at the same time. Multicast forwarding should be enabled when the FortiGate is in NAT mode and you want to forward multicast packets between multicast routers and receivers. However, this function should not

be enabled when the FortiGate itself is operating as a multicast router, or has an applicable routing protocol that uses multicast.

Multicast forwarding is not supported on enhanced MAC VLAN interfaces. To use multicast with enhanced MAC VLAN interfaces, use PIM (Multicast routing and PIM support on page 618).

There are two steps to configure multicast forwarding:

1. Enabling multicast forwarding on page 621
2. Configuring multicast policies on page 622

Enabling multicast forwarding

Multicast forwarding is enabled by default. If a FortiGate is operating in transparent mode, adding a multicast policy enables multicast forwarding. In NAT mode you must use the `multicast-forward` setting to enable or disable multicast forwarding.

Multicast forwarding in NAT mode

When `multicast-forward` is enabled, the FortiGate forwards any multicast IP packets in which the TTL is 2 or higher to all interfaces and VLAN interfaces, except the receiving interface. The TTL in the IP header will be reduced by 1. Even though the multicast packets are forwarded to all interfaces, you must add multicast policies to allow multicast packets through the FortiGate.

To enable multicast forwarding in NAT mode:

```
config system settings
    set multicast-forward enable
end
```

Prevent the TTL for forwarded packets from being changed

You can use the `multicast-ttl-notchange` option so that the FortiGate does not increase the TTL value for forwarded multicast packets. Use this option only if packets are expiring before reaching the multicast router.

To prevent the TTL for forwarded packets from being changed:

```
config system settings
    set multicast-ttl-notchange enable
end
```

Disable multicast traffic from passing through the FortiGate without a policy check in transparent mode

In transparent mode, the FortiGate does not forward frames with multicast destination addresses. The FortiGate should not interfere with the multicast traffic used by routing protocols, streaming media, or other multicast communication. To avoid any issues during transmission, you can disable `multicast-skip-policy` and configure multicast security policies.

To disable multicast traffic from passing through the FortiGate without a policy check in transparent mode:

```
config system settings
    set multicast-skip-policy disable
end
```

Configuring multicast policies

Multicast packets require multicast policies to allow packets to pass from one interface to another. Similar to firewall policies, in a multicast policy you specify the source and destination interfaces, and the allowed address ranges for the source and destination addresses of the packets. You can also use multicast policies to configure source NAT and destination NAT for multicast packets.

Keep the following in mind when configuring multicast policies:

- The matched forwarded (outgoing) IP multicast source IP address is changed to the configured IP address.
- The `snat` setting is optional. Use it when SNAT is needed.

IPv4 and IPv6 multicast policies can be configured in the GUI. Go to *System* > *Feature Visibility*, and enable *Multicast Policy* and *IPv6*.

Sample basic policy

In this basic policy, multicast packets received on an interface are flooded unconditionally to all interfaces on the forwarding domain, except the incoming interface.

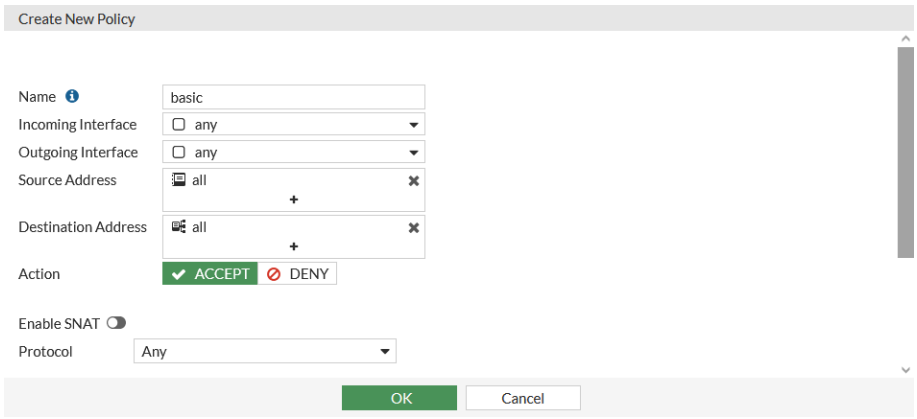
The destination address (`dstaddr`) is a multicast address object. The `all` option corresponds to all multicast addresses in the range 224.0.0.0-239.255.255.255.

To configure the multicast policy in the CLI:

```
config firewall multicast-policy
    edit 1
        set name "basic"
        set srcintf "any"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
    next
end
```

To configure the multicast policy in the GUI:

1. Go to *Policy & Objects* > *Multicast Policy* an click *Create New*.
2. Enter the required information:



Name	basic
Incoming Interface	any
Outgoing Interface	any
Source Address	all
Destination Address	all

3. Click *OK*.

Sample policy with specific source and destination interfaces

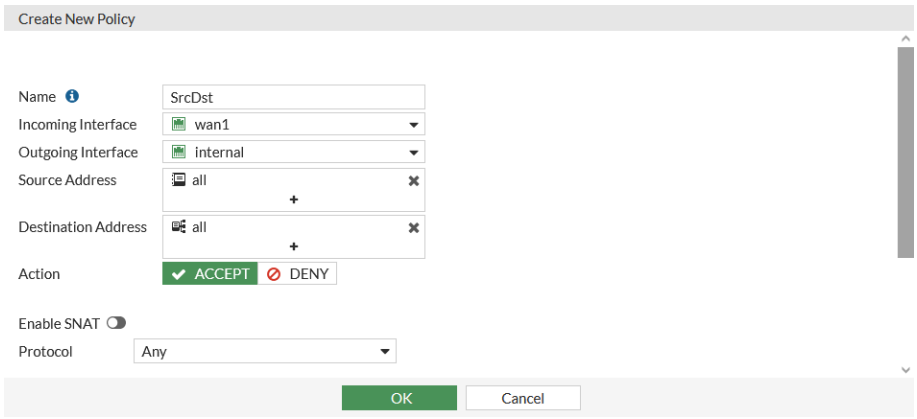
This multicast policy only applies to the source port `wan1` and the destination port `internal`.

To configure the multicast policy in the CLI:

```
config firewall multicast-policy
    edit 1
        set name "SrcDst"
        set srcintf "wan1"
        set dstintf "internal"
        set srcaddr "all"
        set dstaddr "all"
    next
end
```

To configure the multicast policy in the GUI:

1. Go to *Policy & Objects* > *Multicast Policy* an click *Create New*.
2. Enter the required information:



Name	SrcDst
Incoming Interface	wan1
Outgoing Interface	internal
Source Address	all
Destination Address	all

3. Click *OK*.

Sample policy with specific source address object

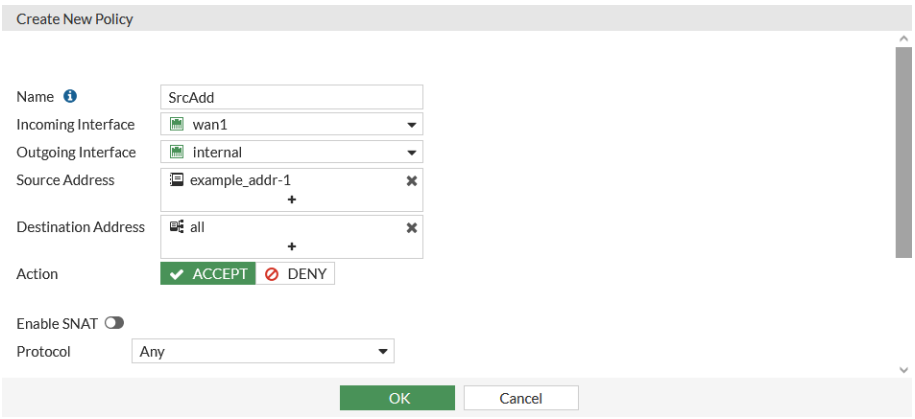
In this policy, packets are allowed to flow from `wan1` to `internal`, and sourced by the address 172.20.120.129, which is represented by the `example_addr-1` address object.

To configure the multicast policy in the CLI:

```
config firewall multicast-policy
    edit 1
        set name "SrcAdd"
        set srcintf "wan1"
        set dstintf "internal"
        set srcaddr "example_addr-1"
        set dstaddr "all"
    next
end
```

To configure the multicast policy in the GUI:

1. Go to *Policy & Objects* > *Multicast Policy* an click *Create New*.
2. Enter the required information:



Name	SrcAdd
Incoming Interface	wan1
Outgoing Interface	internal
Source Address	example_addr-1
Destination Address	all

3. Click *OK*.

Sample detailed policy

This policy accepts multicast packets that are sent from a PC with IP address 192.168.5.18 to destination address range 239.168.4.0-255. The policy allows the multicast packets to enter the `internal` interface and then exit the `external` interface. When the packets leave the external interface, their source address is translated to 192.168.18.10.

```
config firewall address
    edit "192.168.5.18"
        set subnet 192.168.5.18 255.255.255.255
    next
end
```

```
config firewall multicast-address
    edit "239.168.4.0"
        set start-ip 239.168.4.0
        set end-ip 239.168.4.255
    next
end
```

```
config firewall multicast-policy
    edit 1
        set srcintf "internal"
        set dstintf "external"
        set srcaddr "192.168.5.18"
        set dstaddr "239.168.4.0"
        set snat enable
```

```
        set snat-ip 192.168.18.10
    next
end
```

To configure multicast policies in the GUI, enable *Multicast Policy* in *System > Feature Visibility*.

Using multi-VDOM mode

When using multi-VDOM mode, it is important to avoid causing a multicast network loop by creating an all-to-all multicast policy. By default, on models that support NPU virtual links, changing the `vdom-mode` to `multi-vdom` will create a pair of npu0_vlink0 and npu0_vlink1 interfaces in the same root VDOM. By virtue of the all-to-all multicast policy and the fact the npu0_vlink interfaces are virtually connected, it forms a multicast network loop.

Therefore, when using multi-VDOM mode:

1. Ensure there is no existing all-to-all multicast policy before changing to multi-VDOM mode.
2. If an all-to-all multicast policy must be defined, ensure that no two connected interfaces (such as npu0_vlink0 and npu0_vlink1) belong in the same VDOM.

This configuration will result in a multicast loop:

```
config system global
    set vdom-mode multi-vdom
end
config firewall multicast-policy
    edit 1
        set logtraffic enable
        set srcintf "any"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
    next
end
show system interface
config system interface
    edit "npu0_vlink0"
        set vdom "root"
        set type physical
    next
    edit "npu0_vlink1"
        set vdom "root"
        set type physical
    next
end
```

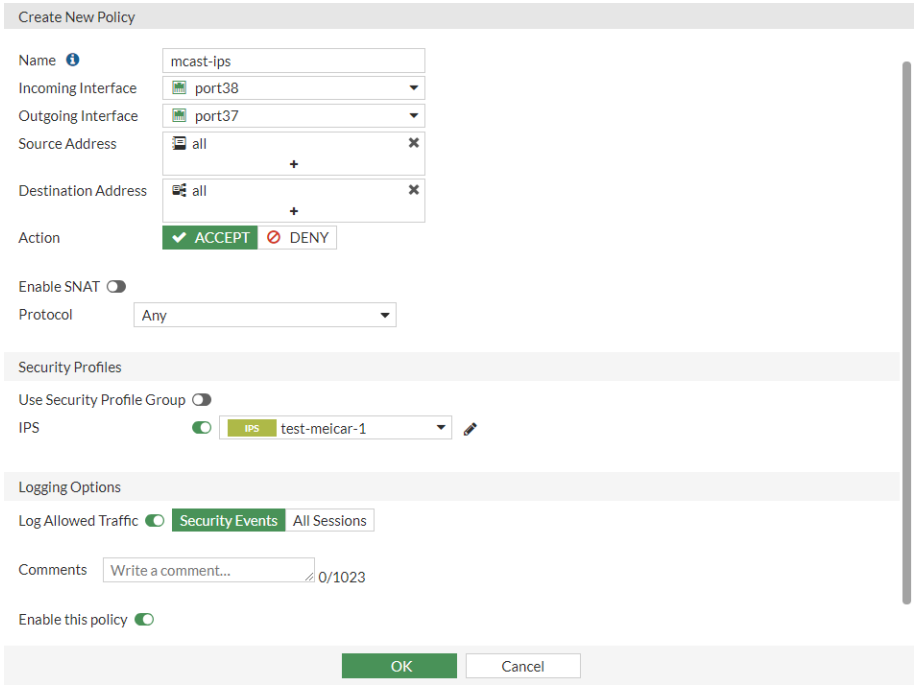
Using IPS inspection for multicast UDP traffic

IPS inspection can be applied for multicast UDP traffic in multicast firewall policies.

```
config firewall {multicast-policy | multicast-policy6}
    edit <id>
        set utm-status {enable | disable}
        set ips-sensor <name>
        set logtraffic {all | utm | disable}
    next
end
```

IPv4 and IPv6 multicast policies can be configured in the GUI. Go to *System* > *Feature Visibility*, and enable *Multicast Policy* and *IPv6*.

The multicast policy dialog page (*Policy & Objects* > *Multicast Policy*) includes a *Security Profiles* section where you can enable *IPS* and apply an IPS profile.



Example

In this example, an IPv4 multicast policy is configured with IPS inspection enabled. Multicast UDP traffic that contains IPS attacks is detected and blocked. A custom IPS signature is created with an infected EICAR pattern for the UDP protocol.

To use IPS inspection for multicast UDP traffic:

1. Configure the IPS custom signature:

```
config ips custom
    edit "meicar"
        set signature "F-SBID( --name \"meicar\"; --attack_id 9999; --protocol udp; --severity
medium; --default_action clear_session; --pattern \"$EICAR-STANDARD-ANTIVIRUS-TEST-FILE\";)"
        set protocol UDP
        set log disable
        set action block
    next
end
```

2. Configure the IPS sensor:

```
config ips sensor
    edit "test-meicar-1"
        config entries
            edit 1
                set rule 9999
                set status enable
                set action block
            next
        end
    next
end
```

3. Configure the multicast policy:

```
config firewall multicast-policy
    edit 1
        set srcintf "port38"
        set dstintf "port37"
        set srcaddr "all"
        set dstaddr "all"
        set utm-status enable
        set ips-sensor "test-meicar-1"
    next
end
```

4. Add the server to the multicast group 239.1.1.10 and join it using a terminal:

```
fosqa@ips_pc5:~$ iperf -s -u -B 239.1.1.10 -i 1
------------------------------------------------------------
Server listening on UDP port 5001
Binding to local address 239.1.1.10
Joining multicast group  239.1.1.10
Receiving 1470 byte datagrams
UDP buffer size:  208 KByte (default)
------------------------------------------------------------
[  3] local 239.1.1.10 port 5001 connected with 10.1.100.11 port 52972
```

5. From a terminal on the client, send multicast UDP traffic with the EICAR file:

```
root@PC01:~# iperf -c 239.1.1.10 -u -T 3 -t 20 -i 1 -F eicar
------------------------------------------------------------
Client connecting to 239.1.1.10, UDP port 5001
Sending 1470 byte datagrams, IPG target: 11215.21 us (kalman adjust)
Setting multicast TTL to 3
UDP buffer size:  208 KByte (default)
------------------------------------------------------------
[  4] local 10.1.100.11 port 33383 connected with 239.1.1.10 port 5001
[ ID] Interval       Transfer     Bandwidth
[  4]  0.0- 0.0 sec  1.44 KBytes  1.03 Mbits/sec
[  4] Sent 1 datagrams
```

The traffic will be blocked, and the server will not be able to receive the packets.

6. Verify that the traffic is blocked.
   a. Verify the IPS event log:

```
# execute log filter category 4
# execute log display
1 logs found.
1 logs returned.

1: date=2023-11-01 time=17:01:43 eventtime=1698883303178500916 tz="-0700"
logid="0419016384" type="utm" subtype="ips" eventtype="signature" level="alert" vd="vd1"
severity="medium" srcip=10.1.100.11 srccountry="Reserved" dstip=239.1.1.10
dstcountry="Reserved" srcintf="port38" srcintfrole="undefined" dstintf="port37"
dstintfrole="undefined" sessionid=18 action="dropped" proto=17 service="udp/5001"
policyid=1 poluuid="09bdd086-78e2-51ee-1d61-0955f9046b53" policytype="multicast-policy"
attack="meicar" srcport=52673 dstport=5001 direction="outgoing" attackid=9999
profile="test-meicar-1" incidentserialno=245366798 msg="custom: meicar" crscore=10
craction=16384 crlevel="medium"
```

   b. Verify the IPS traffic log:

```
# execute log filter category 0
# execute log display
1 logs found.
1 logs returned.

1: date=2023-11-01 time=17:04:39 eventtime=1698883474200006380 tz="-0700"
logid="0002000012" type="traffic" subtype="multicast" level="notice" vd="vd1"
srcip=10.1.100.11 srcport=52673 srcintf="port38" srcintfrole="undefined" dstip=239.1.1.10
dstport=5001 dstintf="port37" dstintfrole="undefined" srccountry="Reserved"
dstcountry="Reserved" sessionid=18 proto=17 action="accept" policyid=1
policytype="multicast-policy" poluuid="09bdd086-78e2-51ee-1d61-0955f9046b53"
policyname="mcast-ips" service="udp/5001" trandisp="noop" duration=180 sentbyte=2996
rcvdbyte=0 sentpkt=2 rcvdpkt=0 appcat="unscanned" utmref=0-266
```

   c. Verify the multicast session list:

```
# diagnose sys mcast-session list

session info: id=19 vf=1 proto=17 10.1.100.11.56538->239.1.1.10.5001
```

```
used=2 path=1 duration=2 expire=177 indev=10
state=00000000:
session-npu-info: ipid/vlifid=0/0 vlanid/vtag_in=0/0 in_npuid=0 tae_index=0 qid=0 fwd_
map=0x00000000
path: log ndr policy=1, outdev=9, tos=0xff
Total 1 sessions
```

Including denied multicast sessions in the session table

Sessions can be created for denied multicast traffic, enabling subsequent packets to be directly matched and dropped, reducing CPU usage and improving performance.

To configure denied multicast session inclusion:

```
config system setting
    set ses-denied-multicast-traffic {disable | enable}
end
```

Value	Description
disable	Do not add denied multicast sessions to the session table (default).
enable	Include denied multicast sessions in the session table.

Example

In this example, denied multicast sessions are included in the session table of the VDOM. A deny multicast policy is created and a packet is then sent that hits the policy. Checking the multicast session list shows that a denied multicast session is created.

To configure and test including denied multicast sessions:

1. Enable including denied multicast sessions:

```
config system setting
    set ses-denied-multicast-traffic enable
end
```

2. Create a deny multicast policy in the multicast policy table:

```
config firewall multicast-policy
    edit 1
        set name "Deny_Multicast_Policy"
        set srcintf "port1"
        set dstintf "port3"
        set srcaddr "172-16-200-0"
        set dstaddr "230-0-0-1"
        set action deny
        set logtraffic all
```

```
        set auto-asic-offload disable
    next
end
```

3. Send packets to hit the deny multicast policy then check the multicast session list. The second session shown is the denied multicast session:

```
# diagnose sys mcast-session list

session info: id=259 vf=1 proto=17 172.16.200.55.34896->230.0.0.10.7878
used=2 path=1 duration=8 expire=174 indev=9 pkts=4 bytes=2160
state=00000000:
session-npu-info: ipid/vlifid=0/0 vlanid/vtag_in=0/0 in_npuid=0 tae_index=0 qid=0 fwd_
map=0x00000000
path: log npu-deny policy=2, outdev=11, tos=0xff

session info: id=260 vf=1 proto=17 172.16.200.55.33488->230.0.0.1.7878
used=2 path=0 duration=6 expire=177 indev=9 pkts=5 bytes=2700
state=00000200: deny
session-npu-info: ipid/vlifid=0/0 vlanid/vtag_in=0/0 in_npuid=0 tae_index=0 qid=0 fwd_
map=0x00000000
Total 2 sessions
```

FortiExtender

Two configuration modes are available on FortiGate for FortiExtender integration: WAN extension mode and LAN extension mode.

For information about configuring FortiExtender, see the FortiExtender Admin Guide (FGT-Managed) and Admin Guide (Standalone).

WAN extension mode

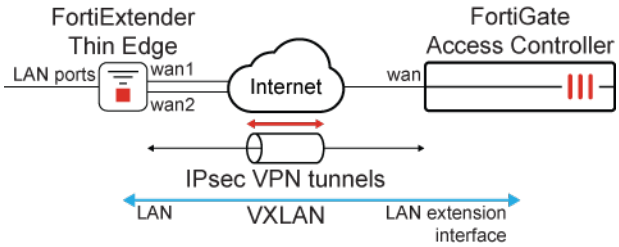
In WAN extension mode, the FortiExtender works as an extended WAN interface in IP pass-through mode. The FortiGate manages FortiExtender over the CAPWAP protocol in IP pass-through mode, and is integrated into FortiOS as a manageable interface.

Sample configurations in WAN extension mode could include connecting a FortiExtender to two FortiGates in HA active-passive mode, or connecting two FortiExtenders to two FortiGates in HA active-active mode to provide dual active redundancy for wireless WAN access.

For more information, see FortiExtender and FortiGate integration in the FortiExtender (Managed) Administration Guide.

LAN extension mode

The LAN extension configuration mode allows FortiExtender to provide remote thin edge connectivity back to the FortiGate over a backhaul connection. A FortiExtender deployed at a remote location will discover the FortiGate access controller (AC) and form an IPsec tunnel (or multiple tunnels when multiple links exist on the FortiExtender) back to the FortiGate. A VXLAN is established over the IPsec tunnels to create an L2 network between the FortiGate and the network behind the remote FortiExtender.



For more information, see FortiExtender as FortiGate LAN extension in the FortiExtender (Managed) Administration Guide.

Maximum FortiExtender devices supported per mode

FortiOS supports a maximum number of FortiExtender devices in WAN or LAN extension mode:

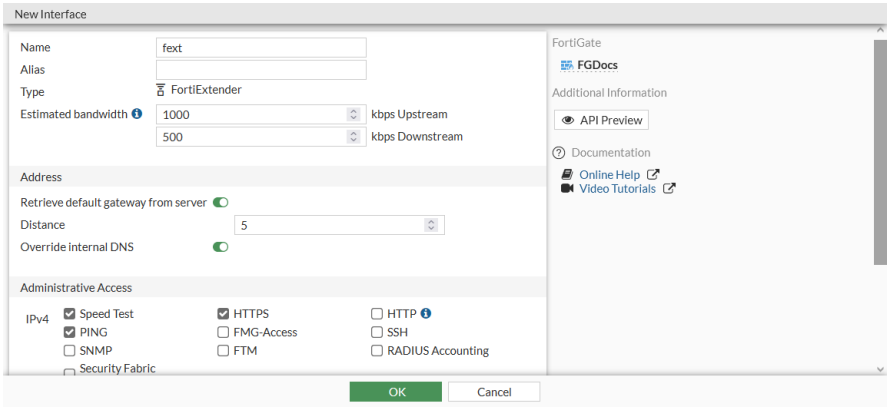
FortiGate Models	WAN	LAN
FortiGate 40F series and its variants, FortiGate VM01	2	0
FortiGate 60F, 70F, 80F series and their variants, FortiGate VM02	2	16
FortiGate 100E to 200F series and their variants	2	16
FortiGate 400F to 900G series and their variants, FortiGate VM04	2	32
FortiGate 1000D to 2600F series and their variants, FortiGate VM08	2	256
FortiGate 3000D and higher, FortiGate VM16 and higher	2	1024

Adding a FortiExtender

To add a FortiExtender to the FortiGate, create a virtual FortiExtender interface, then add a FortiExtender and assign the interface to the modem. Like other interface types, the FortiExtender interface can be used in static routes, SD-WAN (see Manage dual FortiExtender devices), policies, and other functions.

To create a virtual FortiExtender interface in the GUI:

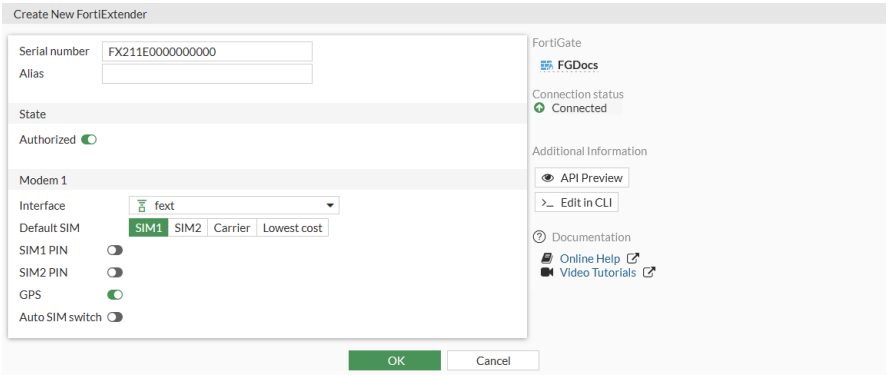
1. Go to *Network* > *Interfaces* and click *Create New* > *FortiExtender*.
2. Enter a name for the interface.
3. Configure the remaining settings as needed. See Interface settings on page 173 for more details.



4. Click *OK*.

To add a FortiExtender in the GUI:

1. Go to *Network* > *FortiExtender* and click *Create New* > *Extenders*.
2. Enter your FortiExtender's serial number in the *Serial number* field.
3. Optionally, set an *Alias* for the FortiExtender.
4. In the *State* section, enable *Authorized*.
5. Set *Interface* to the FortiExtender interface.
6. Configure the remaining setting as required. See the FortiExtender Administration Guide (FGT-Managed) for more information.



7. Click *OK*.
8. In the extenders list, right-click on the FortiExtender and select *Diagnostics and Tools* to review the modem and SIM status, and other details about the FortiExtender.

To create a virtual FortiExtender interface in the CLI:

```
config system interface
    edit "fext"
```

```
        set vdom "root"
        set mode dhcp
        set allowaccess ping https speed-test
        set type fext-wan
        set role wan
        set snmp-index 18
        set estimated-upstream-bandwidth 1000
        set estimated-downstream-bandwidth 500
    next
end
```

To configure the FortiExtender in the CLI:

```
config extension-controller extender
    edit "FX211E"
        set authorized enable
        set device-id 1
        set extension-type wan-extension
        set profile <profile>
        config wan-extension
            set modem1-extension "fext"
        end
    next
end
```

To verify the modem settings in the CLI:

```
get extender modem-status FX211E0000000000 1
Modem 0:
    physical_port:       2-1.2
    manufacture:         Sierra Wireless, Incorporated
    product:             Sierra Wireless, Incorporated
    ....
```

LTE modems

The following topics include information about configuring and using LTE modems:

- Automatic LTE connection establishment on page 635
- Direct IP support for LTE/4G on page 635
- Cellular interface support for IPv6 on page 638
- Active SIM card switching on page 641
- Airplane mode and LTE/BLE on page 649
- Upgrade LTE modem firmware directly from FortiGuard on page 651

Automatic LTE connection establishment

Establishing an LTE connection is now automated. When you insert a SIM card into FortiGate, FortiOS can obtain the Mobile Country Code (MCC) and Mobile Network Code (MNC) from the service provider's radio tower. FortiOS then uses the codes to look up the appropriate APN for the SIM card in a predefined table and automatically creates a wireless profile. Manual configuration is no longer needed, which simplifies the process of establishing an LTE connection.

Direct IP support for LTE/4G

Direct IP is a public IP address that is assigned to a computing device, which allows the device to directly access the internet.

When an LTE modem is enabled in FortiOS, a DHCP interface is created. As a result, the FortiGate can acquire direct IP (which includes IP, DNS, and gateway) from the LTE network carrier.

Since some LTE modems require users to input the access point name (APN) for the LTE network, the LTE modem configuration allows you to set the APN.

LTE modems can only be enabled by using the CLI.

DHCP relay packet flow through the modem interface can be enabled from the CLI using the `dhcp-relay` command.

```
config system lte-modem
    set dhcp-relay enable
end
```

To enable direct IP support using the CLI:

1. Enable the LTE modem:

```
config system lte-modem
  set status enable
end
```

2. Check that the LTE interface was created:

```
config system interface
  edit "wwan"
    set vdom "root"
    set mode dhcp
    set status down
    set distance 1
    set type physical
```

```
    set snmp-index 23
  next
end
```

Shortly after the LTE modem joins its carrier network, `wwan` is enabled and granted direct IP:

```
config system interface
    edit wwan
        get
name                : wwan
....
ip                  : 100.112.75.43 255.255.255.248
....
status              : up
....
defaultgw           : enable
DHCP Gateway        : 100.112.75.41
Lease Expires       : Thu Feb 21 19:33:27 2019
dns-server-override : enable
Acquired DNS1       : 184.151.118.254
Acquired DNS2       : 70.28.245.227
....
```

PCs can reach the internet via the following firewall policy:

```
config firewall policy
  edit 5
    set name "LTE"
    set srcintf "port9"
    set dstintf "wwan"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set fsso disable
    set nat enable
  next
end
```

Sample LTE interface

When an LTE modem is enabled, you can view the LTE interface in the GUI and check the acquired IP, DNS, and gateway.

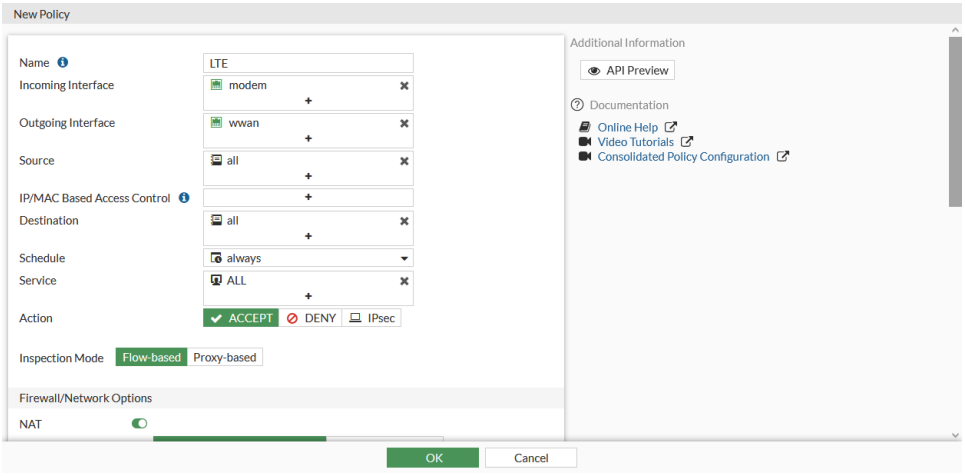
To view the LTE interface in the GUI:

1. Go to *Network* > *Interfaces*.
2. Double-click the LTE interface (*wwan*) to view the properties.
3. Look in the *Address* section to see the *Obtained IP/Netmask*, *Acquired DNS*, and *Default Gateway*.

4. Click *Return*.

To configure the firewall policy that uses the LTE interface:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Edit the LTE policy.
3. In the *Outgoing Interface* field, select the interface (`wwan` in this example).
4. Configure the rest of the policy as needed.



5. Click *OK*.

Limitations

- Most LTE modems have a preset APN in their SIM card. Therefore, the APN does not need to be set in the FortiOS configuration. In cases where the internet cannot be accessed, consult with your carrier and set the APN in the LTE modem configuration (for example, inet.bell.ca):

```
config system lte-modem
  set status enable
  set apn "inet.bell.ca"
end
```

- Some models, such as the FortiGate 30E-3G4G, have built-in LTE modems. In this scenario, the LTE modem is enabled by default. The firewall policy via the LTE interface is also created by default. Once you plug in a SIM card, your network devices can connect to the internet.

  Sample FortiGate 30E-3G4G default configuration:

```
config system lte-modem
  set status enable
  set extra-init ''
  set manual-handover disable
  set force-wireless-profile 0
  set authtype none
  set apn ''
```

```
  set modem-port 255
  set network-type auto
  set auto-connect disable
  set gpsd-enabled disable
  set data-usage-tracking disable
  set gps-port 255
end
```

```
config firewall policy
....
  edit 3
    set srcintf "internal"
    set dstintf "wwan"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
  next
end
```

Cellular interface support for IPv6

The cellular interface of FG-40F-3G4G devices supports IPv6.

```
config system lte-modem
    set pdptype {IPv4 | IPv6 | IPv4v6}
end
```

`pdptype`	Specify the Packet Data Protocol (PDP) for the cellular interface: • `IPv4`: use only IPv4. • `IPv6`: use only IPv6. • `IPv4v6`: use both IPv4 and IPv6 (default).

Example

In this example, PDP type is set to IPv4v6 in the wireless profile.

To use IPv4v6:

1. On FortiGate-40F-3G4G, use the `execute lte-modem wireless-profile` command to create or modify a wireless profile with `pdptype` set to `IPv4v6`. See the 3G4G LTE Modem Operator's Manual for details.
2. List all profiles.
   In the following example, `PDP_Type` is set to `3` to indicate support for both IPv4 and IPv6.

```
# execute lte-modem wireless-profile list
ID   Type  Name               APN                   PDP_Type  Authen  Username
 1   0                           ota.bell.ca              3                0
 2   0        Bell               ota.bell.ca              3                0

Profile Type:
    0 ==> QMI_WDS_PROFILE_TYPE_3GPP

Profile PDP type:
    0 ==> QMI_WDS_PDP_TYPE_IPV4
    1 ==> QMI_WDS_PDP_TYPE_PPP
    2 ==> QMI_WDS_PDP_TYPE_IPV6
    3 ==> QMI_WDS_PDP_TYPE_IPV4_OR_IPV6
Authentication:
    0 ==> QMI_WDS_AUTHENTICATION_NONE
    1 ==> QMI_WDS_AUTHENTICATION_PAP
    2 ==> QMI_WDS_AUTHENTICATION_CHAP
    3 ==> QMI_WDS_AUTHENTICATION_PAP|QMI_WDS_AUTHENTICATION_CHAP
```

3. Apply the correct profile.

   In the following example, profile 2 is selected. The apn setting must also match the apn setting in the selected profile.

```
config sys lte-modem
    set pdptype ipv4v6
    set force-wireless-profile 2
    set apn ota.bell.ca
end
```

4. Wait for the profile to take effect, and then check the data session information:

```
# diagose sys lte-modem data-session-info
LTE Modem data session information:
Interface name:        wwan
IPV4 connection:       QMI_WDS_CONNECTION_STATUS_CONNECTED
IPV6 connection:       QMI_WDS_CONNECTION_STATUS_CONNECTED
Profile ID:            2
Data profile name:     Bell
Profile type:          QMI_WDS_PROFILE_TYPE_3GPP
PDP context type:      QMI_WDS_PDP_TYPE_IPV4_OR_IPV6
APN name:              ota.bell.ca
------------------------------------
IP:                    10.34.139.21
IP gateway:            10.34.139.22
IP netmask:            255.255.255.252
Primary DNS:           161.216.153.1
Secondary DNS:         161.216.157.1
MTU:                   1500
Link protocol:         QMI_WDA_LINK_LAYER_PROTOCOL_RAW_IP
------------------------------------
IPv6:                  2605:b100:93b:cf64:bd33:e6ba:b2ef:5e58
```

```
IPv6 prefix len:       64
IPv6 gateway:          2605:b100:93b:cf64:60c8:e41d:be4b:eaf5
IPv6 GW prefix len:    64
IPv6 PRI DNS:          2605:b100:880:9::1
IPv6 SEC DNS:          2605:b100:680:9::1
MTU:                   1500
Link protocol:         QMI_WDA_LINK_LAYER_PROTOCOL_RAW_IP
Auto connect:          QMI_WDS_AUTOCONNECT_DISABLED
Network type:          Unknown WDS Bearer Tech
Network type(last):    Unknown WDS Bearer Tech
```

5. Verify IPv4.

   In the following example, an IPv4 address is assigned to the wwan interface, and an IPv4 route is automatically added.

```
# diagnose ip address list
IP=192.168.2.111->192.168.2.111/255.255.255.0 index=5 devname=wan
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=13 devname=root
IP=169.254.1.1->169.254.1.1/255.255.255.0 index=17 devname=fortilink
IP=192.168.1.99->192.168.1.99/255.255.255.0 index=18 devname=lan
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=19 devname=vsys_ha
IP=127.0.0.1->127.0.0.1/255.0.0.0 index=21 devname=vsys_fgfm
IP=10.34.139.21->10.34.139.21/255.255.255.255 index=23 devname=wwan

FortiGate-40F-3G4G # get router info routing-table all

```

Active SIM card switching

FortiGates with a cellular modem and dual SIM card can switch in real time from the active SIM card to the passive SIM card when any of the following issues arise with the active SIM card:

- Ping link monitor fails. The SIM switch time depends on the link monitor parameters set.
- An active SIM card cannot be detected. The SIM switch time is about 20 seconds after the SIM card is no longer detected.
- A modem disconnection is detected, and a specified interval has elapsed. The SIM switch time occurs after the specified interval.
- The LTE modem traffic exceeds the specified data plan limit for the configured billing period.

SIM card switching events are captured in the FortiGate event log.

In most cases, SIM cards come with the wireless carrier's APN, which is automatically retrieved at the first connection of the LTE modem. For these cases, you can use SIM cards for different wireless carriers in SIM slot 1 and slot 2.

When one or both SIM cards require their APN settings to be configured on the FortiGate, then both SIM cards should be for the same wireless carrier because `config system lte-modem` currently only supports a single `set apn < apn >` setting.

The following command and options can be used to configure this feature:

```
config system lte-modem
    set data-usage-tracking {enable | disable}
    config sim-switch
        set by-sim-state {enable | disable}
        set by-connection-state {enable | disable}
        set by-link-monitor {enable | disable}
        set by-data-plan {enable | disable}
        set link-monitor <link-monitor-name>
        set sim-switch-log-alert-interval <interval>
        set sim-switch-log-alert-threshold <threshold>
```

```
        set modem-disconnection-time <integer>
    end
    config data-plan
        edit <id>
            set target-sim-slot {SIM-slot-1 | SIM-slot-2}
            set data-limit <integer>
            set data-limit-alert <integer>
            set billing-period {monthly | weekly | daily}
            set billing-date <integer>
            set billing-weekday {sunday | monday | tuesday | wednesday | thursday | friday |
saturday}
            set billing-hour <integer>
            set overage {enable | disable}
            set iccid <string>
            set delay-switch-time <time>
        next
    end
end
```

`data-usage-tracking {enable | disable}`	Enable tracking of data usage for the LTE modem: • `enable`: track data usage. • `disable`: do not track data usage. Must be enabled to configure SIM card switching based on data plan overage.
`config sim-switch`	
`by-sim-state {enable | disable}`	Enable switching based on active SIM card state: • `enable`: switch to the passive SIM card whenever FortiGate cannot detect the active SIM card, such as when the active SIM card is ejected. • `disable`: do not switch SIM cards based on state.
`by-connection-state {enable | disable}`	Enable switching based on the connection state of the active SIM card: • `enable`: switch to the passive SIM card whenever FortiGate detects a modem signal loss after the `modem-disconnection-time` expires. • `disable`: do not switch SIM cards based on the connection state.
`by-link-monitor {enable | disable}`	Enable switching when a configured link monitor fails: • `enable`: switch to the passive SIM card when a link monitor configured with `link-monitor-name` fails. • `disable`: do not switch SIM cards based on the failure of a configured link monitor.
`by-data-plan {enable | disable}`	Enable switching of SIM cards on the LTE modem based on data plan limits: • `enable`: allow SIM card switching when `data-limit` is exceeded. • `disable`: do not switch SIM cards when `data-limit` is exceeded.
`link-monitor <link-monitor-name>`	Specify the name of the link monitor to use with `by-link-monitor`.
`sim-switch-log-alert-interval <interval>`	Identify what number of constant SIM card switch events will trigger an event log after the threshold in `sim-switch-log-alert-threshold` is met.

`sim-switch-log-alert-threshold`	Specify how many minutes to wait before creating an event log when the number of SIM card switches defined in `sim-switch-log-alert-interval` is met.
`modem-disconnection-time <integer>`	Specify how many seconds to wait before switching over to the passive SIM card when `by-connection-state` is enabled and a modem signal loss is detected.
`config data-plan`	
`target-sim-slot {sim-slot-1 | sim-slot-2}`	Specify which SIM slot to configure.
`data-limit <integer>`	Specify the data limit for the SIM slot, in MB (0 - 100000, 0 = unlimited data).
`data-limit-alert <integer>`	Specify at what percentage of used `data-limit` to trigger a log entry (1 - 99).
`billing-period {month | week | day}`	Specify the billing period.
`billing-date <integer>`	When `billing-period` is set to `monthly`, specify what day of the month the bill is issued (1 - 31).
`billing-weekday {sunday | monday | tuesday | wednesday | thursday | friday | saturday}`	When `billing-period` is set to `weekly` specify what day of the week the bill is issued.
`billing-hour <integer>`	When `billing-period` is set to `daily` specify what hour of the day the bill is issued (0 - 23).
`overage {enable | disable}`	Disable data usage from exceeding the configured data limit: • `enable`: allow data usage to exceed the amount specified in `data-limit`. • `disable`: do not allow data usage to exceed the amount specified in `data-limit`. When disabled, SIM cards are switched before the data limit is exceeded. Must be disabled to allow SIM card switching.
`iccid <string>`	Specify the Integrated Circuit Card Identification Number (ICCID) for the SIM card in 19 to 20 digits.
`delay-switch-time <integer:integer>`	Delay SIM card switch to a specified UTC time in format HH:MM.

Example 1

In this example, automatic SIM card switching is disabled. When disabled, the SIM card only works in the default slot1, but you can manually switch the SIM card to slot2. Event logs include details about the SIM card switch.

To manually switch a SIM card:

1. Disable automatic SIM card switching:

```
config system lte-modem
    config sim-switch
        set by-sim-state disable
        set by-connection-state disable
        set by-link-monitor disable
        set sim-slot 1
    end
end
```

2. Manually switch the SIM card from slot1 to slot2, and run the following command:

```
# execute lte-modem sim-switch
```

The SIM card switch may take a few seconds. You can run `diagnose system lte-modem sim-info` to check the results.

The following log is generated after unplugging an active SIM card:

```
7: date=2023-05-02 time=10:41:05 eventtime=1683049264795418820 tz="-0700" logid="0100046518"
type="event" subtype="system" level="information" vd="root" logdesc="LTE modem active SIM card
switch event" msg="LTE modem active SIM card slot changed to 2 by user."
```

Example 2

In this example, automatic SIM card switching is enabled and configured to switch based on SIM state, connection state, or link monitor state, and it includes example event logs for each scenario.

To enable automatic SIM card switching by SIM state:

1. Enable automatic SIM card switching by SIM state:

```
config system lte-modem
    config sim-switch
        set by-sim-state enable
    end
end
```

With this configuration, the second SIM card becomes active when the active SIM card is no longer detected, for example, if the active SIM card is ejected. The following event logs are generated:

```
5: date=2023-04-28 time=17:27:27 eventtime=1682728046989682780 tz="-0700" logid="0100046513"
type="event" subtype="system" level="information" vd="root" logdesc="LTE modem data link
connection event" msg="LTE modem data link changed from QMI_WDS_CONNECTION_STATUS_DISCONNECTED
to QMI_WDS_CONNECTION_STATUS_CONNECTED"

6: date=2023-04-28 time=17:27:17 eventtime=1682728036493684280 tz="-0700" logid="0100046512"
type="event" subtype="system" level="information" vd="root" logdesc="LTE modem SIM card state
event" msg="LTE modem SIM card change from QMI_UIM_CARD_STATE_ABSENT to QMI_UIM_CARD_STATE_
```

```
PRESENT"

7: date=2023-04-28 time=17:27:12 eventtime=1682728032589776580 tz="-0700" logid="0100046513"
type="event" subtype="system" level="information" vd="root" logdesc="LTE modem data link
connection event" msg="LTE modem data link changed from QMI_WDS_CONNECTION_STATUS_CONNECTED to
QMI_WDS_CONNECTION_STATUS_DISCONNECTED"

8: date=2023-04-28 time=17:27:11 eventtime=1682728031245682560 tz="-0700" logid="0100046512"
type="event" subtype="system" level="information" vd="root" logdesc="LTE modem SIM card state
event" msg="LTE modem SIM card change from QMI_UIM_CARD_STATE_PRESENT to QMI_UIM_CARD_STATE_
ABSENT"
```

To enable automatic SIM card switching by connection state:

1. Enable automatic SIM card switching by connection state:

```
config system lte-modem
    config sim-switch
        set by-connection-state enable
        set modem-disconnection-time 30
        set sim-switch-log-alert-interval 15
        set sim-switch-log-alert-threshold 5
    end
end
```

With this configuration, the second SIM card becomes active when the modem cannot establish a connection with the carrier through the active SIM card. For example, a FortiGate is in a room with poor signal quality. With this configuration, the SIM card switch is triggered after the modem is detected as disconnected for 30 seconds, and the following event log is generated:

```
56: date=2023-05-01 time=11:14:56 eventtime=1682964896356933480 tz="-0700" logid="0100046519"
type="event" subtype="system" level="notice" vd="root" logdesc="LTE modem active SIM card
switched: modem disconnection detected" msg="LTE modem active SIM card slot changed to 2, due
to modem connection down."

66: date=2023-05-01 time=11:14:13 eventtime=1682964852964869400 tz="-0700" logid="0100046519"
type="event" subtype="system" level="notice" vd="root" logdesc="LTE modem active SIM card
switched: modem disconnection detected" msg="LTE modem active SIM card slot changed to 1, due
to modem connection down."
```

When poor signal quality causes SIM cards to frequently switch back and forth, and the flapping rate occurs more than five times within the configured 15 minute time period, an event log is triggered to record the flapping severity:

```
65: date=2023-05-01 time=11:14:13 eventtime=1682964853083194400 tz="-0700" logid="0100046521"
type="event" subtype="system" level="warning" vd="root" logdesc="LTE modem active SIM card
slot flipped back and forth in short time" msg="LTE modem switched SIM slot 8 times in last 15
minutes, which is greater than 5 times threshold."
```

To enable automatic SIM card switching based on link monitor:

1. Enable automatic SIM card switching by link monitor, and specify the link monitor:

```
config system lte-modem
    config sim-switch
        set by-link-monitor enable
        set link-monitor "modem"
        set sim-switch-log-alert-interval 15
        set sim-switch-log-alert-threshold 5
    end
    config system link-monitor
    edit "modem"
        set srcintf "wwan"
        set server "8.8.8.8"
        set interval 1000
        set probe-timeout 100
        set failtime 3
        set recoverytime 8
    next
end
```

   With this configuration, the second SIM card becomes active when the link monitor detects the active SIM card exceeds the SLA.

2. Check the link monitor status. In this example, the link monitor status is dead:

```
# diagnose system link-monitor status modem

Link Monitor: modem, Status: dead, Server num(1), cfg_version=7 HA state: local(dead), shared
(dead)
Flags=0x9 init log_downgateway, Create time: Fri Apr 28 16:34:56 2023
Source interface: wwan (19)
VRF: 0
Interval: 1000 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
  Peer: 8.8.8.8(8.8.8.8)
        Source IP(10.192.195.164)
        Route: 10.192.195.164->8.8.8.8/32, gwy(10.192.195.165)
        protocol: ping, state: dead
                Packet lost: 11.667%
                MOS: 4.353
                Number of out-of-sequence packets: 0
                Recovery times(5/8) Fail Times(1/3)
                Packet sent: 60, received: 56, Sequence(sent/rcvd/exp): 61/61/62
```

   The following event log is generated when the link-monitor status is dead:

```
15: date=2023-04-28 time=16:31:38 eventtime=1682724697936494139 tz="-0700" logid="0100046520"
type="event" subtype="system" level="notice" vd="root" logdesc="LTE modem active SIM card
switched: link monitor probe failure detected" msg="LTE modem active SIM card slot changed to
2, due to link monitor probe failures."
```

```
19: date=2023-04-28 time=16:31:13 eventtime=1682724673152506599 tz="-0700" logid="0100022932"
type="event" subtype="system" level="warning" vd="root" logdesc="Link monitor status warning"
name="modem" interface="wwan" probeproto="ping" msg="Link Monitor changed state from alive to
dead, protocol: ping."
```

Example 3

In this example, data tracking and SIM card switching by data plan are enabled for the LTE modem. Each SIM card for the LTE modem is configured with a data plan.

When traffic causes data usage to surpass the configured data limit for one SIM card, the LTE modem disconnects, and the wwan interface loses its IP address and gateway. The idle SIM card becomes active, as long as it has available data to be used. After the SIM card switch completes, the LTE modem reconnects, and the wwan interface gains its IP address and gateway again.

To configure SIM card switching by data plan overage:

1. Enable data tracking for the LTE modem:

```
config system lte-modem
    set data-usage-tracking enable
end
```

2. Enable SIM card switching by data plan for the LTE modem:

```
config system lte-modem
    config sim-switch
        set by-data-plan enable
    end
end
```

3. Configure a data plan for each SIM card on the LTE modem:

   In this example, SIM-slot-1 is configured with a data limit of 50 MB for a monthly bill issued on the 10th day of the month.

   SIM-slot-2 is configured is configured with a data limit of 60 MB for a monthly bill issued on the first day of the month.

   Data overage is disabled for both SIM card slots to allow the SIM cards to switch when the data limits are exceeded.

```
config system lte-modem
    config data-plan
        edit "1"
            set target-sim-slot SIM-slot-1
            set data-limit 50
            set billing-period monthly
            set overage disable
            set billing-date 10
        next
        edit "2"
```

```
            set target-sim-slot SIM-slot-2
            set data-limit 60
            set billing-period monthly
            set overage disable
            set billing-date 1
        next
    end
end
```

When the specified `data-limit` is exceeded while `overage` is disabled, the SIM card switch is triggered.

When `overage` is enabled, the specified `data-limit` can be exceeded, and a SIM card switch is not triggered.

Data usage is reset after the billing period passes.

4. Monitor data usage against the data limit:

```
# diagnose sys lte-modem data-usage
Estimated LTE Modem data usage in this billing cycle:
Active data plan:              1
Active SIM slot:               slot-1
Plan data limit:               60(MB)
Plan overage status:           disable
sim-switch.by-data-plan:       enable
Usage:                         67(MB)
Usage percentage:              111.67%
Current time:                  2023-07-20 16:16:38
Plan refresh time:             2023-08-05 01:00:00
============================================
Idle data plan:                2
Idle SIM slot:                 slot-2
Idle Plan data limit:          100(MB)
Idle Plan overage status:      disable
Idle Plan Usage:               78(MB)
Idle Plan Usage percentage:    78.00%
Idle Plan refresh time:        2023-08-10 01:00:00
```

5. After the SIM card switch completes, view the active SIM card:

```
# diagnose sys lte-modem sim-info
LTE Modem SIM card information:
Active Slot: Slot 2
SIM state: QMI_UIM_CARD_STATE_PRESENT
ICCID: 89302370323035043340
IMSI: 302370605258650
Country: Canada
Network: Fido
SIM PIN status: Verified
```

Airplane mode and LTE/BLE

Airplane mode is supported on FGR-70F-3G4G models to enable/disable radio frequency signals for the internal LTE modem and Bluetooth Low Energy (BLE) module:

```
config system global
    set airplane-mode {disable | enable}
end
```

By default airplane mode is disabled, and LTE and BLE radio frequency signals are transmitted. Airplane mode can be enabled with a CLI command followed by a reboot of the FortiGate. Once airplane mode is enabled, LTE and BLE radio frequency signals remain silent during normal operation of the FortiGate.

A specific BIOS version is required to ensure radio frequency signals remain silent for LTE and BLE modules when FortiGate is rebooted.

`set airplane-mode {disable | enable}`	Enable or disable airplane mode on FGR-70F-3G4G models: • `disable`: disable airplane mode, which means radio frequency signals of the internal LTE modem and BLE module are enabled and transmitted. • `enable`: enable airplane mode, which means radio frequency signals of the internal LTE modem and BLE module are turned off.

Example

To disable airplane mode:

1. Disable airplane mode:

   ```
   config system global
       ...
       set airplane-mode disable
       ...
   end
   ```

   Radio frequency signals of the LTE modem and BLE module are turned on.
2. Use the following commands to verify the settings:

`execute usb-device list`	Check the status of the LTE modem.
`diagnose test application lted 5`	Check the signal strength of the LTE modem.
`diagnose sys lte-modem modem-details`	Get detailed information about the LTE modem.
`diagnose sys lte-modem data-session-info`	Get session information about the LTE modem.

`diagnose bluetooth test_ bt_conn`	Check the status of the BLE mode.
`diagnose bluetooth status`	Check the bluetooth status of the BLE mode.

To enable airplane mode:

1. Enable airplane mode:

```
config system global
    ...
    set airplane-mode enable
    ...
Enabling airplane mode will turn off LTE modem and Bluetooth RF signals.
Do you want to continue? (y/n)y
end
```

2. Reboot the FortiGate.

```
execute reboot
This operation will reboot the system !
Do you want to continue? (y/n)y
```

The LTE modem and BLE module are disabled, and radio frequency signals are turned off.

3. Show the configuration to confirm that airplane mode is enabled.

```
show full-configuration
config system global
    ...
    set airplane-mode enable
    ...
end
```

4. Check the USB device list (`execute usb-device list`) to confirm that the modem is not displayed in the list.
5. Check the signal strength to confirm that the modem is not found.

```
# diagnose test application lted 5
Modem device not currently connected! Please try again later...
```

6. Check the modem details to confirm that airplane mode is enabled, and the modem is not detected.

```
# diagnose sys lte-modem modem-details
LTE Modem detailed information:
system.global.airplane-mode:      On
Modem detected:   No
```

7. Check the modem session information to confirm that the modem is not detected.

```
# diagnose sys lte-modem data-session-info
LTE Modem data session information:
Modem not detected!
```

8. Run a Bluetooth test to confirm that airplane mode is on and Bluetooth testing is not allowed.

```
# diagnose bluetooth test_bt_conn
It's on airplane mode now. Bluetooth testing is not allowed.
```

9. Check Bluetooth status to confirm that the BLE module is disabled.

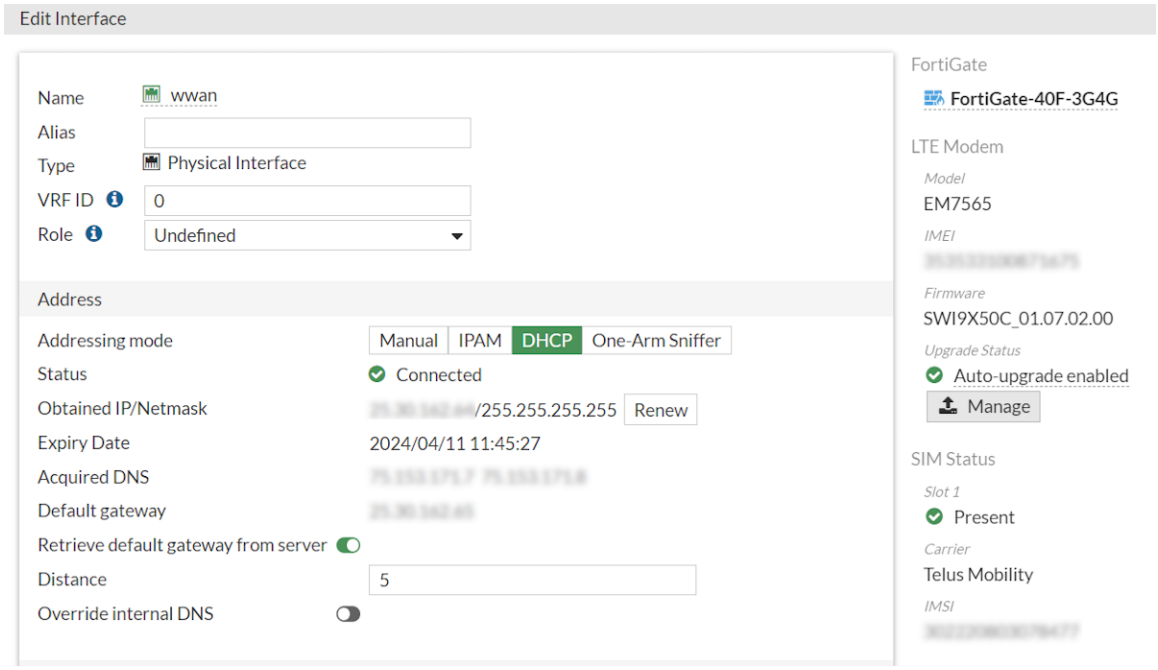
```
# diagnose bluetooth status
Bluetooth Status: RESET BOOTLOADER
Connect State(0):  BLE_MODE_DISABLED
```

Upgrade LTE modem firmware directly from FortiGuard

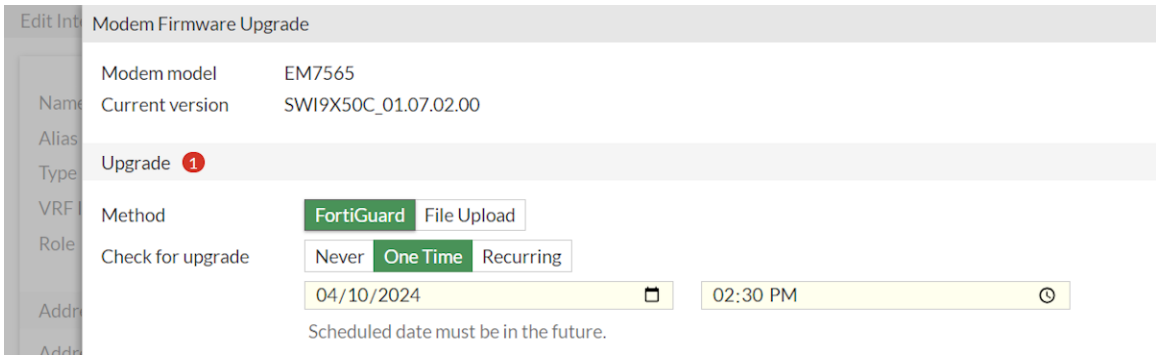
LTE modem firmware can be upgraded directly from the FortiGuard. This simplifies the process by eliminating the need for manual downloading and uploading, and offers users the flexibility to schedule the upgrade.

To schedule LTE modem firmware upgrades from FortiGuard in the GUI:

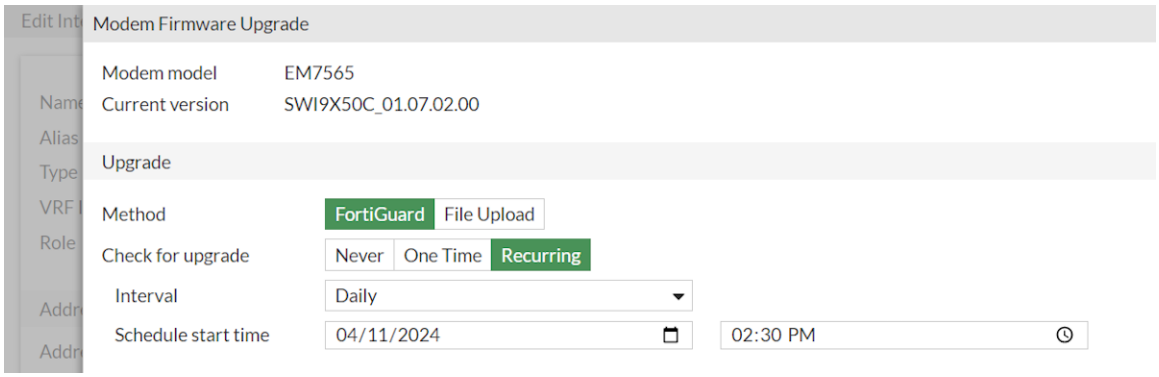
1. Go to *Network* > *Interfaces*.
2. Select the LTE modem interface and click *Edit*.



3. Click *Manage*.
4. Set the *Method* as *FortiGuard*.
5. Configure the upgrade schedule:
   - *Never*: Disable LTE modem firmware upgrades from FortiGuard.
   - *One Time*: Schedule a date and time to upgrade the firmware from FortiGuard.



- *Recurring*: Schedule a recurring upgrade to the firmware from FortiGuard based on a set *Interval*, start date, and start time.



6. Click *OK*.

To schedule a one time LTE modem firmware upgrade from FortiGuard in the CLI:

```
config system central-management
    set type fortiguard
    set ltefw-upgrade-time <YYYY-MM-DD HH:MM:SS>
end
```

To schedule recurring LTE modem firmware upgrades from FortiGuard in the CLI:

```
config system central-management
    set type fortiguard
    set ltefw-upgrade-time <YYYY-MM-DD HH:MM:SS>
    set ltefw-upgrade-frequency {everyHour | every12hour | everyDay | everyWeek}
end
```

To disable LTE modem firmware upgrades from FortiGuard in the CLI:

```
config system central-management
    set type fortiguard
    set allow-remote-lte-firmware-upgrade disable
end
```

LLDP reception

Device detection can scan LLDP as a source for device identification, but the FortiGate does not read or store the full information. Enabling LLDP reception allows the FortiGate to receive and store LLDP messages, learn about active neighbors, and makes the LLDP information available via the CLI, REST API, and SNMP.

You need to enable device detection (`device-identification`) at the interface level, and then `lldp-reception` can be enabled on three levels: globally, per VDOM, or per interface.

To configure device identification on an interface:

```
config system interface
    edit <port>
        set device-identification enable
    next
end
```

To configure LLDP reception globally:

```
config system global
    set lldp-reception enable
end
```

To configure LLDP reception per VDOM:

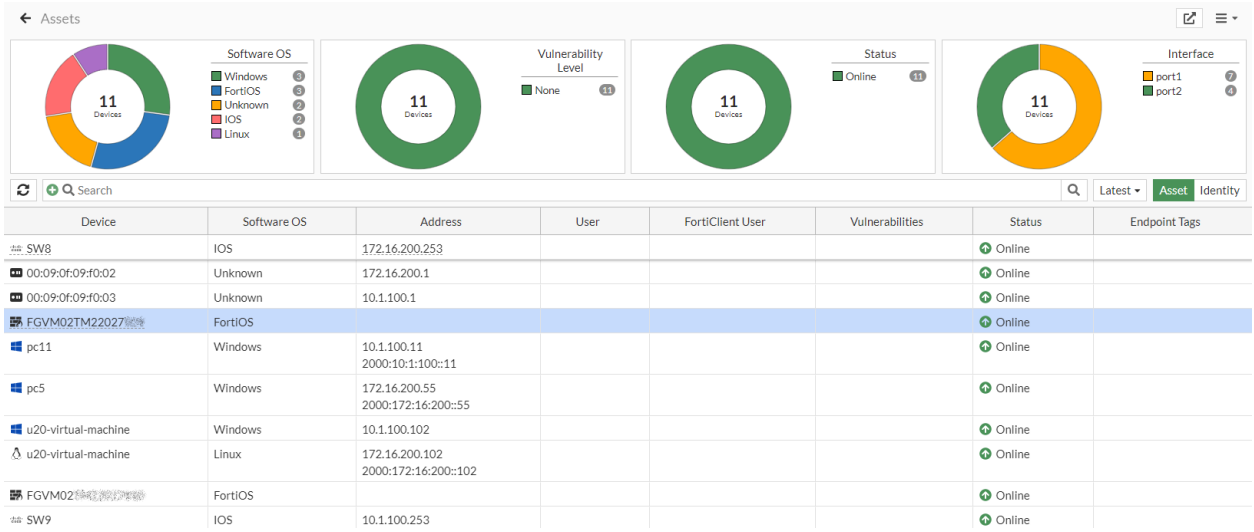
```
config system setting
    set lldp-reception enable
end
```

To configure LLDP reception per interface:

```
config system interface
    edit <port>
        set lldp-reception enable
    next
end
```

To view the LLDP information in the GUI:

1. Go to *Dashboard* > *Assets & Identities*.
2. Expand the *Assets* widget to full screen.



To view the received LLDP information in the CLI:

```
# diagnose user device list
hosts
vd root/0  00:0c:29:1c:03:ca  gen 4320  req 0
    created 515971s  gen 31  seen 28s  port1  gen 12
    hardware vendor 'Fortinet'  src lldp  id 4120  weight 255
    type 'Router'  src lldp  id 4120  weight 255
    family 'FortiGate'  src lldp  id 4120  weight 255
    os 'FortiOS'  src lldp  id 4120  weight 255
    hardware version 'VM64'  src lldp  id 4120  weight 255
    software version '7.4.0 Build 2360'  src lldp  id 4120  weight 255
    host 'FGVM02TM22027XXX'  src lldp
```

To view additional information about LLDP neighbors and ports:

```
# diagnose lldprx neighbor {summary | details | clear}
```

```
# diagnose lldprx port {details | summary | neighbor | filter}
```

```
# diagnose lldprx port neighbor {summary | details}
```

Note that the port index in the output corresponds to the port index from the following command:

```
# diagnose netlink interface list port2 port3 | grep index
      if=port2 family=00 type=1 index=4 mtu=1500 link=0 master=0
      if=port3 family=00 type=1 index=5 mtu=1500 link=0 master=0
```

To view the received LLDP information in the REST API:

```
{
  "http_method":"GET",
  "results":[
```

```
    {
      "mac":"90:9c:9c:c9:c9:90",
      "chassis_id":"90:9C:9C:C9:C9:90",

  "version":"v7.4.0",
  "build":2360
}
```

Virtual routing and forwarding

Virtual Routing and Forwarding (VRF) is used to divide the FortiGate's routing functionality (layer 3), including interfaces, routes, and forwarding tables, into separate units. Packets are only forwarded between interfaces that have the same VRF.

An exception applies to VRF 0. When traffic that is destined for a local IP (IP assigned to an interface) in another VRF comes into an interface in VRF 0, the packet is considered a local-in packet in VRF 0 and is allowed to pass.

VDOMs divide the FortiGate into two or more complete and independent virtual units that include all FortiGate functions. VDOMs can be used for routing segmentation, but that should not be the only reason to implement them when a less complex solution (VRFs) can be used. VDOMs also support administration boundaries, but VRFs do not.

Up to 512 VRFs can be configured per VDOM for any device, but only ten VDOMs can be configured by default on a FortiGate (more VDOMs can be configured on larger devices with additional licenses).

- Implementing VRF on page 656
- VRF routing support on page 657
- Route leaking between VRFs with BGP on page 667
- Route leaking between multiple VRFs on page 670
- VRF with IPv6 on page 681
- IBGP and EBGP support in VRF on page 685
- Support cross-VRF local-in and local-out traffic for local services on page 687
- Support specific VRF ID for local-out traffic on page 690

Implementing VRF

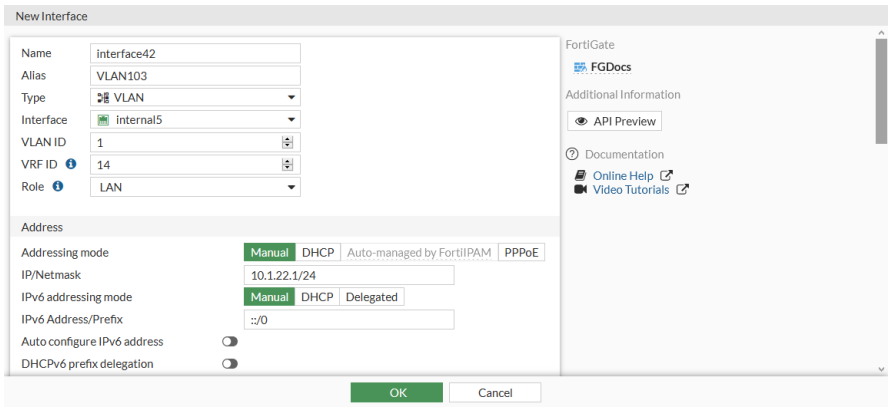
VRFs are always enabled and, by default, all routing is done in VRF 0. To use additional VRFs, assign a VRF ID to an interface. All routes relating to that interface are isolated to that VRF specific routing table. Interfaces in one VRF cannot reach interfaces in a different VRF.

If some traffic does have to pass between VRFs, route leaking can be used. See Route leaking between VRFs with BGP on page 667.

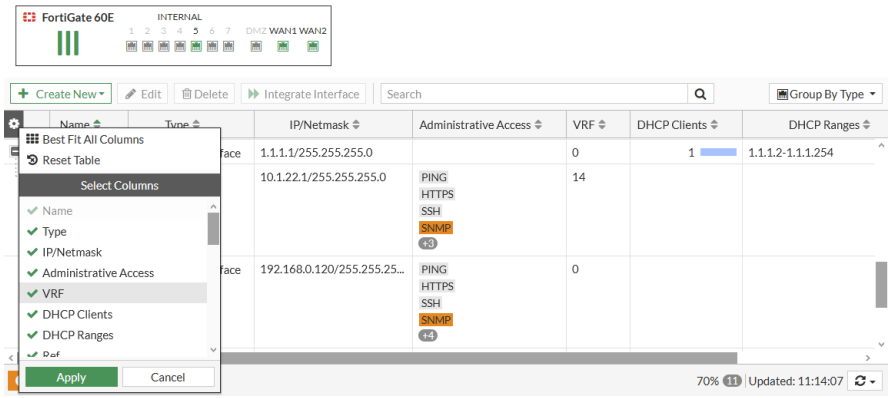
Enable *Advanced Routing* in *System* > *Feature Visibility* to configure VRFs.

To configure a VRF ID on an interface in the GUI:

1. Go to *Network* > *Interfaces* and click *Create New* > *Interface*.
2. Enter a value in the VRF ID field.
3. Configure the other settings as needed.



4. Click *OK*.
5. To add the VRF column in the interface table, click the gear icon, select *VRF*, and click *Apply*.

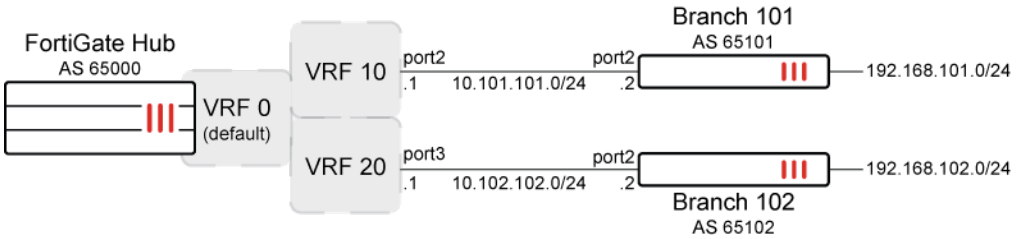


To configure a VRF ID on an interface in the CLI:

```
config system interface
    edit interface42
        ...
        set vrf 14
    next
end
```

VRF routing support

VRF supports static routing, OSPF, and BGP. Other routing protocols require using VDOMs.



BGP

The following BGP examples are provided:

- BGP example 1: update VRF neighbors on page 658
- BGP example 2: use overlapping subnets on page 661

BGP example 1: update VRF neighbors

In this example, BGP is used to update the VRF that it is neighbors with.

The hub is configured with two neighbors connected to two interfaces. The branches are configured to match the hub, with branch networks configured to redistribute into BGP.

Policies must be created on the hub and branches to allow traffic between them.

To configure the hub:

```
config router bgp
    set as 65000
    config neighbor
        edit "10.101.101.2"
            set soft-reconfiguration enable
            set interface "port2"
            set remote-as 65101
            set update-source "port2"
        next
        edit "10.102.102.2"
            set soft-reconfiguration enable
            set interface "port3"
            set remote-as 65102
            set update-source "port3"
        next
    end
end
```

To configure branch 101:

```
config router bgp
    set as 65101
    config neighbor
        edit "10.101.101.1"
            set soft-reconfiguration enable
            set interface "port2"
            set remote-as 65000
            set update-source "port2"
        next
    end
    config redistribute connected
        set status enable
```

```
    end
end
```

To configure branch 102:

```
config router bgp
    set as 65102
    config neighbor
        edit "10.102.102.1"
            set soft-reconfiguration enable
            set interface "port2"
            set remote-as 65000
            set update-source "port2"
        next
    end
    config redistribute connected
        set status enable
    end
end
```

To verify the BGP neighbors and check the routing table on the hub:

```
# get router info bgp summary
BGP router identifier 192.168.0.1, local AS number 65000
BGP table version is 2
2 BGP AS-PATH entries
0 BGP community entries

Neighbor               V       AS              MsgRcvd MsgSent TblVer  InQ     OutQ Up/Down    State/PfxRcd
10.101.101.2   4       65101           4               4               2               0       0       00:01:05
10.102.102.2   4       65102           3               3               1               0       0       00:00:30

Total number of neighbors 2
```

```
# get router info routing-table all
Routing table for VRF=0
Codes (…)
S*     0.0.0.0/0 [10/0] via 192.168.0.254, port1
C      10.101.101.0/24 is directly connected, port2
C      10.102.102.0/24 is directly connected, port3
C      192.168.0.0/24 is directly connected, port1
B      192.168.101.0/24 [20/0] via 10.101.101.2, port2, 00:01:25
B      192.168.102.0/24 [20/0] via 10.102.102.2, port3, 00:00:50
```

To configure VRF on the hub:

1. Put the interfaces into VRF:

```
config system interface
    edit port2
```

```
        set vrf 10
    next
    edit port3
        set vrf 20
    next
end
```

2. Restart the router to reconstruct the routing tables:

```
# execute router restart
```

3. Check the routing tables:

```
# get router info routing-table all
Routing table for VRF=0
Codes (…)
S*     0.0.0.0/0 [10/0] via 192.168.0.254, port1
C      192.168.0.0/24 is directly connected, port1

Routing table for VRF=10
C      10.101.101.0/24 is directly connected, port2
B      192.168.101.0/24 [20/0] via 10.101.101.2, port2, 00:02:25

Routing table for VRF=20
C      10.102.102.0/24 is directly connected, port3
B      192.168.102.0/24 [20/0] via 10.102.102.2, port2, 00:01:50
```

4. Check the BGP summary:

```
# get router info bgp summary

VRF 10 BGP router identifier 10.101.101.1, local AS number 65000
BGP table version is 1
2 BGP AS-PATH entries
0 BGP community entries

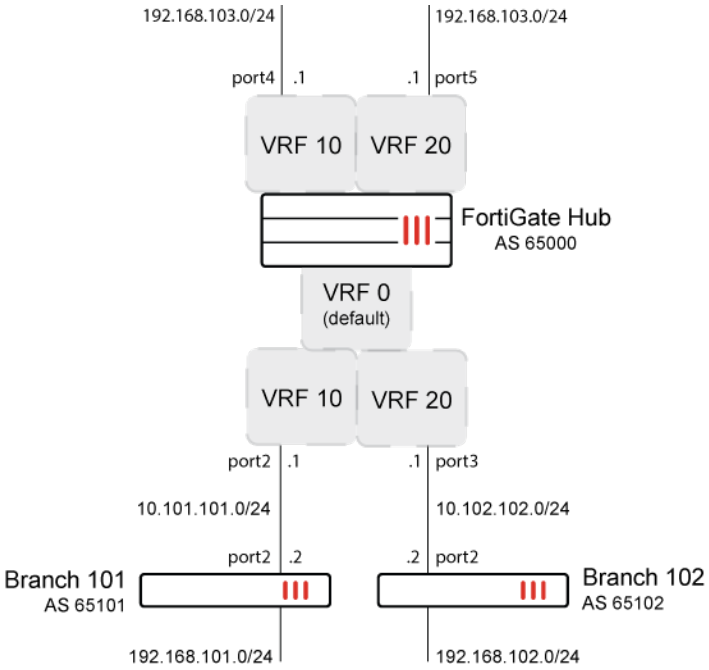
```

BGP example 2: use overlapping subnets

Building on BGP example 1: update VRF neighbors on page 658, example 2 includes two additional interfaces assigned to different VRFs: port4 belongs to VRF 10, and port5 belongs to VRF 20. The IP address and subnet configuration on port4 and port5 are identical, resulting in subnet overlap.



The hub needs to selectively advertise the overlapping prefix through BGP only to the peer within VRF 10. By default, the `config network` command of BGP does not advertise prefix on a per-VRF basis.

Thus to achieve selective route advertisement to a BGP peer belonging to specific VRF, route maps can be used.

To configure the hub:

1. Allow configuration of subnet overlap:

```
config system settings
    set allow-subnet-overlap enable
end
```

2. Configure IP addresses on port4 and port5:

```
config system interface
    edit "port4"
        set ip 192.168.103.1 255.255.255.0
    next
end
config system interface
    edit "port5"
        set ip 192.168.103.1 255.255.255.0
```

```
   next
end
```

3. Put port4 into VRF 10 and port5 into VRF 20:

```
config system interface
    edit "port4"
        set vrf 10
    next
end
config system interface
    edit "port5"
        set vrf 20
    next
end
```

4. Advertise the overlapped subnet inside BGP using the `config network` command.
   By default, prefix 192.168.103.0/24 is advertised to BGP peers of all VRFs.

```
config router bgp
    set as 65000
    config neighbor
        edit "10.101.101.2"
            set soft-reconfiguration enable
            set interface "port4"
            set remote-as 65101
            set update-source "port4"
        next
        edit "10.102.102.2"
            set soft-reconfiguration enable
            set interface "port3"
            set remote-as 65102
            set update-source "port3"
        next
    end
    config network
        edit 1
            set prefix 192.168.103.0 255.255.255.0
        next
    end
end
```

To verify the routing table before using route-map:

1. Verify that the routing table on Branch 101 displays only BGP routes:

```
# get router info routing-table bgp
Routing table for VRF=0
B       192.168.103.0/24 [20/0] via 10.102.102.1, port2, 00:17:04, [1/0]
```

2. Verify that the routing table on Branch 102 displays only BGP routes:

```
# get router info routing-table bgp
Routing table for VRF=0
B       192.168.103.0/24 [20/0] via 10.101.101.1, port2, 00:18:48
```

To use a route map to advertise a prefix for each VRF:

1. Configure `route-map` on hub to match VRF 10:

```
config router route-map
    edit "VRF_10"
        config rule
            edit 1
                set match-vrf 10
            next
        end
    next
end
```

2. Use `route-map` inside hub's BGP configuration (that is, inside the `config network` command) to selectively advertise a prefix 192.168.103.0/24 to BGP peers that belong to VRF 10 (that is, Branch 101):

```
config router bgp
    set as 65000
    config neighbor
        edit "10.101.101.2"
            set soft-reconfiguration enable
            set interface "port4"
            set remote-as 65101
            set update-source "port4"
        next
        edit "10.102.102.2"
            set soft-reconfiguration enable
            set interface "port3"
            set remote-as 65102
            set update-source "port3"
        next
    end
    config network
        edit 1
            set prefix 192.168.103.0 255.255.255.0
            set route-map "VRF_10"
        next
    end
end
```

To verify the routing table after using route-map:

1. Verify the routing table on Branch 101:

```
# get router info routing-table bgp
Routing table for VRF=0
B       192.168.103.0/24 [20/0] via 10.102.102.1, port2, 00:17:04, [1/0]
```

2. Check the routing table on Branch 102. The routes are not advertised to BGP peer belonging to VRF 20.

```
# get router info routing-table bgp
No route available
```

3. Verify advertised BGP routes on hub on per-neighbor basis:

```
# get router info bgp neighbors 10.101.101.2 advertised-routes
VRF 10 BGP table version is 1, local router ID is 192.168.103.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network          Next Hop            Metric     LocPrf Weight RouteTag Path
*> 192.168.103.0    10.101.101.1                   100  32768        0 i <-/->

Total number of prefixes 1

# get router info bgp neighbors 10.102.102.2 advertised-routes
% No prefix for neighbor 10.102.102.2
```

OSPF

OSPF routes in VRFs work the same as BGP: the interface that OSPF is using is added to the VRF.

To configure the hub:

1. Configure OSPF:

```
config router ospf
    set router-id 1.1.1.1
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit Branch101
            set interface “port2”
            set dead-interval 40
            set hello-interval 10
        next
        edit Branch102
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 0
```

```
            set prefix 10.101.101.0 255.255.255.0
        next
        edit 0
            set prefix 10.102.102.0 255.255.255.0
        next
        edit 0
            set prefix 192.168.1.0 255.255.255.0
        next
    end
end
```

2. Put the interfaces into VRF:

```
config system interface
    edit port2
        set vrf 10
    next
    edit port3
        set vrf 20
    next
end
```

To configure branch 101:

```
config router ospf
    set router-id 101.101.101.101
    config area
        edit 0.0.0.0
        next
    end
    config ospf-interface
        edit HUB
            set interface port2
            set dead-interval 40
            set hello-interval 10
        next
    end
    config network
        edit 0
            set prefix 10.101.101.0 255.255.255.0
        next
        edit 0
            set prefix 192.168.101.0 255.255.255.0
        next
    end
end
```

To check the routing table and OSPF summary:

```
# get router info routing-table ospf
```

```
# get router info ospf interface
```

Static route

Static routes in VRFs work the same as BGP and OSPF because the interface that the static route is using is added to the VRF.

To add a VRF ID in a static route in the GUI:

1. Configure the interface:
   a. Go to *Network* > *Interfaces*.
   b. Click *Create New* > *Interface* or *Edit* an existing interface.
   c. Enter a value in the *VRF ID* field.
   d. Configure the other settings as needed.
   e. Click *OK*.
2. Add a static route to VRF. For example, using blackhole:
   a. Go to *Network* > *Static Routes*.
   b. Click *Create New* and select the type of static route.
   c. Enter a *Subnet*.
   d. In the *Interface* field, select *Blackhole*.
   e. In the *VRF ID* field, enter the ID created in step one.
   f. Click *OK*.

To add a VRF ID in a static route in the CLI:

1. Configure the interface:

```
config system interface
    edit port2
        set vrf 10
    next
end
```

2. Add a static route to the VRF. For example, using blackhole:

```
config router static
    edit 3
        set dst 0.0.0.0/0
        set blackhole enable
        set vrf 10
    next
end
```

A static route can also be added to the VRF when using an IPsec interface by enabling VPN ID with IPIP encapsulation. See SD-WAN segmentation over a single overlay on page 1299 for more information.

To add a static route to the VRF when using IPsec:

```
config vpn ipsec phase1-interface
    edit "vpn1"
        set interface "port2"
        set auto-discovery-receiver enable
        set encapsulation vpn-id-ipip
        set remote-gw 1.1.101.1
        set psksecret ******
    next
end
config router static
    edit 1
        set dst 10.32.0.0 255.224.0.0
        set device "vpn1"
        set vrf 10
    next
end
```

To check the routing table:

```
# get router info routing-table static
```

Route leaking between VRFs with BGP

Route leaking allows you to configure communication between VRFs. If route leaking is not configured, then the VRFs are isolated. This example shows route leaking with BGP using virtual inter-VDOM links.

In this example, a hub FortiGate forms BGP neighbors with two branches. It learns the networks 192.168.101.0/24 and 192.168.102.0/24 from the neighbors and separates them into VRF 10 and VRF 20.

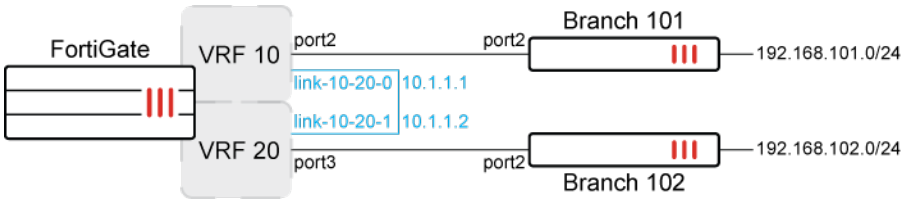
To leak the learned routes to each other, an inter-VDOM link (IVL) is formed. An IVL normally bridges two VDOMs, but in this case the links reside on the same VDOM and are used to bridge the two VRFs. NPU inter-VDOM links could also be used on models that support it to deliver better performance.

You can use the following command to enable NPU inter-VDOM links:

```
config system global
   set single-vdom-npuvlink enable
end
```

After entering this command, the NPU inter-VDOM links (npu0_vlink0, npu0_vlink1, and so on) are visible from the GUI and CLI and you can configure them to send traffic between VRFs.

VRF 10 has a leaked route to 192.168.102.0/24 on IVL *link-10-20-0*, and VRF 20 has a leaked route to 192.168.101.0/24 on IVL *link-10-20-1*,



To configure route leaking:

1. Allow interface subnets to use overlapping IP addresses:

```
config system settings
    set allow-subnet-overlap enable
end
```

2. Configure the inter-VDOM links:

```
config system vdom-link
    edit link-10-20-
    next
end
```

3. Configure the interface settings:

```
config system interface
    edit link-10-20-0
        set vdom "root"
        set vrf 10
        set ip 10.1.1.1/30
    next
    edit link-10-20-1
        set vdom "root"
        set vrf 20
        set ip 10.1.1.2/30
    next
end
```

4. Create the prefix lists:
   These objects define the subnet and mask that are leaked.

```
config router prefix-list
    edit VRF10_Route
        config rule
            edit 1
                set prefix 192.168.101.0 255.255.255.0
            next
        end
    next
    edit VRF20_Route
        config rule
            edit 1
                set prefix 192.168.102.0 255.255.255.0
```

```
            next
        end
    next
end
```

5. Create the route map:
   The route map can be used to group one or more prefix lists.

```
config router route-map
    edit "Leak_from_VRF10_to_VRF20"
        config rule
            edit 1
                set match-ip-address "VRF10_Route"
            next
        end
    next
    edit "Leak_from_VRF20_to_VRF10"
        config rule
            edit 1
                set match-ip-address "VRF20_Route"
            next
        end
    next
end
```

6. Configure the VRF leak in BGP, specifying a source VRF, destination VRF, an the route map to use:

```
config router bgp
    config vrf
        edit "10"
            config leak-target
                edit "20"
                    set route-map "Leak_from_VRF10_to_VRF20"
                    set interface "link-10-20-0"
                next
            end
        next
        edit "20"
            config leak-target
                edit "10"
                    set route-map "Leak_from_VRF20_to_VRF10"
                    set interface "link-10-20-1"
                next
            end
        next
    end
end
```

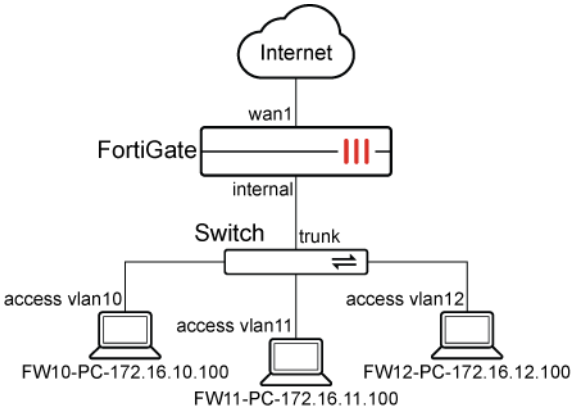
7. Create policies to allow traffic between the VRFs.
   Without a policy permitting traffic on the route between the VRFs, the VRFs are still isolated.

Route leaking between multiple VRFs

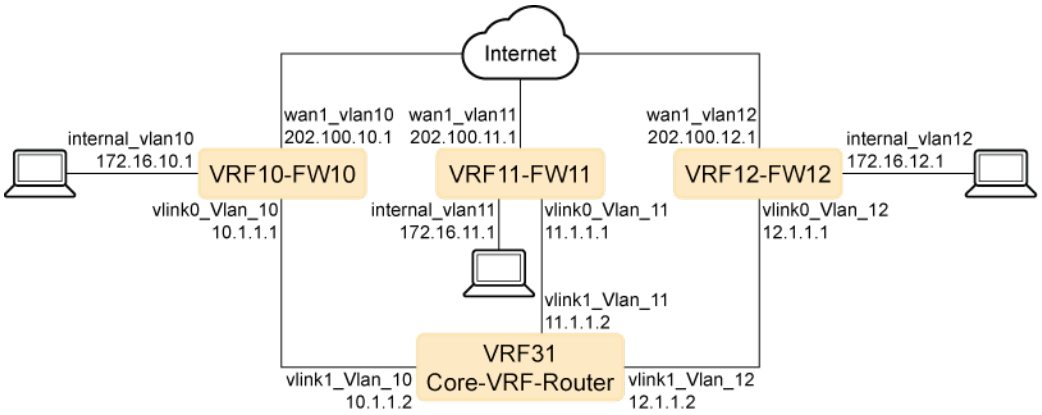
In this example, routing leaking between three VRFs in a star topology is configured. This allows the solution to be scaled to more VRFs without building full mesh, one-to-one connections between each pair of VRFs. VLAN subinterfaces are created on VDOM links to connect each VRF to the central VRF, allowing routes to be leaked from a VRF to the central VRF, and then to the other VRFs. Static routes are used for route leaking in this example.

For instructions on creating route leaking between two VRFs, see Route leaking between VRFs with BGP on page 667.

Physical topology:



Logical topology:



In this example, a specific route is leaked from each of the VRFs to each of the other VRFs. VLAN subinterfaces are created based on VDOM links to connect each VRF to the core VRF router.

NPU inter-VDOM links are used to accelerate traffic between VRFs. The setup could be configured by creating non-NPU VDOM links, but this is not recommended as these links are not offloaded to the NPU.

This example includes using the `single-vdom-npuvlink` option of the `config system global` command to enable NPU inter-VDOM links. You can also enable NPU inter-VDOM links by enabling multi-VDOM mode. Enabling multi-VDOM mode just to support VRF route leaking is not recommended.

To configure the FortiGate:

1. Enable NPU inter-VDOM links:

```
config system global
    set single-vdom-npuvlink enable
end
```

   You can enter the following command to view the NPU inter-VDOM links that are now available:

```
# show system interface
config system interface
    ...
    edit "npu0_vlink0"
        set vdom "root"
        set type physical
    next
    edit "npu0_vlink1"
        set vdom "root"
        set type physical
    next
    ...
end
```

2. Allow interface subnets to use overlapping IP addresses:

```
config vdom
    edit root
        config system settings
            set allow-subnet-overlap enable
        end
```

3. Configure the inter-connecting VLAN subinterfaces between VRF based on VDOM-LINK:

```
config system interface
    edit "vlink0_Vlan_10"
        set vdom "root"
        set vrf 10
        set ip 10.1.1.1 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink0_Vlan_10"
        set role lan
        set interface "npu0_vlink0"
        set vlanid 10
    next
    edit "vlink1_Vlan_10"
```

```
        set vdom "root"
        set vrf 31
        set ip 10.1.1.2 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink1_Vlan_10"
        set role lan
        set interface "npu0_vlink1"
        set vlanid 10
    next
    edit "vlink0_Vlan_11"
        set vdom "root"
        set vrf 11
        set ip 11.1.1.1 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink0_Vlan_11"
        set role lan
        set interface "npu0_vlink0"
        set vlanid 11
    next
    edit "vlink1_Vlan_11"
        set vdom "root"
        set vrf 31
        set ip 11.1.1.2 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink1_Vlan_11"
        set role lan
        set interface "npu0_vlink1"
        set vlanid 11
    next
    edit "vlink0_Vlan_12"
        set vdom "root"
        set vrf 12
        set ip 12.1.1.1 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink0_Vlan_12"
        set role lan
        set interface "npu0_vlink0"
        set vlanid 12
    next
    edit "vlink1_Vlan_12"
        set vdom "root"
        set vrf 31
        set ip 12.1.1.2 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink1_Vlan_12"
        set role lan
        set interface "npu0_vlink1"
        set vlanid 12
    next
end
```

4. Configure a zone to allow intrazone traffic between VLANs in the central VRF:

```
config system zone
    edit "Core-VRF-Router"
        set intrazone allow
        set interface "vlink1_Vlan_10" "vlink1_Vlan_11" "vlink1_Vlan_12"
    next
end
```

5. Add allow policies for the VRF31 core router:

```
config firewall policy
    edit 0
        set name "any_to_core_vrf31"
        set srcintf "any"
        set dstintf "Core-VRF-Router"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 0
        set name "core_vrf31_to_any"
        set srcintf "Core-VRF-Router"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
end
```

6. Configure VRF10, VRF11, and VRF12 on the Internal and WAN VLAN sub-interfaces:

```
config system interface
    edit "Internal_VRF10"
        set vdom "root"
        set vrf 10
        set ip 172.16.10.1 255.255.255.0
        set allowaccess ping https ssh http
        set alias "Internal_VRF10"
        set role lan
        set interface "internal"
        set vlanid 10
    next
    edit "Internal_VRF11"
        set vdom "root"
        set vrf 11
        set ip 172.16.11.1 255.255.255.0
        set allowaccess ping https ssh http
```

```
        set alias "Internal_VRF11"
        set role lan
        set interface "internal"
        set vlanid 11
    next
    edit "Internal_VRF12"
        set vdom "root"
        set vrf 12
        set ip 172.16.12.1 255.255.255.0
        set allowaccess ping https ssh http
        set alias "Internal_VRF12"
        set role lan
        set interface "internal"
        set vlanid 12
    next
    edit "wan1_VRF10"
        set vdom "root"
        set vrf 10
        set ip 202.100.10.1 255.255.255.0
        set allowaccess ping
        set alias "wan1_VRF10"
        set role wan
        set interface "wan1"
        set vlanid 10
    next
    edit "wan1_VRF11"
        set vdom "root"
        set vrf 11
        set ip 202.100.11.1 255.255.255.0
        set allowaccess ping
        set alias "wan1_VRF11"
        set role wan
        set interface "wan1"
        set vlanid 11
    next
    edit "wan1_VRF12"
        set vdom "root"
        set vrf 12
        set ip 202.100.12.1 255.255.255.0
        set allowaccess ping
        set alias "wan1_VRF12"
        set role wan
        set interface "wan1"
        set vlanid 12
    next
end
```

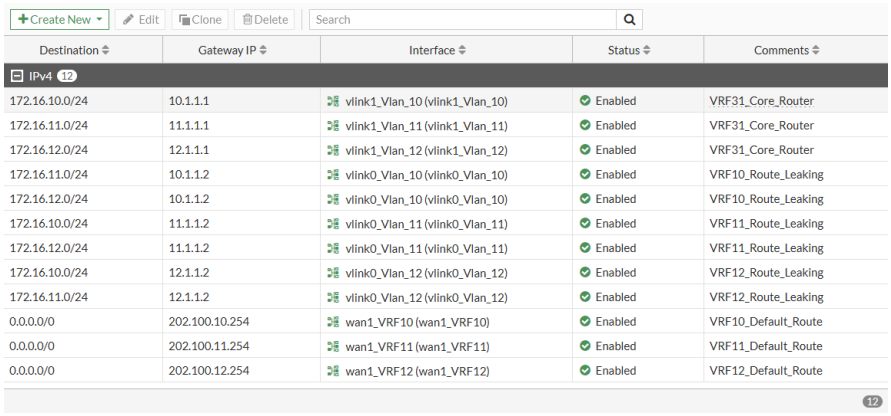
7. Configure static routing and route leaking between each VRF and Core-VRF-Router:

```
config router static
    edit 1
        set dst 172.16.10.0 255.255.255.0
```

```
        set gateway 10.1.1.1
        set device "vlink1_Vlan_10"
        set comment "VRF31_Core_Router"
    next
    edit 2
        set dst 172.16.11.0 255.255.255.0
        set gateway 11.1.1.1
        set device "vlink1_Vlan_11"
        set comment "VRF31_Core_Router"
    next
    edit 3
        set dst 172.16.12.0 255.255.255.0
        set gateway 12.1.1.1
        set device "vlink1_Vlan_12"
        set comment "VRF31_Core_Router"
    next
    edit 4
        set dst 172.16.11.0 255.255.255.0
        set gateway 10.1.1.2
        set device "vlink0_Vlan_10"
        set comment "VRF10_Route_Leaking"
    next
    edit 5
        set dst 172.16.12.0 255.255.255.0
        set gateway 10.1.1.2
        set device "vlink0_Vlan_10"
        set comment "VRF10_Route_Leaking"
    next
    edit 6
        set dst 172.16.10.0 255.255.255.0
        set gateway 11.1.1.2
        set device "vlink0_Vlan_11"
        set comment "VRF11_Route_Leaking"
    next
    edit 7
        set dst 172.16.12.0 255.255.255.0
        set gateway 11.1.1.2
        set device "vlink0_Vlan_11"
        set comment "VRF11_Route_Leaking"
    next
    edit 8
        set dst 172.16.10.0 255.255.255.0
        set gateway 12.1.1.2
        set device "vlink0_Vlan_12"
        set comment "VRF12_Route_Leaking"
    next
    edit 9
        set dst 172.16.11.0 255.255.255.0
        set gateway 12.1.1.2
        set device "vlink0_Vlan_12"
        set comment "VRF12_Route_Leaking"
```

```
    next
    edit 10
        set gateway 202.100.10.254
        set device "wan1_VRF10"
        set comment "VRF10_Default_Route"
    next
    edit 11
        set gateway 202.100.11.254
        set device "wan1_VRF11"
        set comment "VRF11_Default_Route"
    next
    edit 12
        set gateway 202.100.12.254
        set device "wan1_VRF12"
        set comment "VRF12_Default_Route"
    next
end
```

In the GUI, go to *Network* > *Static Routes* to view the static routes:



+Create New | Edit | Clone | Delete | Search

Destination	Gateway IP	Interface	Status	Comments
IPv4 12				
172.16.10.0/24	10.1.1.1	vlink1_Vlan_10 (vlink1_Vlan_10)	Enabled	VRF31_Core_Router
172.16.11.0/24	11.1.1.1	vlink1_Vlan_11 (vlink1_Vlan_11)	Enabled	VRF31_Core_Router
172.16.12.0/24	12.1.1.1	vlink1_Vlan_12 (vlink1_Vlan_12)	Enabled	VRF31_Core_Router
172.16.11.0/24	10.1.1.2	vlink0_Vlan_10 (vlink0_Vlan_10)	Enabled	VRF10_Route_Leaking
172.16.12.0/24	10.1.1.2	vlink0_Vlan_10 (vlink0_Vlan_10)	Enabled	VRF10_Route_Leaking

8. Configure firewall policies for VRF10, VRF11, and VRF12

```
config firewall policy
    edit 6
        set name "VRF10_to_Internet_Policy"
        set srcintf "Internal_VRF10"
        set dstintf "wan1_VRF10"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set nat enable
    next
    edit 7
        set name "VRF10_to_VRF_Leaking_Route"
        set srcintf "Internal_VRF10"
        set dstintf "vlink0_Vlan_10"
```

```
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 8
        set name "VRF_Leaking_Route_to_VRF10"
        set srcintf "vlink0_Vlan_10"
        set dstintf "Internal_VRF10"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 9
        set name "VRF11_to_Internet_Policy"
        set srcintf "Internal_VRF11"
        set dstintf "wan1_VRF11"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set nat enable
    next
    edit 10
        set name "VRF11_to_VRF_Leaking_Route"
        set srcintf "Internal_VRF11"
        set dstintf "vlink0_Vlan_11"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 11
        set name "VRF_Leaking_Route_to_VRF11"
        set srcintf "vlink0_Vlan_11"
        set dstintf "Internal_VRF11"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
```

```
    next
    edit 12
        set name "VRF12_to_Internet_Policy"
        set srcintf "Internal_VRF12"
        set dstintf "wan1_VRF12"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set nat enable
    next
    edit 13
        set name "VRF12_to_VRF_Leaking_Route"
        set uuid 92bccf8e-b27b-51eb-3c56-6d5259af6299
        set srcintf "Internal_VRF12"
        set dstintf "vlink0_Vlan_12"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
    edit 14
        set name "VRF_Leaking_Route_to_VRF12"
        set srcintf "vlink0_Vlan_12"
        set dstintf "Internal_VRF12"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
end
```

In the GUI, go to *Policy & Objects* > *Firewall Policy* to view the policies.

To check the results:

1. On the FortiGate, check the routing table to see each VRF:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
```

```

VRF with IPv6

IPv6 routes support VRF. Static, connected, OSPF, and BGP routes can be isolated in different VRFs. BGP IPv6 routes can be leaked from one VRF to another.

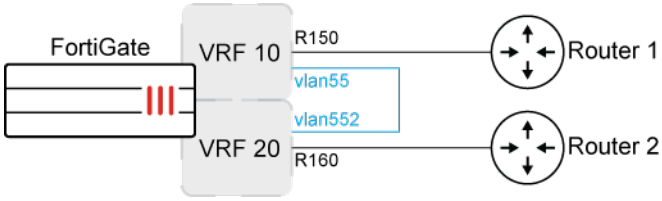
```
config router bgp
    config vrf6
        edit <origin vrf-id>
            config leak-target
                edit <target vrf-id>
                    set route-map <route-map>
                    set interface <interface>
                next
            end
        next
    end
end
```

The origin or target VRF ID is an integer value from 0 - 31.

```
config router static6
    edit <id>
        set vrf <vrf-id>
    next
end
```

Using a VRF leak on BGP

In this example, the route 2000:5:5:5::/64 learned from Router 1 is leaked to VRF 20 through the interface vlan552. Conversely, the route 2009:3:3:3::/64 learned from Router 2 is leaked to VRF 10 through interface vlan55.



To configure VRF leaking in BGP:

1. Configure the BGP neighbors:

```
config router bgp
    set as 65412
    config neighbor
        edit "2000:10:100:1::1"
            set activate disable
            set remote-as 20
            set update-source "R150"
        next
        edit "2000:10:100:1::5"
            set activate disable
            set soft-reconfiguration enable
            set interface "R160"
            set remote-as 20
        next
    end
end
```

2. Configure the VLAN interfaces:

```
config system interface
    edit "vlan55"
        set vdom "root"
        set vrf 10
        set ip 55.1.1.1 255.255.255.0
        set device-identification enable
        set role lan
        set snmp-index 51
        config ipv6
            set ip6-address 2000:55::1/64
        end
        set interface "npu0_vlink0"
        set vlanid 55
    next
    edit "vlan552"
        set vdom "root"
```

```
        set vrf 20
        set ip 55.1.1.2 255.255.255.0
        set device-identification enable
        set role lan
        set snmp-index 53
        config ipv6
            set ip6-address 2000:55::2/64
        end
        set interface "npu0_vlink1"
        set vlanid 55
    next
end
```

3. Configure the IPv6 prefixes:

```
config router prefix-list6
    edit "1"
        config rule
            edit 1
                set prefix6 2000:5:5:5::/64
                unset ge
                unset le
            next
        end
    next
    edit "2"
        config rule
            edit 1
                set prefix6 2009:3:3:3::/64
                unset ge
                unset le
            next
        end
    next
end
```

4. Configure the route maps:

```
config router route-map
    edit "from106"
        config rule
            edit 1
                set match-ip6-address "1"
            next
        end
    next
    edit "from206"
        config rule
            edit 1
                set match-ip6-address "2"
            next
        end
```

```
    next
end
```

5. Configure the IPv6 route leaking (leak route 2000:5:5:5::/64 learned from Router 1 to VRF 20, then leak route 2009:3:3:3::/64 learned from Router 2 to VRF 10):

```
config router bgp
    config vrf6
        edit "10"
            config leak-target
                edit "20"
                    set route-map "from106"
                    set interface "vlan55"
                next
            end
        next
        edit "20"
            config leak-target
                edit "10"
                    set route-map "from206"
                    set interface "vlan552"
                next
            end
        next
    end
end
```

To verify the VRF leaking:

1. Check the routing table before the leak:

```
# get router info6 routing-table bgp
Routing table for VRF=10
B       2000:5:5:5::/64 [20/0] via fe00::2000:0000:0000:00, R150, 00:19:45

Routing table for VRF=20
B       2008:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:18:49
B       2009:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:18:49
```

2. Check the routing table after the leak:

```
# get router info6 routing-table bgp
Routing table for VRF=10
B       2000:5:5:5::/64 [20/0] via fe00::2000:0000:0000:0, R150, 00:25:45
B       2009:3:3:3::/64 [20/0] via fe80::10:0000:0000:4245, vlan55, 00:00:17

Routing table for VRF=20
B       2000:5:5:5::/64 [20/0] via fe80::10:0000:0000:4244, vlan552, 00:00:16
B       2008:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:24:49
B       2009:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:24:49
```

Using VRF on a static route

In this example, a VRF is defined on static route 22 so that it will only appear in the VRF 20 routing table.

To configure the VRF on the static route:

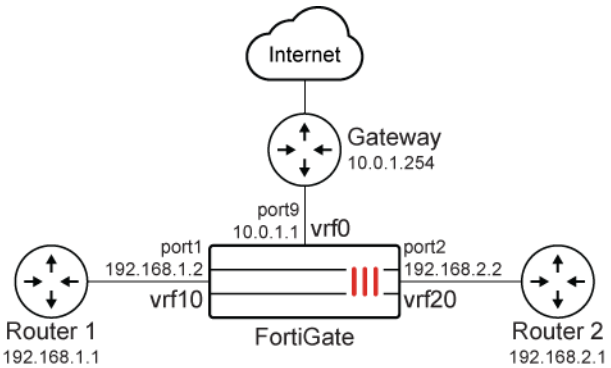
```
config router static6
    edit 22
        set dst 2010:2:2:2::/64
        set blackhole enable
        set vrf 20
    next
end
```

IBGP and EBGP support in VRF

Support is included for internal and external border gateway protocols (IBGP and EBGP) in virtual routing and forwarding (VRF).

FortiGate can establish neighbor connections with other FortiGates or routers, and the learned routes are put into different VRF tables according to the neighbor's settings.

This example uses the following topology:



- BGP routes learned from the Router1 neighbor are put into vrf10.
- BGP routes learned from the Router2 neighbor are put into vrf20.

To configure this example:

```
config system interface
    edit port1
        set vrf 10
    next
    edit port2
        set vrf 20
    next
end
```

```
config router bgp
    config neighbor
        edit "192.168.1.1"
            set update-source port1
        next
        edit "192.168.2.1"
            set interface port2
        next
    end
end
```

Results

Using the above topology:

- Both Router1 and Router2 establish OSPF and BGP neighbor with the FortiGate.
- Router1 advertises 10.10.1.0/24 into OSPF and 10.10.2.0/24 into BGP.
- Router2 advertises 20.20.1.0/24 into OSPF and 20.20.2.0/24 into BGP.

When port1 and port2 have not set VRF, all of the routing is in VRF=0:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
S*      0.0.0.0/0 [5/0] via 10.0.1.254, port9
C       10.0.1.0/24 is directly connected, port9
O       10.10.1.0/24 [110/10] via 192.168.1.1, port1, 00:18:31
B       10.10.2.0/24 [20/200] via 192.168.1.1, port1, 00:01:31
O       20.20.1.0/22 [110/10] via 192.168.2.1, port2, 00:19:05
B       20.20.2.0/24 [20/200] via 192.168.2.1, port2, 00:01:31
C       192.168.1.0/24 is directly connected, port1
C       192.168.2.0/24 is directly connected, port2
```

After VRF is set for BGP, BGP routes are added to the VRF tables along with OSPF and connected routes:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
S*      0.0.0.0/0 [5/0] via 10.0.1.254, port9
C       10.0.1.0/24 is directly connected, port9
```

```
Routing table for VRF=10
O       10.10.1.0/24 [110/10] via 192.168.1.1, port1, 00:18:31
B       10.10.2.0/24 [20/200] via 192.168.1.1, port1, 00:01:31
C       192.168.1.0/24 is directly connected, port1

Routing table for VRF=20
O       20.20.1.0/22 [110/10] via 192.168.2.1, port2, 00:19:05
B       20.20.2.0/24 [20/200] via 192.168.2.1, port2, 00:01:31
C       192.168.2.0/24 is directly connected, port2
```

BGP neighbor groups

This feature is also supported in the BGP neighbor groups. For example:

```
config router bgp
    config neighbor-group
        edit "FGT"
            set update-source "port1"
        next
    end
    config neighbor-range
        edit 1
            set prefix 172.16.201.0 255.255.255.0
            set neighbor-group "FGT"
        next
    end
end
```

Note that the `set interface` command is not supported.

Support cross-VRF local-in and local-out traffic for local services

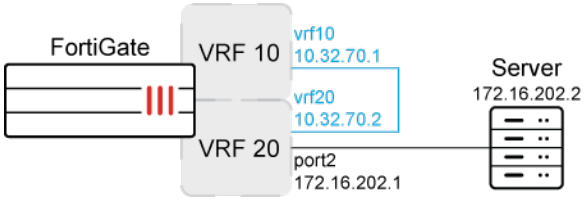
When local-out traffic such as SD-WAN health checks, SNMP, syslog, and so on are initiated from an interface on one VRF and then pass through interfaces on another VRF, the reply traffic will be successfully forwarded back to the original VRF.

VRF 0 is a special VRF. By default, all routing is done in VRF 0. So all routes in different VRFs, such as VRF 10 or VRF 20, will all be included in VRF 0. VRF 0 cannot be used in the cross-VRF case.

For local-in and local-out traffic, all routes relating to one VRF are isolated from other VRFs so interfaces in one VRF cannot reach interfaces in a different VRF, except for VRF 0.

Example

In this example, there is an NPU inter-VDOM link that is configured on the root VDOM. Two VLANs, vrf10 and vrf20, are created on either ends of the NPU inter-VDOM link, each belonging to a different VRF.



When pinging from the vrf10 interface in VRF 10 to the destination server 172.16.202.2, since there is a single static route for VRF 10 with a gateway of vrf20/10.32.70.2, traffic is sent to the next hop and subsequently routed through port12 to the server.

As seen in the sniffer trace, the ICMP replies are received on port12 in VRF 20, then pass through vrf20, and are ultimately forwarded back to vrf10 in VRF 10. The traffic flow demonstrates that local-out traffic sourced from one VRF passing through another VRF can return back to the original VRF.

To configure cross-VRF local-out traffic for local services:

1. Configure the interfaces:

```
config system interface
    edit "vrf10"
        set vdom "root"
        set vrf 10
        set ip 10.32.70.1 255.255.255.0
        set allowaccess ping
        set device-identification enable
        set role lan
        set snmp-index 35
        set interface "npu0_vlink0"
        set vlanid 22
    next
    edit "vrf20"
        set vdom "root"
        set vrf 20
        set ip 10.32.70.2 255.255.255.0
        set allowaccess ping
        set device-identification enable
        set role lan
        set snmp-index 36
        set interface "npu0_vlink1"
        set vlanid 22
    next
    edit "port12"
        set vdom "root"
        set vrf 20
        set ip 172.16.202.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet fgfm radius-acct probe-response fabric
```

```
ftm speed-test
        set type physical
        set alias "TO_FGT_D_port22"
        set snmp-index 14
        config ipv6
            set ip6-address 2003:172:16:202::1/64
            set ip6-allowaccess ping
        end
    next
end
```

2. Configure the firewall policy:

```
config firewall policy
    edit 1
        set srcintf "vrf20"
        set dstintf "port12"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
    next
end
```

3. Configure the static route:

```
config router static
    edit 2
        set gateway 10.32.70.2
        set distance 3
        set device "vrf10"
    next
end
```

To test the configuration:

1. Execute a ping from the vrf10 interface in VRF 10 to the destination server (172.16.202.2):

```
# execute ping-options interface vrf10
# execute ping 172.16.202.2
PING 172.16.202.2 (172.16.202.2): 56 data bytes
64 bytes from 172.16.202.2: icmp_seq=0 ttl=254 time=0.1 ms
64 bytes from 172.16.202.2: icmp_seq=1 ttl=254 time=0.0 ms

--- 172.16.202.2 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max = 0.0/0.0/0.1 ms
```

2. Run a sniffer trace on 172.16.202.2 for ICMP:

```
# diagnose sniffer packet any "host 172.16.202.2 and icmp" 4
interfaces=[any]
filters=[host 172.16.202.2 and icmp]
3.393920 vrf10 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393922 npu0_vlink0 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393927 vrf20 in 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393943 port12 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393977 port12 in 172.16.202.2 -> 10.32.70.1: icmp: echo reply
3.393987 vrf20 out 172.16.202.2 -> 10.32.70.1: icmp: echo reply

```

Support specific VRF ID for local-out traffic

A Virtual Routing and Forwarding (VRF) instance can be specified for local-out traffic to provide traffic segregation, optimized routing, and enhanced policy enforcement.

The following configuration commands include the option to set a VRF instance number:

```
config system interface
    edit "port2"
        set dhcp-relay-vrf-select
    next
end
```

`set dhcp-relay-vrf-select <integer>`	VRF ID used for connection to sever. Set VRF instance number (0 to 511, default = 0).

```
config system settings
  set dhcp-proxy-vrf-select <integer>
end
```

`set dhcp-proxy-vrf-select <integer>`	VRF ID used for connection to sever. Set VRF instance number (0 to 511, default = 0).

```
config system dns
    set vrf-select <integer>
end

config system fortiguard
    set vrf-select <integer>
```

```
end

config system snmp community
  edit <id>
    config hosts
        edit <id>
          set vrf-select <integer>
        next
    config hosts6
        edit <id>
            set vrf-select <integer>
        next
    next
end

config system snmp user
    edit <name>
        set vrf-select <integer>
    next
end

config system email-server
    set vrf-select <integer>
end

config system vdom-dns
    set vrf-select <integer>
end

config system external-resource
    set vrf-select <integer>
end

config system fortindr
    set vrf-select <integer>
end

config system central-management
    set vrf-select <integer>
end

config system netflow|vdom-netflow
    config collectors
        edit <id>
            set vrf-select
        next
    next
end

config system ntp
    config ntpserver
        edit <id>
```

```
            set vrf-select <integer>
        next
    next
end

config system fortisandbox
    set vrf-select <integer>
end

config log syslogd setting
    set vrf-select <integer>
end

config log fortiguard setting
    set vrf-select <integer>
end

config log disk setting
    set vrf-select <integer>
end

config log tacacs+accounting setting
    set vrf-select <integer>
end

config log fortianalyzer|fortianalyzer2|fortianalyzer3|fortianalyzer-cloud setting
    set vrf-select <integer>
end

config system dns-database
    edit <name>
        set vrf-select <integer>
    end
end

config user external-identity-provider
    edit <name>
        set vrf-select <integer>
    end
end

config user fsso
    edit <name>
        set vrf-select <integer>
    end
end

config user ldap
    edit <name>
        set vrf-select <integer>
    end
end
```

```
config user radius
    edit <name>
        set vrf-select <integer>
        config accounting-server
            edit <id>
                set vrf-select <integer>
            end
        end
    end
end

config user tacacs+
    edit <name>
        set vrf-select <integer>
    end
end

config vpn certificate setting
    set vrf-select <integer>
end

config vpn kmip-server
    edit <name>
        set vrf-select <integer>
    end
end
```

`set vrf-select <integer>`	VRF ID used for connection to sever. Set VRF instance number (0 to 511, default = 0).

The following execute commands now include the option to specify a VRF instance number:

```
# execute ping-options vrf <integer>
# execute ping6-options vrf <integer>
# execute traceroute-options vrf <integer>
```

`vrf <integer>`	VRF ID (0 to 511).

The following execute command now includes the option to specify a VRF instance number:

```
# execute tracert6 -v <integer>
```

`-v <integer>`	VRF ID (0 to 511).

The following diagnose commands now include the option to specify a VRF instance number:

```
# diagnose ip proute match <dst> <src> <iif> <proto> <dport> <sport> <vrf>
# diagnose ipv6 proute match <dst> <src> <iif> <proto> <dport> <sport> <vrf>
# diagnose test authserver radius-direct <server_name or IP> <port number (0 default port)> <udp |
tcp | tls> <secret> <pap | chap | mschap | mschap2> <vrf> <user> <password
```

`vrf <integer>`	VRF ID (0 to 511).

Example 1: RADIUS server and VRF ID

In this example, the local-out traffic flows through the VRF interface to its destination. The VRF server can be reached by port1 (VRF 22), but not port2 (VRF 0).

To configure a VRF ID for a RADIUS server:

1. Specify a VRF ID for the RADIUS server:

```
config user radius
    edit "FAC"
        set server "192.168.100.129"
        set secret ftntxxxxxx
        set password-renewal disable
        set vrf-select 22
    next
end
```

2. Get the static routing table:

```
# get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [5/0] via 10.100.1.249, npu0_vlink0, [1/0]
S       192.168.100.0/24 [10/0] via 172.16.205.11, port2, [1/0]

Routing table for VRF=22
S*      0.0.0.0/0 [2/0] via 172.16.200.254, port1, [1/0]
```

Example 2: ping command and VRF ID

In this example, the local-out traffic flows through the VRF interface to its destination. IP address 3.3.3.3 can be reached by port1 (VRF 22).

To use a VRF ID with ping:

1. Get the static routing table:

```
# get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [5/0] via 10.100.1.249, npu0_vlink0, [1/0]
S       3.3.3.0/24 [10/0] via 172.16.205.11, port2, [1/0]
S       192.168.100.0/24 [10/0] via 172.16.205.11, port2, [1/0]

Routing table for VRF=22
S*      0.0.0.0/0 [2/0] via 172.16.200.254, port1, [1/0]
```

2. Specify a VRF ID for the interface with ping access allowed:

```
config system interface
    edit "loop2"
        set vdom "root"
        set vrf 22
        set ip 1.1.1.2 255.255.255.255
        set allowaccess ping https http
        set type loopback
        set snmp-index 84
    next
end
```

3. Execute the ping command:

```
# execute ping-options vrf 22

# execute ping-options source 1.1.1.2

# execute ping 3.3.3.3
PING 3.3.3.3 (3.3.3.3): 56 data bytes
64 bytes from 3.3.3.3: icmp_seq=0 ttl=255 time=0.1 ms
```

Example 3: traceroute command and VRF ID

The VRF ID can be used with the `traceroute` command.

To use a VRF ID with traceroute:

1. Get the routing table details for IP address 3.3.3.3:

```
# get router info routing-table details 3.3.3.3

Routing table for VRF=0
Routing entry for 3.3.3.3/32
  Known via "ospf", distance 110, metric 10200, best
  Last update 05:53:57 ago
  * vrf 0 172.16.203.2, via agg1

Routing table for VRF=22
Routing entry for 3.3.3.3/32
  Known via "ospf", distance 110, metric 11000, best
  Last update 05:31:31 ago
  * vrf 22 172.16.200.4, via port1
  * vrf 22 172.16.200.40, via port1
```

2. Execute a traceroute for VRF 22:

```
# execute traceroute 3.3.3.3
VRF 22, traceroute to 3.3.3.3 (3.3.3.3), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  3.3.3.3  0.135 ms  0.090 ms  0.073 ms
```

Example 4: diagnose command and VRF ID

Like the other examples in this topic, port1 is in VRF 22, and port2 is in VRF 0. This example demonstrates how the `diagnose ip proute match` command works with and without a specified VRF ID.

To use a VRF ID with a diagnose command:

1. Configure the router policy for port1 and port2:

```
config router policy
    edit 1
        set dst "23.23.23.23/255.255.255.255"
        set gateway 172.16.200.55
        set output-device "port1"
    next
    edit 2
        set dst "23.23.23.23/255.255.255.255"
        set gateway 172.16.205.11
        set output-device "port2"
    next
end
```

2. Run the `diagnose firewall proute list` command:

```
# diagnose firewall proute list
list route policy info(vf=root):

id=1(0x01) dscp_tag=0xfc 0xfc flags=0x0 tos=0x00 tos_mask=0x00 protocol=0 port=src(0->0):dst
(0->0) iif=0(any)
path(1): oif=7(port1) gwy=172.16.200.55
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 23.23.23.23/255.255.255.255
hit_count=1 rule_last_used=2024-10-11 15:40:23

id=2(0x02) dscp_tag=0xfc 0xfc flags=0x0 tos=0x00 tos_mask=0x00 protocol=0 port=src(0->0):dst
(0->0) iif=0(any)
path(1): oif=8(port2) gwy=172.16.205.11
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 23.23.23.23/255.255.255.255
hit_count=2 rule_last_used=2024-10-11 15:40:39
```

3. Run the `diagnose ip route match` command without a VRF ID:
   When the VRF is not specified, VRF 0 is used, and it will match port2.

```
# diagnose ip proute match 23.23.23.23 2.2.2.22 port4 6 23 23
dst=23.23.23.23 src=2.2.2.22 smac=00:00:00:00:00:00 iif=10 protocol=6 sport=23 dport=23 vrf=-1
id=00000002 type=Policy Route
seq-num=2 oif=8(port2)flags=0x0
```

4. Run the `diagnose ip route match` command with a VRF ID:
   When VRF 22 is specified, it will match policy route with port1, which is in VRF 22:

```
# diagnose ip proute match 23.23.23.23 2.2.2.22 port4 6 23 23 22
dst=23.23.23.23 src=2.2.2.22 smac=00:00:00:00:00:00 iif=10 protocol=6 sport=23 dport=23 vrf=22
id=00000001 type=Policy Route
seq-num=1 oif=7(port1)flags=0x0
```

NetFlow

NetFlow allows you to collect IP network traffic statistics for an interface, and then export those statistics for analysis. NetFlow samplers, that sample every packet, are configured per interface. Full NetFlow is supported through the information maintained in the firewall session.

To configure NetFlow:

```
config system netflow
    set active-flow-timeout <integer>
    set inactive-flow-timeout <integer>
    set template-tx-timeout <integer>
    set template-tx-counter <integer>
    config collectors
        edit <id>
            set collector-ip <IP address>
            set collector-port <port>
            set source-ip <IP address>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        next
    end
end
```

The `source-ip-interface` and `source-ip` commands are unavailable for NetFlow configurations when `ha-direct` is enabled. (See config system ha in the CLI Reference guide).

The `source-ip-interface` and `source-ip` commands are also mutually exclusive; they cannot be used at the same time, but one or the other can be used together with the *interface-select-method* command

`active-flow-timeout <integer>`	Timeout to report active flows, in seconds (60 - 3600, default = 1800).
`inactive-flow-timeout <integer>`	Timeout for periodic report of finished flows, in seconds (10 - 600, default = 15).
`template-tx-timeout <integer>`	Timeout for periodic template flowset transmission, in seconds (60 - 86400, default = 1800).

`template-tx-counter <integer>`	Counter of flowset records, before resending a template flowset record (10 - 6000, default = 20).
`collector-ip <ip>`	Collector IPv4 or IPv6 address.
`collector-port <port>`	NetFlow collector port number (0 - 65535).
`source-ip <ip>`	Source IPv4 or IPv6 address, for communication with the NetFlow agent.
`interface-select-method {auto | sdwan | specify}`	Routing of the NetFlow messages is determined by the selected method. If neither `source-ip-interface` nor `source-ip` is configured, then the source address of the message is the IP address of the interface selected by the interface select method. See Local out traffic on page 1125 for details.
`source-ip-interface <name>`	Utilize the IP address of the specified interface as the source when sending out the NetFlow messages. Routing of the messages does not change based on this setting. The `source-ip-interface` is unavailable for NetFlow configurations when FortiGate is in transparent VDOM mode.
`interface <interface>`	The outgoing interface to reach the server.

To configure NetFlow in a specific, non-management VDOM:

```
config vdom
    edit <vdom>
        config system vdom-netflow
            set vdom-netflow enable
            config collectors
                edit <id>
                    set collector-ip <IP address>
                    set collector-port <port>
                    set source-ip <IP address>
                    set interface-select-method {auto | sdwan | specify}
                    set interface <interface>
                next
            end
        end
    next
end
```

The `vdom-netflow` command is only available for non-management VDOMs. The management VDOM utilizes the global NetFlow settings.

To configure a NetFlow sampler on an interface:

```
config system interface
    edit <interface>
        set netflow-sampler {disable | tx | rx | both}
```

```
    next
end
```

disable	Disable the NetFlow protocol on this interface (default).
tx	Monitor transmitted traffic on this interface.
rx	Monitor received traffic on this interface.
both	Monitor transmitted/received traffic on this interface.

To configure a source interface for syslog:

1. Configure the interface:

```
config system interface
    edit "loopback"
        set vdom "vdom1"
        set ip 10.10.10.2 255.255.255.0
        set allowaccess ping
        set type loopback
    next
end
```

2. Configure the syslog device:

```
config log syslogd setting
    set status enable
    set server "172.16.200.55"
    set facility local6
    set source-ip-interface "loopback"
end
```

Verification and troubleshooting

If data are not seen on the NetFlow collector after it has been configured, use the following sniffer commands to verify if the FortiGate and the collector are communicating:

- By collector port:

```
# diagnose sniffer packet 'port <collector-port>'  6 0 a
```

- By collector IP address:

```
# diagnose sniffer packet 'host <collector-ip>' 6 0 a
```

NetFlow uses the sflow daemon. The current NetFlow configuration can be viewed using test level 3 or 4:

```
# diagnose test application sflowd 3
```

```
# diagnose test application sflowd 4
Netflow Cache Stats:
vdoms=1 Collectors=1 Cached_intf=2 Netflow_enabled_intf=1 Live_sessions=0 Session cache max
count:71950
```

NetFlow templates

NetFlow uses templates to capture and categorize the data that it collects. FortiOS supports the following NetFlow templates:

Name	Template ID	Description
STAT_OPTIONS	256	Statistics information about exporter
APP_ID_OPTIONS	257	Application information
IPV4	258	No NAT IPv4 traffic
IPV6	259	No NAT IPv6 traffic
ICMP4	260	No NAT ICMPv4 traffic
ICMP6	261	No NAT ICMPv6 traffic
IPV4_NAT	262	Source/Destination NAT IPv4 traffic
IPV4_AF_NAT	263	AF NAT IPv4 traffic (4->6)
IPV6_NAT	264	Source/Destination NAT IPv6 traffic
IPV6_AF_NAT	265	AF NAT IPv6 traffic (6->4)
ICMP4_NAT	266	Source/Destination NAT ICMPv4 traffic
ICMP4_AF_NAT	267	AF NAT ICMPv4 traffic (4->6)
ICMP6_NAT	268	Source/Destination NAT ICMPv6 traffic
ICMPv6_AF_NAT	269	AF NAT ICMPv6 traffic (6->4)

NetFlow on FortiExtender and tunnel interfaces

NetFlow sampling is supported on FortiExtender and VPN tunnel interfaces.

VPN tunnel interfaces can be IPsec, IP in IP, or GRE tunnels. NetFlow sampling is supported on both NPU and non-NPU offloaded tunnels.

Examples

In the following examples, a FortiExtender and a VPN tunnel interface are configured with NetFlow sampling.

To configure a FortiExtender interface with NetFlow sampling:

1. Configure a FortiExtender interface with NetFlow sampling enabled for both transmitted and received traffic:

```
config system interface
    edit "fext-211"
        set vdom "root"
        set mode dhcp
        set type fext-wan
        set netflow-sampler both
        set role wan
        set snmp-index 8
        set macaddr 2a:4e:68:a3:f4:6a
    next
end
```

2. Check the NetFlow status and configuration:
   Device index 26 is the FortiExtender interface `fext-211`.

```
# diagnose test application sflowd 3
===== Netflow Vdom Configuration =====
Global collector:172.18.60.80:[2055] source ip: 0.0.0.0 active-timeout(seconds):60 inactive-
timeout(seconds):600
____ vdom: root, index=0, is master, collector: disabled (use global config) (mgmt vdom)
   |_ coll_ip:172.18.60.80[2055],src_ip:10.6.30.105,seq_num:300,pkts/time to next template:
18/29
   |_ exported: Bytes:3026268, Packets:11192, Sessions:290 Flows:482
   |____ interface:fext-211 sample_direction:both device_index:26 snmp_index:8
```

3. Check the network interface list:

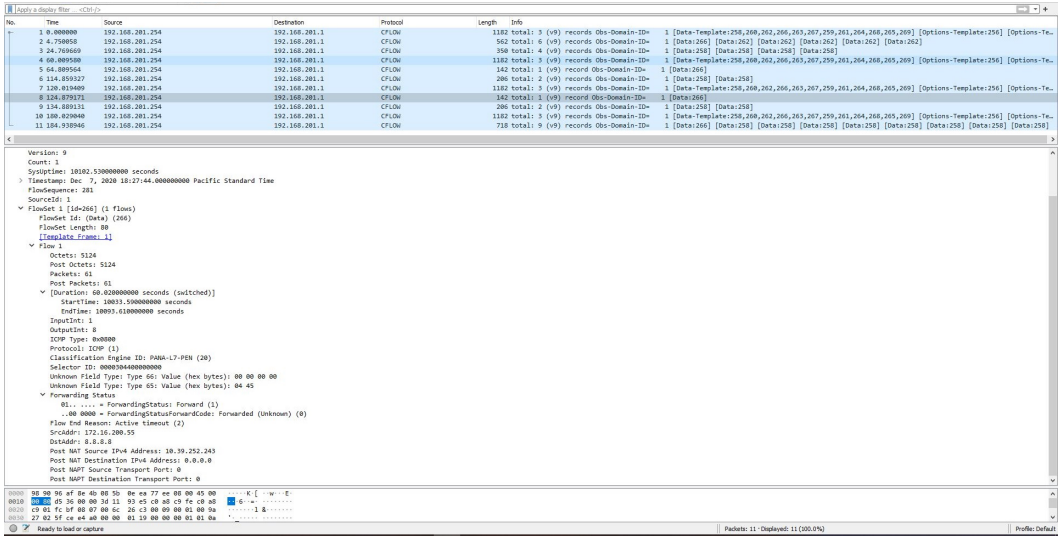
```
# diagnose netlink interface list
...
if=fext-211 family=00 type=1 index=26 mtu=1500 link=0 master=0
ref=27 state=start present fw_flags=60000 flags=up broadcast run multicast
...
```

4. Check the session list for the FortiExtender interface and NetFlow flowset packet:

```
# diagnose sys session list
session info: proto=1 proto_state=00 duration=1732 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty netflow-origin netflow-reply
statistic(bytes/packets/allow_err): org=145572/1733/1 reply=145572/1733/1 tuples=2
tx speed(Bps/kbps): 83/0 rx speed(Bps/kbps): 83/0
orgin->sink: org pre->post, reply pre->post dev=5->26/26->5 gwy=10.39.252.244/172.16.200.55
hook=post dir=org act=snat 172.16.200.55:61290->8.8.8.8:8(10.39.252.243:61290)
hook=pre dir=reply act=dnat 8.8.8.8:61290->10.39.252.243:0(172.16.200.55:61290)
```

```
misc=0 policy_id=1 auth_info=0 chk_client_info=0 vd=0
serial=00001298 tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x040000
no_ofld_reason:  non-npu-intf
total session 1
```

5. The flowset packet can be captured on UDP port 2055 by a packet analyzer, such as Wireshark:



To configure a VPN tunnel interface with NetFlow sampling:

1. Configure a VPN interface with NetFlow sampling enabled for both transmitted and received traffic:

```
config system interface
    edit "A-to-B_vpn"
        set vdom "vdom1"
        set type tunnel
        set netflow-sampler both
        set snmp-index 42
        set interface "port3"
    next
end
```

2. Configure the VPN tunnel:

```
config vpn ipsec phase1-interface
    edit "A-to-B_vpn"
        set interface "port3"
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set comments "VPN: A-to-B_vpn [Created by VPN wizard]"
        set wizard-type static-fortigate
        set remote-gw 10.2.2.2
```

```
        set psksecret ENC
    next
end
```

```
config vpn ipsec phase2-interface
    edit "A-to-B_vpn"
        set phase1name "A-to-B_vpn"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm aes256gcm
chacha20poly1305
        set comments "VPN: A-to-B_vpn [Created by VPN wizard]"
        set src-addr-type name
        set dst-addr-type name
        set src-name "A-to-B_vpn_local"
        set dst-name "A-to-B_vpn_remote"
    next
end
```

3. Check the NetFlow status and configuration:
   Device index 52 is the VPN interface `A-to-B_vpn`.

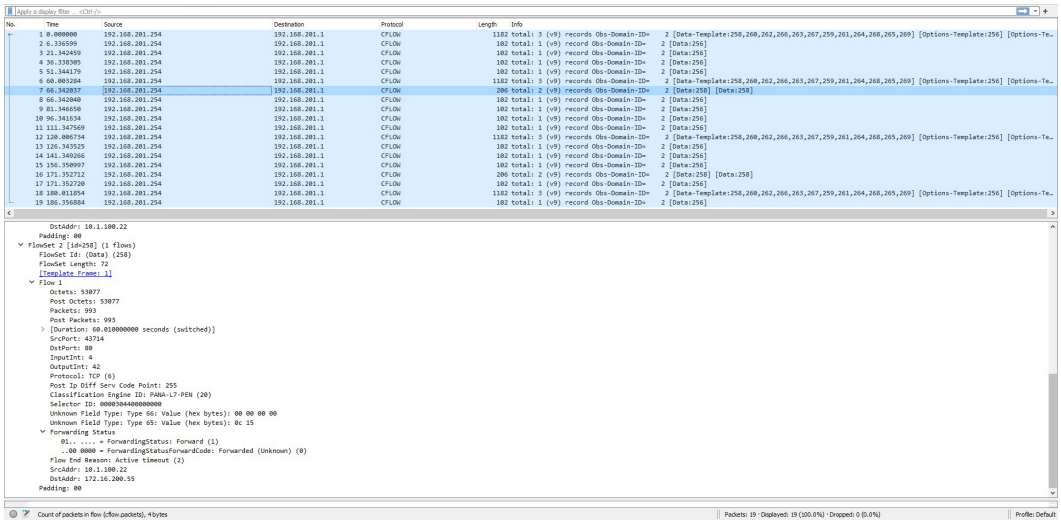
```
# diagnose test application sflowd 3
===== Netflow Vdom Configuration =====
Global collector:172.18.60.80:[2055] source ip: 0.0.0.0 active-timeout(seconds):60 inactive-
timeout(seconds):15
____ vdom: vdom1, index=1, is master, collector: disabled (use global config) (mgmt vdom)
   |_ coll_ip:172.18.60.80[2055],src_ip:10.1.100.1,seq_num:60,pkts/time to next template: 15/6
   |_ exported: Bytes:11795591, Packets:48160, Sessions:10 Flows:34
   |____ interface:A-to-B_vpn sample_direction:both device_index:52 snmp_index:42
```

4. Check the session list for the VPN interface and NetFlow flowset packet (unencapsulated traffic going through the VPN tunnel):

```
# diagnose sys session list
session info: proto=6 proto_state=01 duration=6 expire=3599 timeout=3600 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty npu netflow-origin netflow-reply
statistic(bytes/packets/allow_err): org=6433/120/1 reply=884384/713/1 tuples=2
tx speed(Bps/kbps): 992/7 rx speed(Bps/kbps): 136479/1091
orgin->sink: org pre->post, reply pre->post dev=10->52/52->10 gwy=10.2.2.2/10.1.100.22
hook=pre dir=org act=noop 10.1.100.22:43714->172.16.200.55:80(0.0.0.0:0)
hook=post dir=reply act=noop 172.16.200.55:80->10.1.100.22:43714(0.0.0.0:0)
pos/(before,after) 0/(0,0), 0/(0,0)
src_mac=00:0c:29:ac:ae:4f
misc=0 policy_id=5 auth_info=0 chk_client_info=0 vd=1
serial=00003b6c tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x000001 no_offload
```

```
npu info: flag=0x82/0x00, offload=0/0, ips_offload=0/0, epid=0/0, ipid=0/0, vlan=0x0000/0x0000
vlifid=0/0, vtag_in=0x0000/0x0000 in_npu=0/0, out_npu=0/0, fwd_en=0/0, qid=0/0
no_ofld_reason:  disabled-by-policy
total session 1
```

5. The flowset packet can be captured on UDP port 2055 by a packet analyzer, such as Wireshark:



Allow multiple NetFlow collectors

FortiOS can be configured with a maximum of six NetFlow collectors. This also applies to multi-VDOM environments where a maximum of six NetFlow collectors can be used globally or on a per-VDOMs basis. This feature enables up to a maximum of six unique parallel NetFlow streams or transmissions per NetFlow sample to six different NetFlow collectors. The NetFlow collector configuration can only be configured in the CLI.

The `netflow` command is global, and utilized by the management VDOM. The `vdom-netflow` command is only available for non-management VDOMs.

```
config system {netflow | vdom-netflow}
    config collectors
        edit <id>
            set collector-ip <IP address>
            set collector-port <port>
            set source-ip <IP address>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        next
    end
end
```

`collector-ip`	Enter the IPv4 or IPv6 address of the NetFlow collector that NetFlow agents added to interfaces in this VDOM send NetFlow datagrams to.
`collector-port`	Enter the UDP port number used for sending NetFlow datagrams; only configure if it is required by the NetFlow collector or network configuration

	(0 - 65535, default = 6343).
`source-ip`	Enter the source IPv4 or IPv6 address for the NetFlow agent.
`interface-select-method`	Specify how to select the outgoing interface to reach the server. • `auto`: Set the outgoing interface automatically. • `sdwan`: Set the outgoing interface by SD-WAN or policy routing rules. • `specify`: Set the outgoing interface manually.
`interface <interface>`	Enter the outgoing interface to reach the server.

If the `interface-select-method` is set to `auto`, the outgoing interface that is used to send the sampled NetFlow traffic to the NetFlow collector is decided by the routing table lookup.

Example 1: Multiple NetFlow collectors in a non-VDOM environment

In this example, six NetFlow collectors are configured in a non-VDOM environment with NetFlow sampling on the port1 interface.

To configure multiple NetFlow collectors:

1. Configure the NetFlow collectors:

```
config system netflow
   config collectors
   set active-flow-timeout 60
   set template-tx-timeout 60
        edit 1
            set collector-ip 172.16.200.155
            set collector-port 2055
            set source-ip 172.16.200.6
            set interface-select-method specify
            set interface "port1"
        next
        edit 2
            set collector-ip 10.1.100.59
            set collector-port 2056
            set source-ip 10.1.100.6
            set interface-select-method specify
            set interface "port2"
        next
        edit 3
            set collector-ip 172.18.60.80
            set collector-port 2057
            set interface-select-method specify
            set interface "port1"
        next
```

```
        edit 4
            set collector-ip "172.18.60.1"
            set collector-port 2058
        next
        edit 5
            set collector-ip "172.18.60.3"
            set collector-port 2059
        next
        edit 6
            set collector-ip "172.18.60.4"
            set collector-port 2060
        next
    end
end
```

2. Configure NetFlow sampling on port1:

```
config system interface
    edit port1
        set netflow-sampler both
    next
end
```

3. Verify the NetFlow diagnostics.
   a. Verify the NetFlow configuration status:

```
# diagnose test application sflowd 3

===== Netflow Vdom Configuration =====
Global collector(s) active-timeout(seconds):60 inactive-timeout(seconds):15
    Collector id:1: 172.16.200.155[2055] source IP:172.16.200.6
    Collector id:2: 10.1.100.59[2056] source IP:10.1.100.6
    Collector id:3: 172.18.60.80[2057] source IP:
    Collector id:4: 172.18.60.1[2058] source IP:
    Collector id:5: 172.18.60.3[2059] source IP:
    Collector id:6: 172.18.60.4[2060] source IP:
____ vdom: root, index=0, is master, collector: disabled (use global config) (mgmt vdom)
   |_ coll_ip:172.16.200.155:2056,src_ip:172.16.200.6
   |_ coll_ip:10.1.100.59:2057,src_ip:10.1.100.6
   |_ coll_ip:172.18.60.80:2058,src_ip:172.16.200.6

   |____ interface:port1 sample_direction:both device_index:9 snmp_index:3
```

   b. Verify the sampled NetFlow traffic packet capture:

```
# diagnose sniffer packet any 'udp and port 2056 or 2057 or 2058' 4
```

```
filters=[udp and port 2056 or 2057 or 2058]
5.717060 port1 out 172.16.200.6.2472 -> 172.16.200.155.2055: udp 60
5.717068 port2 out 10.1.100.6.2472 -> 10.1.100.59.2056: udp 60
5.717075 port1 out 172.16.200.6.2472 -> 172.18.60.80.2057: udp 60
5.717078 port1 out 172.16.200.6.2472 -> 172.18.60.1.2058: udp 60
5.717081 port1 out 172.16.200.6.2472 -> 172.18.60.3.2059: udp 60
5.717085 port1 out 172.16.200.6.2472 -> 172.18.60.4.2060: udp 60
```

Example 2: Multiple NetFlow collectors in a multi-VDOM environment

In this example, six NetFlow collectors are configured in a multi-VDOM environment globally and per VDOM. NetFlow sampling is on the port1 and port4 interfaces.

Please note it is not mandatory to set up per-VDOM NetFlow collectors in a multi-vdom environment. However, if you don't enable per-VDOM collectors, the settings of the global NetFlow Collector will be used instead.

To configure multiple NetFlow collectors:

1. Configure the global NetFlow collectors:

```
config system netflow
   config collectors
   set active-flow-timeout 60
   set template-tx-timeout 60
        edit 1
            set collector-ip 172.16.200.155
            set collector-port 2055
            set source-ip 172.16.200.6
            set interface-select-method specify
            set interface "port1"
        next
        edit 2
            set collector-ip 10.1.100.59
            set collector-port 2056
            set source-ip 10.1.100.6
            set interface-select-method specify
            set interface "port2"
        next
        edit 3
            set collector-ip 172.18.60.80
            set collector-port 2057
            set interface-select-method specify
            set interface "port1"
        next
        edit 4
            set collector-ip "172.18.60.1"
```

```
            set collector-port 2058
        next
        edit 5
            set collector-ip "172.18.60.3"
            set collector-port 2059
        next
        edit 6
            set collector-ip "172.18.60.4"
            set collector-port 2060
        next
    end
end
```

2. Configure the per-VDOM NetFlow collectors:

```
config system vdom-netflow
    set vdom-netflow enable
    config collectors
        edit 1
            set collector-ip "172.10.100.101"
            set collector-port 2059
        next
        edit 2
            set collector-ip "172.10.100.102"
            set collector-port 2060
        next
        edit 3
            set collector-ip "172.10.100.103"
            set collector-port 2061
        next
        edit 4
            set collector-ip "172.10.100.104"
            set collector-port 2062
        next
        edit 5
            set collector-ip "172.10.100.105"
            set collector-port 2063
        next
        edit 6
            set collector-ip "172.10.100.106"
            set collector-port 2064
        next
    end
end
```

3. Configure NetFlow sampling on port1 and port4:

```
config system interface
    edit port1
        set netflow-sampler both
    next
    edit port4
```

```
        set netflow-sampler both
    next
end
```

In a multi-VDOM environment, ensure the interface selected for NetFlow sampling is in the same VDOM as the per-VDOM NetFlow collector. For global NetFlow collectors, the interface selected for NetFlow sampling should be in the management VDOM.

4. Verify the NetFlow diagnostics.
   a. Verify the NetFlow configuration status:

```
# diagnose test application sflowd 3

===== Netflow Vdom Configuration =====
Global collector(s) active-timeout(seconds):60 inactive-timeout(seconds):15
    Collector id:1: 172.16.200.155[2055] source IP:172.16.200.6
    Collector id:2: 10.1.100.59[2056] source IP:10.1.100.6

7.005834 port4 out 20.1.100.111.2472 -> 172.10.100.105.2063: udp 60
7.005838 port4 out 20.1.100.111.2472 -> 172.10.100.106.2064: udp 60
```

Netflow sampling NEW

Netflow sampling counts the number of packets or bytes an interface has sampled. If the packet count for a session surpasses the configured threshold for transmitted or received traffic on a NetFlow-enabled interface, a NetFlow report is exported. This helps reduce the load on the collector.

```
config system interface
    edit <name>
        set netflow-sampler {tx | rx | both}
        set netflow-sample-rate <integer>
        set netflow-sampler-id <integer>
    next
end
```

`netflow-sampler {tx | rx | both}`	Enable/disable NetFlow on this interface and set the data that NetFlow collects.
`netflow-sample-rate <integer>`	NetFlow sample rate. Sample one packet every configured number of packets (1 - 65535, default = 1, which means standard NetFlow where all packets are sampled).
`netflow-sampler-id <integer>`	NetFlow sampler ID.

All sessions that hit the interface with NetFlow sampling configured are still reported to the exporter daemon (sflowd), which keeps a tally of the sampled packets and bytes. If the session has more ingress, egress, or both, packets than the configured threshold (`netflow-sample-rate`), then a NetFlow report is exported. The Netflow report includes rounded-up numbers of packets and bytes divided by the sampling rate.

In this example, FortiGate is connect on port2 to a NetFlow collector, NetFlow sampling is configured on port2 with a sampling rate of 100. It is assumed that policies are already configured. Packets are sent that hit the policy. If the number of packets is less than the sampling, then no flowset is sent to the collector. If the number of packets is more than the sampling rate, then a flowset is sent to the collector.

To configure the interface and test sending different numbers of packets:

1. Connect the FortiGate port2 interface to the NetFlow collector.
2. Configure the interface:

```
config system interface
    edit "port2"
        set vdom "root"
        set ip 10.1.100.6 255.255.255.0
```

```
        set allowaccess https ssh snmp http telnet
        set type physical
        set netflow-sampler both
        set netflow-sample-rate 100
        set netflow-sampler-id 99
        set alias "To_vlan20"
        set snmp-index 2
        config ipv6
            set ip6-address 2000:10:1:100::6/64
            set ip6-allowaccess https ssh http telnet
        end
        set speed 1000auto
    next
end
```

3. Send 80 ICMP packets to pass through port2.
   Because this is less than the sample rate of 100, the FortiGate does not send any flowsets to the collector after the session timeout.

```
# diagnose sys session list

session info: proto=1 proto_state=00 duration=114 expire=26 timeout=0 refresh_dir=both
flags=00000000 socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=log may_dirty f00 netflow-origin netflow-reply
statistic(bytes/packets/allow_err): org=6720/80/1 reply=6720/80/1 tuples=2
tx speed(Bps/kbps): 0/0 rx speed(Bps/kbps): 0/0
orgin->sink: org pre->post, reply pre->post dev=8->7/7->8 gwy=0.0.0.0/0.0.0.0
hook=post dir=org act=snat 10.1.100.41:20043->172.16.200.155:8(172.16.200.6:20043)
hook=pre dir=reply act=dnat 172.16.200.155:20043->172.16.200.6:0(10.1.100.41:20043)
misc=0 policy_id=44 pol_uuid_idx=8183 auth_info=0 chk_client_info=0 vd=0
serial=0001e4be tos=ff/ff app_list=0 app=0 url_cat=0
rpdb_link_id=00000000 ngfwid=n/a
npu_state=0x000001 no_offload
no_ofld_reason:  disabled-by-policy
total session: 1
```

4. Send 105 ICMP packets to pass through port2.
   Because this is more than the sample rate of 100, the FortiGate sends one flowset packet to the collector after the session timeout.

```
# diagnose sys session list

session info: proto=1 proto_state=00 duration=110 expire=55 timeout=0 refresh_dir=both
flags=00000000 socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
```

```
state=log may_dirty f00 netflow-origin netflow-reply
statistic(bytes/packets/allow_err): org=8820/105/1 reply=8820/105/1 tuples=2
tx speed(Bps/kbps): 78/0 rx speed(Bps/kbps): 78/0
orgin->sink: org pre->post, reply pre->post dev=8->7/7->8 gwy=0.0.0.0/0.0.0.0
hook=post dir=org act=snat 10.1.100.41:20072->172.16.200.155:8(172.16.200.6:20072)
hook=pre dir=reply act=dnat 172.16.200.155:20072->172.16.200.6:0(10.1.100.41:20072)
misc=0 policy_id=44 pol_uuid_idx=8183 auth_info=0 chk_client_info=0 vd=0
serial=0001e56f tos=ff/ff app_list=0 app=0 url_cat=0
rpdb_link_id=00000000 ngfwid=n/a
npu_state=0x000001 no_offload
no_ofld_reason:  disabled-by-policy
total session: 1
```

5. Check the flowset:

```
Octets: 88
Post Octets: 88
Packets: 1
Post Packets: 1
......
SamplerID: 99
Srcaddr: 10.1.100.41
Dstaddr: 172.16.200.155
......
```

Because the sample rate is 100, the flowset means:

- 88 * 100 = 8800 Bytes
- 1 * 100 = 100 Packets

This is basically equal to the actual value of 8820 bytes / 105 packets. This shows that after configuring the NetFlow sampling rate, the received flowsets have been reduced, and the flowsets' values are consistent with the actual values, although not exactly the same.

Filter NetFlow sampling NEW

Exclusion filters can be applied to NetFlow sampling based on criteria including source and destination IP addresses, source and destinations ports, and IP protocol. This enhances the relevance of collected data, streamlines data management processes, and reduces excess network traffic. Exclusion filters are defined globally, and up to 64 can be configured.

```
config system netflow
    config exclusion-filters
        edit <id>
            set source-ip <IP_address>
            set destination-ip <IP_address>
            set source-port <port>
            set destination-port <port>
            set protocol <protocol_ID>
        next
    end
end
```

source-ip <IP_address>	Session source address.
destination-ip <IP_address>	Session destination address.
source-port <port>	Session source port number or range.
destination-port <port>	Session destination port number or range.
protocol <protocol_ID>	Session IP protocol (0 - 255, default = 255, meaning any).

In this example, IPv4-IPv4 and IPv6-IPv4 exclusion filters are configured on a FortiGate that is connected to a NetFlow connector. Packets are sent that hit the filters, then the session lists are checked for the NetFlow flag and the sessions are checked on the collector.

To configure and test the NetFlow exclusion filters:

1. Create NetFlow exclusion filters:

```
config system netflow
    set active-flow-timeout 60
    set template-tx-timeout 60
    config exclusion-filters
        edit 44
            set source-ip 10.1.100.41
            set destination-ip 172.16.200.155
        next
        edit 66
            set source-ip 2000:10:1:100::41
            set destination-ip 2000:172:16:200::155
        next
        edit 64
            set source-ip 2000:10:1:100::41
            set destination-ip 65:ff9b::ac10:c837
        next
        edit 46
            set source-ip 10.1.100.41
            set destination-ip 10.1.100.101
        next
    end
    config collectors
        edit 1
            set collector-ip "10.1.100.59"
        next
    end
end
```

2. Send packets to generate sessions.
3. Check if the NetFlow flag is attached in the session/session6 list:
   - If there are two IPv4-IPv4 sessions, and only the first one matches filter ID 44:

```
# diagnose sys session list
session info: proto=1 proto_state=00 duration=17 expire=59 timeout=0 refresh_dir=both
flags=00000000 socktype=0 sockport=0 av_idx=0 use=3
```

```
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=log may_dirty f00 netflow-origin netflow-reply
statistic(bytes/packets/allow_err): org=1512/18/1 reply=1512/18/1 tuples=2
tx speed(Bps/kbps): 84/0 rx speed(Bps/kbps): 84/0
orgin->sink: org pre->post, reply pre->post dev=8->7/7->8 gwy=0.0.0.0/0.0.0.0
hook=post dir=org act=snat 10.1.100.41:11165->172.16.200.155:8(172.16.200.6:11165)
hook=pre dir=reply act=dnat 172.16.200.155:11165->172.16.200.6:0(10.1.100.41:11165)
misc=0 policy_id=2 pol_uuid_idx=8173 auth_info=0 chk_client_info=0 vd=0
serial=000032e9 tos=ff/ff app_list=0 app=0 url_cat=0
rpdb_link_id=00000000 ngfwid=n/a
npu_state=0x000001 no_offload
no_ofld_reason:  disabled-by-policy

session info: proto=1 proto_state=00 duration=16 expire=59 timeout=0 refresh_dir=both
flags=00000000 socktype=0 sockport=0 av_idx=0 use=3

```

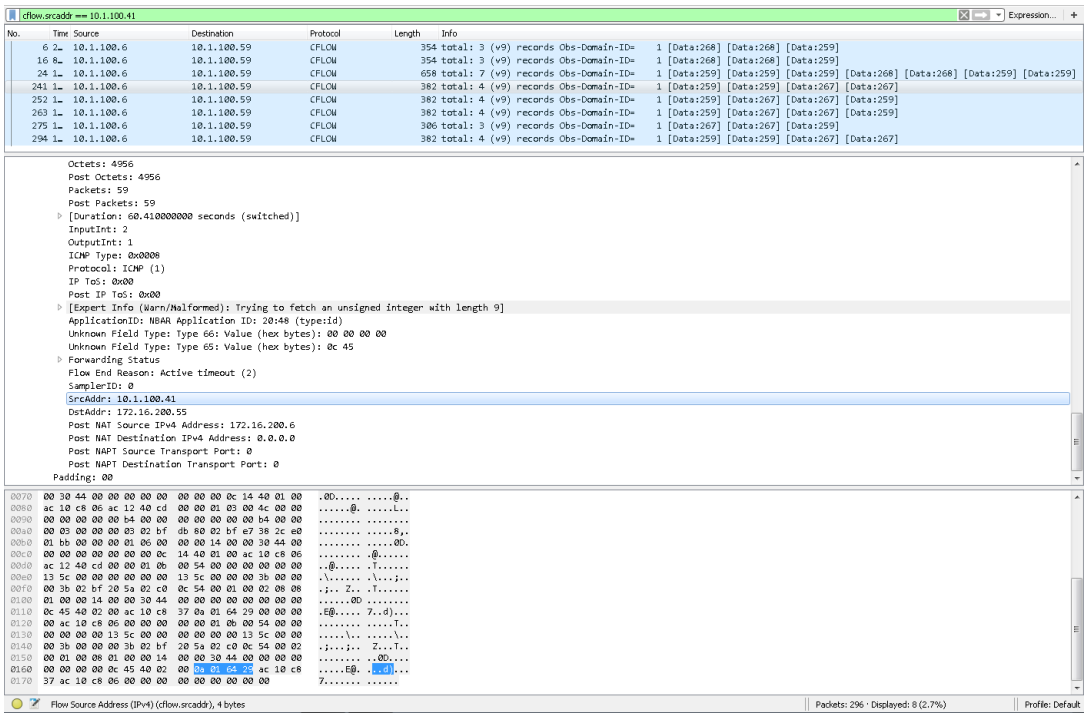
4. Check on the collector server. The FlowSets are received on collector for the session/session6 if they do not match the filters. If the sessions match the filter in the system NetFlow, then no FlowSets are received on the collector.
   - IPv4-IPv4 FlowSets:

     Do not receive FlowSets that match exclusion filter ID 44:

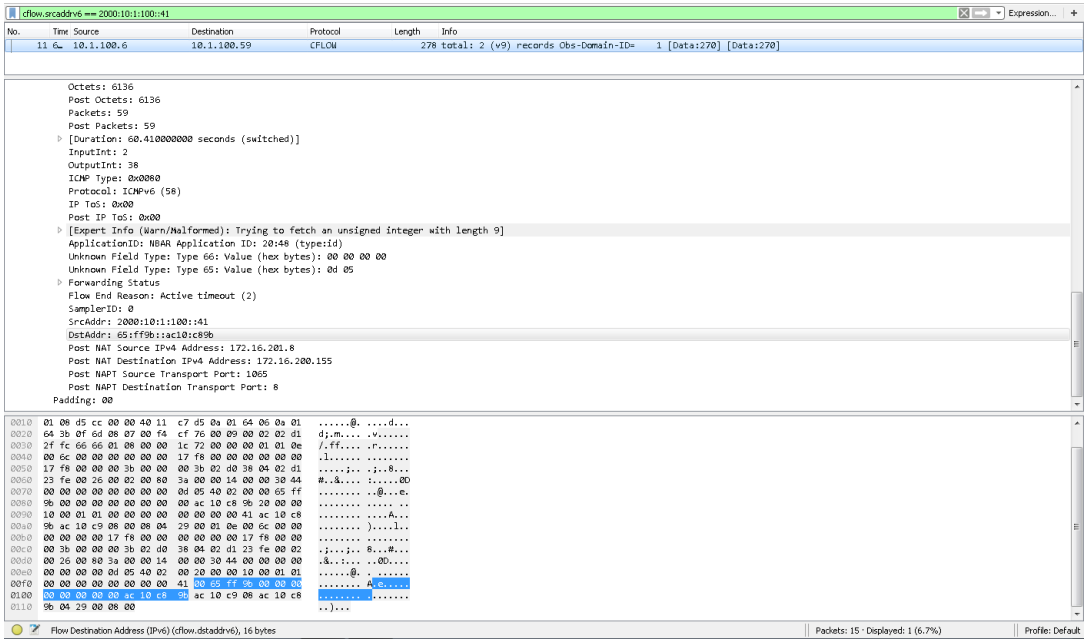
     
     Receive FlowSets that do not match any exclusion filters:



- IPv6-IPv4 FlowSets:

  Do not receive FlowSets that match exclusion filter ID 64:

  Receive FlowSets that do not match any exclusion filters:



sFlow

sFlow is a method of monitoring the traffic on your network to identify areas on the network that may impact performance and throughput. FortiGate supports sFlow v5. sFlow collector software is available from a number of third-party software vendors. For more information about sFlow, see www.sflow.org.

The packet information that the FortiGate's sFlow agent collects depends on the interface type:

- On an internal interface, when the interface receives packets from devices with private IP addresses, the collected information includes the private IP addresses.
- On an external, or WAN, interface, when the interface receives to route to or from the internet, the collected information includes the IP address of the WAN interface as the source or destination interface, depending on the direction of the traffic. It does not include IP addresses that are NATed on another interface.

sFlow datagrams contain the following information:

- Packet headers, such as MAC, IPv4, and TCP
- Sample process parameters, such as rate and pool
- Input and output ports
- Priority (802.1p and ToS)
- VLAN (802.1Q)
- Source prefixes, destination prefixes, and next hop addresses
- BGP source AS, source peer AS, destination peer AS, communities, and local preference
- User IDs (TACACS, RADIUS) for source and destination
- Interface statistics (RFC 1573, RFC 2233, and RFC 2358)

Configuring sFlow

sFlow can be configured globally, then on traffic VDOMs and individual interfaces. When configuring sFlow on a VDOM, the collector can be specified, or the collector that is configured globally can be used.

FortiOS can be configured with a maximum of three sFlow collectors. This also applies to multi-VDOM environments where a maximum of three sFlow collectors can be used globally and/or on a per-VDOMs basis. This enables up to a maximum of three unique parallel sFlow streams or transmissions per sFlow sample to three different sFlow collectors.

sFlow is supported on some interface types, such as physical, VLAN, and aggregate. It is not supported on virtual interfaces, such as VDOM link, IPsec, GRE, or SSL. When configuring sFlow on an interface, the rate that the agent samples traffic, the direction of that traffic, and the frequency that the agent sends sFlow datagrams to the sFlow collector can be specified. If sFlow is configured on the VDOM that the interface belongs to, the agent sends datagrams to the collector configured for the VDOM. Otherwise, the datagrams are sent to the collector that is configured globally.

Configuring sFlow for an interface disables NP offloading for all traffic on that interface.

To configure sFlow globally:

```
config system sflow
    config collectors
        edit <id>
            set collector-ip <ipv4_address>
            set collector-port <port>
            set source-ip <ipv4_address>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        next
    end
end
```

`collector-ip <ipv4_address>`	Enter the IPv4 address of the sFlow collector that sFlow agents added to interfaces in this VDOM send sFlow datagrams to (default = 0.0.0.0).
`collector-port <port>`	Enter the UDP port number used for sending sFlow datagrams; only configure if required by the sFlow collector or network configuration (0 - 65535, default = 6343).
`source-ip <ipv4_address>`	Enter the source IP address for the sFlow agent.
`interface-select-method {auto | sdwan | specify}`	Specify how to select the outgoing interface to reach the server (default = auto).
`interface <interface>`	Enter the outgoing interface to reach the server.

To configure sFlow for a VDOM:

```
config vdom
    edit <vdom>
        config system vdom-sflow
            set vdom-sflow {enable | disable}
            set collector-ip <ipv4_address>
            set collector-port <port>
            set source-ip <ipv4_address>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        end
    next
end
```

`vdom-sflow {enable | disable}`	Enable/disable the sFlow configuration for the current VDOM (default = disable).
`collector-ip <ipv4_address>`	Enter the IPv4 address of the sFlow collector that sFlow agents added to interface (default = 0.0.0.0). If this option is not configured, the global setting will be used.
`collector-port <port>`	Enter the UDP port number used for sending sFlow datagrams (0 - 65535, default = 6343).

	Only configured this option if required by the sFlow collector or your network configuration. If this option is not configured, the global setting will be used.
`source-ip <ipv4_address>`	Enter the source IPv4 address that the sFlow agent used to send datagrams to the collector (default = 0.0.0.0). If this option is not configured, the FortiGate uses the IP address of the interface that it sends the datagram through.
`interface-select-method {auto | sdwan | specify}`	Specify how the outgoing interface to reach the server is selected (default = auto).
`interface <interface>`	Enter the outgoing interface used to reach the server. This option is only available when `interface-select-method` is `specify`.

To configure sFlow on an interface:

```
config system interface
    edit <interface>
        set sflow-sampler {enable | disable}
        set sample-rate <integer>
        set polling-interval <integer>
        set sample-direction {tx | rx | both}
    next
end
```

`sflow-sampler {enable | disable}`	Enable/disable sFlow on this interface (default = disable).
`sample-rate <integer>`	Enter the average number of packets that the agent lets pass before taking a sample (10 - 99999, default = 2000). Setting a lower rate will sample a higher number of packets, increasing the accuracy or the sampling data, but also increasing the CPU and network bandwidth usage. The default value is recommended.
`polling-interval <integer>`	Enter the amount of time that the agent waits between sending datagrams to the collector, in seconds (1 - 255, default = 20). Setting a higher value lowers the amount of data that the agent sends across the network, but makes the collector's view of the network less current.
`sample-direction {tx | rx | both}`	Select the direction of the traffic that the agent collects (default = both).

Example 1: multiple sFlow collectors in a non-VDOM environment

In this example, three sFlow collectors are configured in a non-VDOM environment with sFlow sampling on the wan1 interface.

To configure multiple sFlow collectors:

1. Configure the sFlow collectors:

```
config system sflow
    config collectors
        edit 1
            set collector-ip 10.1.1.1
            set collector-port 6344
            set source-ip 0.0.0.0
            set interface-select-method auto
        next
        edit 2
            set collector-ip 10.1.1.2
            set collector-port 6345
            set source-ip 0.0.0.0
            set interface-select-method auto
        next
        edit 3
            set collector-ip 10.1.1.3
            set collector-port 6346
            set source-ip 0.0.0.0
            set interface-select-method auto
        next
    end
end
```

2. Configure sFlow sampling on wan1:

```
config system interface
    edit wan1
        set sflow-sampler enable
        set sample-rate 2000
        set polling-interval 20
        set sample-direction both
    next
end
```

3. Verify the sFlow diagnostics.
   a. Verify the sFlow configuration status:

```
# diagnose test application sflowd 1

global collector:10.1.1.1:[6344]
 global source ip: 0.0.0.0:[1399]

global collector:10.1.1.2:[6345]
 global source ip: 0.0.0.0:[1399]

global collector:10.1.1.3:[6346]
 global source ip: 0.0.0.0:[1399]
vdom: root, index=0, vdom sflow collector is disabled(use global sflow config), primary
```

```
(management vdom)
  intf:wan1 sample_rate:2000 polling_interval:20 sample_direction:both
```

b. Verify the sampled sFlow traffic packet capture:

```
# diagnose sniffer packet any 'port 1399' 4 0 l
interfaces=[any]
filters=[port 6344 or port 6345 or port 6346]
2023-11-14 15:44:41.658799 wan1 out 172.16.151.157.1399 -> 10.1.1.1.6344: udp 144
2023-11-14 15:44:41.658829 wan1 out 172.16.151.157.1399 -> 10.1.1.2.6345: udp 144
2023-11-14 15:44:41.658848 wan1 out 172.16.151.157.1399 -> 10.1.1.3.6346: udp 144
```

The outgoing interface that is used to send the sampled sFlow traffic to the sFlow collector is decided by the routing table lookup.

Example 2: multiple sFlow collectors in a multi-VDOM environment

In this example, three sFlow collectors are configured in a multi-VDOM environment globally and per VDOM. sFlow sampling is on the wan1 and dmz interfaces.

To configure multiple sFlow collectors:

1. Configure the global sFlow collectors:

```
config system sflow
    config collectors
        edit 1
            set collector-ip 10.1.1.1
            set collector-port 6344
            set source-ip 0.0.0.0
            set interface-select-method auto
        next
        edit 2
            set collector-ip 10.1.1.2
            set collector-port 6345
            set source-ip 0.0.0.0
            set interface-select-method auto
        next
        edit 3
            set collector-ip 10.1.1.3
            set collector-port 6346
            set source-ip 0.0.0.0
            set interface-select-method auto
        next
    end
end
```

2. Configure the per-VDOM sFlow collectors:

```
config vdom
    edit testvdom
        config system vdom-sflow
            set vdom-sflow enable
            config collectors
                edit 1
                    set collector-ip 10.1.1.4
                    set collector-port 6347
                    set source-ip 0.0.0.0
                    set interface-select-method auto
                next
                edit 2
                    set collector-ip 10.1.1.5
                    set collector-port 6348
                    set source-ip 0.0.0.0
                    set interface-select-method auto
                next
                edit 3
                    set collector-ip 10.1.1.6
                    set collector-port 6349
                    set source-ip 0.0.0.0
                    set interface-select-method auto
                next
            end
        end
    next
end
```

3. Configure sFlow sampling on wan1 and dmz:

```
config system interface
    edit wan1
        set vdom "root"
        set sflow-sampler enable
        set sample-rate 2000
        set polling-interval 20
        set sample-direction both
    next
    edit dmz
        set vdom "testvdom"
        set sflow-sampler enable
        set sample-rate 2000
        set polling-interval 20
        set sample-direction both
    next
end
```

4. Verify the sFlow diagnostics.

a. Verify the sFlow configuration status:

```
# diagnose test application sflowd  1

global collector:10.1.1.1:[6344]
 global source ip: 0.0.0.0:[1399]

global collector:10.1.1.2:[6345]
 global source ip: 0.0.0.0:[1399]

global collector:10.1.1.3:[6346]
 global source ip: 0.0.0.0:[1399]
vdom: root, index=0, vdom sflow collector is disabled(use global sflow config), primary
(management vdom)
  intf:wan1 sample_rate:2000 polling_interval:20 sample_direction:both
vdom: testvdom, index=1, vdom sflow collector is enabled, primary
  collector:10.1.1.4:[6347] src:192.168.1.1:[1399]
  collector:10.1.1.5:[6348] src:192.168.1.1:[1399]
  collector:10.1.1.6:[6349] src:192.168.1.1:[1399]
  intf:dmz sample_rate:2000 polling_interval:20 sample_direction:both
```

b. Verify the sampled sFlow traffic packet capture:

```
# sudo root diagnose sniffer packet any 'port 1399' 4 0 l
interfaces=[any]
filters=[port 1399]
2023-11-14 16:50:11.118807 wan1 out 172.16.151.157.1399 -> 10.1.1.1.6344: udp 144
2023-11-14 16:50:11.118838 wan1 out 172.16.151.157.1399 -> 10.1.1.2.6345: udp 144
2023-11-14 16:50:11.118865 wan1 out 172.16.151.157.1399 -> 10.1.1.3.6346: udp 144
2023-11-14 16:50:20.198784 dmz out 192.168.1.1.1399 -> 10.1.1.4.6347: udp 144
2023-11-14 16:50:20.198813 dmz out 192.168.1.1.1399 -> 10.1.1.5.6348: udp 144
2023-11-14 16:50:20.198832 dmz out 192.168.1.1.1399 -> 10.1.1.6.6349: udp 144
```

The outgoing interface that is used to send the sampled sFlow traffic to the sFlow collector is decided by the routing table lookup.

Link monitor

The link monitor is a mechanism that allows the FortiGate to probe the status of a detect server in order to determine the health of the link, next hop, or the path to the server. Ping, TCP echo, UDP echo, HTTP, and TWAMP protocols can be used for the probes. Typically, the detect server is set to a stable server several hops away. Multiple servers can also be configured with options to define the protocol and weights for each server.

The link monitor serves several purposes. In the most basic configuration, it can be used to detect failures and remove routes associated with the interface and gateway to prevent traffic from routing out the failed link. More granularity is added in 7.0 that allows only the routes specified in the link monitor to be removed from the

routing table. With this benefit, only traffic to specific routing destinations are removed, rather than all routing destinations.

Another enhancement starting in 7.0.1 is an option to toggle between enabling or disabling policy route updates when a link health monitor fails.

The link monitor can also monitor remote servers for HA failover. Using the HA built-in link monitor, it is only able to detect physical link failovers to trigger HA link failover. With the link monitor, remote servers can be used to monitor the health of the path to the server in order to trigger HA failover.

Finally, the link monitor can cascade the failure to other interfaces. When the `update-cascade-interface` option is enabled, the interface can be configured in conjunction with `fail-detect` enabled to trigger a link down event on other interfaces.

The following topics provide more information about the link monitor:

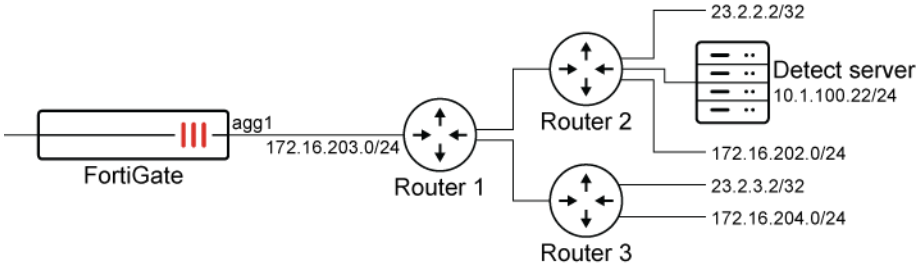
- Link monitor with route updates on page 736
- Enable or disable updating policy routes when link health monitor fails on page 737
- Add weight setting on each link health monitor server on page 740
- Dual internet connections on page 492
- SLA link monitoring for dynamic IPsec and SSL VPN tunnels on page 743

Link monitor with route updates

When a link monitor fails, only the routes that are specified in the link monitor are removed from the routing table, instead of all the routes with the same interface and gateway. If no routes are specified, then all of the routes are removed. Only IPv4 routes are supported.

Example

In this example, the FortiGate has several routes to 23.2.2.2/32 and 172.16.202.2/24, and is monitoring the link *agg1* by pinging the server at 10.1.100.22. The link monitor uses the gateway 172.16.203.2.



When the link monitor fails, only the routes to the specified subnet using interface *agg1* and gateway 172.16.203.2 are removed.

To configure the link monitor:

```
config system link-monitor
    edit "22"
```

```
        set srcintf "agg1"
        set server "10.1.100.22"
        set gateway-ip 172.16.203.2
        set route "23.2.2.2/32" "172.16.202.0/24"
    next
end
```

To check the results:

1. When the link monitor is alive:

```
# get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [5/0] via 10.100.1.249, port12
S       10.1.100.0/24 [10/0] via 172.16.203.2, agg1
S       23.2.2.2/32 [10/0] via 172.16.203.2, agg1
S       23.2.3.2/32 [10/0] via 172.16.203.2, agg1
S       172.16.201.0/24 [10/0] via 172.16.200.4, port9
S       172.16.202.0/24 [10/0] via 172.16.203.2, agg1
S       172.16.204.0/24 [10/0] via 172.16.200.4, port9
                        [10/0] via 172.16.203.2, agg1
                        [10/0] via 172.16.206.2, vlan100, [100/0]
```

2. When the link monitor is dead:

```
# get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [5/0] via 10.100.1.249, port12
S       10.1.100.0/24 [10/0] via 172.16.203.2, agg1
S       23.2.3.2/32 [10/0] via 172.16.203.2, agg1
S       172.16.201.0/24 [10/0] via 172.16.200.4, port9
S       172.16.204.0/24 [10/0] via 172.16.200.4, port9
                        [10/0] via 172.16.203.2, agg1
                        [10/0] via 172.16.206.2, vlan100, [100/0]
```

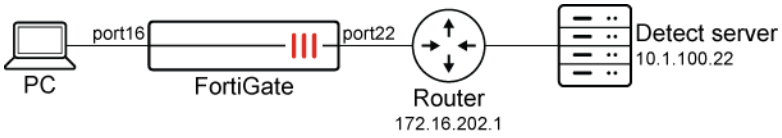
Enable or disable updating policy routes when link health monitor fails

An option has been added to toggle between enabling or disabling policy route updates when a link health monitor fails. By disabling policy route updates, a link health monitor failure will not cause corresponding policy-based routes to be removed.

```
config system link-monitor
    edit <name>
        set update-policy-route {enable | disable}
    next
end
```

Example

In the following topology, the FortiGate is monitoring the detect server, 10.1.100.22. The FortiGate has a policy-based route to destination 172.16.205.10 using the same gateway (172.16.202.1) and interface (port22). By configuring `update-policy-route disable`, the policy-based route is not removed when the link health monitor detects a failure.



To disable updating policy routes when the link health monitor fails:

1. Configure the link health monitor:

```
config system link-monitor
    edit "test-1"
        set srcintf "port22"
        set server "10.1.100.22"
        set gateway-ip 172.16.202.1
        set failtime 3
        set update-policy-route disable
    next
end
```

2. Configure the policy route:

```
config router policy
    edit 1
        set input-device "port16"
        set dst "172.16.205.10/255.255.255.255"
        set gateway 172.16.202.1
        set output-device "port22"
        set tos 0x14
        set tos-mask 0xff
    next
end
```

3. When the health link monitor status is up, verify that the policy route is active.
   a. Verify the link health monitor status:

```
# diagnose sys link-monitor status
Link Monitor: test-1, Status: alive, Server num(1), HA state: local(alive), shared(alive)
Flags=0x1 init, Create time: Fri May 28 15:20:15 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
  Peer: 10.1.100.22(10.1.100.22)
```

```
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
        protocol: ping, state: alive
                Latency(Min/Max/Avg): 0.374/0.625/0.510 ms
                Jitter(Min/Max/Avg): 0.008/0.182/0.074
                Packet lost: 0.000%
                Number of out-of-sequence packets: 0
                Fail Times(0/3)
                Packet sent: 7209, received: 3400, Sequence(sent/rcvd/exp): 7210/7210/7211
```

b. Verify the policy route list:

```
# diagnose firewall proute  list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x0 tos=0x14 tos_mask=0xff protocol=0 sport=0-0 iif=41
dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33
```

4. When the health link monitor status is down, verify that the policy route is active:

a. Verify the link health monitor status:

```
# diagnose sys link-monitor status
Link Monitor: test-1, Status: die, Server num(1), HA state: local(die), shared(die)
Flags=0x9 init log_downgateway, Create time: Fri May 28 15:20:15 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
  Peer: 10.1.100.22(10.1.100.22)
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
        protocol: ping, state: die
                Packet lost: 11.000%
                Number of out-of-sequence packets: 0
                Recovery times(0/5) Fail Times(0/3)
                Packet sent: 7293, received: 3471, Sequence(sent/rcvd/exp): 7294/7281/7282
```

b. Verify the policy route list:

```
# diagnose firewall proute list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x0 tos=0x14 tos_mask=0xff protocol=0 sport=0-0 iif=41
dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33
```

If the `update-policy-route` setting is enabled, the link health monitor would be down and the policy-based route would be disabled:

```
# diagnose firewall proute list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x8 disable tos=0x14 tos_mask=0xff protocol=0 sport=0-0 iif=41
dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33
```

Add weight setting on each link health monitor server

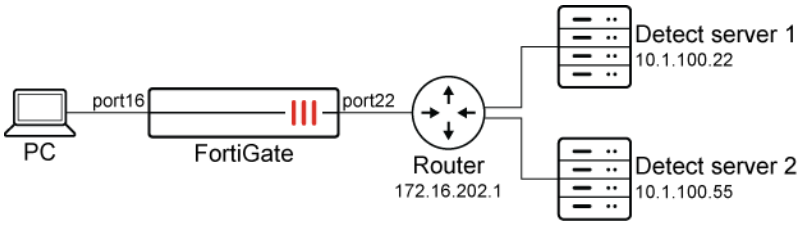
Prior to FortiOS 7.0.1, the link health monitor is determined to be dead when all servers are unreachable. Starting in 7.0.1, the link health monitor can configure multiple servers and allow each server to have its own weight setting. When the link health monitor is down, it will trigger static route updates and cascade interface updates if the weight of all dead servers exceeds the monitor's fail weight threshold.

```
config system link-monitor
    edit <name>
        set srcintf <interface>
        set server-config {default | individual}
        set fail-weight <integer>
        config server-list
            edit <id>
                set dst <address>
                set weight <integer>
            next
        end
    next
end
```

server-config	Set the server configuration mode: • default: all servers share the same attributes. • individual: some attributes can be specified for individual servers.
fail-weight <integer>	Threshold weight to trigger link failure alert (0 - 255, default = 0).
server-list	Configure the servers to be monitored by the link monitor.
dst <address>	Enter the IP address of the server to be monitored.
weight <integer>	Weight of the monitor to this destination (0 - 255, default = 0).

Examples

In the following topology, there are two detect servers that connect to the FortiGate through a router: server 1 (10.1.100.22) and server 2 (10.1.100.55).



Alive link health monitor

In this configuration, one server is dead and one server alive. The failed server weight is not over the threshold, so the link health monitor status is alive.

To configure the weight settings on the link health monitor:

1. Configure the link health monitor:

```
config system link-monitor
    edit "test-1"
        set srcintf "port22"
        set server-config individual
        set gateway-ip 172.16.202.1
        set failtime 3
        set fail-weight 40
        config server-list
            edit 1
                set dst "10.1.100.22"
                set weight 60
            next
            edit 2
                set dst "10.1.100.55"
                set weight 30
            next
        end
    next
end
```

2. Trigger server 2 to go down. The link monitor is still alive because the fail weight threshold has not been reached.
3. Verify the link health monitor status:

```
# diagnose sys link-monitor status test-1
Link Monitor: test-1, Status: alive, Server num(2), HA state: local(alive), shared(alive)
Flags=0x1 init, Create time: Fri Jun  4 17:23:29 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
Fail-weight (40): not activated
  Peer: 10.1.100.22(10.1.100.22)
```

```
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
        protocol: ping, state: alive
                Latency(Min/Max/Avg): 0.417/0.585/0.530 ms
                Jitter(Min/Max/Avg): 0.007/0.159/0.057
                Packet lost: 0.000%
                Number of out-of-sequence packets: 0
                Fail Times(0/3)
                Packet sent: 239, received: 236, Sequence(sent/rcvd/exp): 240/240/241
  Peer: 10.1.100.55(10.1.100.55)
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.55/32, gwy(172.16.202.1)
        Fail weight 30 applied
        protocol: ping, state: dead
                Packet lost: 100.000%
                Number of out-of-sequence packets: 0
                Recovery times(0/5) Fail Times(1/3)
                Packet sent: 239, received: 3, Sequence(sent/rcvd/exp): 240/4/5
```

Dead link health monitor

In this configuration, one server is dead and one server alive. The failed server weight is over the threshold, so the link health monitor status is dead.

To configure the weight settings on the link health monitor:

1. Configure the link health monitor:

```
config system link-monitor
    edit "test-1"
        set srcintf "port22"
        set server-config individual
        set gateway-ip 172.16.202.1
        set failtime 3
        set fail-weight 40
        config server-list
            edit 1
                set dst "10.1.100.22"
                set weight 30
            next
            edit 2
                set dst "10.1.100.55"
                set weight 50
            next
        end
    next
end
```

2. Trigger server 2 to go down. The link monitor is dead because the fail weight threshold has been reached.

3. Verify the link health monitor status:

```
# diagnose sys link-monitor status  test-1
Link Monitor: test-1, Status: dead, Server num(2), HA state: local(dead), shared(dead)
Flags=0x9 init log_downgateway, Create time: Fri Jun  4 17:23:29 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
Fail-weight (40): activated
  Peer: 10.1.100.22(10.1.100.22)
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
        protocol: ping, state: alive
                Latency(Min/Max/Avg): 0.393/0.610/0.520 ms
                Jitter(Min/Max/Avg): 0.009/0.200/0.095
                Packet lost: 0.000%
                Number of out-of-sequence packets: 0
                Fail Times(0/3)
                Packet sent: 680, received: 677, Sequence(sent/rcvd/exp): 681/681/682
  Peer: 10.1.100.55(10.1.100.55)
        Source IP(172.16.202.2)
        Route: 172.16.202.2->10.1.100.55/32, gwy(172.16.202.1)
        Fail weight 50 applied
        protocol: ping, state: dead
                Packet lost: 100.000%
                Number of out-of-sequence packets: 0
                Recovery times(0/5) Fail Times(1/3)
                Packet sent: 680, received: 3, Sequence(sent/rcvd/exp): 681/4/5
```

SLA link monitoring for dynamic IPsec and SSL VPN tunnels

The link health monitor settings can measure SLA information of dynamic VPN interfaces, which assign IP addresses to their clients during tunnel establishment. This includes SSL VPN tunnels, IPsec remote access, and IPsec site-to-site tunnels.

This feature currently only supports IPv4 and the ICMP monitoring protocol. In the IPsec tunnel settings, `net-device` must be disabled.

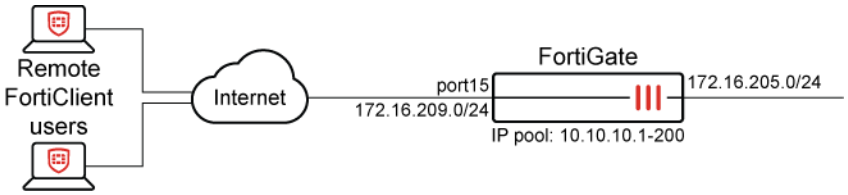
```
config system link-monitor
    edit <name>
        set server-type {static | dynamic}
    next
end
```

To view the dial-up tunnel statistics:

```
# diagnose sys link-monitor tunnel {name | all} [<tunnel_name>]
```

Example

In this example, endpoint users dial up using FortiClient to create IPSec tunnels with the FortiGate and obtain IP addresses. The link monitor on the FortiGate's dynamic VPN interface detects the path quality to the endpoints.



To configure SLA link health monitoring in dynamic IPsec tunnels:

1. Configure the IPsec phase 1 interface:

```
config vpn ipsec phase1-interface
    edit "for_Branch"
        set type dynamic
        set interface "port15"
        set mode aggressive
        set peertype any
        set net-device disable
        set mode-cfg enable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set dpd on-idle
        set dhgrp 5
        set xauthtype auto
        set authusrgrp "vpngroup"
        set assign-ip-from name
        set ipv4-netmask 255.255.255.0
        set dns-mode auto
        set ipv4-split-include "172.16.205.0"
        set ipv4-name "client_range"
        set save-password enable
        set psksecret **********
        set dpd-retryinterval 60
    next
end
```

2. Configure the IPsec phase 2 interface:

```
config vpn ipsec phase2-interface
    edit "for_Branch_p2"
        set phase1name "for_Branch"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm aes256gcm
chacha20poly1305
```

```
        set dhgrp 5
    next
end
```

3. Configure the dynamic interface:

```
config system interface
    edit "for_Branch"
        set vdom "root"
        set ip 10.10.10.254 255.255.255.255
        set type tunnel
        set remote-ip 10.10.10.253 255.255.255.0
        set snmp-index 100
        set interface "port15"
    next
end
```

4. Add the IPsec dial-up tunnel to the link health monitor:

```
config system link-monitor
    edit "1"
        set srcintf "for_Branch"
        set server-type dynamic
    next
end
```

5. Once endpoint users have connected using FortiClient, verify the tunnel information:

```
# get vpn ipsec tunnel summary
'for_Branch_0' 10.1.100.23:0  selectors(total,up): 1/1  rx(pkt,err): 21091/0  tx(pkt,err):
20741/0
'for_Branch_1' 10.1.100.13:0  selectors(total,up): 1/1  rx(pkt,err): 19991/0  tx(pkt,err):
20381/0
```

6. Verify the link health monitor status:

```
# diagnose sys link-monitor tunnel all
for_Branch_0 (1): state=alive, peer=10.10.10.1, create_time=2022-02-08 10:43:11, srcintf=for_
Branch, latency=0.162, jitter=0.018, pktloss=0.000%
for_Branch_1 (1): state=alive, peer=10.10.10.2, create_time=2022-02-08 10:49:24, srcintf=for_
Branch, latency=0.266, jitter=0.015, pktloss=0.000%
```

7. Manually add 200 ms latency on the path between the FortiGate and FortiClients.
8. Verify the link health monitor status again:

```
# diagnose sys link-monitor tunnel all
for_Branch_0 (1): state=alive, peer=10.10.10.1, create_time=2022-02-08 10:43:11, srcintf=for_
Branch, latency=200.177, jitter=0.021, pktloss=0.000%
for_Branch_1 (1): state=alive, peer=10.10.10.2, create_time=2022-02-08 10:49:24, srcintf=for_
Branch, latency=200.257, jitter=0.017, pktloss=0.000%
```

IPv6

From an administrative point of view IPv6 works almost the same as IPv4 in FortiOS. The primary difference is the use of IPv6 format for addresses. See IPv6 overview on page 747 for more information.

By default, the IPv6 settings are not displayed in the GUI.

To enable IPv6 in the GUI:

1. Go to *System* > *Feature Visibility*.
2. Under *Core Features*, enable *IPv6*.
3. Click *Apply*.

Once enabled, you will be able to use IPv6 addresses as well as the IPv4 addressing for the following FortiGate firewall features which are not limited to:

- Interfaces
- DHCP Server
- DHCP Relay
- DNS
- Static Routes
- Firewall Policy
- NAT
- Addresses
- Virtual IPs
- IP Pools
- IPsec VPN
- GRE over IPsec

This section also contains the following topics:

IPv6 overview

Internet Protocol version 6 (IPv6) is the latest version of the Internet Protocol (IP) and was developed to address the limitations of its predecessor, IPv4. The primary issue with IPv4 is its limited number of addresses, which are based on a 32-bit scheme and have a theoretical limit of 2 to the power of 32. In contrast, IPv6 uses a 128-bit address scheme, allowing for a much larger theoretical limit of 2 to the power of 128 addresses.

In simpler terms:

- IPv4 can support 4 294 967 296 addresses.
- IPv6 can support 340 282 366 920 938 463 463 374 607 431 768 211 456 addresses.

In addition to the expanded number of addresses, some of the other benefits of IPv6 include:

- More efficient routing due to reduction in the size of routing tables. This is achieved through hierarchical address allocation, which allows for more efficient routing of data packets.
- Reduced management requirements by supporting stateless auto-reconfiguration of hosts. This means that devices can automatically configure their network settings without the need for manual intervention.
- Improved methods to change Internet Service Providers. With IPv6, it is easier for users to switch between different ISPs without experiencing any service disruption.
- Better mobility support by providing seamless connection. This means that devices can move between different networks without losing their connection.
- Multi-homing. This allows a device to have multiple network connections, providing increased reliability and redundancy.
- Improved security with built-in support for IPsec. IPsec is a security protocol that provides authentication and encryption for data transmitted over a network.
- IPv6 offers scoped addresses with link-local, unique local, and global address spaces. This allows for more flexible addressing and improved network organization.

Address Type	Notation	Description	Example
Link-local Unicast	FE80::/10	Designed for use on a local link and are automatically configured on all interfaces. These addresses are not routable.	FE80::1
Unique Local Unicast	FC00::/7	Similar to IPv4 private addresses and can be used on your own network. They are not routable globally.	FC00::1 FD00::1
Global Unicast	2001::/3	Similar to IPv4 public addresses and can be used on the Internet. They are routable globally.	2001::1 3000::1

See Internet Protocol Version 6 Address Space for more information.

IPv6 quick start

This section provides an introduction to setting up a few basic IPv6 settings on the FortiGate. See Summary of steps on page 31 for more information about basic FortiGate administration.

This chapter provides instructions for basic IPv6 configuration that should work in most cases, regardless of whether the device has an existing IPv4 configuration or is a new FortiGate device.

The topics covered in this section include:

- Configuring an interface on page 748
- Configuring the default route on page 749
- Configuring the DNS on page 749
- Configuring the address object on page 749
- Configuring the address group on page 750
- Configuring the firewall policy on page 750

Before starting, make sure to enable the IPv6 feature.

To enable IPv6 in the GUI:

1. Go to *System* > *Feature Visibility*.
2. Under *Core Features*, enable *IPv6*.
3. Click *Apply*. See IPv6 quick start example on page 800 for a sample configuration.

Configuring an interface

To configure an interface in the GUI:

1. Go to *Network* > *Interfaces*.
2. Select an interface and click *Edit*.
3. In the *Address* section, enter the *IPv6 Address/Prefix*.
4. In the *Administrative Access* section, select the IPv6 access options as needed (such as *PING*, *HTTPS*, and *SSH*).
5. Click *OK*.

To configure an interface in the CLI:

```
config system interface
    edit <interface name>
        config ipv6
            set ip6-address <IPv6 prefix>
            set ip6-allowaccess{ping | https | ssh | snmp | http | telnet | fgfm | fabric}
        end
    next
end
```

Configuring the default route

Setting the default route enables basic routing to allow the FortiGate to return traffic to sources that are not directly connected. The gateway address should be your existing router or L3 switch that the FortiGate is connected to. Set the interface to be the interface the gateway is connected to.

To configure the default route in the GUI:

1. Go to *Network* > *Static Routes*.
2. Click *Create New* > *IPv6 Static Route*.
3. Leave the *Destination* prefix as ::/0. This is known as a default route, since it would match any IPv6 address.
4. Enter the *Gateway Address*.
5. Select an *Interface*.
6. Click *OK*.

To configure the default route in the CLI:

```
config router static6
    edit 0
        set gateway <IPv6 address>
        set device <interface name>
    next
end
```

Configuring the DNS

To configure a DNS domain list in the GUI:

1. Go to *Network* > *DNS*.
2. Under *IPv6 DNS Settings*, configure the primary and secondary DNS servers as needed.
3. Click *Apply*.

To configure a DNS domain list in the CLI:

```
config system dns
    set ip6-primary <IPv6 address>
    set ip6-secondary <IPv6 address>
end
```

Configuring the address object

Addresses define sources and destinations of network traffic and can be used in many functions such as firewall policies, ZTNA, and so on. When creating an IPv6 address object, several different types of addresses can be specified similar to IPv4 addresses. See Address Types on page 1745 for more information.

To configure an IPv6 address in the GUI:

1. Go to *Policy & Objects* > *Addresses* and select *IPv6 Address*.
2. Select *Create new*.
3. Enter a *Name* for the address object.
4. In the *Type* field, select one of the types from the dropdown menu.
5. Configure the rest of the settings as required.
6. Click *OK*.

To configure an IPv6 address in the CLI:

```
config firewall address6
    edit <name>
        set type {ipprefix | iprange | fqdn | geography | dynamic | template | mac | route-tag}
    next
end
```

Configuring the address group

Address groups are designed for ease of use in the administration of the device. See Address group on page 1763 for more information.

To create an address group:

1. Go to *Policy & Objects* > *Addresses* and select *IPv6 Address Group*.
2. Go to *Create new*.
3. Enter a *Name* for the address object.
4. Select the *+* in the *Members* field. The *Select Entries* pane opens.
5. Select members of the group. It is possible to select more than one entry. Select the *x* icon in the field to remove an entry.
6. Enter any additional information in the *Comments* field.
7. Click *OK*.

To configure an address group in the CLI:

```
config firewall addrgrp6
    edit <name>
        set member <name>
    next
end
```

Configuring the firewall policy

A firewall policy must be in place for any traffic that passes through a FortiGate. See Firewall policy on page 1563 for more information.

To create a firewall policy in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Enter a *Name* and configure the following necessary settings:

Incoming Interface	Incoming (ingress) interface
Outgoing Interface	Outgoing (egress) interface
Source	Source IPv6 address name and address group names
Destination	Destination IPv6 address name and address group names
Schedule	Schedule name
Service	Service and service group names
Action	Policy action

To configure a firewall policy in the CLI:

```
config firewall policy
    edit <policyid>
        set srcintf <name>
        set dstintf <name>
        set action {accept | deny}
        set srcaddr6 <name>
        set dstaddr6 <name>
        set schedule <name>
        set service <name>
    next
end
```

See IPv6 quick start example on page 800 for a sample configuration.

Neighbor discovery proxy

This feature provides support for proxying the IPv6 Neighbor Discovery Protocol (NDP) to allow the following ICMP messages to be forwarded between upstream and downstream interfaces.

Message type	Function
Router Solicitation (RS)	Used by hosts to find any routers in a local segment and to request that they advertise their presence on the network.
Router Advertisement (RA)	Used by an IPv6 router to advertise its presence on the network.
Neighbor Solicitation (NS)	Sent by a host to determine a remote host's link layer IPv6 address. Verifies the reachability of the neighbor or remote host in the Neighbor Discovery (ND) table

Message type	Function
Neighbor Advertisement (NA)	Message used by the host to respond to an NS message. If an NS message is received by a remote host, it reciprocates with an NA message to the originating host. Additionally, this message is used by a host to announce a link layer address change.
Network Redirect	Message used by IPv6 routers to notify an originating host of a more optimal next-hop address for a specific destination. Only routers can send redirect messages. Redirect messages are exclusively processed by hosts.

Typically only one interface receives RA traffic, and the interface is automatically considered the upstream interface.

The Neighbor Discovery Protocol (NDP) is a layer 2 protocol that performs several tasks to improve the efficiency and consistency of data transmission across multiple networks and processes. NDP uses ICMPv6 messages to perform the following tasks:

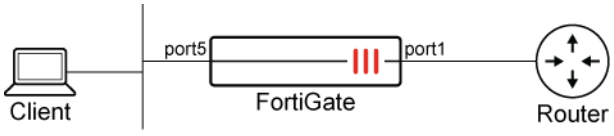
- Stateless auto-configuration: This enables the auto-configuration of IPv6 addresses without the need for a DHCP server. This means that each host on the network can automatically configure its unique IPv6 link-local address and global unicast address.
- Address Resolution: NDP performs a function similar to IPv4's Address Resolution Protocol (ARP), but instead of using ARP, it uses NDP to dynamically resolve IPv6 addresses to their corresponding MAC addresses.
- Neighbor Unreachability Detection (NUD): This function detects when a host is no longer reachable, allowing for more efficient routing and data transmission.
- Duplicate Address Detection (DAD): This function verifies that there is no duplication of unicast IPv6 addresses in the network, ensuring that each host has a unique address.

Configure ND proxy in the CLI using the following syntax:

```
config system nd-proxy
    set status {enable|disable}
    set member <interface> <interface> [<interface>...]
end
```

Option	Description
status	Enable/disable the use of neighbor discovery proxy.
member	List of interfaces using the neighbor discovery proxy.

In this example, the client is connected to a FortiGate device that is configured as an ND (Neighbor Discovery) proxy. Port1 is the upstream interface that receives Router Advertisement (RA) traffic, and port5 is the downstream interface that connects to the client. This setup allows the FortiGate device to facilitate communication between the client and the IPv6 router.



To configure ND Proxy on FortiGate:

1. Enable address auto-configuration on the upstream interface:

```
config system interface
    edit "port1"
        config ipv6
            set autoconf enable
        end
    next
end
```

2. Enable ND proxy on the interfaces:

```
config system nd-proxy
   set status enable
   set member "port1" "port5"
end
```

See RFC 4389 for more information on Neighbor Discovery Proxies (ND Proxy).

IPv6 address assignment

On the FortiGate, an interface can use the following methods to obtain an IPv6 address:

Method	Overview
IPv6 stateless address auto-configuration (SLAAC) on page 754	• Enables each network host to auto-configure a unique IPv6 address. • The lack of a state eliminates the need for a centralized server, thereby simplifying network management. • SLAAC does not provide DNS server addresses to hosts.
DHCPv6 stateful server on page 755	• Provides IPv6 addresses and additional information to hosts, such as a DNS server list and a domain name. • Offers more control to the administrator in assigning addresses, but requires extra configuration.
SLAAC with DHCPv6 stateless server on page 760	• Combines the benefits of SLAAC and DHCPv6. • Enables each host on the network to auto-configure a unique IPv6 address and allows them to obtain additional information, such as a DNS server list and a domain name.
IPv6 prefix delegation on page 763	• Enables internet service providers (ISPs) to provide organizations with a block of addresses that can be distributed throughout their network.

Deciding which method to employ should be based on the requirements of your system and your overall IT practice.

You can configure IPv6 using the CLI. To configure IPv6 using the GUI, ensure IPv6 is enabled by going to *System* > *Feature Visibility* and enabling *IPv6*.

IPv6 stateless address auto-configuration (SLAAC)

FortiGate can easily obtain an IPv6 address on any given interface using SLAAC (stateless address auto-configuration). SLAAC is designed only for IP assignments and does not provide DNS server addresses to hosts. See RFC 4862 for more information.

Use one of the following options to obtain a DNS server address:

- DHCPv6 stateful server on page 755
- SLAAC with DHCPv6 stateless server on page 760

In this example, the Enterprise Core FortiGate is connected to the First Floor FortiGate. The Enterprise Core FortiGate has SLAAC enabled, which allows the First Floor FortiGate to automatically obtain an IPv6 address using the auto-configuration IPv6 address option.

To enable IPv6 auto-configuration in the GUI:

1. Configure SLAAC on the Enterprise Core FortiGate:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Configure the following settings:

IPv6 addressing mode	Manual
IPv6 Address/Prefix	2001:db8:d0c:1::1/64
Stateless Address Auto-configuration (SLAAC)	Enable
IPv6 prefix list	Enable
IPv6 prefix	2001:db8:d0c:1::/64

   c. Click *OK*.
2. Configure the First Floor FortiGate to automatically obtain an IPv6 address:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Enable *Auto configure IPv6 address*. The First Floor FortiGate uses the prefix that it obtains from the Enterprise Core FortiGate interface, and automatically generates an IPv6 address.
3. Verify that the First Floor FortiGate automatically generated an IPv6 address:
   a. Go to *Network* > *Interfaces* and edit port5. The *IPv6 Address/Prefix* field is prepopulated with an IPv6 address.

To enable IPv6 auto-configuration in the CLI:

1. Configure SLAAC on the Enterprise Core FortiGate:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-address 2001:db8:d0c:1::1/64
            set ip6-send-adv enable
            config ip6-prefix-list
                edit 2001:db8:d0c:1::/64
                next
            end
        end
    next
end
```

2. Configure the First Floor FortiGate to automatically obtain an IPv6 address:

```
config system interface
    edit "port5"
        config ipv6
            set autoconf enable
        end
    next
end
```

3. Verify that the First Floor FortiGate automatically generated an IPv6 address:

```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2001:db8:d0c:1:20c:29ff:fe4d:f83d
preferred=604419 valid=2591619 cstamp=976270 tstamp=979470
```

DHCPv6 stateful server

Similar to a DHCPv4 server, a DHCPv6 server is stateful. It can track client/server states, assign IP addresses to clients, and maintain full control over the process. In addition to assigning IP addresses, a DHCP server can also provide DNS server addresses. However, this IP address assignment method does not support failover protection. If the DHCPv6 server fails, hosts are unable to obtain an IPv6 address, and the network ceases to function. Furthermore, DHCPv6 does not provide gateway information. See RFC 3315 for more information.

DHCPv6 server/client can accommodate multiple DHCP options, including fqdn, hex (default), ip6, and string. Option 16 or Vendor Class Option is also supported, which allows IP pools and options to be assigned based on VCI matching for DHCPv6 server and client.

Example: basic configuration

In this example, the Enterprise Core FortiGate is connected to the First Floor FortiGate. The Enterprise Core FortiGate has a stateful DHCPv6 server configured that allows the First Floor FortiGate to automatically obtain an IPv6 address and DNS server address using the DHCP option.

To configure a DHCPv6 stateful server in the GUI:

1. Configure the Enterprise Core FortiGate with DHCPv6 stateful server:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Configure the following settings:

DHCPv6 Server	Enable
IPv6 subnet	2001:db8:d0c:1::/64
DNS service	Same as System DNS
Stateful server.	Enable
IP mode	IP range
Address range	2001:db8:d0c:1::a to 2001:db8:d0c:1::f

   c. Click *OK*.
2. Configure the First Floor FortiGate to obtain an IPv6 address using DHCP:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Set *IPv6 addressing mode* to *DHCP*.
   c. Click *OK*.
3. Verify that the First Floor FortiGate obtained an IPv6 address and DNS server address from the DHCPv6 server:
   a. Go to *Network* > *Interfaces* and edit port5. The *Obtained IP/Netmask* and *Acquired DNS* fields are populated with an IPv6 address.

To configure a DHCPv6 stateful server in the CLI:

1. Configure the Enterprise Core FortiGate with DHCPv6 stateful server:

```
config system dhcp6 server
    edit 1
        set dns-service default
        set subnet 2001:db8:d0c:1::/64
        set interface "port5"
        config ip-range
            edit 1
                set start-ip 2001:db8:d0c:1::a
                set end-ip 2001:db8:d0c:1::f
            next
        end
    next
end
```

2. Configure the First Floor FortiGate to obtain an IPv6 address using DHCP:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-mode dhcp
        end
    next
end
```

3. Verify that the First Floor FortiGate obtained an IPv6 address and DNS server address from the DHCPv6 server:

```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag=P scope=0 prefix=128 addr=2001:db8:d0c:1::a preferred=4294967295
valid=4294967295 cstamp=1298969 tstamp=1298969ip6-address
# dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::ff:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0 probe=0
failure=1 last_failed=19812
```

Example: multiple DHCP options

The DHCPv6 server/client can accommodate multiple (more than three) DHCP options: fqdn, hex (default), ip6, and string.

To configure the options and IP range when the FortiGate is the DHCPv6 server:

```
config system dhcp6 server
    edit 1
        set dns-service default
        set subnet 2000:11:1:1::/64
        set interface "port3"
        config options
            edit 1
                set code 16
                set type string
                set value "vendor class option"
            next
            edit 2
                set code 15
                set type string
                set value "user class option"
            next
            edit 3
                set code 72
                set type fqdn
                set value "www.test.com"
            next
            edit 4
```

```
                set code 70
                set type ip6
                set ip6 2000:8:8:8::8
            next
            edit 5
                set code 96
                set type hex
                set value "0000013700084d53465420352e30"
            next
        end
        config ip-range
            edit 1
                set start-ip 2000:11:1:1::2
                set end-ip 2000:11:1:1::10
            next
        end
    next
    edit 2
        set subnet 2000:10:1:100::/64
        set interface "port2"
        config ip-range
            edit 1
                set start-ip 2000:10:1:100::11
                set end-ip 2000:10:1:100::11
            next
        end
    next
end
```

To configure the options and IP range when the FortiGate is a DHCPv6 client:

```
config system interface
    edit "port3"
        set vdom "vdom1"
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set snmp-index 5
        config ipv6
            set ip6-mode dhcp
            config client-options
                edit 1
                    set code 16
                    set type hex
                    set value "0000013700084d53465420352e30"
                next
            end
            set ip6-allowaccess ping https ssh http telnet
        end
        set macaddr 00:09:0f:09:00:00
    next
end
```

Example: VCI matching in IP ranges

DHCPv6 supports option 16, also known as the Vendor Class Option. This allows IP pools and options assignment based on VCI matching for DHCPv6 server and client.

VCI matching in IP ranges

There are three cases:

1. If VCI matching is disabled in the IP range, then the DHCP client can get an IP address. This is the default.
2. If VCI matching is enabled and the VCI value matches the DHCP client, then the DHCP client can get an IP address.
3. If VCI matching is enabled and the VCI value does not match the DHCP client, then the DHCP client cannot get an IP address.

To enable VCI matching in an IP range:

```
config system dhcp6 server
    edit 2
        set subnet 2000:10:1:100::/64
        set interface "port2"
        config ip-range
            edit 1
                set start-ip 2000:10:1:100::11
                set end-ip 2000:10:1:100::11
                set vci-match enable
                set vci-string "PC1"
            next
        end
    next
end
```

VCI matching in DHCPv6 options

There are three cases:

1. If VCI matching is disabled in the option, then all options are sent back to the client. This is the default.
2. If VCI matching is enabled and the VCI value matches the DHCP client, then all options are sent back to the client.
3. If VCI matching is enabled and the VCI value does not matches the DHCP client, then the unmatched options cannot be sent back to the client.

To enable VCI matching in an option:

```
config system dhcp6 server
    edit 2
        set subnet 2000:10:1:100::/64
        set interface "port2"
        config options
            edit 1
```

```
                set code 16
                set type string
                set value "vendor class option"
                set vci-match enable
                set vci-string "PC1"
            next
        end
        config ip-range
            edit 1
                set start-ip 2000:10:1:100::11
                set end-ip 2000:10:1:100::11
            next
        end
    next
end
```

SLAAC with DHCPv6 stateless server

Using Stateless Address Auto Configuration (SLAAC) with a stateless DHCPv6 server provides a solution for obtaining other host configurations, such as DNS server addresses, while retaining the auto-configuration aspect of SLAAC. This approach also provides failover protection in the event that the DHCPv6 server fails. In addition to obtaining host configurations through the stateless DHCPv6 server, interfaces can also obtain gateway information through Router Advertisements (RAs). This allows for a robust and flexible IPv6 network configuration.

In this example, the Enterprise Core FortiGate is connected to the First Floor FortiGate. The Enterprise Core FortiGate has both SLAAC and stateless DHCPv6 server enabled. This allows the First Floor FortiGate to automatically obtain an IPv6 address using the *Auto configure IPv6 address* option and to acquire a DNS server address using the `dhcp6-information-request` option.

To enable IPv6 auto-configuration with DHCPv6 stateless server in the GUI:

1. Configure SLAAC on the Enterprise Core FortiGate:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Configure the following settings:

IPv6 addressing mode	Manual
IPv6 Address/Prefix	2001:db8:d0c:1::1/64
Stateless Address Auto-configuration (SLAAC)	Enable
IPv6 prefix list	Enable
IPv6 prefix	2001:db8:d0c:1::/64

   c. Click *OK*.

d. Input the following commands from the CLI:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-other-flag enable
        end
    next
end
```

2. Configure DHCPv6 stateless server on the Enterprise Core FortiGate:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Configure the following settings:

DHCPv6 Server	Enable
DNS service	Same as System DNS
Stateful server	Disable

   c. Click *OK*.
3. Configure the First Floor FortiGate to automatically obtain an IPv6 address and DNS server address from the DHCPv6 server:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Enable *Auto configure IPv6 address*. The First Floor FortiGate uses the prefix obtained from the Enterprise Core FortiGate interface to automatically generate an IPv6 address.
   c. Input the following commands from the CLI:

```
config system interface
    edit "port5"
        config ipv6
            set dhcp6-information-request enable
        end
    next
end
```

   d. Click *OK*.
4. Verify that the First Floor FortiGate automatically generated an IPv6 address and obtained the DNS server address from the DHCPv6 server:
   a. Go to *Network* > *Interfaces* and edit port5. The IPv6 Address/Prefix field is populated with an IPv6 address
   b. Use the below CLI command to verify the DNS server address:

```
#dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::1:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0 probe=0
failure=1 last_failed=46738
...
```

To enable IPv6 auto-configuration with DHCPv6 stateless server in the CLI:

1. Configure SLAAC on the Enterprise Core FortiGate:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-address 2001:db8:d0c:1::1/64
            set ip6-send-adv enable
            set ip6-other-flag enable
            config ip6-prefix-list
                edit 2001:db8:d0c:1::/64
            next
        end
    next
end
```

2. Configure DHCPv6 stateless server on the Enterprise Core FortiGate:

```
config system dhcp6 server
    edit 1
        set dns-service default
        set interface "port5"
    next
end
```

3. Configure the First Floor FortiGate to obtain an IPv6 address automatically:

```
config system interface
    edit "port5"
        config ipv6
            set autoconf enable
            set dhcp6-information-request enable
        end
    next
end
```

4. Verify that the First Floor FortiGate automatically generated an IPv6 address and obtained the DNS server address from the DHCPv6 server:

```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2001:db8:d0c:1:20c:29ff:fe4d:f83d
preferred=604681 valid=2591881 cstamp=1675487 tstamp=1772919
# dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::1:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0 probe=0
failure=1 last_failed=46738
…
```

IPv6 prefix delegation

IPv6 prefix delegation allows the dynamic assignment of an address prefix and DNS server address to an upstream interface. An upstream interface is typically the interface that is connected to an Internet Service Provider (ISP). This process also automates the assignment of prefixes to downstream interfaces. A downstream interface is any interface that is not an upstream interface and uses delegated addressing mode. Downstream interfaces can be configured to request specific IPv6 subnets from the upstream interface. Once a downstream interface receives the IPv6 address, other devices connected to the downstream interface can obtain an IPv6 address by using DHCPv6 or by configuring their own IP address using auto-configuration.

In this example, the Enterprise Core FortiGate is connected to a DHCPv6 server provided by the ISP through an upstream interface (port1). The Enterprise Core FortiGate is configured with a delegate interface (port5) to receive the IPv6 prefix and DNS server address from the upstream interface.

A downstream interface (port5) connects the First Floor FortiGate to the Enterprise Core FortiGate. The First Floor FortiGate interface (port5) is configured to receive the IPv6 address and DNS server address from the Enterprise Core FortiGate using DHCP addressing mode or auto-configuration.

Using the GUI or CLI to configure a downstream FortiGate to obtain the IPv6 and DNS server address from delegated interface using DHCP mode requires the following steps:

1. Configure the following items on the Enterprise Core FortiGate:
   - Upstream interface
   - Downstream interface
   - DHCPv6 server on the downstream interface.
2. Configure First Floor FortiGate to receive IPv6 prefix and DNS from the delegated interface.

Instead of configuring a DHCPv6 server on the downstream interface of the Enterprise Core FortiGate, you can configure SLAAC. See IPv6 prefix delegation with SLAAC on page 766.

GUI configuration

To configure the Enterprise Core FortiGate:

1. Configure the upstream interface on Enterprise Core FortiGate:
   a. Go to *Network* > *Interfaces* and edit port1.
   b. Enable *DHCPv6 prefix delegation*.
   c. Select the + in the IAPD prefix hint to open the ID and prefix field.
   d. Enter *1* for *ID* and *::/48* for *prefix* field. You can add two or more entries. Select the *x* icon in the field to remove an entry.

   e. Click *OK*.
2. Verify that the upstream interface obtained the prefix delegation, see Verify upstream interface obtained prefix delegation and DNS server address.
3. Configure the downstream interface on Enterprise Core FortiGate:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Set *IPv6 addressing mode* to *Delegated*.
   c. Enter *1* for *Identity association identifier* field.
   d. Set *IPv6 upstream* interface to *port1*.
   e. Click *OK*.
4. Verify that the downstream interface obtained an IPv6 address/prefix:
   a. Go to *Network* > *Interfaces* and edit port5. The *IPv6 Address/Prefix* field is prepopulated.
5. Configure the DHCPv6 server on the downstream interface:
   a. Go to *Network* > *Interfaces* and edit port5
   b. Enable *DHCPv6 Server*.
   c. Set *DNS service* to *Delegated*.
   d. From the *Upstream interface* dropdown list, select *port1*.
   e. Input the following commands from the CLI:

```
config system dhcp6 server
    edit 1
        set delegated-prefix-iaid 1
    next
end
```

   f. Enable *Stateful server*.
   g. Set *IP mode* to *Delegated*.
   h. Click *OK*.

To configure the First Floor FortiGate:

1. Configure the First Floor FortiGate interface using DHCP mode:
   a. Go to *Network* > *Interfaces* and edit the port5.
   b. Set *IPv6 addressing mode* to *DHCP*. This allows the First Floor FortiGate to obtain the IPv6 prefix and DNS from the delegated interface.
   c. Click *OK*.
2. Verify that the First Floor FortiGate obtained an IPv6 address and the DNS server address from the delegated interface:
   a. Go to *Network* > *Interfaces* and edit port5. The *Obtained IP/Netmask* and *Acquired DNS* fields are prepopulated with an IPv6 address.

CLI configuration

Using the CLI to configure a downstream FortiGate to obtain the IPv6 and DNS server address from delegated interface using DHCP mode requires the following steps:

To configure the Enterprise Core FortiGate:

1. Configure the upstream interface on the Enterprise Core FortiGate:

```
config system interface
    edit "port1"
        config ipv6
            set dhcp6-prefix-delegation enable
            config dhcp6-iapd-list
                edit 1
                    set prefix-hint ::/48
                next
            end
        end
    next
end
```

2. Verify that the upstream interface obtained a prefix delegation and DNS server address:

```
config system interface
     edit port1
        config ipv6
Enterprise Core FortiGate # get
ip6-mode            : static
…
dhcp6-prefix-delegation: enable
delegated-prefix iaid 1     : 2001:db8:d0c::/48
preferred-life-time         : 4294967295
valid-life-time     : 4294967295
delegated-DNS1      : 2001:db8::35
delegated-DNS2      : ::
…
dhcp6-iapd-list:
    == [ 1 ]
    iaid:     1       prefix-hint: ::/48           prefix-hint-plt: 604800           prefix-
hint-vlt: 2592001
```

3. Configure the downstream interface on the Enterprise Core FortiGate:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-mode delegated
            set ip6-delegated-prefix-iaid 1
            set ip6-upstream-interface "port1"
        end
    next
end
```

4. Verify that the downstream interface obtained an IPv6 address/prefix:

```
config system interface
    edit "port5"
```

```
        config ipv6
Enterprise Core FortiGate # get
ip6-mode            : delegated
nd-mode             : basic
ip6-address         : 2001:db8:d0c::/48
…
ip6-delegated-prefix-iaid: 1
ip6-upstream-interface: port1
ip6-subnet          : ::/0
```

5. Configure the DHCPv6 server on the downstream interface:

```
config system dhcp6 server
    edit 1
        set dns-service delegated
        set interface "port5"
        set upstream-interface "port1"
        set delegated-prefix-iaid 1
        set ip-mode delegated
    next
end
```

To configure the First Floor FortiGate:

1. Configure the First Floor FortiGate interface to use DHCP mode:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-mode dhcp
        end
    next
end
```

2. Verify that the First Floor FortiGate obtained an IPv6 address and DNS server address from the delegated interface:

```
# diagnose ipv6 address list | grep port5
dev=7 devname=port5 flag=P scope=0 prefix=128 addr=2001:db8:d0c::1 preferred=4294967295
valid=4294967295 cstamp=43208325 tstamp=43208325
# dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8::35:53 vrf=0 tz=0 encrypt=none req=3 to=2 res=0 rt=1046 ready=1 timer=0 probe=0
failure=2 last_failed=65131
```

IPv6 prefix delegation with SLAAC

A downstream FortiGate can be configured to obtain the IPv6 address and DNS server address from a delegated interface using SLAAC instead of DHCPv6. Following is a summary of the configuration steps:

1. Configure the following items on the Enterprise Core FortiGate:
   - Upstream interface
   - Downstream interface
   - SLAAC on the downstream interface
2. Configure the First Floor FortiGate to receive an IPv6 prefix and DNS server address from the delegated interface.

To configure the Enterprise Core FortiGate:

1. Configure the upstream interface on Enterprise Core FortiGate:
   a. Go to *Network* > *Interfaces* and edit port1.
   b. Enable *DHCPv6 prefix delegation*.
   c. Select the *+* in the IAPD prefix hint to open the ID and prefix field.
   d. Enter *1* for *ID* and *::/48* for *prefix* field. You can add two or more entries. Select the *x* icon in the field to remove an entry.

   e. Click *OK*.
2. Verify that the upstream interface obtained the prefix delegation, see Verify upstream interface obtained prefix delegation and DNS server address.
3. Configure the downstream interface on Enterprise Core FortiGate:
   a. Go to *Network* > *Interfaces* and edit port5.
   b. Set *IPv6 addressing mode* to *Delegated*.
   c. Enter *1* for *Identity association identifier* field.
   d. Set *IPv6 upstream* interface to *port1*.
   e. Click *OK*.
4. Verify that the downstream interface obtained an IPv6 address/prefix:
   a. Go to *Network* > *Interfaces* and edit port5. The *IPv6 Address/Prefix* field is prepopulated.
5. Configure SLAAC on the downstream interface:

```
config system interface
    edit "port5"
        config ipv6
            set ip6-mode delegated
            set ip6-send-adv enable
            set ip6-delegated-prefix-iaid 1
            set ip6-upstream-interface "port1"
            config ip6-delegated-prefix-list
                edit 1
                    set upstream-interface "port1"
                    set delegated-prefix-iaid 1
                    set subnet 0:0:0:1::/64
                    set rdnss-service delegated
                next
```

```
            end
        end
    next
end
```

To configure the First Floor FortiGate:

1. Configure the First Floor FortiGate interface using auto-configure:

```
config system interface
    edit "port5"
        config ipv6
            set autoconf enable
        end
    next
end
```

2. Verify that the First Floor FortiGate automatically generated an IPv6 address and obtained the DNS server address from the delegated interface:

```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2000:db8:d0c:1:20c:29ff:fe4d:f847
preferred=4294967295 valid=4294967295 cstamp=17203697 tstamp=17225377
```

FortiGate can send DNS server addresses using Router Advertisement (RA), which allows any device that is capable of receiving DNS server addresses by using RA to obtain DNS server addresses.

Additionally, FortiGate can receive DNS server addresses through the use of SLAAC with a DHCPv6 stateless server, even though it is currently unable to receive DNS server addresses using RA due to RFC 4862 implementation. See SLAAC with DHCPv6 stateless server on page 760 for more information.

NAT66, NAT46, NAT64, and DNS64

NAT66, NAT46, NAT64, and DNS64 each offer their own distinct strategies and solutions to tackle the obstacles encountered during the transition from IPv4 to IPv6. This section provides a concise overview of these methods.

Method	Overview
NAT66	• NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. • Not a common method, since most IPv6 networks do not require NAT66.
NAT46	• NAT46 is used to translate IPv4 addresses to IPv6 addresses. • Enable a client on an IPv4 network to communicate transparently with a server on an IPv6 network.

Method	Overview
NAT64 and DNS64	• NAT64 is used to translate IPv6 addresses to IPv4 addresses. • Enable a client on an IPv6 network to communicate transparently with a server on an IPv4 network. • Typically used when networks are being transitioned from IPv4 to IPv6. • NAT64 is typically employed in tandem with DNS64. DNS64 is responsible for synthesizing AAAA records from A records.

Note that these are broad use cases and the specific use of each type of NAT can vary depending on the network configuration and requirement.

NAT66 policy

NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. NAT66 is not as common or as important as IPv4 NAT, as many IPv6 addresses do not need NAT66 as much as IPv4 NAT. However, NAT66 can be useful for a number of reasons. For example, you may have changed the IP addresses of some devices on your network but want traffic to still appear to be coming from their old addresses. You can use NAT66 to translate the source addresses of packets from the devices to their old source addresses.

In FortiOS, NAT66 options can be added to an IPv6 security policy. Configuring NAT66 is very similar to configuring NAT in an IPv4 security policy.

To configure NAT66:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New*.
3. Configure the required policy parameters.
4. Enable *NAT* and select *Use Outgoing Interface Address*. For packets that match this policy, its source IP address is translated to the IP address of the outgoing interface.
5. Click *OK*.

Nat66 can also translate one IPv6 source address to another address that is not the same as the address of the existing interface. You can do this using IP pools.

To configure the IPv6 pool:

1. Go to *Policy & Objects > IP Pools* and navigate to the *IPv6 IP Pool* tab.
2. Click *Create new*.
3. Enter the following:

Name	test-ippool6-1
External IP Range	2000:172:16:101::1-2000:172:16:101::1

4. Click *OK*.

To use the IPv6 pool in the firewall policy:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Click *Create New* or edit an existing policy.
3. Configure the required policy parameters.
4. Enable *NAT* and select *Use Dynamic IP Pool*.
5. Click *OK*.

NAT66 destination address translation

NAT66 can also be used to translate destination addresses. This is done in an IPv6 policy by using IPv6 virtual IPs. For example, the destination address 2001:db8::dd can be mapped to 2001:db8::ee.

To configure the IPv6 VIP:

1. Go to *Policy & Objects* > *Virtual IPs* and navigate to the *Virtual IP* tab.
2. Click *Create new*.
3. Enter the following:

VIP type	IPv6
Name	example-vip6
External IP address/range	2001:db8::dd
Map to IPv6 address/range	2001:db8::ee

4. Click *OK*.

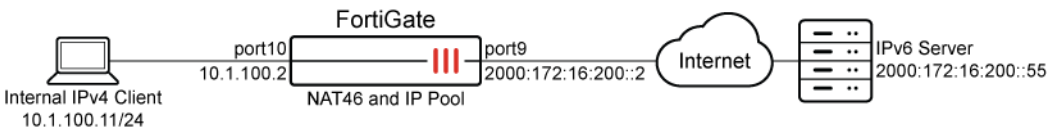
To use the IPv6 VIP in the firewall policy:

1. Go to *Policy & Objects* > *Firewall Policy*.
2. Click *Create New* or edit an existing policy.
3. Configure the required policy parameters.
4. In the *Destination* field, select *example-vip6* from the dropdown menu.
5. Click *OK*.

NAT46 policy

NAT46 refers to the mechanism that allows IPv4 addressed hosts to communicate with IPv6 hosts. Without such a mechanism, IPv4 environments cannot connect to IPv6 networks.

Sample topology



In this example, an IPv4 client tries to connect to an IPv6 server. A VIP is configured on FortiGate to map the server IPv6 IP address `2000:172:16:200:55` to an IPv4 address `10.1.100.55`. On the other side, an IPv6 IP pool is configured and the source address of packets from client are changed to the defined IPv6 address. In this setup, the client PC can access the server by using IP address `10.1.100.55`.

Sample configuration

To configure NAT46 in the GUI:

1. Enable IPv6:
   a. Go to *System* > *Feature Visibility*.
   b. In the *Core Features* section, enable *IPv6*.
   c. Click *Apply*.
2. Configure the VIP:
   a. Go to *Policy & Objects* > *Virtual IPs* and navigate to the *Virtual IP* tab.
   b. Click *Create new*.
   c. Enter the following:

Name	vip46_server
Interface	port2
Type	Static NAT
External IP address/range	10.1.100.55
Map to IPv6 address/range	2000:172:16:200::55

   d. Click *OK*.
3. Configure the IPv6 IP pool:
   a. Go to *Policy & Objects* > *IP Pools* and navigate to the *IPv6 IP Pool* tab.
   b. Click *Create new*.
   c. Enter the following:

Name	client_external
External IP address/range	2000:172:16:201::-2000:172:16:201::7
NAT46	Enable

   d. Click *OK*.
4. Configure the firewall policy:
   a. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
   b. Enter the following:

Name	policy46-1
Incoming Interface	port10
Outgoing Interface	port9

Source	all
Destination	vip46_server
Schedule	always
Service	ALL
Action	ACCEPT
NAT	NAT46
IP Pool Configuration	client_external

c. Configure the other settings as needed.

d. Click *OK*.

To configure NAT46 in the CLI:

1. Enable IPv6:

```
config system global
    set gui-ipv6 enable
end
```

2. Configure the VIP:

```
config firewall vip
    edit "vip46_server"
        set extip 10.1.100.55
        set nat44 disable
        set nat46 enable
        set extintf "port2"
        set ipv6-mappedip 2000:172:16:200::55
    next
end
```

3. Configure the IPv6 IP pool:

```
config firewall ippool6
    edit "client_external"
        set startip 2000:172:16:201::
        set endip 2000:172:16:201::7
        set nat46 enable
    next
end
```

4. Configure the firewall policy:

```
config firewall policy
    edit 2
        set name "policy46-1"
        set srcintf "port10"
```

```
        set dstintf "port9"
        set action accept
        set nat46 enable
        set srcaddr "all"
        set dstaddr "vip46_server"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set ippool enable
        set poolname6 "client_external"
    next
end
```

Sample troubleshooting

To trace the flow and troubleshoot:

```
# diagnose debug flow filter saddr 10.1.100.11
# diagnose debug flow show function-name enable
show function name
# diagnose debug flow show iprope enable
show trace messages about iprope
# diagnose debug flow trace start 5

NAT64 policy and DNS64 (DNS proxy)

NAT64 policy translates IPv6 addresses to IPv4 addresses so that a client on an IPv6 network can communicate transparently with a server on an IPv4 network.

NAT64 policy is usually implemented in combination with the DNS proxy called DNS64. DNS64 synthesizes AAAA records from A records and is used to synthesize IPv6 addresses for hosts that only have IPv4 addresses. DNS proxy and DNS64 are interchangeable terms.

Sample topology

In this example, a host on the internal IPv6 network communicates with `ControlPC.qa.fortinet.com` that only has IPv4 address on the Internet. Central NAT is disabled.

1. The host on the internal network does a DNS lookup for `ControlPC.qa.fortinet.com` by sending a DNS query for an AAAA record for `ControlPC.qa.fortinet.com`.
2. The DNS query is intercepted by the FortiGate DNS proxy. The DNS proxy performs an A-record query for `ControlPC.qa.fortinet.com` and gets back an RRSet containing a single A record with the IPv4 address `172.16.200.55`.
3. The DNS proxy then synthesizes an AAAA record. The IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits and the received IPv4 address in the lower 32 bits. By default, the resulting IPv6 address is `64:ff9b::172.16.200.55`.
4. The host on the internal network receives the synthetic AAAA record and sends a packet to the destination address `64:ff9b::172.16.200.55`.
5. The packet is routed to the FortiGate internal interface (port10) where it is accepted by the NAT64 security policy.
6. The FortiGate translates the destination address of the packets from IPv6 address `64:ff9b::172.16.200.55` to IPv4 address `172.16.200.55` and translates the source address of the packets to `172.16.200.200` (or another address in the IP pool range) and forwards the packets out the port9 interface to the Internet.

Sample configuration

To configure a NAT64 policy with DNS64 in the GUI:

1. Enable IPv6 and DNS database:
   a. Go to *System > Feature Visibility*.
   b. In the *Core Features* section, enable *IPv6*.
   c. In the *Additional Features* section, enable *DNS Database*.
   d. Click *Apply*.
2. Enable DNS proxy on the IPv6 interface:
   a. Go to *Network > DNS Servers*.
   b. In the *DNS Service on Interface* table, click *Create New*.
   c. For *Interface*, select *port10*.
   d. For *Mode*, select *Forward to System DNS*.
   e. Click *OK*.
3. Configure the IPv6 DHCP server:
   a. Go to *Network > Interfaces* and edit port10.
   b. Enable *DHCPv6 Server* and enter the following:

IPv6 subnet	2001:db8:1::/64
DNS service	Specify
DNS server 1	2001:db8:1::10

   c. Click *OK*.
4. Configure the IPv6 VIP for the destination IPv6 addresses:
   These are all of the IPv6 addresses that the FortiGate DNS proxy synthesizes when an IPv6 device performs a DNS query that resolves to an IPv4 Address. In this example, the synthesized IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits, so the VIP is for all the IPv6 addresses that begin with 64:ff9b.
   a. Go to *Policy & Objects > Virtual IPs* and navigate to the *IPv6 Virtual IP* tab.
   b. Click *Create new*.
   c. Enter the following:

Name	vip6
Eternal IP address/range	64:ff9b::-64:ff9b::ffff:ffff
Map to IPv4 address/range	Use Embedded

   d. Click *OK*.
5. Configure the IPv6 firewall address for the internal network:
   a. Click *Create New > Address*.
   b. Enter the following:

Category	IPv6 Address

Name	internal-net6
Type	IPv6 Subnet
IP/Netmask	2001:db8:1::/48

c. Click *OK*.

6. Configure the IP pool containing the IPv4 address that is used as the source address of the packets exiting port9:
   a. Go to *Policy & Objects* > *IP Pools* and navigate to the *IP Pool* tab.
   b. Click *Create new*.
   c. Enter the following:

Name	exit-pool4
Type	Overload
External IP address/range	172.16.200.200-172.16.200.207
NAT64	Enable

External IP address/range must start and end on the boundaries of a valid subnet. For example, 172.16.200.0-172.16.200.7 and 172.16.200.16-172.16.200.31 are a valid subnets (/29 and /28 respectively).

   d. Click *OK*.

7. Configure the NAT64 policy:
   a. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
   b. Enter the following:

Name	policy64-1
Incoming Interface	port10
Outgoing Interface	port9
Source	internal-net6
Destination	vip6
Schedule	always
Service	ALL
Action	ACCEPT
NAT	NAT64
IP Pool Configuration	exit-pool4

   c. Click *OK*.

To configure a NAT64 policy with DNS64 in the CLI:

1. Enable IPv6 and DNS database:

```
config system global
   set gui-ipv6 enable
end
```

```
config system settings
   set gui-dns-database enable
end
```

2. Enable DNS proxy on the IPv6 interface:

```
config system dns-server
   edit "port10"
       set mode forward-only
   next
end
```

3. Configure the IPv6 DHCP server:

```
config system dhcp6 server
   edit 1
       set subnet 2001:db8:1::/64
       set interface "port10"
       set dns-server1 2001:db8:1::10
   next
end
```

4. Configure the IPv6 VIP for the destination IPv6 addresses:

```
config firewall vip6
    edit "vip6"
        set extip 64:ff9b::-64:ff9b::ffff:ffff
        set embedded-ipv4-address enable
    next
end
```

5. Configure the IPv6 firewall address for the internal network:

```
config firewall address6
    edit "internal-net6"
        set ip6 2001:db8:1::/48
    next
end
```

6. Configure the IP pool containing the IPv4 address that is used as the source address of the packets exiting port9:

```
config firewall ippool
    edit "exit-pool4"
        set startip 172.16.200.200
```

```
        set endip 172.16.200.207
        set nat64 enable
    next
end
```

External IP address/range must start and end on the boundaries of a valid subnet. For example, 172.16.200.0-172.16.200.7 and 172.16.200.16-172.16.200.31 are a valid subnets (/29 and /28 respectively).

7. Configure the NAT64 policy:

```
config firewall policy
    edit 1
        set name "policy64-1"
        set srcintf "port10"
        set dstintf "port9"
        set action accept
        set nat64 enable
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 internal-net6
        set dstaddr6 vip6
        set schedule "always"
        set service "ALL"
        set ippool enable
        set poolname "exit-pool4"
    next
end
```

To enable DNS64 and related settings using the CLI:

Enabling DNS64 means that all IPv6 traffic received by the current VDOM can be subject to NAT64 if the source and destination address matches an NAT64 security policy.

By default, the setting `always-synthesize-aaaa-record` is enabled. If you disable this setting, the DNS proxy (DNS64) will attempt to find an AAAA records for queries to domain names and therefore resolve the host names to IPv6 addresses. If the DNS proxy cannot find an AAAA record, it synthesizes one by adding the NAT64 prefix to the A record.

```
config system dns64
    set status {enable | disable}
    set dns64-prefix <ipv6-prefix>
    set always-synthesize-aaaa-record {enable | disable}
end
```

By default, the `dns64-prefix` is `64:ff9b::/96`.

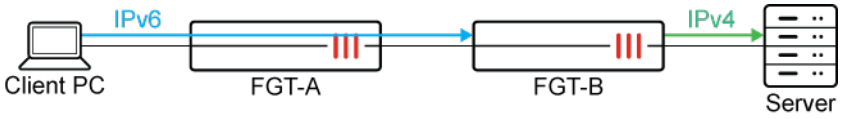
Port block allocation with NAT64

Port block allocation (PBA) support for NAT64 is supported on FortiGates with a hyperscale firewall license. This feature has been added to mainstream FortiOS to make it available to non-hyperscale customers, including customers running a VM version of FortiOS. Hyperscale firewall logging is designed for optimal performance and does not have the same detailed logging features as are available for non-hyperscale traffic.

```
config firewall ippool
    edit <name>
        set type port-block-allocation
        set nat64 enable
    next
end
```

Example

In this example, a NAT64 virtual IPv6 address and PBA IP pool are configured on FGT-B. IPv6 traffic from the client PC is able to access the IPv4 server.



The IPv6 addresses used in this example are for demonstrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

To configure PBA for NAT64 on FGT-B:

1. Configure the IP pools and enable NAT 64:

```
(vdom1) config firewall ippool
    edit "ippool4-1072390-1"
        set type port-block-allocation
        set startip 172.16.164.164
        set endip 172.16.164.164
        set block-size 64
        set num-blocks-per-user 1
        set pba-timeout 60
        set nat64 enable
    next
    edit "ippool4-1072390-2"
        set type port-block-allocation
        set startip 172.16.164.165
        set endip 172.16.164.165
        set block-size 64
        set num-blocks-per-user 1
        set pba-timeout 60
```

```
        set nat64 enable
    next
end
```

2. Configure the virtual IP for IPv6:

```
(vdom1) config firewall vip6
    edit "vip64-1072390"
        set extip 64:ff9b::-64:ff9b::ffff:ffff
        set nat66 disable
        set nat64 enable
        set embedded-ipv4-address enable
    next
end
```

3. Configure the firewall policy:

```
(vdom1) config firewall policy
    edit 1072390
        set srcintf "port7"
        set dstintf "port1"
        set action accept
        set nat64 enable
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all"
        set dstaddr6 "vip64-1072390"
        set schedule "always"
        set service "ALL"
        set auto-asic-offload disable
        set ippool enable
        set poolname "ippool4-1072390-1" "ippool4-1072390-2"
    next
end
```

4. Send IPv6 packets from the client to access the IPv4 server.
5. Verify the NAT64 sessions:

```
(vdom1) # diagnose sys session6 stat
misc info:  session_count=128 setup_rate=0 exp_count=0 reflect_count=0 clash=0
      memory_tension_drop=0 ephemeral=0/0 removeable=0 extreme_low_mem=0
      npu_session_count=0
      nturbo_session_count=0
delete=0, flush=3, dev_down=0/0 ses_walkers=0
```

There are 128 sessions allocated to the two PBA IP pools.

6. Verify the PBA IP pools status:

```
(vdom1) # diagnose firewall ippool list
list ippool info:(vf=vdom1)
ippool ippool4-1072390-1: id=1, block-sz=64, num-block=1, fixed-port=no, use=5
      nat ip-range=172.16.164.164-172.16.164.164 start-port=5117, num-pba-per-ip=944
```

```
      clients=2, inuse-NAT-IPs=1
      total-PBAs=944, inuse-PBAs=1, expiring-PBAs=1, free-PBAs=99.89%
      allocate-PBA-times=2, reuse-PBA-times=0
ippool ippool4-1072390-2: id=2, block-sz=64, num-block=1, fixed-port=no, use=4
      nat ip-range=172.16.164.165-172.16.164.165 start-port=5117, num-pba-per-ip=944
      clients=1, inuse-NAT-IPs=1
      total-PBAs=944, inuse-PBAs=1, expiring-PBAs=0, free-PBAs=99.89%
      allocate-PBA-times=1, reuse-PBA-times=0
```

Each IP pool uses one IPv4 address and one block (64 ports) for SNAT.

7. Verify the PBAs in the IP pools in the current VDOM:

```
(vdom1) # diagnose firewall ippool list pba
user 2001:db8:d0c:1::1, 172.16.164.164, 5181-5244, idx=1, use=66
user 2001:db8:d0c:1::1, 172.16.164.165, 5117-5180, idx=0, use=66
```

This output includes the client IP, NAT IP, NAT port range, port block index, and a kernel reference counter.

8. Verify the NAT IPs in use in the current VDOM:

```
(vdom1) # diagnose firewall ippool list nat-ip
NAT-IP 172.16.164.164, pba=1, use=3
NAT-IP 172.16.164.165, pba=1, use=3
```

This output includes the number of PBAs allocated for the NAT IP and the number of PBAs in use.

9. Verify the number of PBAs assigned to the user IP and the number of PBAs being used:

```
(vdom1) # diagnose firewall ippool list user
User-IP 2001:db8:d0c:1::1, pba=1, use=3
User-IP 2001:db8:d0c:1::1, pba=1, use=3
```

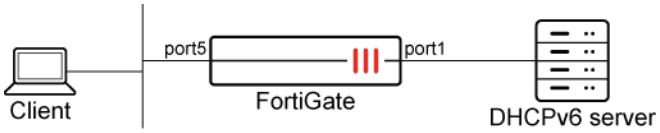
DHCPv6 relay

Similar to DHCPv4, DHCPv6 facilitates communication between networks by relaying queries and responses between a client and a DHCP server on separate networks. The FortiGate device serves as a DHCPv6 relay agent and forwards DHCPv6 messages between clients and servers. The relay agent receives DHCPv6 messages from clients and forwards them to the appropriate DHCPv6 server. In response, the server sends a message containing configuration information for the client, which the relay agent forwards to the client. This enables seamless information exchange between the two networks.

Configure DHCPv6 relay in the CLI using the following syntax:

```
config system interface
    edit <interface>
        config ipv6
            set dhcp6-relay-service {enable|disable}
            set dhcp6-relay-type regular
            set dhcp6-relay-ip <ip6-address>
        end
    next
end
```

In this example, a client connects to a FortiGate device that is configured to function as a DHCPv6 relay. Port1 on the FortiGate device connects to a DHCPv6 server, and port5 is configured as a DHCPv6 relay. The DHCPv6 server has an IP address of 2000:db8:d0c::a. This configuration enables the FortiGate device to facilitate communication between the client and the DHCPv6 server on separate networks.



To configure DHCPv6 relay on the FortiGate:

```
config system interface
    edit port5
        config ipv6
            set dhcp6-relay-service enable
            set dhcp6-relay-type regular
            set dhcp6-relay-ip 2000:db8:d0c::a
        end
    next
end
```

IPv6 tunneling

IPv6 tunneling involves tunneling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. This is different than NAT because once the packet reaches its final destination, the true originating address of the sender is still readable. The IPv6 packets are encapsulated within packets with IPv4 headers that carry their IPv6 payload through the IPv4 network. IPv6 tunneling is suitable in networks that have completely transitioned over to IPv6 but need an internet connection, which is still mostly IPv4 addresses.

Both IPv6 tunneling devices, whether they are a host or a network device, must be dual stack compatible. The tunneling process is as follows:

1. The tunnel entry node creates an encapsulating IPv4 header and transmits the encapsulated packet.
2. The tunnel exit node receives the encapsulated packet.
3. The IPv4 header is removed.
4. The IPv6 header is updated and the IPv6 packet is processed.

There are two types of tunnels in IPv6 tunneling, automatic and configured. Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address. The IPv6 address of the destination host includes information about which IPv4 address the packet should be tunneled to. Configured tunnels are manually configured, and they are used for IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the tunnel endpoints must be specified.

Tunnel configurations

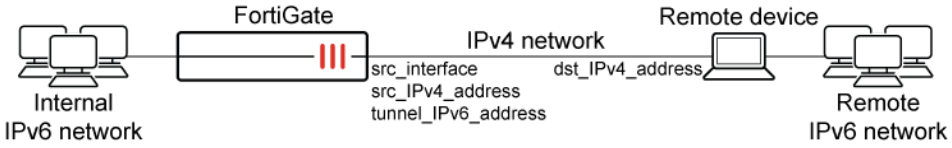
There are four tunneling configurations available depending on which segment of the path between the endpoints of the session the encapsulation takes place.

Type	Description
Network device-to-network device	Dual stack capable devices connected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. The tunnel spans one segment of the path taken by the IPv6 packets.
Host-to-network device	Dual stack capable hosts can tunnel IPv6 packets to an intermediary IPv6 or IPv4 network device that is reachable through an IPv4 infrastructure. The tunnel spans the first segment of the path taken by the IPv6 packets.
Host-to-host	Dual stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. The tunnel spans the entire path taken by the IPv6 packets.
Network device-to-host	Dual stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. The tunnel spans only the last segment of the path taken by the IPv6 packets.

Regardless of whether the tunnel starts at a host or a network device, the node that does the encapsulation needs to maintain soft state information, such as the maximum transmission unit (MTU), about each tunnel in order to process the IPv6 packets.

6in4 tunnel

The following tunnel configuration tunnels IPv6 traffic over an IPv4 network. An internal IPv6 interface can be configured under `config system interface`.



To configure an IPv6 tunnel over IPv4:

```
config system sit-tunnel
    edit <name>
        set source <src_IPv4_address>
        set destination <dst_IPv4_address>
        set interface <src_interface>
        set ip6 <tunnel_IPv6_address>
    next
end
```

4in6 tunnel

Conversely, the following tunnel configuration tunnels IPv4 traffic over an IPv6 network.

To configure an IPv4 tunnel over IPv6:

```
config system ipv6-tunnel
    edit <name>
        set source <src_IPv6_address>
        set destination <dst_IPv6_address>
        set interface <src_interface>
    next
end
```

The preceding configurations are not available in transparent mode.

This section includes:

- IPv6 IPsec VPN on page 784
- IPv6 GRE tunnels on page 786
- IPv6 tunnel inherits MTU based on physical interface on page 786
- Configuring IPv4 over IPv6 DS-Lite service on page 789

IPv6 IPsec VPN

This topic describes how to configure the IPv6 IPsec VPN feature on your FortiGate device.

You can configure IPv6 using the CLI. To configure IPv6 using GUI, ensure IPv6 is enabled by going to *System* > *Feature Visibility* and enabling IPv6.

Overview

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes different ways IPv6 IPsec can be used:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors. See Site-to-site IPv4 over IPv6 VPN example on page 815 for sample configuration.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors. See Site-to-site IPv6 over IPv4 VPN example on page 824 for sample configuration.
IPv6 over IPv6	Both the VPN gateways and the protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors. See Site-to-site IPv6 over IPv6 VPN example on page 806 for sample configuration.

Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN:

Phase 1 and Phase 2 settings	The configuration is the same as for an IPv4 route-based VPN, except that `ip-version` is set to `6` and the `remote-gw6` keyword is used to specify an IPv6 remote gateway address. See Phase 1 configuration on page 2370 and Phase 2 configuration on page 2396 for more information.
Security policies	To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network's port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6. See VPN security policies on page 2400 for more information.
Routing	Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them: • You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. • You need a route to the remote protected network via the IPsec interface. • You need a blackhole route to the remote protected network to ensure that IPsec traffic doesn't match the default route when the IPsec tunnel is down. Routing is dependent on the method: • **IPv4 over IPv6**: The route to the remote VPN gateway is an IPv6 route. The route to the remote protected network is an IPv4 route. • **IPv6 over IPv4**: The route to the remote VPN gateways is an IPv4 route. The route to the remote protected network is an IPv6 route. • **IPv6 over IPv6**: Routes to both the remote VPN gateway and the remote protected network are IPv6 routes. You can create a new IPv6 static route from *Network* > *Static Routes*.

You can configure Phase 1 and Phase 2 settings from *VPN* > *IPsec Wizard*.

To configure Phase 1 and phase 2 settings:

1. Go to *VPN* > *IPsec Wizard*.
2. Enter a name and set *Template type* to *Custom*.
3. Click *Next*.
4. Under *Network*, set *IP Version* to *IPv6* .
5. Configure the rest of phase 1 and phase 2 settings as required and click *OK*.

IPv6 GRE tunnels

IPv6 addresses can be used at both ends of a GRE tunnel in the same way as with IPv4. See GRE over IPsec on page 2446 for more information.

The configuration is similar to a tunnel for IPv4. However, when you configure the specific tunnel, you need to set the `ip-version` option to `6`. This will enable IPv6-specific options for the tunnel.

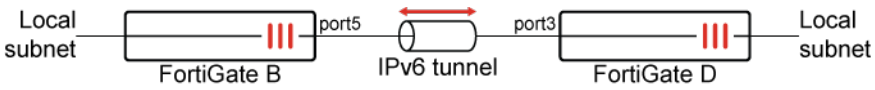
To configure a GRE tunnel:

```
config system gre-tunnel
    edit <name of tunnel>
        set ip-version 6
        set remote-gw6 <IPv6 address of the remote gateway>
        set local-gw6 <IPv6 address of the local gateway>
    next
end
```

IPv6 tunnel inherits MTU based on physical interface

The MTU of an IPv6 tunnel interface is calculated from the MTU of its parent interface minus headers.

Example



In this topology, FortiGate B and FortiGate D are connected over an IPv6 network. An IPv6 tunnel is formed, and IPv4 can be used over the IPv6 tunnel. The tunnel interface MTU is based on the physical interface MTU minus the IP and TCP headers (40 bytes). On FortiGate B's physical interface port5, the MTU is set to 1320. The IPv6 tunnel is based on port5, and its MTU value of 1280 is automatically calculated from the MTU value of its physical interface minus the header. The same is true for port3 on FortiGate D.

To verify the MTU for the IPv6 tunnel on FortiGate B:

1. Configure port5:

```
config system interface
    edit "port5"
        set vdom "root"
        set type physical
        set snmp-index 7
        config ipv6
            set ip6-address 2000:172:16:202::1/64
            set ip6-allowaccess ping
        end
        set mtu-override enable
        set mtu 1320
```

```
    next
end
```

2. Configure the IPv6 tunnel:

```
config system ipv6-tunnel
    edit "B_2_D"
        set source 2000:172:16:202::1
        set destination 2000:172:16:202::2
        set interface "port5"
    next
end
```

3. Configure the tunnel interface:

```
config system interface
    edit "B_2_D"
        set vdom "root"
        set ip 172.16.210.1 255.255.255.255
        set allowaccess ping https http
        set type tunnel
        set remote-ip 172.16.210.2 255.255.255.255
        set snmp-index 33
        config ipv6
            set ip6-address 2000:172:16:210::1/64
            set ip6-allowaccess ping
            config ip6-extra-addr
                edit fe80::2222/10
                next
            end
        end
        set interface "port5"
    next
end
```

4. Verify the interface lists:

```
# diagnose netlink interface list port5
if=port5 family=00 type=1 index=13 mtu=1320 link=0 master=0
ref=68 state=start present fw_flags=0 flags=up broadcast run multicast
Qdisc=mq hw_addr=**:**:**:**:**:** broadcast_addr=**:**:**:**:**:**

To verify the MTU for the IPv6 tunnel on FortiGate D:

1. Configure port3:

```
config system interface
    edit "port3"
        set vdom "root"
        set type physical
        set snmp-index 5
        config ipv6
            set ip6-address 2000:172:16:202::2/64
            set ip6-allowaccess ping
        end
        set mtu-override enable
        set mtu 1320
    next
end
```

2. Configure the IPv6 tunnel:

```
config system ipv6-tunnel
    edit "D_2_B"
        set source 2000:172:16:202::2
        set destination 2000:172:16:202::1
        set interface "port3"
    next
end
```

3. Configure the tunnel interface:

```
config system interface
    edit "D_2_B"
        set vdom "root"
        set ip 172.16.210.2 255.255.255.255
        set allowaccess ping https http
        set type tunnel
        set remote-ip 172.16.210.1 255.255.255.255
        set snmp-index 36
        config ipv6
            set ip6-address 2000:172:16:210::2/64
            set ip6-allowaccess ping
            config ip6-extra-addr
                edit fe80::4424/10
                next
            end
```

```
        end
        set interface "port3"
    next
end
```

4. Verify the interface lists:

```
# diagnose netlink interface list port3
```

```
# diagnose netlink interface list D_2_B
```

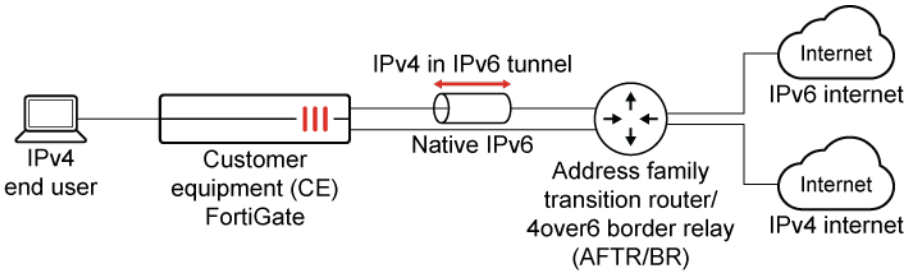
Configuring IPv4 over IPv6 DS-Lite service

IPv4 over IPv6 DS-Lite service can be configured on a virtual network enabler (VNE) tunnel. In addition, VNE tunnel fixed IP mode supports username and password authentication.

```
config system vne-tunnel
    set status enable
    set mode {map-e | fixed-ip | ds-lite}
    set ipv4-address <IPv4_address>
    set br <IPv6_address or FQDN>
    set http-username <string>
    set http-password <password>
end
```

`mode {map-e | fixed-ip | ds-lite}`	Set the VNE tunnel mode: • map-e: MAP-E • fixed-ip: fixed IP • ds-lite: DS-Lite
`ipv4-address <IPv4_address>`	Enter the tunnel IPv4 address and netmask. This setting is optional.
`br <IPv6_address or FQDN>`	Enter the IPv6 or FQDN of the border relay.
`http-username <string>`	Enter the HTTP authentication user name.
`http-password <password>`	Enter the HTTP authentication password.

DS-Lite allows applications using IPv4 to access the internet with IPv6. DS-Lite is supported by internet providers that do not have enough public IPv4 addresses for their customers, so DS-Lite is used for IPv6 internet connections. When a DS-Lite internet connections is used, the FortiGate encapsulates all data from IPv4 applications into IPv6 packets. The packets are then transmitted to the internet service provider using the IPv6 connection. Next, a dedicated server unpacks the IPv6 packets and forwards the IPv4 data to the actual destination on the internet.



DS-Lite example

In this example, DS-Lite VNE tunnel mode is used between the FortiGate and the BR.

To configure a DS-Lite tunnel between the FortiGate and the BR:

1. Configure the IPv6 interface:

```
config system interface
    edit "wan1"
        set vdom "root"
        set mode dhcp
        set allowaccess ping fgfm
        set type physical
        set role wan
        set snmp-index 1
        config ipv6
            set ip6-allowaccess ping
            set dhcp6-information-request enable
            set autoconf enable
            set unique-autoconf-addr enable
        end
    next
end
```

2. Configure the VNE tunnel:

```
config system vne-tunnel
    set status enable
    set interface "wan1"
    set ssl-certificate "Fortinet_Factory"
    set auto-asic-offload enable
    set ipv4-address 192.168.1.99 255.255.255.255
    set br "dgw.xxxxx.jp"
    set mode ds-lite
end
```

3. View the wan1 IPv6 configuration details:

```
config system interface
    edit "wan1"
        config ipv6
```

```
            get
                ip6-mode            : static
                nd-mode             : basic
                ip6-address         : 2001:f70:2880:xxxx:xxxx:xxxx:fe39:ccd2/64
                ip6-allowaccess     : ping
                icmp6-send-redirect : enable
                ra-send-mtu         : enable
                ip6-reachable-time  : 0
                ip6-retrans-time    : 0
                ip6-hop-limit       : 0
                dhcp6-information-request: enable
                cli-conn6-status    : 1
                vrrp-virtual-mac6   : disable
                vrip6_link_local    : ::
                ip6-dns-server-override: enable
                Acquired DNS1       : 2001:f70:2880:xxxx:xxxx:xxxx:fe40:9082
                Acquired DNS2       : ::
                ip6-extra-addr:
                ip6-send-adv        : disable
                autoconf            : enable
                prefix      : 2001:f70:2880:xxxx::/64
                preferred-life-time         : 942735360
                valid-life-time     : 1077411840
                unique-autoconf-addr: enable
                interface-identifier: ::
                dhcp6-relay-service : disable
        end
    next
end
```

4. Verify the IPv6 address list:

```
# diagnose ipv6 address list
dev=5 devname=wan1 flag= scope=0 prefix=64 addr=2001:f70:2880:xxxx:xxxx:xxxx:fe39:ccd2
preferred=11525 valid=13325 cstamp=6520 tstamp=6892
dev=5 devname=wan1 flag=P scope=253 prefix=64 addr=fe80::xxxx:xxxx:fe39:ccd2
preferred=4294967295 valid=4294967295 cstamp=6373 tstamp=6373
dev=18 devname=root flag=P scope=254 prefix=128 addr=::1 preferred=4294967295 valid=4294967295
cstamp=3531 tstamp=3531
dev=25 devname=vsys_ha flag=P scope=254 prefix=128 addr=::1 preferred=4294967295
valid=4294967295 cstamp=5604 tstamp=5604
dev=27 devname=vsys_fgfm flag=P scope=254 prefix=128 addr=::1 preferred=4294967295
valid=4294967295 cstamp=6377 tstamp=6377
```

5. Test the tunnel connection by pinging the Google public DNS IPv6 address:

```
# execute ping6 2001:4860:4860::8888
PING 2001:4860:4860::8888(2001:4860:4860::8888) 56 data bytes
64 bytes from 2001:4860:4860::8888: icmp_seq=1 ttl=114 time=6.89 ms
```

```
64 bytes from 2001:4860:4860::8888: icmp_seq=2 ttl=114 time=3.39 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=3 ttl=114 time=3.46 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=4 ttl=114 time=3.34 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=5 ttl=114 time=3.39 ms
--- 2001:4860:4860::8888 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss, time 4079ms
rtt min/avg/max/mdev = 3.340/4.097/6.895/1.400 ms
```

Fixed IP mode example

In this example, fixed IP VNE tunnel mode with HTTP authentication is used between the FortiGate and the BR.

To configure a fixed IP mode with HTTP authentication between the FortiGate and the BR:

1. Configure the IPv6 interface:

```
config system interface
    edit "wan1"
        set vdom "root"
        set mode dhcp
        set allowaccess ping fgfm
        set type physical
        set role wan
        set snmp-index 1
        config ipv6
            set ip6-allowaccess ping
            set dhcp6-information-request enable
            set autoconf enable
        end
    next
end
```

2. Configure the VNE tunnel:

```
config system vne-tunnel
    set status enable
    set interface "wan1"
    set ipv4-address 120.51.xxx.xxx1 255.255.255.255
    set br "2001:f60:xxxx:xxxx::1"
    set update-url "https://ddnsweb1.ddns.xxxxxx.jp/cgi-bin/ddns_
api.cgi?d=xxxxxx.v4v6.xxxxx.jp&p=**********&a=[IP6]&u=xxxxxx.v4v6.xxxxx.jp"
    set mode fixed-ip
    set http-username "laptop-1"
    set http-password **********
end
```

3. Verify the wan1 IPv6 configuration details:

```
config system interface
    edit "wan1"
        config ipv6
```

```
            get
                ....
```

4. Verify the VNE daemon:

```
# diagnose test application vned 1
------------------------------------------------------------------------
vdom: root/0, is master, devname=wan1 link=0 tun=vne.root mode=fixed-ip ssl_cert=Fortinet_
Factory
end user ipv6 perfix: 2001:f70:2880:xxxx::/64
interface ipv6 addr: 2001:f70:2880:xxxx:xxxx:xxxx:fe39:ccd2
config ipv4 perfix: 120.51.xxx.xxx1/255.255.255.255
config br: 2001:f60:xxxx:xxxx::1
HTTP username: laptop-1
update url: https://ddnsweb1.ddns.xxxxxx.jp/cgi-bin/ddns_

--- 2001:4860:4860::8888 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss, time 4039ms
rtt min/avg/max/mdev = 3.276/4.195/6.992/1.409 ms
```

IPv6 Simple Network Management Protocol

Simple Network Management Protocol (SNMP) in IPv6 is similar to IPv4, with the main difference being the address format. Despite this, SNMP's principles and functionalities, including network management, device monitoring, and performance information gathering, remain consistent across both versions. See SNMP on page 3533 for more information.

SNMP for monitoring interface status example

In this example, SNMP manager (2001:db8:d0c:2::1) is configured to receive notifications when a FortiGate port either goes down or is brought up. Additionally, the SNMP manager has the capability to query the current status of the FortiGate port.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

To configure SNMP for monitoring interface status in the GUI:

1. Configure the Interface access:
   a. Go to *Network* > *Interfaces* and edit *port1*.
   b. In the *Administrative Access* options, enable *SNMP* under *IPv6*.
   c. Click *OK*.
2. Configure the SNMP agent:
   a. Go to *System* > *SNMP*.
   b. Enable *SNMP Agent*.
   c. Configure the following fields:

Description	Branch
Location	Burnaby
Contact Info	Jane Doe

   d. Click *Apply*.
3. Configure an SNMP v3 user:

a. Go to *System* > *SNMP*.
b. In the *SNMP v3* table, click *Create New*.
c. Configure the following fields:

User Name	Interface_Status
Security Level	Authentication
Authentication Algorithm	SHA1
Password	*******
IPv6 Hosts > IP Address	2001:db8:d0c:2::1

d. Click *OK*.
e. Click *Apply*.

To configure SNMP for monitoring interface status in the CLI:

1. Configure the Interface access:

```
config system interface
    edit port1
        config ipv6
            append ip6-allowaccess snmp
        end
    next
end
```

2. Configure the SNMP agent:

```
config system snmp sysinfo
    set status enable
    set description Branch
    set contact-info "Jane Doe"
    set location Burnaby
end
```

3. Configure an SNMP v3 user:

```
config system snmp user
    edit "Interface_Status"
        set notify-hosts6 2001:db8:d0c:2::1
        set security-level auth-no-priv
        set auth-proto sha
        set auth-pwd ********************
    next
end
```

Verification

To verify the SNMP configuration:

1. Start the packet capture on interface port1 with the filter set to port 162. See Using the packet capture tool on page 884 for more information.
2. Turn off one of the FortiGate interface statuses to down; in this case, port2.
3. Save the packet capture.

```
> Internet Protocol Version 6, Src: 2001:db8:d0c:2::f, Dst: 2001:db8:d0c:2::1

        v snmpV2-trap
            request-id: 753
            error-status: noError (0)
            error-index: 0
          v variable-bindings: 9 items
            > 1.3.6.1.2.1.1.3.0: 18925675
            > 1.3.6.1.6.3.1.1.4.1.0: 1.3.6.1.6.3.1.1.5.3 (iso.3.6.1.6.3.1.1.5.3)
            > 1.3.6.1.2.1.2.2.1.1.2: 2
            > 1.3.6.1.2.1.2.2.1.7.2: 1
            > 1.3.6.1.2.1.2.2.1.8.2: 2
            > 1.3.6.1.4.1.12356.100.1.1.1.0: "FGVM08TM22004645"
            > 1.3.6.1.2.1.1.5.0: "Root"
            > 1.3.6.1.2.1.31.1.1.1.1.2: "port2"
            > 1.3.6.1.2.1.2.2.1.2.2: <MISSING>
```

   The SNMP v3 trap is observed to be transmitted from port1 to the SNMP manager. It's also noteworthy that the *msgAuthenticationParameters* are configured, signifying that authentication is active. However, the absence of *msgPrivacyParameters* suggests that encryption is not in place, a fact further corroborated by the plaintext nature of the *msgData*.
4. Verify that the SNMP manager has received the trap. See Important SNMP traps on page 3539 for an example of a trap.
5. Verify that the SNMP manager can successfully query and receive a response on the current status of the FortiGate ports.

```

```

Dynamic routing in IPv6

The principles that govern dynamic routing in IPv6 are fundamentally the same as those in IPv4. However, it's crucial to understand that while IPv6 operates similarly to IPv4 in terms of routing, it utilizes a distinct routing table and process.

When a router receives a packet, the routing scheme of the packet determines how the traffic will be routed. If the packet is using the IPv4 scheme, the router will refer to the IPv4 routing table to determine the best path for the packet. This table contains all the necessary information about network paths within the IPv4 framework. See Dynamic routing on page 497 for more information.

Conversely, if the router receives a packet with an IPv6 address, it will consult the IPv6 routing table. This separate table contains all the relevant information for routing within the IPv6 framework.

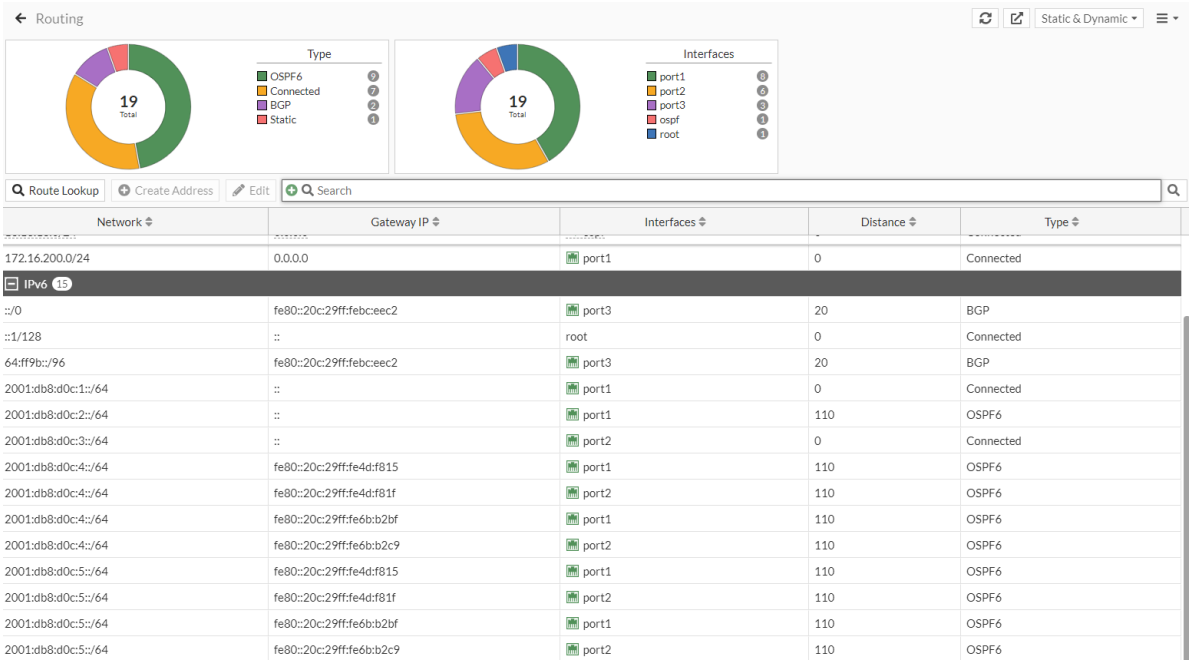
In essence, while both IPv4 and IPv6 use similar methods for routing packets, they each have their own dedicated processes and tables to ensure efficient and accurate routing.

Go to *System* > *Feature Visibility* and enable *Advanced Routing* to configure dynamic routing options in the GUI. See Feature visibility on page 3595 for more information.

This section includes:

- OSPFv3 and IPv6 on page 798
- BGP and IPv6 on page 799

To view the routing table and perform route look-ups in the GUI, go to *Dashboard* > *Network* and expand the *Routing* widget.



To view the routing table in the CLI:

```
# get router info6 routing-table
IPv6 Routing Table
Codes: K - kernel route, C - connected, S - static, R - RIP, O - OSPF,
       IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, B - BGP, V - BGP VPNv6
       * - candidate default

Timers: Uptime

Routing table for VRF=0
B*      ::/0 [20/0] via fe80::20c:29ff:febc:eec2, port3, 02:45:56, [1024/0]
C       ::1/128 via ::, root, 03:45:04
B       64:ff9b::/96 [20/0] via fe80::20c:29ff:febc:eec2, port3, 02:45:56, [1024/0]
C       2001:db8:d0c:1::/64 via ::, port1, 00:33:21
O       2001:db8:d0c:2::/64 [110/2] via fe80::20c:29ff:fe4d:f81f, port1, 00:33:04, [1024/0]
                            [110/2] via fe80::20c:29ff:fe6b:b2c9, port2, 00:33:04, [1024/0]
C       2001:db8:d0c:3::/64 via ::, port2, 03:45:04
O       2001:db8:d0c:4::/64 [110/2] via fe80::20c:29ff:fe4d:f81f, port1, 00:33:04, [1024/0]
O       2001:db8:d0c:5::/64 [110/2] via fe80::20c:29ff:fe6b:b2c9, port2, 02:51:32, [1024/0]
C       2001:db8:d0c:6::/64 via ::, port3, 03:45:04
```

OSPFv3 and IPv6

OSPF version 3 (OSPFv3) includes support for IPv6 and can only be configured via the CLI. Unlike its predecessor, OSPFv2, which uses IPv4, OSPFv3 utilizes IPv6 addresses. However, the area numbers in OSPFv3

still adhere to the 32-bit numbering system of OSPFv2, as described in RFC 2740. Likewise, the router ID and area ID are in the same format as OSPFv2. See OSPF on page 520 for more information.

For IPv6, the main difference in OSPFv3 is that rather than using a network statement to enable OSPFv3 on an interface, you define OSPF6 (OSPF for IPv6) interfaces, which are bound to the interface and area. This configuration must be done in the CLI, as follows:

```
config router ospf6
    set router-id <id>
    config area
        edit <id>
        next
    end
    config ospf6-interface
        edit <name>
            set interface <string>
            set area-id <id>
        next
    end
end
```

Note that OSPFv3 neighbors use link-local IPv6 addresses, but with broadcast and point-to-point network types, and neighbors are automatically discovered. You only have to manually configure neighbors when using non-broadcast network types.

See Basic OSPFv3 example on page 833 for a sample configuration.

BGP and IPv6

Border Gateway Protocol (BGP) is a standardized routing protocol that is used to route traffic across the internet. See BGP on page 538 for more information.

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config network6` or `set allowas-in6`.

See config router bgp for a comprehensive list of commands.

See Basic IPv6 BGP example on page 841 for a sample configuration.

IPv6 configuration examples

The following topics provide instructions on different IPv6 configuration examples:

- IPv6 quick start example on page 800
- Site-to-site IPv6 over IPv6 VPN example on page 806
- Site-to-site IPv4 over IPv6 VPN example on page 815
- Site-to-site IPv6 over IPv4 VPN example on page 824
- Basic OSPFv3 example on page 833

- Basic IPv6 BGP example on page 841
- NPTv6 protocol for IPv6 address translation example on page 844
- Enhancing SIP reliability in 464XLAT environments on page 848

IPv6 quick start example

In this example, a host belonging to a specific range on the internal IPv6 network can communicate exclusively with the web server and FTP server.

Additionally, all internal clients can access the Internet.

Prerequisites

Before you begin to configure IPv6, go through the following steps:

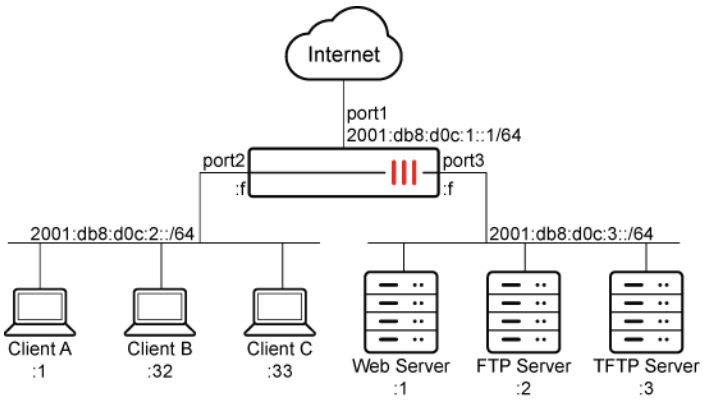
1. Obtain an IPv6 /48 global routing prefix, commonly known as a site prefix. To procure a 48-bit IPv6 site prefix for your organization simply liaise with your ISP.
2. Design a subnetting plan for your organization's IPv6 network using a 16-bit subnet ID, allowing for up to 65 535 subnets. The specific scheme will depend on the network's size, structure, and the organization's needs.

At this stage, the following installation and configuration conditions are assumed:

- You have administrative access to the GUI or CLI.
- The FortiGate unit is incorporated into your WAN or other networks, but for simplicity, only the standalone ForiGate configuration is displayed.

Topology

The following topology is used for this example:



- The company is assigned the site prefix of 2001:db8:d0c::/48 by their ISP.
- The IPv6 address for the Web Server is 2001:db8:d0c:3::1/64.
- The IPv6 address for the FTP Server is 2001:db8:d0c:3::2/64.
- The IPv6 address for the TFTP Server is 2001:db8:d0c:3::3/64.
- The range on the internal IPv6 network that can access both servers is from 2001:db8:d0c:2::1 to 2001:db8:d0c:2::32.

- The IPv6 address of port1 is 2001:db8:d0c:1::1/64.
- The IPv6 address of port2 is 2001:db8:d0c:2::f/64.
- The IPv6 address of port3 is 2001:db8:d0c:3::f/64.
- The IPv6 address of the default gateway is 2001:db8:d0c:1::f/64.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

To configure the example in the GUI:

1. Configure the IPv6 address on port1, port2 and port3:
   a. Go to *Network* > *Interfaces* and edit port1.
   b. For *IPv6 addressing Mode*, select manual and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::1/64

   c. Click *OK*.
   d. Repeat steps a and b for port2.

IPv6 Address/Prefix	2001:db8:d0c:2::f/64

   e. Repeat steps a and b for port3.

IPv6 Address/Prefix	2001:db8:d0c:3::f/64

2. Configure the default route:
   a. Go to *Network* > *Static Routes*.
   b. Click *Create New* > *IPv6 Static Route*.
   c. Configure the following settings:

Destination	::/0
Gateway Address	2001:db8:d0c:1::f
Interface	port1

   d. Select *OK*.
3. Configure the IPv6 firewall address for the Web Server:
   a. Go to *Policy & Objects* > *Addresses* and select *IPv6 Address*.
   b. Select *Create new*.
   c. Fill out the fields with the following information:

Name	Web_Server
Type	IPv6 Subnet
IPv6 Address	2001:db8:d0c:3::1/128

   d. Select *OK*.

4. Configure the IPv6 firewall address for the FTP Server:
   a. Go to *Policy & Objects > Addresses* and select *IPv6 Address*.
   b. Select *Create new*.
   c. Fill out the fields with the following information:

Name	FTP_Server
Type	IPv6 Subnet
IPv6 Address	2001:db8:d0c:3::2/128

   d. Select *OK*.
5. Configure the IPv6 address group, which includes both the Web and FTP servers:
   a. Go to *Policy & Objects > Addresses* and select *IPv6 Address Group*.
   b. Fill out the fields with the following information:

Group name	Custom_Server
Members	Web_Server, FTP_Server

   c. Select *OK*.
6. Configure the IPv6 firewall address for the Internal IPv6 network range which can access both the Web and FTP server:
   a. Go to *Policy & Objects > Addresses* and select *IPv6 Address*.
   b. Select *Create new*.
   c. Fill out the fields with the following information:

Name	Internal_Custom_Range
Type	IPv6 Range
IP Range	2001:db8:d0c:2::1 - 2001:db8:d0c:2::32

   d. Select *OK*.
7. Configure the IPv6 firewall policy to allow IPv6 traffic from *Internal_Custom_Range* to *Custom_Server*:
   a. Go to *Policy & Objects > Firewall Policy*.
   b. Click *Create New*.
   c. Name the policy and configure the following parameters:

Incoming Interface	port2
Outgoing Interface	port3
Source	Internal_Custom_Range
Destination	Custom_Server
Schedule	always
Service	FTP, HTTPS
Action	ACCEPT

   d. Click *OK*.

8. Configure the IPv6 firewall policy to allow IPv6 traffic from internal clients to the Internet:
   a. Go to *Policy & Objects* > *Firewall Policy*.
   b. Click *Create New*.
   c. Name the policy and configure the following parameters:

Incoming Interface	port2
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   d. Click *OK*.

To configure the example in the CLI:

1. Configure the IPv6 address on port1, port2, and port3:

```
config system interface
    edit "port1"
        config ipv6
            set ip6-address 2001:db8:d0c:1::1/64
        end
    next
    edit "port2"
        config ipv6
            set ip6-address 2001:db8:d0c:2::f/64
        end
    next
    edit "port3"
        config ipv6
            set ip6-address 2001:db8:d0c:3::f/64
        end
    next
end
```

2. Configure the default route:

```
config router static6
    edit 0
        set gateway 2001:db8:d0c:1::f
        set device "port1"
    next
end
```

3. Configure the IPv6 firewall address for the Web Server:

```
config firewall address6
    edit "Web_Server"
        set ip6 2001:db8:d0c:3::1/128
    next
end
```

4. Configure the IPv6 firewall address for the FTP Server:

```
config firewall address6
    edit "FTP_Server"
        set ip6 2001:db8:d0c:3::2/128
    next
end
```

5. Configure the IPv6 address group, which includes for the Web and FTP Servers:

```
config firewall addrgrp6
    edit "Custom_Server"
        set member "FTP_Server" "Web_Server"
    next
end
```

6. Configure the IPv6 firewall address for the Internal IPv6 network range which can access both the Web and FTP Server:

```
config firewall address6
    edit "Internal_Custom_Range"
        set type iprange
        set start-ip 2001:db8:d0c:2::1
        set end-ip 2001:db8:d0c:2::32
    next
end
```

7. Configure the IPv6 firewall policy to allow IPv6 traffic from *Internal_Custom_Range* to *Custom_Server*:

```
config firewall policy
    edit 1
        set name "IPv6_internal_to_server"
        set srcintf "port2"
        set dstintf "port3"
        set action accept
        set srcaddr6 "Internal_Custom_Range"
        set dstaddr6 "Custom_Server"
        set schedule "always"
        set service "FTP" "HTTPS"
        set utm-status enable
        set logtraffic all
    next
end
```

8. Configure the IPv6 firewall policy to allow IPv6 traffic from Internal clients to the Internet:

```
config firewall policy
    edit 1
        set name "IPv6_internal_to_internet"
        set srcintf "port2"
        set dstintf "port1"
        set action accept
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set logtraffic all
    next
end
```

Verification

The following commands can be used to verify that IPv6 traffic is entering and leaving the FortiGate as expected. See Debugging the packet flow on page 4327 for more information.

```
diagnose debug enable
diagnose debug flow trace start6 200
```

The output below indicates that hosts belonging to the *Internal_Custom_Range* can successfully reach both the *Web_Server* and *FTP_Server* defined in the *Custom_Server* address group.

However, they are unable to reach the TFTP server, as it is not included in the *Custom_Server* group. Furthermore, hosts with IPv6 addresses that do not belong to the *Internal_Custom_Range* are not able to access *Custom_Server*.

Host belonging to *Internal_Custom_Range* accessing *Web_Server*:

```
id=65308 trace_id=21 func=resolve_ip6_tuple_fast line=4962 msg="vd-root:0 received a packet

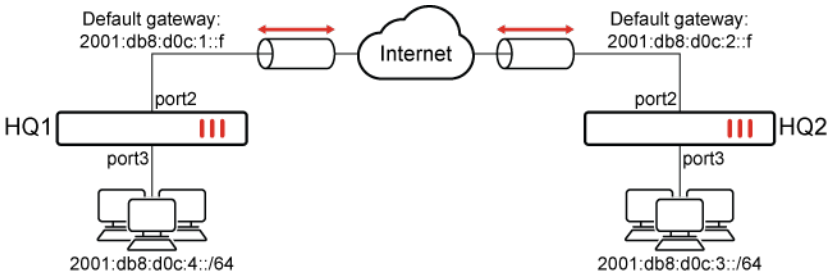
Site-to-site IPv6 over IPv6 VPN example

In this example, clients on IPv6-addressed networks communicate securely over public IPv6 infrastructure.

The following topology is used for this example:



- Port2 connects to the public network and port3 connects to the local network.
- The IPv6 address for HQ1 port2 and port3 is 2001:db8:d0c:1::e and 2001:db8:d0c:4::e, respectively.
- The IPv6 address for HQ2 port2 and port3 is 2001:db8:d0c:2::e and 2001:db8:d0c:3::e, respectively.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

To configure the example in the GUI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv6 address on port2 and port3:
      i. Go to *Network* > *Interfaces* and edit port2.
      ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::e/64

      iii. Click *OK*.
      iv. Repeat these steps for port3.

IPv6 Address/Prefix	2001:db8:d0c:4::e/64

   b. Configure IPsec settings:
      i. Go to *VPN* > *IPsec Wizard* and enter a VPN name.
      ii. Set *Template type* to *Custom*.
      iii. Click *Next*.
      iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:2::e
Interface	port2

      v. Configure the following *Authentication* settings:

Method	Pre-shared Key

Pre-shared Key	sample

vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:
   i. Go to *Policy & Objects > Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.
d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
   i. Go to *Policy & Objects > Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.
e. Configure the static routes:
   i. Go to *Network > Static Routes*.
   ii. Click *Create New > IPv6 Static Route*.
   iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	::/0

Gateway Address	2001:db8:d0c:1::f
Interface	port2

iv. Select *OK*.

v. Repeat the first two steps and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:3::/64
Interface	to_HQ2

vi. Select *OK*.

vii. Repeat the first two steps and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:3::/64
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

2. Configure the HQ2 FortiGate:
   a. Configure the IPv6 address on port2 and port3:
      i. Go to *Network > Interfaces* and edit port2.
      ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:2::e/64

      iii. Click *OK*.
      iv. Repeat these steps for port3.

IPv6 Address/Prefix	2001:db8:d0c:3::e/64

   b. Configure IPsec settings:
      i. Go to *VPN > IPsec Wizard* and enter a VPN name.
      ii. Set *Template type* to *Custom*.
      iii. Click *Next*.
      iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:1::e
Interface	port2

      v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:
   i. Go to *Policy & Objects > Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.
d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
   i. Go to *Policy & Objects > Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.
e. Configure the static routes:
   i. Go to *Network > Static Routes*.
   ii. Click *Create New > IPv6 Static Route*.
   iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	::/0
Gateway Address	2001:db8:d0c:2::f
Interface	port2

iv. Select *OK*.

v. Repeat the first two steps and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:4::/64
Interface	to_HQ1

vi. Select *OK*.

vii. Repeat the first two steps and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:4::/64
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:1::e/64
        end
    next
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:4::e/64
        end
    next
end
```

   b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ2"
        set interface port2
        set ip-version 6
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:2::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ2"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
```

```
aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end
```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ2"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
        set gateway 2001:db8:d0c:1::f
        set device "port2"
    next
    edit 2
        set dst 2001:db8:d0c:3::/64
        set device "to_HQ2"
    next
    edit 3
        set dst 2001:db8:d0c:3::/64
        set blackhole enable
        set distance 254
    next
end
```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:2::e/64
        end
    next
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:3::e/64
        end
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ1"
        set interface port2
        set ip-version 6
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:1::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end
```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ1"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ1"
        set dstintf "port3"
```

```
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
        set gateway 2001:db8:d0c:2::f
        set device "port2"
    next
    edit 2
        set dst 2001:db8:d0c:4::/64
        set device "to_HQ1"
    next
    edit 3
        set dst 2001:db8:d0c:4::/64
        set blackhole enable
        set distance 254
    next
end
```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```
vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 2001:db8:d0c:1::e:500 -> 2001:db8:d0c:2::e:500
tun_id: 10.0.0.1/::10.0.0.1
remote_location: 0.0.0.0
network-id: 0

```

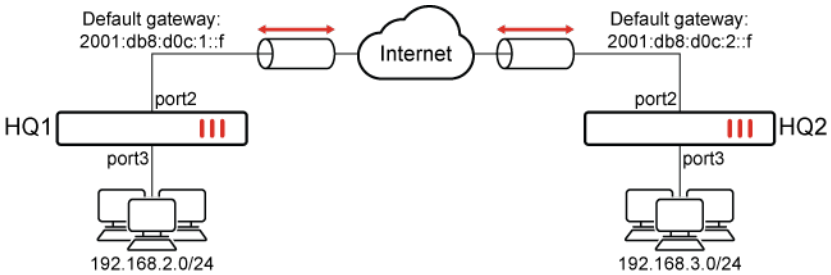
Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

The following topology is used for this example:



- Port2 connects to the IPv6 public network and port3 connects to the IPv4 local network.
- HQ1 port2 IPv6 address is 2001:db8:d0c:1::e and port3 IPv4 address is 192.168.2.1.
- HQ2 port2 IPv6 address is 2001:db8:d0c:2::e and port3 IPv4 address is 192.168.3.1.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

To configure the example in the GUI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv6 address on port2 and IPv4 address on port3:
      i. Go to *Network* > *Interfaces* and edit port2.
      ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::e/64

      iii. Click *OK*.
      iv. Go to *Network* > *Interfaces* and edit port3.
      v. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	192.168.2.1/24

   b. Configure IPsec settings:
      i. Go to *VPN* > *IPsec Wizard* and enter a VPN name.
      ii. Set *Template type* to *Custom*.
      iii. Click *Next*.
      iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:2::e
Interface	port2

      v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

      vi. Configure the following *New Phase 2* settings:

Local Address	addr_subnet
Remote Address	addr_subnet

   c. Configure the IPv4 firewall policy to allow IPv4 traffic from port3 to the IPsec interface:
      i. Go to *Policy & Objects* > *Firewall Policy*.
      ii. Click *Create New*.
      iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

d. Configure the IPv4 firewall policy to allow IPv4 traffic from the IPsec interface to port3:
   i. Go to *Policy & Objects > Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.

e. Configure the static routes:
   i. Go to *Network > Static Routes*.
   ii. Click *Create New > IPv6 Static Route*.
   iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	2001:db8:d0c:1::f
Interface	port2

   iv. Select *OK*.
   v. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the route to the remote protected network:

Destination	192.168.3.0/24
Interface	to_HQ2

   vi. Select *OK*.

vii. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the blackhole route:

Destination	192.168.3.0/24
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

2. Configure the HQ2 FortiGate:
   a. Configure the IPv6 address on port2 and IPv4 address on port3:
      i. Go to *Network > Interfaces* and edit port2.
      ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:2::e/64

      iii. Click *OK*.
      iv. Go to *Network > Interfaces* and edit port3.
      v. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	192.168.3.1/24

   b. Configure IPsec settings:
      i. Go to *VPN > IPsec Wizard* and enter a VPN name.
      ii. Set *Template type* to *Custom*.
      iii. Click *Next*.
      iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:1::e
Interface	port2

      v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

      vi. Configure the following *New Phase 2* settings:

Local Address	addr_subnet
Remote Address	addr_subnet

   c. Configure the IPv4 firewall policy to allow IPv4 traffic from port3 to the IPsec interface:
      i. Go to *Policy & Objects > Firewall Policy*.
      ii. Click *Create New*.
      iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

d. Configure the IPv4 firewall policy to allow IPv4 traffic from the IPsec interface to port3:
   i. Go to *Policy & Objects > Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.

e. Configure the static routes:
   i. Go to *Network > Static Routes*.
   ii. Click *Create New > IPv6 Static Route*.
   iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	2001:db8:d0c:2::f
Interface	port2

   iv. Select *OK*.
   v. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the route to the remote protected network:

Destination	192.168.2.0/24
Interface	to_HQ1

   vi. Select *OK*.

vii. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the blackhole route:

Destination	192.168.2.0/24
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv6 address on port2 and IPv4 address on port3:

```
config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:1::e/64
        end
    next
    edit port3
        set ip 192.168.2.1/24
    next
end
```

   b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ2"
        set interface port2
        set ip-version 6
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:2::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ2"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet
        set dst-addr-type subnet
    next
end
```

   c. Configure the IPv4 firewall policy to allow IPv4 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
```

```
        set srcintf "port3"
        set dstintf "to_HQ2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
        set gateway 2001:db8:d0c:1::f
        set device "port2"
    next
end
config router static
    edit 1
        set dst 192.168.3.0 255.255.255.0
        set device "to_HQ2"
    next
    edit 2
        set dst 192.168.3.0 255.255.255.0
        set device blackhole
        set distance 254
    next
end
```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and IPv4 address on port3:

```
config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:2::e/64
        end
    next
    edit port3
        set ip 192.168.3.1/24
```

```
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ1"
        set interface port2
        set ip-version 6
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:1::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet
        set dst-addr-type subnet
    next
end
```

c. Configure the IPv4 firewall policy to allow IPv4 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ1"
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
        set gateway 2001:db8:d0c:2::f
        set device "port2"
    next
end
config router static
    edit 1
        set dst 192.168.2.0 255.255.255.0
        set device "to_HQ1"
    next
    edit 2
        set dst 192.168.2.0 255.255.255.0
        set device blackhole
        set distance 254
    next
end
```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```
vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 2001:db8:d0c:1::e:500 -> 2001:db8:d0c:2::e:500
tun_id: 10.0.0.1/::10.0.0.1
remote_location: 0.0.0.0
network-id: 0
created: 7215s ago
peer-id: 2001:db8:d0c:2::e
peer-id-auth: no
IKE SA: created 1/1  established 1/1  time 0/0/0 ms
IPsec SA: created 1/2  established 1/2  time 0/5/10 ms

  id/spi: 160 8d7231820bb5ffd9/6c840a4c11b57927
  direction: initiator
  status: established 7215-7215s ago = 0ms
  proposal: aes128-sha256
  key: 32d8521a77d98529-5fe4b67914d30f87
  lifetime/rekey: 86400/78884
  DPD sent/recv: 00000007/00000003
  peer-id: 2001:db8:d0c:2::e
```

2. Run the `diagnose vpn tunnel list` command on HQ1. The system should return the following:

```
list all ipsec tunnel in vd 0
-----------------------------------------------------
name=to_HQ2 ver=1 serial=1 2001:db8:d0c:1::e:0->2001:db8:d0c:2::e:0 tun_id=10.0.0.1 tun_

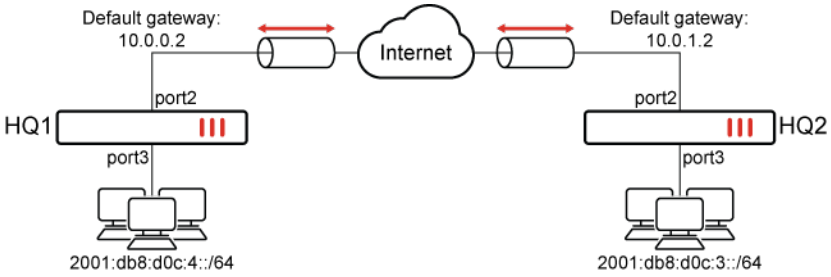
Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed networks communicate securely over IPv4 public infrastructure.

The following topology is used for this example:



- Port2 connects to the IPv4 public network and port3 connects to the IPv6 local network.
- HQ1 port2 IPv4 address is 10.0.0.1 and port3 IPv6 address is 2001:db8:d0c:4::e.
- HQ2 port2 IPv4 address is 10.0.1.1 and port3 IPv6 address is 2001:db8:d0c:3::e.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

To configure the example in the GUI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv4 address on port2 and IPv6 address on port3:
      i. Go to *Network* > *Interfaces* and edit port2.
      ii. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	10.0.0.1/24

      iii. Click *OK*.
      iv. Go to *Network* > *Interfaces* and edit port3.
      v. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:4::e/64

   b. Configure IPsec settings:
      i. Go to *VPN* > *IPsec Wizard* and enter a VPN name.
      ii. Set *Template type* to *Custom*.
      iii. Click *Next*.
      iv. Configure the following *Network* settings:

IP Version	IPv4
Remote Gateway	Static IP Address
IP Address	10.0.1.1
Interface	port2

      v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

      vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

   c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:
      i. Go to *Policy & Objects* > *Firewall Policy*.
      ii. Click *Create New*.
      iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all

Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
   i. Go to *Policy & Objects > Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.

e. Configure the static routes:
   i. Go to *Network > Static Routes*.
   ii. Click *Create New > IPv4 Static Route*.
   iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	10.0.0.2
Interface	port2

   iv. Select *OK*.
   v. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:3::/64
Interface	to_HQ2

   vi. Select *OK*.
   vii. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:3::/64
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

2. Configure the HQ2 FortiGate:
   a. Configure the IPv4 address on port2 and IPv6 address on port3:
      i. Go to *Network* > *Interfaces* and edit port2.
      ii. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	10.0.1.1/24

      iii. Click *OK*.
      iv. Go to *Network* > *Interfaces* and edit port3.
      v. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:3::e/64

   b. Configure IPsec settings:
      i. Go to *VPN* > *IPsec Wizard* and enter a VPN name.
      ii. Set *Template type* to *Custom*.
      iii. Click *Next*.
      iv. Configure the following *Network* settings:

IP Version	IPv4
Remote Gateway	Static IP Address
IP Address	10.0.0.1
Interface	port2

      v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

      vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

   c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:
      i. Go to *Policy & Objects* > *Firewall Policy*.
      ii. Click *Create New*.
      iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all

Schedule	always
Service	ALL
Action	ACCEPT

iv. Click *OK*.

d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
   i. Go to *Policy & Objects > Firewall Policy*.
   ii. Click *Create New*.
   iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

   iv. Click *OK*.

e. Configure the static routes:
   i. Go to *Network > Static Routes*.
   ii. Click *Create New > IPv4 Static Route*.
   iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	10.0.1.2
Interface	port2

   iv. Select *OK*.
   v. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:4::/64
Interface	to_HQ1

   vi. Select *OK*.
   vii. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:4::/64
Interface	Blackhole
Administrative Distance	254

viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.
   a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        set ip 10.0.0.1/24
    next
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:4::e/64
        end
    next
end
```

   b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ2"
        set interface port2
        set ip-version 4
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw 10.0.1.1
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ2"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end
```

   c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ2"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
```

```
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static
    edit 1
        set gateway 10.0.0.2
        set device "port2"
    next
end
config router static6
    edit 1
        set dst 2001:db8:d0c:3::/64
        set device "to_HQ2"
    next
    edit 2
        set dst 2001:db8:d0c:3::/64
        set device blackhole
        set distance 254
    next
end
```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        set ip 10.0.1.1/24
    next
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:3::e/64
        end
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ1"
        set interface port2
```

```
        set ip-version 4
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw 10.0.0.1
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end
```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ1"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ1"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static
    edit 1
        set gateway 10.0.1.2
        set device "port2"
    next
end
config router static6
    edit 1
        set dst 2001:db8:d0c:4::/64
```

```
        set device "to_HQ1"
    next
    edit 2
        set dst 2001:db8:d0c:4::/64
        set device blackhole
        set distance 254
    next
end
```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```
vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 10.0.0.1:500 -> 10.0.0.2:500
tun_id: 10.0.0.2/::10.0.0.2
remote_location: 0.0.0.0
network-id: 0
created: 576319s ago
peer-id: 10.0.0.2
peer-id-auth: no
IKE SA: created 1/8  established 1/8  time 0/1127/9000 ms
IPsec SA: created 1/7  established 1/7  time 0/5/10 ms

  id/spi: 8 c04ab0ead989f579/267813e164d4ec22
  direction: initiator
  status: established 59710-59710s ago = 0ms
  proposal: aes128-sha256
  key: 034a0c3bf3deb551-8d647af9b6f76578
  lifetime/rekey: 86400/26389
  DPD sent/recv: 00000044/00000047
  peer-id: 10.0.0.2
```

2. Run the `diagnose vpn tunnel list` command on HQ1. The system should return the following:

```
list all ipsec tunnel in vd 0
------------------------------------------------------

```

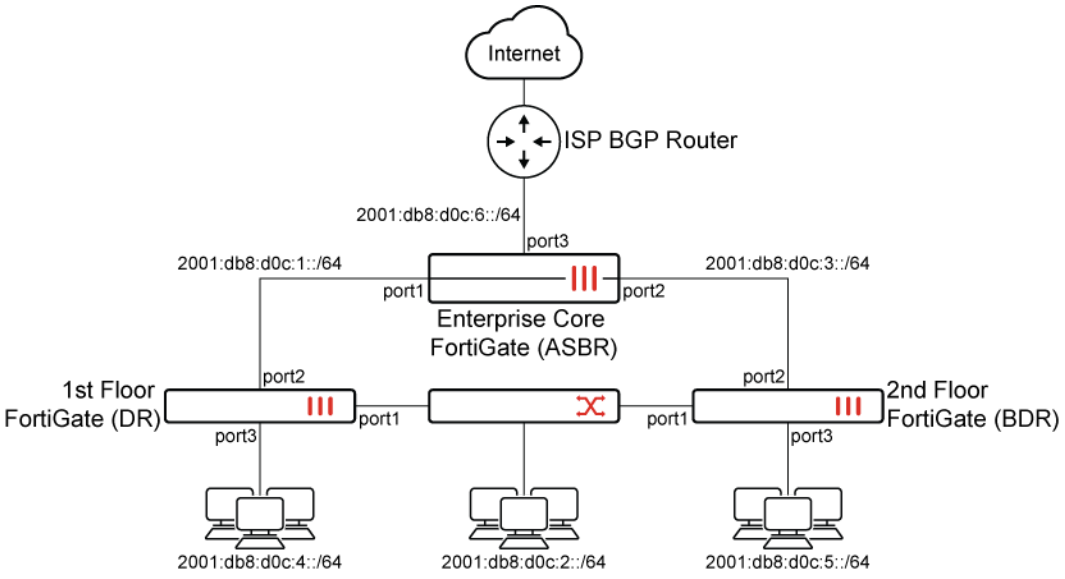
Basic OSPFv3 example

In this example, three FortiGate devices are configured in an OSPF network.

- 1st Floor FortiGate is the Designated Router (DR). It has the highest priority and the lowest IP address, to ensure that it becomes the DR.
- 2nd Floor FortiGate is the Backup Designated Router (BDR). It has a high priority to ensure that it becomes the BDR.
- Enterprise Core FortiGate is the Autonomous System Border Router (ASBR). It routes all traffic to the ISP BGP router for internet access. It redistributes routes from BGP and advertises a default route to its neighbors. It can allow different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics can be assigned to these routes to make them more or less preferred than regular OSPF routes. Route maps could be used to further control what prefixes are advertised or received from the ISP.



Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

FortiGate	Interface	IP address
1st Floor FortiGate (DR)	loopback	1.1.1.1
	port1	2001:db8:d0c:2::1/64
	port2	2001:db8:d0c:1::2/64
	port3	2001:db8:d0c:4::1/64
2nd Floor FortiGate (BDR)	loopback	2.2.2.2
	port1	2001:db8:d0c:2::2/64
	port2	2001:db8:d0c:3::2/64
	port3	2001:db8:d0c:5::1/64
Enterprise Core FortiGate (ASBR)	loopback	13.13.13.13
	port1	2001:db8:d0c:1::1/64
	port2	2001:db8:d0c:3::1/64
	port3	2001:db8:d0c:6::1/64

- Firewall policies are already configured to allow unfiltered traffic in both directions between all of the connected interfaces.
- The interfaces are already configured. The cost for all of the interfaces is left at 0.
- The OSPF network belongs to Area 0, and is not connected to any other OSPF networks. All of the routers are part of the backbone 0.0.0.0 area, so no inter-area communications are needed.
- Enterprise Core FortiGate redistributes BGP routes into the OSPF AS and peers with the ISP BGP Router over eBGP. For information about configuring BGP, see Basic IPv6 BGP example on page 841.
- The ISP IPv6 address is 2001:db8:d0c:6::2/64.

1st Floor FortiGate

To configure 1st Floor FortiGate in the CLI:

```
config router ospf6
    set router-id 1.1.1.1
    config area
        edit 0.0.0.0
        next
    end
    config ospf6-interface
        edit "1st-Floor-FortiGate-Internal-DR"
            set interface "port1"
            set priority 255
            set dead-interval 40
            set hello-interval 10
        next
        edit "1st-Floor-FortiGate-External"
            set interface "port2"
```

```
            set dead-interval 40
            set hello-interval 10
        next
    end
    edit "1st-Floor-FortiGate-Internal"
        set interface "port3"
        set dead-interval 40
        set hello-interval 10
    next
end
```

2nd Floor FortiGate

To configure 2nd Floor FortiGate in the CLI:

```
config router ospf6
    set router-id 2.2.2.2
    config area
        edit 0.0.0.0
        next
    end
    config ospf6-interface
        edit "2nd-Floor-FortiGate-Internal"
            set interface "port1"
            set priority 250
            set dead-interval 40
            set hello-interval 10
        next
        edit "2nd-Floor-FortiGate-External"
            set interface "port2"
            set dead-interval 40
            set hello-interval 10
        next
    end
    edit "2nd-Floor-FortiGate-Internal1"
        set interface "port3"
        set dead-interval 40
        set hello-interval 10
    next
end
```

Enterprise Core FortiGate

To configure Enterprise Core FortiGate in the CLI:

```
config router ospf6
    set default-information-originate enable
    set router-id 13.13.13.13
    config area
        edit 0.0.0.0
```

```
        next
    end
    config ospf6-interface
        edit "Enterprise-Core-FortiGate-Internal"
            set interface "port1"
            set dead-interval 40
            set hello-interval 10
        next
        edit "Enterprise-Core-FortiGate-Internal2"
            set interface "port2"
            set dead-interval 40
            set hello-interval 10
        next
    end
    config redistribute "bgp"
        set status enable
    end
end
```

Testing and configuration

Both the network connectivity and OSPF routing are tested. When a link goes down, routes should converge as expected.

1. Working state
   - Enterprise Core FortiGate:

```
# get router info6 ospf neighbor
OSPFv3 Process (root)
Neighbor ID     Pri   State           Dead Time   Interface
1.1.1.1           1   Full/Backup     00:00:38    port1

The default route advertised by Enterprise Core FortiGate using `default-information-originate` is considered an OSPF E2 route. Other routes redistributed from BGP are also E2 routes.

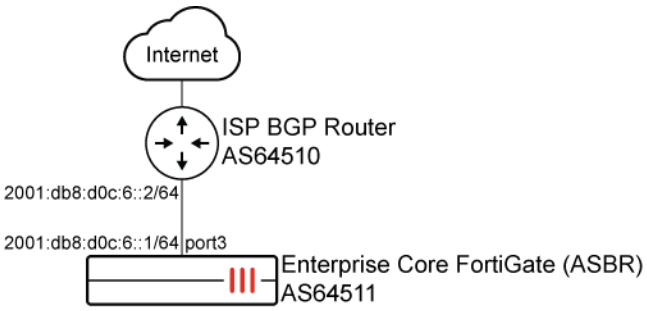
Basic IPv6 BGP example

In this example, Enterprise Core FortiGate peers with the ISP BGP Router over eBGP to receive a default route.

Topology

The following topology is used for this example:



Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See RFC 3849 for more information.

Please note that the Autonomous System Numbers (ASN) used in this example are reserved for documentation use only and should not be used in your environment. See RFC 5398 for more information.

To configure BGP on the Enterprise Core FortiGate in the GUI:

1. Go to *Network* > *BGP*.
2. Set *Local AS* to *64511*.
3. Set *Router ID* to *13.13.13.13*.
4. In the *Neighbors* table, click *Create New* and set the following:

IP	2001:db8:d0c:6::2
Remote AS	64510

5. Click *OK*.
6. Under *IPv6 Networks*, set *IP/Netmask* to *2001:db8:d0c:6::/64*.
7. Click *Apply*.

To configure BGP on the Enterprise Core FortiGate in the CLI:

```
config router bgp
    set as 64511
    set router-id 13.13.13.13
```

```
    config neighbor
        edit "2001:db8:d0c:6::2"
            set remote-as 64510
        next
    end
    config network6
        edit 1
            set prefix6 2001:db8:d0c:6::/64
        next
    end
end
```

Testing the configuration

To verify the status of the neighbors:

```
# get router info6 bgp neighbors
VRF 0 neighbor table:
BGP neighbor is 2001:db8:d0c:6::2, remote AS 64510, local AS 64511, external link
  BGP version 4, remote router ID 1.1.1.2
  BGP state = Established, up for 02:43:35
  Last read 00:00:14, hold time is 180, keepalive interval is 60 seconds
  Configured hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
    Address family IPv4 Unicast: advertised and received
    Address family VPNv4 Unicast: advertised and received
    Address family IPv6 Unicast: advertised and received
    Address family L2VPN EVPN: advertised and received
  Received 263 messages, 0 notifications, 0 in queue
  Sent 260 messages, 1 notifications, 0 in queue
  Route refresh request: received 0, sent 0
  NLRI treated as withdraw: 0
  Minimum time between advertisement runs is 30 seconds

 For address family: IPv4 Unicast
  BGP table version 1, neighbor version 0
  Index 1, Offset 0, Mask 0x2
  Community attribute sent to this neighbor (both)
  0 accepted prefixes, 0 prefixes in rib
  0 announced prefixes

 For address family: VPNv4 Unicast
  BGP table version 1, neighbor version 0
  Index 1, Offset 0, Mask 0x2
  Community attribute sent to this neighbor (both)
  0 accepted prefixes, 0 prefixes in rib
  0 announced prefixes

 For address family: IPv6 Unicast
  BGP table version 3, neighbor version 2
```

```
  Index 1, Offset 0, Mask 0x2
  Community attribute sent to this neighbor (both)
  3 accepted prefixes, 3 prefixes in rib

NPTv6 protocol for IPv6 address translation example

FortiOS adds partial support of the Network Prefix Translation (NPTv6) protocol in RFC6296 for IPv6 address translation, ensuring end-to-end connectivity, address independence, and 1:1 address mapping. It allows the use of private IPv6 addresses internally while translating them to globally routable IPv6 addresses when communicating with external networks. It operates at the prefix level by translating the network, prefix portion of an IPv6 address while leaving the host information unchanged. This enhances network scalability and facilitates efficient IPv6 network management.

A new NPTv6 type IP pool is introduced which allows an internal prefix of a IPv6 address to be translated to an external prefix. This enables administrators the freedom to use any internal prefix, but efficiently translate these to the prefix provided by their provider that can be routed globally.

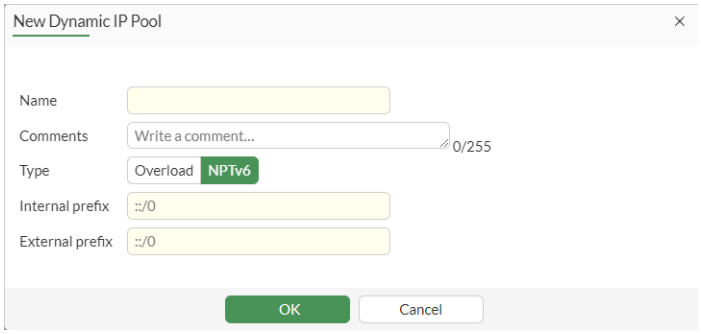
To configure NPTv6 in the CLI:

```
config firewall ippool6
    edit <IPv6 IP pool name>
        set type nptv6
        set internal-prefix <internal NPTv6 prefix length>
        set external-prefix <external NPTv6 prefix length>
    next
end
```

To configure NPTv6 in the GUI:

1. Go to *Policy & Objects* > *IP Pools*.
2. Go to the *IPv6 IP Pool* tab.
3. Click *Create new*.
4. Configure the IP pool:
   a. Enter a *Name*.
   b. Set the *Type* to *NPTv6*.

c. Enter the *Internal prefix* and *External prefix*.
d. Click *OK*.



How NPTv6 works

NPTv6 works on the principle that network translation is accomplished using a stateless approach, and that it is checksum-neutral at the transport layer. For instance, at the TCP layer, TCP checksums should remain unchanged even after the IP address has been translated.

In brief, TCP checksum is calculated based on a pseudo-header that includes the source and destination IP address. When the source address is translated, it needs to be done in a way that offsets the change to keep the checksum unchanged. This can be accomplished with the following rules:

- For an IPv6 with prefix length of 48-bit or shorter, a 16-bit adjustment can be made on the 4th word (4th hextat) of the IPv6 address which is the subnet field.
- For an IPv6 with prefix length greater than 48-bit, a 16-bit adjustment can be made on the 5th, 6th, 7th or 8th word of the IPv6 address.

For example, to translate from an internal prefix of fc00:1::/48 to an external prefix of 2003:db8:1::/48, an “adjustment” of 0xce45 has to be made in the 5th word, by adding 0xce45 to the 16-bit subnet field.

Therefore, the internal address fc00:1::1/48 becomes 2003:db8:1:**ce45**::1/48.

For more information, see section RFC6296 Section 3 – NPTv6 Algorithmic Specification.

Example

In the following example, an NPTv6 pool will be created and applied to the firewall policy. The packet IPv6 address translation will then be verifeid.

To configure the NPTv6 IP pool:

1. Configure the NPTv6 IP pool and prefix length:

The internal and external prefix must be the same length.

```
config firewall ippool6
    edit "NPTv6-ippool6-1"
        set type nptv6
        set internal-prefix 2000:10:1:100::/64
        set external-prefix 2000:172:16:200::/64
    next
end
```

2. Apply the IP pool in the firewall policy:

```
config firewall policy
    edit 2
        set name "NPTv6_policy6-1"
        set srcintf "port2"
        set dstintf "port1"
        set action accept
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set nat enable
        set ippool enable
        set poolname6 "NPTv6-ippool6-1"
    next
end
```

To verify the address translation:

1. Start an ICMP ping from 2000:10:1:100::41 to 2000:172:16:200::155.
2. Identify the 16-bit subnet field adjustment that is calculated according to the algorithm specified by RFC6296:

```
# diagnose firewall iprope6 list 100004
policy id: 2, group: 00100004, uuid_idx=8162
  action: accept, schedule: always
  cos_fwd=255 cos_rev=255
  flag (08050109): log redir nat master use_src pol_stats
  flag2(00004000): resolve_sso
  flag3(00000080): best-route
  shapers: / per_ip=
  sub_groups: av 00004e20 auth 00000000 split 00000000 misc 00000000
  app_list: 0 ips_view: 0
```

```
  vdom_id: 0
  zone_from(1): 8
  zone_to(1): 7
  address_src(1):
      all uuid_idx=8045
  address_dst(1):
      all uuid_idx=8045
  service(1):
      [0:0x0:0/(0,65535)->(0,65535)] helper:auto
  nat(0):
  nat_64(0):
  nptv6(1):
      2000:10:1:100::/64->2000:172:16:200::/64 adjust=FD88
```

3. Verify the session table. The translated IP address shows 2000:172:16:200:**fd88**::41 after applying the external prefix and the adjustment.

```
# diagnose sys session6 list
session6 info: proto=58 proto_state=00 duration=15 expire=45 timeout=0 refresh_dir=both
flags=00000000 sockport=0 socktype=0 use=3

The IPv6 prefix and subnet fields have been translated but the host field remains unchanged.

Enhancing SIP reliability in 464XLAT environments

FortiGate can now disable IP address translation within the SIP payload in 464XLAT environments as needed. This ensures SIP packets with IPv4 information reach user equipment without translation, which addresses an issue where the customer-side translator (CLAT) component does not revert the IPv6 address to IPv4 within the SIP header and body, which leads to RTP connection issues in 464XLAT environments. By preventing unnecessary translation, FortiGate ensures seamless communication and robust connectivity to improve the reliability of SIP-based services in complex network scenarios.

FortiGate only uses this feature as needed. A flag is added to each `voip_session_stream`, and FortiGate uses the flag and other information to identify 464XLAT environments. When a client initiates SIP traffic to a server, such as a `REGISTER` request to a server, and if the VOIP daemon detects an IPv6 layer address, but the SIP payload header contains an IPv4 address, the payload is identified as for a 464XLAT environment, and FortiGate stops NAT46 on the SIP payload.

Scope and limitations

Only one TCP connection is used between each SIP client and the SIP server, and the TCP connection remains up (in other words, doesn't tear down).

All SIP traffic between each SIP client and the SIP server must use the same TCP connection.

Because of the above requirements, SIP pinhole is not created.

The SIP server must offer its own IP address. The twin case for hnt_464xlat is not supported.

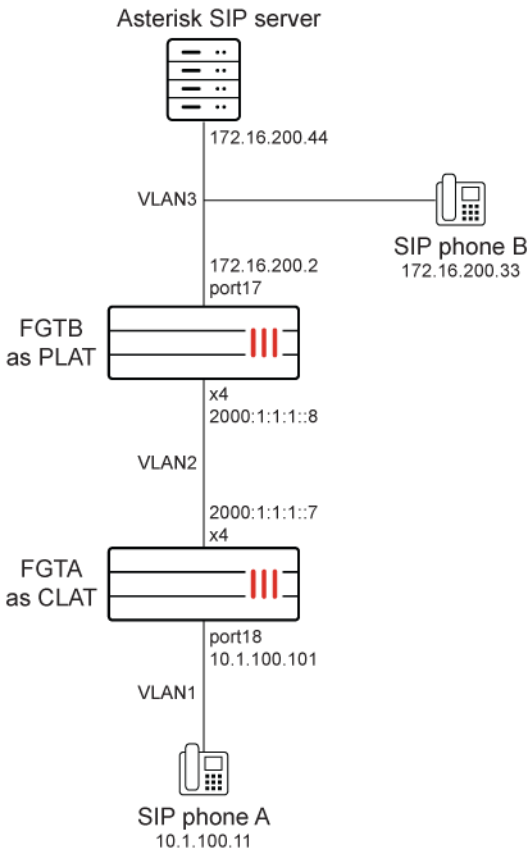
Only SIP/TCP-5060 is supported, and `session-helper` must be configured:

```
config system session-helper
    edit 13
        set name sip
        set protocol 6
        set port 5060
```

```
    next
end
```

Example

The example uses the following topology:



1. The CLAT component run insides the user equipment (UE) and performs a one-to-one (IPv4 to IPv6) stateless translation. The CLAT component translates traffic with an IPv4 destination to IPv6. While the IPv4 address is converted to IPv6 in the IP header, the IP information within the payload, including the SIP header and body, remains unchanged (IPv4).
2. FortiGate as PLAT performs many-to-one (IPv6 to IPv4) stateful translation to translate the IP address within the IP header from IPv6 to IPv4. Furthermore, SIP-ALG modifies the IP address within the payload in the SIP header and body by substituting the IPv4 address with a publicly NATed IP address.
3. For traffic returning from SIP server, FortiGate stops NAT46 on the SIP payload and only translates the IPv4 addresses in the IP header into an IPv6 address. Thus, the IP address contained within the SIP header and body remains IPv4, which the user equipment can recognize, and RTP connections can be successfully established.
4. The packet reaches UE, and the CLAT component translates the IP address of the IP header from IPv6 to IPv4. The CLAT component does not function as an ALG and does not modify the IP address within the SIP header and body.
5. The UE receives the packet but cannot establish RTP connection with the IPv6 destination.

To check the SIP calls when phone A (10.1.100.11) and phone B (172.16.200.33) are registering to the SIP server (172.16.200.44):

1. View the SIP proxy SIP calls:

```
# diagnose sys sip-proxy calls

```

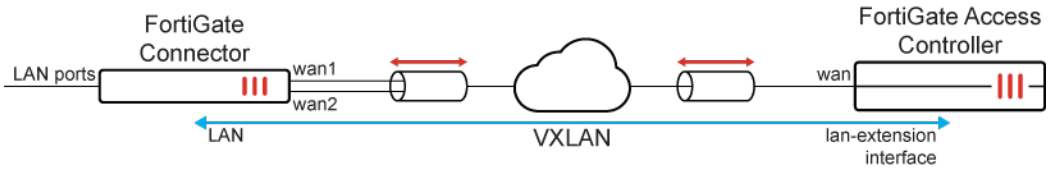
FortiGate LAN extension

LAN extension mode allows a remote FortiGate to provide remote connectivity to a local FortiGate over a backhaul connection.

The remote FortiGate, called the FortiGate Connector, discovers the local FortiGate, called the FortiGate Controller, and forms one or more IPsec tunnels back to the FortiGate Controller. A VXLAN is established over the IPsec tunnels creating an L2 network between the FortiGate Controller and the network behind the FortiGate Connector.



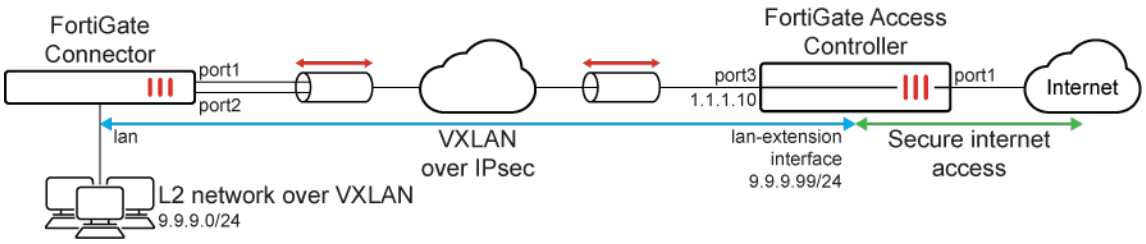
The following topics describe further details about the FortiGate LAN extension feature:

- Example CLI configuration on page 854
- Example GUI configuration on page 861
- DHCP client mode for inter-VDOM links on page 866
- FortiGate secure edge to FortiSASE on page 867
- WiFi access point with internet connectivity on page 871

Example CLI configuration

In this example, the Controller provides secure internet access to the remote network behind the Connector. The Controller has two WAN connections: an inbound backhaul connection and an outbound internet connection. The Connector has two wired WAN/uplink ports that are connected to the internet.

After the Connector discovers the Controller and is authorized by the Controller, the Controller pushes a FortiGate LAN extension profile to the Connector. The Connector uses the profile configurations to form two IPsec tunnels back to the Controller. Additional VXLAN aggregate interfaces are automatically configured to create an L2 network between the Connector LAN port and a virtual LAN extension interface on the Controller. Clients behind the Connector can then connect to the internet through the Controller that is securing the internet connection.



To discover and authorize the FortiGate Controller:

1. On the FortiGate Controller:
   a. For high-end models (1000 series and higher), enable the FortiExtender setting:

```
config system global
    set fortiextender enable
end
```

   This command is configured by default on entry-level and mid-range models (900 series and lower).

   b. Enable IPAM and management of LAN extension interface addresses:

```
config system ipam
    set status enable
    set manage-lan-extension-addresses enable
end
```

   c. Enable security fabric connections on port3 to allow the Connector to connect over CAPWAP:

```
config system interface
    edit "port3"
        set vdom "root"
        set ip 1.1.1.10 255.255.255.0
        set allowaccess fabric ping
        set ip-managed-by-fortiipam disable
    next
end
```

   IPAM is specifically disabled for this interface since a static IP address is desired for this topology.

2. On the FortiGate Connector:
   a. Enable VDOMs:

```
config system global
    set vdom-mode multi-vdom
end
```

You will be logged out of the device when VDOM mode is enabled.

b. For high-end models (1000 series and higher), enable the FortiExtender setting in the global VDOM:

```
config global
    config system global
        set fortiextender enable
    end
end
```

This command is configured by default on entry-level and mid-range models (900 series and lower).

c. Create the lan-ext VDOM while setting the VDOM type to LAN extension (making the VDOM act as a FortiExtender in LAN extension mode), and add the Controller IP address:

```
config vdom
    edit lan-ext
        config system settings
            set vdom-type lan-extension
            set lan-extension-controller-addr "1.1.1.10"
            set ike-port 4500
        end
    next
end
```

d. Configure port1 and port2 to access the Controller:

```
config system interface
    edit "port1"
        set vdom "lan-ext"
        set ip 5.5.5.1 255.255.255.0
        set allowaccess ping fabric
        set type physical
        set lldp-reception enable
        set role wan
    next
    edit "port2"
        set vdom "lan-ext"
        set ip 6.6.6.1 255.255.255.0
        set allowaccess ping fabric
        set type physical
        set lldp-reception enable
        set role wan
    next
end
```

3. On the FortiGate Controller:

a. Extension controller configurations are automatically initialized:

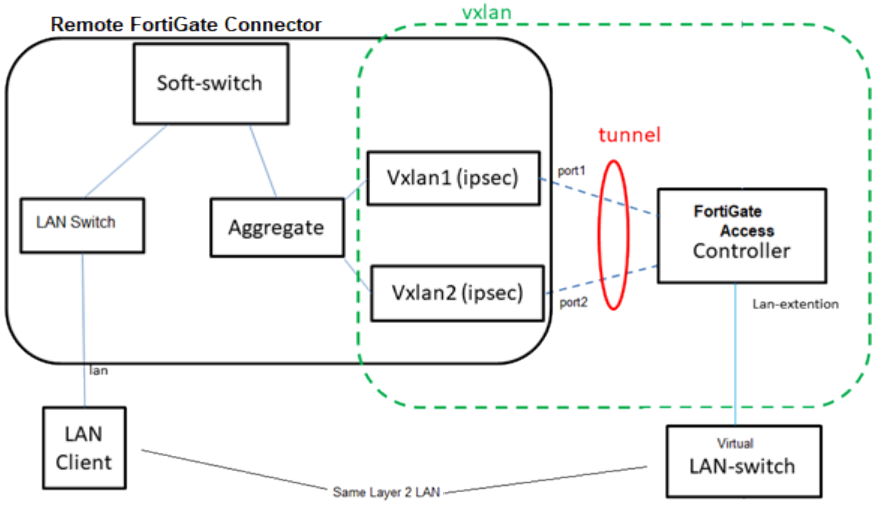
```
config extension-controller fortigate-profile
    edit "FGCONN-lanext-default"
        set id 0
        config lan-extension
            set ipsec-tunnel "fg-ipsec-XdSpij"
            set backhaul-interface "port3"
        end
    next
end
```

```
config extension-controller fortigate
    edit "FGT60F0000000001"
        set id "FG5H1E0000000001"
        set device-id 0
        set profile "FGCONN-lanext-default"
    next
end
```

b. Authorize the Connector:

```
config extension-controller fortigate
    edit "FGT60F0000000001"
        set authorized enable
    next
end
```

4. After the FortiGate Connector has been authorized, the Controller pushes the IPsec tunnel configuration to the Connector, forcing it to establish the tunnel and form the VXLAN mechanism.



The VXLANs are built on the IPsec tunnels between the Connector and Controller. The VXLAN interfaces are aggregated for load balancing and redundancy. A softswitch combines the aggregate interface with the local LAN ports, allowing the LAN ports to be part of the VXLAN. This combines the local LAN ports with the virtual LAN extension interface on the FortiGate Controller.

a. The Connector receives the IPsec configurations from the Controller, and automatically creates tunnels for each uplink:

```
config vpn ipsec phase1-interface
    edit "ul-port1"
        set interface "port1"
        set ike-version 2
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set localid "peerid-T4YLv2rp62SU6JhoCPIv02MzjLtS7P5HlxRER1Qpi6O9ZsAsbPSpvoiE"
        set dpd on-idle
        set comments "[FGCONN] Do NOT edit. Automatically generated by extension
controller."
        set remote-gw 1.1.1.10
        set psksecret ******
    next
    edit "ul-port2"
        set interface "port2"
        set ike-version 2
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set localid "peerid-T4YLv2rp62SU6JhoCPIv02MzjLtS7P5HlxRER1Qpi6O9ZsAsbPSpvoiE"
        set dpd on-idle
        set comments "[FGCONN] Do NOT edit. Automatically generated by extension
controller."
        set remote-gw 1.1.1.10
        set psksecret ******
    next
end
```

b. VXLAN interfaces are automatically configured and formed over each tunnel:

```
config system vxlan
    edit "vx-port1"
        set interface "ul-port1"
        set vni 1
        set dstport 9999
        set remote-ip "10.252.0.1"
    next
    edit "vx-port2"
        set interface "ul-port2"
        set vni 1
        set dstport 9999
        set remote-ip "10.252.0.1"
    next
end
```

c. An aggregate interface is automatically configured to load balance between the two VXLAN interfaces, using the source MAC and providing link redundancy:

```
config system interface
    edit "le-agg-link"
        set vdom "lan-ext"
        set type aggregate
```

```
        set member "vx-port1" "vx-port2"
        set snmp-index 35
        set lacp-mode static
        set algorithm Source-MAC
    next
end
```

d. The softswitch is automatically configured and bridges the aggregate interface and the local LAN to connect the LAN to the VXLAN bridged L2 network that goes to the FortiGate LAN extension interface:

```
config system switch-interface
    edit "le-switch"
        set vdom "lan-ext"
        set member "le-agg-link" "lan"
    next
end
```

To configure the LAN extension interface and firewall policy on the FortiGate Controller:

1. After the IPsec tunnel is setup and the VXLAN is created over the tunnel, the LAN extension interface is automatically created on the Controller:

```
config system interface
    edit "FGT60F0000000001"
        set vdom "root"
        set ip 192.168.0.254 255.255.255.0
        set allowaccess ping ssh
        set type lan-extension
        set role lan
        set snmp-index 27
        set ip-managed-by-fortiipam enable
        set interface "fg-ipsec-XdSpij"
    next
end
```

   Devices on the remote LAN network will use this IP address as their gateway.

2. Observe that with IPAM enabled on the Controller that the DHCP server settings have been automatically configured:

```
config system dhcp server
    edit 3
        set dns-service default
        set default-gateway 9.9.9.99
        set netmask 255.255.255.0
        set interface "FGT60F0000000001"
        config ip-range
            edit 1
                set start-ip 9.9.9.100
                set end-ip 9.9.9.254
            next
        end
        set dhcp-settings-from-fortiipam enable
```

```
        config exclude-range
            edit 1
                set start-ip 9.9.9.254
                set end-ip 9.9.9.254
            next
        end
    next
end
```

3. Configure the firewall policy to allow traffic from the LAN extension interface to the WAN interface (port1):

```
config firewall policy
    edit "2"
        set name "lan-ext"
        set srcintf "FGT60F0000000001"
        set dstintf "port1"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Optionally, security profiles and other settings can be configured.

The policy allows remote LAN clients to access the internet through the backhaul channel. Clients in the remote LAN behind the Connector receive an IP address over DHCP and access the internet securely through the Controller.

To verify the FortiGate LAN extension configuration:

1. Verify the IPsec tunnels' phase 1 and phase 2 negotiations on the Controller and Connector:

```
# diagnose ike vpn gateway list
# diagnose vpn tunnel list
```

2. Verify the VXLAN tunnel forwarding database list on the Controller and Connector:

```
# diagnose sys vxlan fdb list
```

3. Verify the DHCP server lease list on the Controller:

```
# execute dhcp lease-list
```

4. Verify the LAN extension session information on the Controller:

```
Controller-FGT # get extender session-info
Total 1 WS sessions, 0 AS sessions:
fg connector sessions:
FGT60F0000000001 : 1.1.1.10:5246 (dport 65535)lan-extension,  running,  install, data-enable,
```

```
refcnt 6, miss_echos -1, up-time 1554 secs, change 1
extender sessions:
```

In this example, the Connector is in a working state.

5. Verify the LAN extension status on the Connector:*

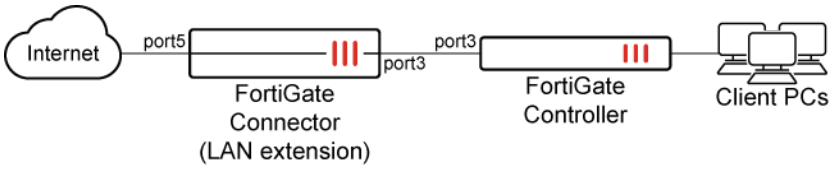
```
Connector-FGT (lan-ext) # get extender lanextension-vdom-status

Control-Channel:
        controller ip: 1.1.1.0
        controller port: 5246
        controller name: FG5H1E0000000001
        missed echo: 0
        up time(seconds): 29483
        status: EXTWS_RUN
Data-Channel:
uplink [0]: port1
        IPsec tunnel ul-port1
        VxLAN interface vx-port1
uplink [1]: port2
        IPsec tunnel ul-port2
        VxLAN interface vx-port2
downlink [0]: lan
```

In this example, the Connector is in a working state.

Example GUI configuration

In this example, the FortiGate Controller has CAPWAP access allowed on port3. The FortiGate Connector has its WAN port3 connected to the FortiGate Controller, and LAN port5 is connected to the client PCs.



To configure the FortiGate LAN extension:

1. On the FortiGate Controller, enable the FortiExtender setting. For high-end models (1000 series and higher) and VM models, enter:

```
config system global
    set fortiextender enable
end
```

This command is configured by default on entry-level and mid-range models (900 series and lower).

2. On the FortiGate Controller, configure the port3 settings:
   a. Go to *Network* > *Interfaces* and edit *port3*.
   b. Set the *Addressing mode* to *IPAM*.
   c. In this example, IPAM is not enabled yet. Click *Enable IPAM*. The *IPAM Settings* pane opens.
   d. Set the *Status* to *Enabled*, enable *FortiExtender LAN extensions*, then click *OK*.
   e. In the *Administrative Access* > *IPv4* section, select *Security Fabric Connection* to enable CAPWAP on the interface.
   f. Enable *DHCP Server*.
   g. Click *OK*.
3. On the FortiGate Connector, enable VDOMs:
   a. Go to *System* > *Settings*.
   b. In the *System Operation Settings* sections, enable *Virtual Domains*.
   c. Click *OK*. You will be logged out of the device when VDOM mode is enabled.
4. On the FortiGate Connector, enable the FortiExtender setting. For high-end models (1000 series and higher) and VM models, enter:

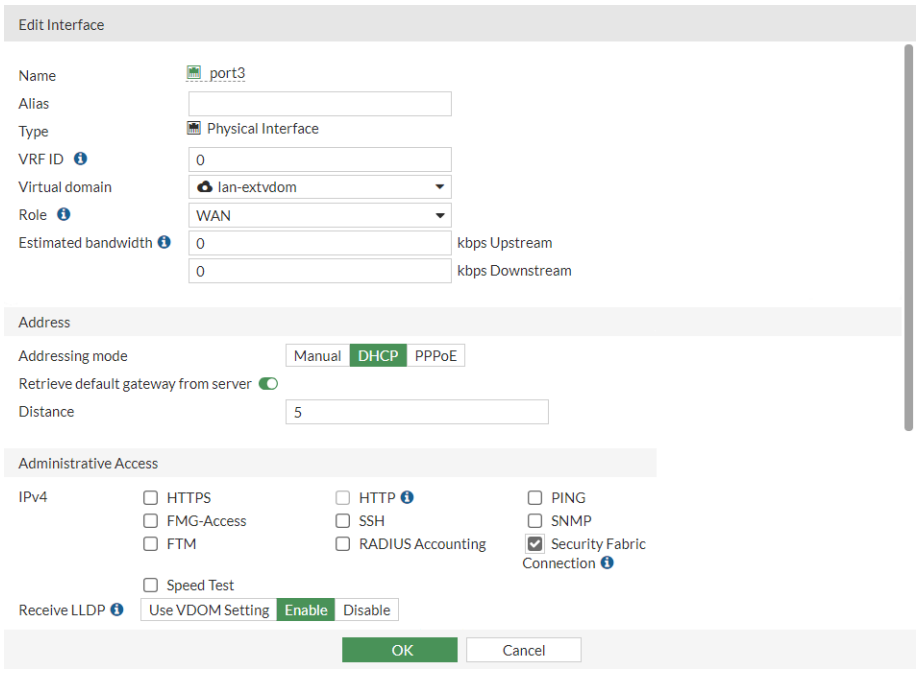
```
config system global
    set fortiextender enable
end
```

This command is configured by default on entry-level and mid-range models (900 series and lower).

5. On the FortiGate Connector, configure the LAN extension VDOM:
   a. Go to *System* > *VDOM* and click *Create New*.
   b. Enter a name (*lan-extvdom*) and set the *Type* to *LAN Extension*.

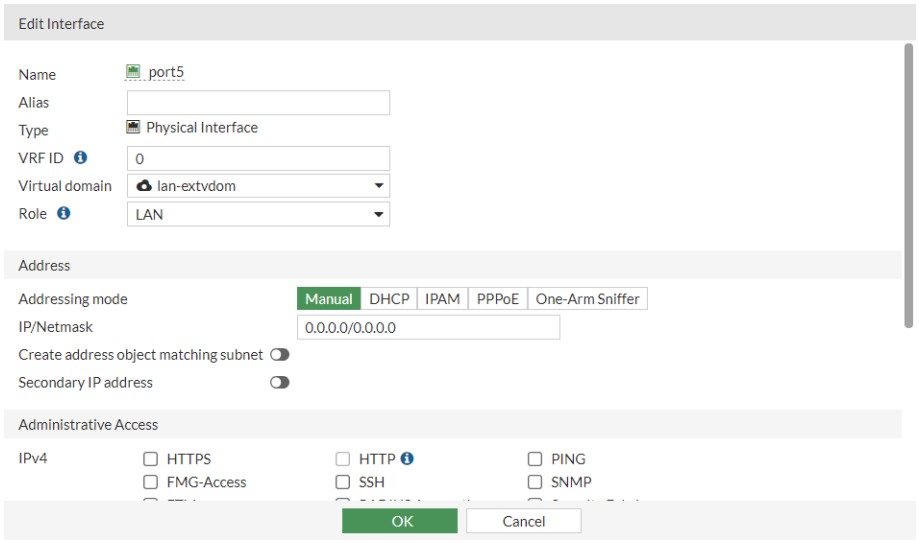
   c. Click *OK*. The *LAN Extension VDOM Created* prompt appears.

   d. Click *Go to interface list page* to assign a role (LAN or WAN) and the LAN extension VDOM.
6. On the FortiGate Connector, edit port3:
   a. Set the *Role* to *WAN*.
   b. Set the *Virtual domain* to *lan-extvdom*.



c. Click *OK*.

7. On the FortiGate Connector, edit port5:
   a. Set the *Role* to *LAN*.
   b. Set the *Virtual domain* to *lan-extvdom*.



The addressing mode is set to *Manual* and the *IP/Netmask* set to 0.0.0.0/0.0.0.0 because port5 will become part of the *le-switch* software switch, which has its own IP address already assigned.

c. Click *OK*.

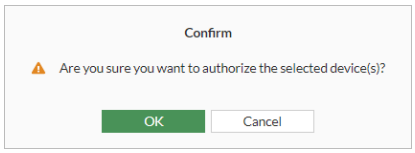
Setting the *Role* to *LAN* will automatically add this interface to the *le-switch* LAN extension software switch, which forms an L2 network with the VXLAN.

To add more LAN ports to *le-switch* automatically, set the *Role* to *LAN* for other desired LAN ports.

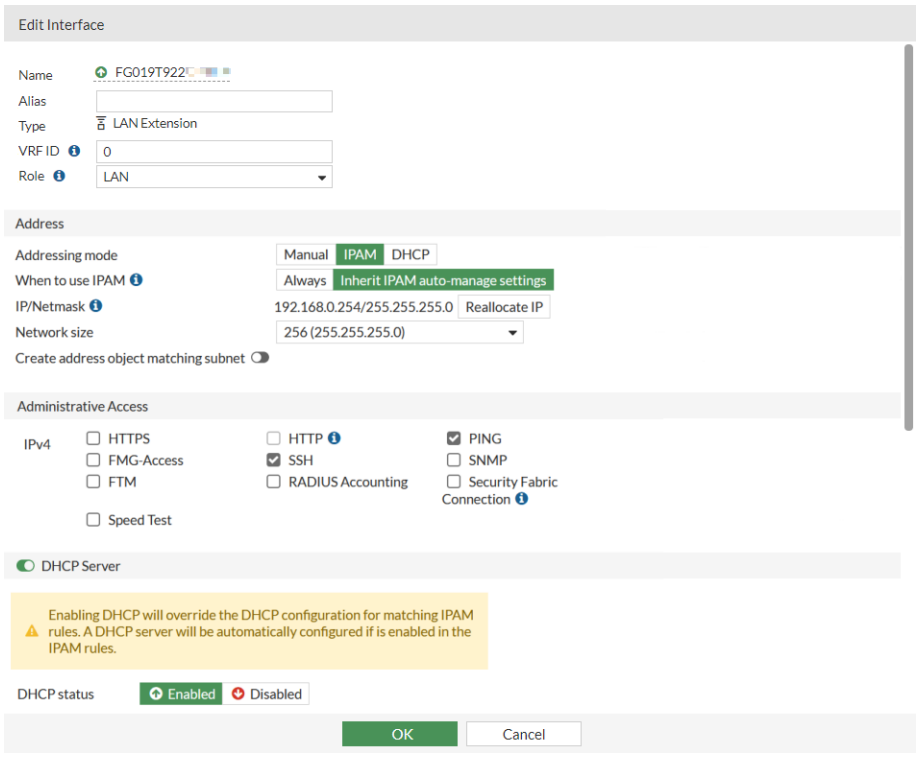
8. On the FortiGate Connector, select the LAN extension VDOM, and enter the IP address of the FortiGate controller:
   a. Go to *Network* > *LAN Extension*.
   b. Set the *Access Controller (AC) address* to the IP address of port3 on the FortiGate Controller. In this example, use *172.31.0.254*.

   c. Click *Apply*.
9. On the FortiGate Controller, enable the FortiExtender feature visibility in the GUI, and authorize the FortiGate connector:
   a. Go to *System* > *Feature Visibility*. In the *Additional Features* section, enable *FortiExtender* and click *Apply*.
   b. Go to *Network* > *FortiExtenders* and select the *Managed FortiExtenders* tab.
   c. Select the device, then right-click and select *Authorization* > *Authorize*.

   d. Click *OK* to authorize the device.



10. On the FortiGate Controller, configure the LAN extension interface:
    a. Go to *Network* > *Interfaces* and edit the LAN extension interface.
    b. Set the *Addressing mode* to *IPAM* and set *When to use IPAM* to *Inherit IPAM auto-manage settings* (default).
    c. Enable *DHCP Server*, and configure the settings as needed (see DHCP servers and relays on page 445 for more information).



d. Click *OK*.

11. On the FortiGate Controller, configure the default gateway if a static WAN IP configuration is used:

a. Go to *Network* > *Static Routes* and edit the default gateway settings to specify the correct internet gateway address and WAN interface.

b. Click *OK*.

12. On the FortiGate Controller, configure the firewall policy to allow traffic to pass:

a. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.

b. Set the *Incoming Interface* to the LAN extension interface.

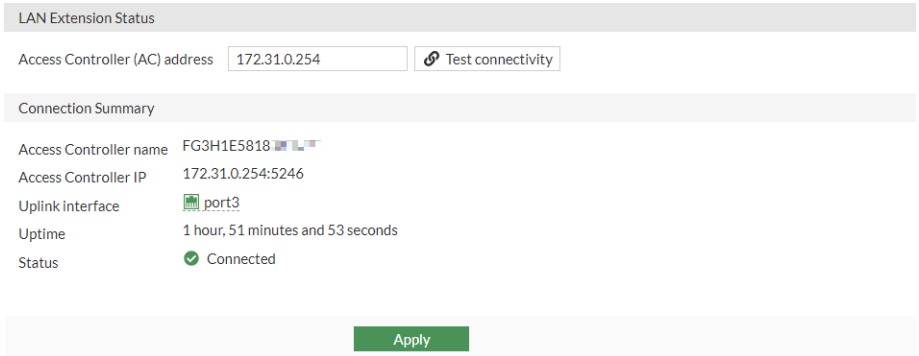
c. Configure the other settings as needed.

d. Click *OK*.

13. On the FortiGate Connector, verify that the LAN extension is connected:

a. Go to *Network* > *LAN Extension*.

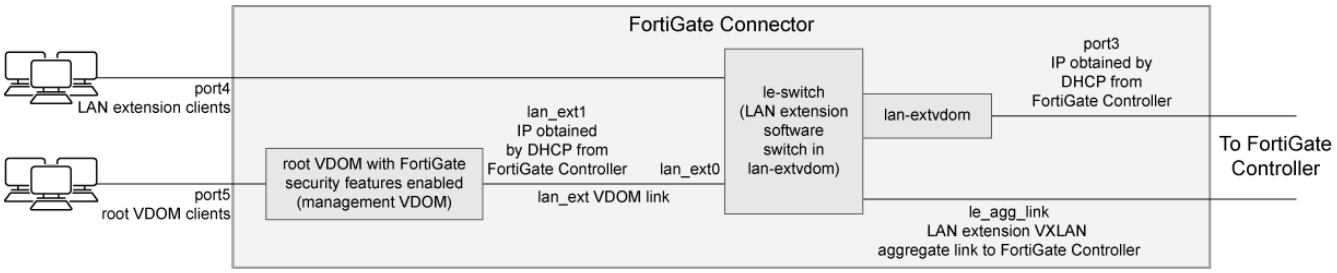
b. Verify that the *Status* is *Connected*.



DHCP client mode for inter-VDOM links

Continuing with the same configuration as Example GUI configuration on page 861, a new VDOM named lan-extvdom was created on the FortiGate Connector and its type was set to LAN extension. This configuration allows the VDOM to function as a FortiExtender in LAN extension mode. However, it should be noted that this configuration results in the loss of FortiGate security features on that VDOM. For users who wish to utilize the security features of the FortiGate locally on the FortiGate Connector, another VDOM, such as the root VDOM, can be used.

Once the DHCP server is enabled on the FortiGate Controller (as shown in step 2 of Example GUI configuration on page 861), an inter-VDOM link belonging to another VDOM (in this case, the root VDOM) can receive an IP address by DHCP from the FortiGate Controller.



In this topology, the DHCP clients on the FortiGate Connector interact with the different DHCP servers on the FortiGate Controller.

- The port3 IP address is obtained by DHCP from the FortiGate Controller DHCP server on the port3 connected interface.
- The lan_ext1 IP address is obtained by DHCP from the FortiGate Controller DHCP server on the LAN extension interface.

To configure DHCP client mode on the inter-VDOM link on the FortiGate Connector:

1. Add the VDOM link with an Ethernet type:

```
config system vdom-link
    edit "lan-extvdom"
        set type ethernet
    next
end
```

2. Configure the VDOM link interfaces:

```
config system interface
    edit "lan_ext0"
        set vdom "lan-extvdom"
        set role lan
    next
    edit "lan_ext1"
        set vdom "root"
        set mode dhcp
```

```
    next
end
```

Since lan_ext0 has its role set to `lan`, this interface is added to the le-switch software switch in the lan-extvdom VDOM. This software switch provides network connectivity to the LAN extension clients (in Example GUI configuration on page 861) and the root VDOM clients (in this example) through the FortiGate Connector LAN extension VXLAN aggregate link.

3. Verify that the lan_ext1 interface obtained an IP address from the FortiGate Controller (the client IP address for the lan_ext1 VDOM link is from the same 192.168.0.0/24 subnet in step 10c of Example GUI configuration on page 861):

```
Connector-FGT (lan-ext) # diagnose ip address list | grep lan_ext1
IP=192.168.0.1->192.168.0.1/255.255.255.0 index=30 devname=lan_ext1
```

FortiGate secure edge to FortiSASE

VDOM configuration for the FortiGate LAN extension has been simplified. When you configure the FortiGate LAN extension VDOM, FortiOS automatically configures a VDOM link between a traffic VDOM, which is by default the root VDOM, and the LAN extension VDOM.

After connecting to the FortiGate Controller, the following settings are automatically configured on the FortiGate Connector:

- VDOM link interface in the LAN extension VDOM is a part of the LAN extension software switch.
- VDOM link interface in the traffic VDOM is dynamically assigned an IP address obtained through the FortiGate Controller.

The traffic VDOM can be used to:

- Apply application steering to the local internet connection or to FortiGate Controller network (FortiSASE) using SD-WAN.
- Apply local security features for traffic egressing the local internet connection, such as antivirus, intrusion prevention security (IPS), application control, and web filtering, by creating a firewall policy with the destination interface configured as either the FortiGate WAN interface or an SD-WAN zone with the FortiGate WAN interface as a member.

Example

This example demonstrates how to configure the FortiGate Connector to connect to FortiSASE as the FortiGate Controller. In FortiSASE, the FortiGate Connector is more commonly known as the FortiGate secure edge.

To configure the FortiGate Connector using the CLI:

1. Enable multi-VDOM mode from the CLI:

```
config system global
    set vdom-mode multi-vdom
end
```

2. Verify that the FortiExtender setting is enabled in the global VDOM:

```
# config global
# show full system global | grep fortiextender -f
…
    set fortiextender enable
…
```

3. Create a new LAN extension VDOM with the LAN extension controller address as the FortiSASE domain name.

   See Connecting FortiGate to FortiSASE using GUI and CLI for details on how to find the FortiSASE domain name.

   In this example, the VDOM name is `ext`, and the FortiSASE domain name is `turbo-a1p0hv3p.edge.prod.fortisase.com`.

```
config vdom
    edit ext
        config system settings
            set vdom-type lan-extension
            set lan-extension-controller-addr turbo-a1p0hv3p.edge.prod.fortisase.com
            set ike-port 4500
        end
    next
end
```

4. Move interfaces from the root VDOM to the new LAN extension VDOM, and set the appropriate WAN and LAN roles.
   - Before moving an interface to a new VDOM, delete all references, such as firewall policies or firewall objects. See Finding object dependencies on page 4338.
   - If interfaces are already part of a hardware switch, remove them from the hardware switch to make them available for the new VDOM. See Hardware switch on page 232.

   In this example from the global VDOM, the *wan1* and *internal1* interfaces are moved to the LAN extension VDOM named *ext*, and their roles are set appropriately as *WAN* and *LAN*.

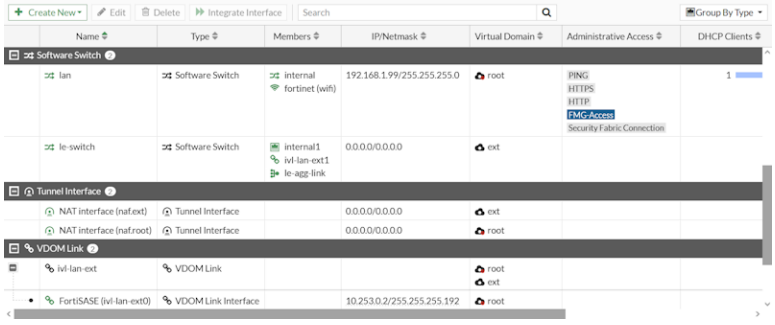
   a. From the GUI, go to the *Global* VDOM.
   b. Go to *Network* > *Interfaces* and edit the *wan1* interface:
      i. Set the *Role* to *WAN*.
      ii. Set the *Virtual domain* to *ext*.
      iii. Click *OK*.
   c. Go to *Network* > *Interfaces* and edit the *internal1* interface:
      i. Set the *Role* to *LAN*.
      ii. Set the *Virtual domain* to *ext*.
      iii. Click *OK*.
5. For the WAN interface within the LAN extension VDOM, edit the interface and ensure that Security Fabric connections are allowed:
   a. From the GUI, go to the *Global* VDOM.
   b. Go to *Network* > *Interfaces* and edit the *WAN1* interface.
   c. Under *Administrative Access*, ensure *PING* and *Security Fabric Connection* are selected.
   d. Click *OK*.

This configuration assumes that the WAN and LAN interfaces are already configured with static IP addresses or configured to use DHCP accordingly.

6. (Optional) If your LAN extension VDOM is not configured as the management VDOM, and you require a custom DNS server to resolve the FortiGate Controller hostname, then you must configure the VDOM DNS settings within the VDOM:

```
config vdom
    edit ext
        config system vdom-dns
            set vdom-dns enable
            set primary 1.2.3.4
            set secondary 2.3.4.5
        end
    next
end
```

7. In FortiSASE, authorize the FortiGate as a LAN extension in the *Edge Devices > FortiGates* page. See Authorizing a FortiGate.
8. In the LAN extension VDOM, in *Network > LAN Extension* observe that the *Connection Summary* shows values for the *Access Controller Name*, *Access Controller IP*, and *Connected* status. These all indicate the LAN extension VDOM established a successful connection with FortiSASE.
9. After the LAN extension VDOM connects to FortiSASE, observe from the *Global* VDOM under *Network > Interfaces*:
   - A VDOM link *ivl-lan-ext* is created.
   - The VDOM link interface in the LAN extension VDOM (*ivl-lan-ext1*) is part of the *le-switch* LAN extension software switch. Network connectivity to the FortiGate Controller (that is, to FortiSASE) is achieved through the software switch.
   - The VDOM link interface in the traffic (*root*) VDOM (*ivl-lan-ext0*) has obtained an IP address dynamically from the FortiGate Controller.



10. Within the *root* VDOM, create a firewall policy with *ivl-lan-ext0* as the destination and *lan* as the source within the traffic VDOM to allow local traffic in the IP address range for DHCP clients in the LAN subnet (LAN-DHCP-RANGE) from the FortiGate Connector to access the internet through the FortiGate Controller (FortiSASE).
    a. From the GUI, go to the *root* VDOM.
    b. Go to *Policy & Objects > Firewall Policy*.
    c. Click *Create New*.
    d. Create a new policy with the following settings:

Name	traffic-VDOM-to-FortiSASE
Incoming Interface	lan
Outgoing Interface	ivl-lan-ext0
Source	LAN-DHCP-RANGE
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enabled

e. Click *OK*.

a. Within the *root* VDOM, create a firewall policy with *wan2* (second ISP link on FortiGate with proper routing already set up) as the destination and *lan* as the source within the traffic VDOM to allow local traffic in the IP address range for static IP clients in the LAN subnet (LAN-STATIC-RANGE) from the FortiGate Connector to access the internet through the FortiGate Controller (FortiSASE). Security Profiles and SSL certificate inspection are also enabled on this policy.

i. From the GUI, go to the *root* VDOM.

ii. Go to *Policy & Objects > Firewall Policy*.

iii. Click *Create New*.

iv. Create a new policy with the following settings:

Name	traffic-VDOM-to-wan2
Incoming Interface	lan
Outgoing Interface	wan2
Source	LAN-STATIC-RANGE
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enabled
AntiVirus	g-default
Web filter	g-default
DNS filter	default
Application control	g-default
SSL inspection	certificate-inspection

v. Click *OK*.

WiFi access point with internet connectivity

A FortiGate LAN extension can be configured to allow clients that are connected to a WiFi access point on FortiExtender to have access to the internet. This example describes how to configure a WiFi access point with internet access for a managed FortiExtender. An overview of the configuration steps is provided followed by the details:

1. Create a LAN extension SSID for FortiExtender.
2. Configure a FortiExtender profile.
3. Apply the profile to FortiExtender and authorize the device.
4. Configure the LAN extension interface as a DHCP server.
5. Configure a firewall policy to allow internet access.
6. Verify settings.

Creating a LAN extension SSID for FortiExtender

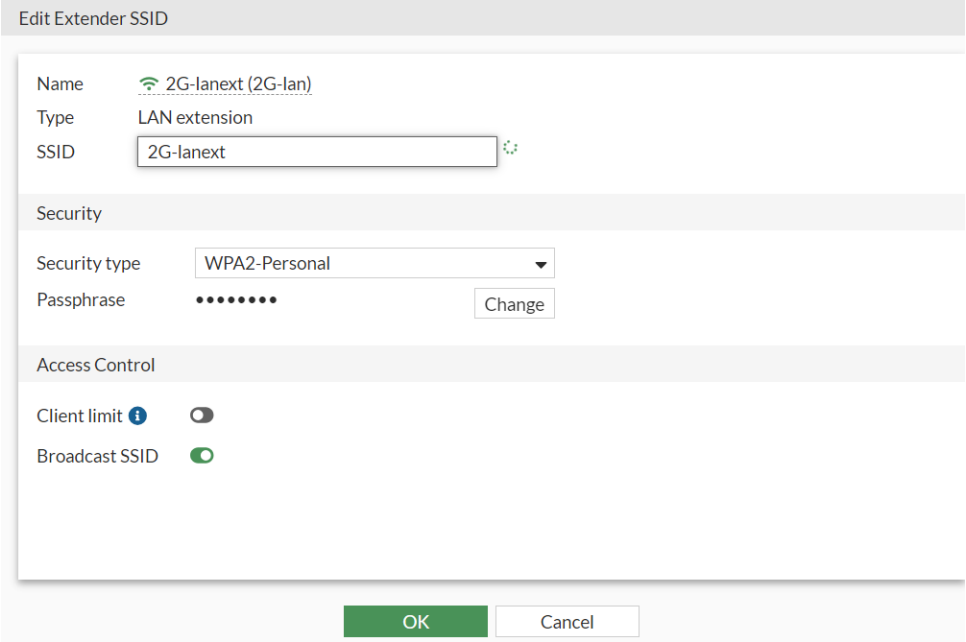
Use the *FortiExtender SSIDs* tab to create a LAN extension SSID for a managed FortiExtender device.

In this The SSID name in this example is *2G-lanext*.

To create a LAN extension SSID for FortiExtender in the GUI:

1. Go to *Network* > *FortiExtenders* > *FortiExtender SSIDs*, and click *Create New*.
2. Set the following options:

Type	Select *LAN extension*.
SSID	Enter a name, such as *2G-lanext*.
Security Type	Select a type of security.
Passphrase	Enter a passphrase.



3. Set the remaining options as desired, and click *OK*.

To create a LAN extension SSID for FortiExtender in the CLI:

```
config extension-controller extender-vap
    edit "2G-lan"
        set type lan-ext-vap
        set ssid "2G-lanext"
        set max-clients 0
        set broadcast-ssid enable
        set security WPA2-Personal
        set passphrase 12345678
    next
end
```

Configuring a FortiExtender profile

Use a FortiExtender profile to define the LAN extension settings, such as the radio band for the LAN extension SSID, to create a WiFi SSID.

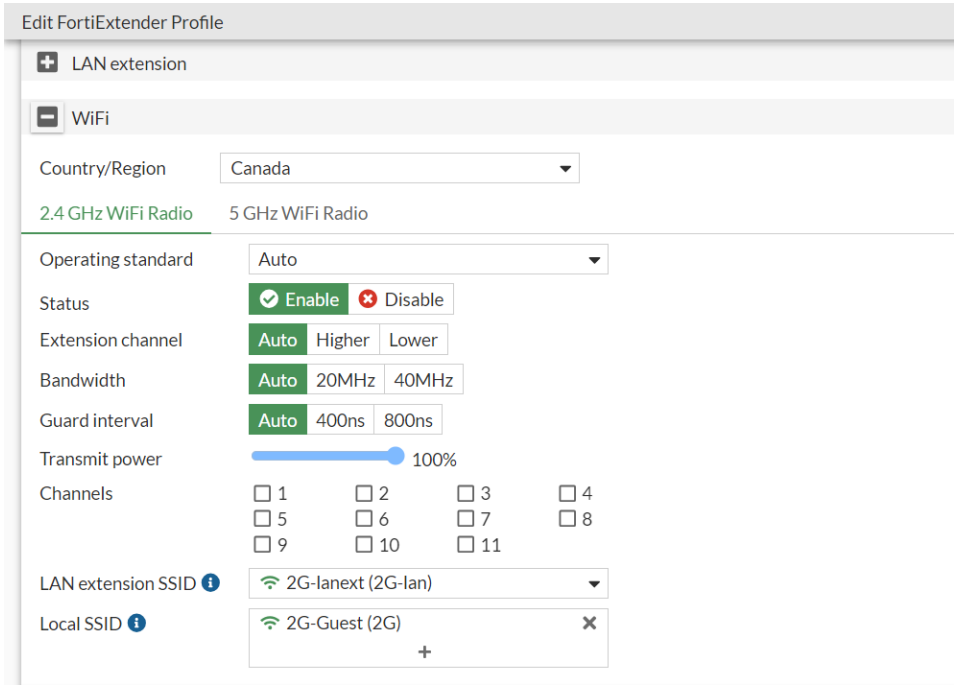
The FortiExtender profile in this example is named *FVA22F-lanext-default*, and the LAN extension named *2G-lanext* is selected to create a WiFi SSID named *2G-lanext (2G-lan)*.

To configure a FortiExtender profile in the GUI:

1. Go to *Network* > *FortiExtenders*, and create a new profile or double-click an existing profile to open it for editing.
2. Expand *WiFi* and set the following options:

2.4 GHz WiFi Radio	Click to display 2 GHz radio band options.

5 GHz WiFi Radio	Click to display 5 GHz radio band options.
LAN extension SSID	Select the LAN extension SSID, for example, *2G-lanext*.
Local SSID	Select an SSID.



3. Set the remaining options as desired, and click *OK*.

To configure a FortiExtender profile in the CLI:

```
config extension-controller extender-profile
    edit "FVA22F-lanext-default"
        set id 5
        set model FVA22F
        set extension lan-extension
        config cellular
            config sms-notification
            end
            config modem1
            end
            config modem2
            end
        end
        config lan-extension
            set ipsec-tunnel "fext-ipsec-g180"
            set backhaul-interface "lan"
            config backhaul
                edit "1"
                    set port wan
                    set role primary
                next
```

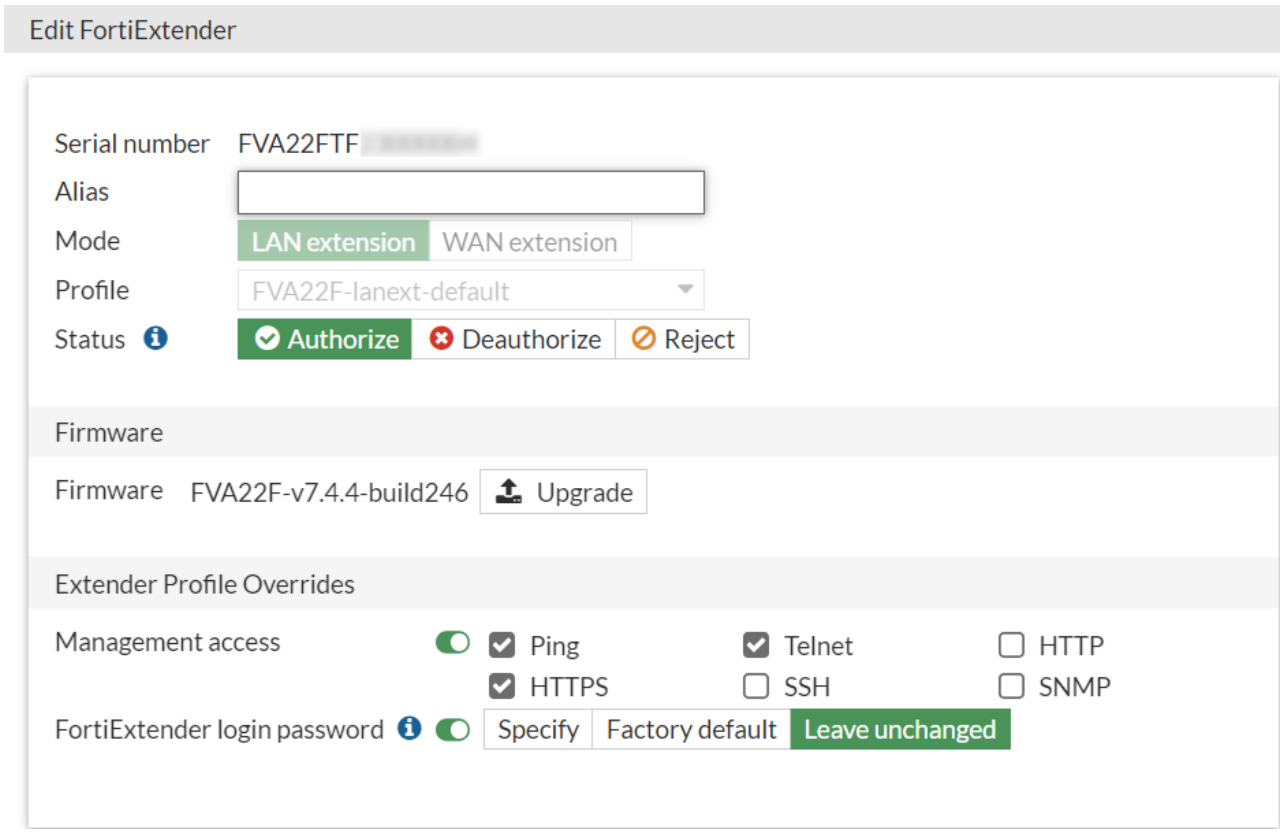
```
                edit "2"
                    set port lte1
                    set role secondary
                next
        config wifi
            set country CA
            config radio-1
                set mode AP
                set band 2.4GHz
                set status enable
                set operating-standard auto
                set lan-ext-vap "2G-lan"
                set local-vaps "2G"
            end
            config radio-2
                set mode AP
                set band 5GHz
                set status enable
                set operating-standard auto
                set local-vaps "5G"
            end
        end
    next
end
```

Apply the profile to FortiExtender and authorize the device

Associate the profile with FortiExtender and authorize the device. The profile settings are applied to the device during the authorization process.

To apply the profile and authorize FortiExtender in the GUI:

1. Go to *Network* > *FortiExtenders*, and double-click a FortiExtender device to open its settings.
2. In the *Profile* list, select the profile.
3. Click *Authorize*.



4. Set the remaining settings as desired, and click *OK*.

To apply the profile and authorize FortiExtender in the CLI:

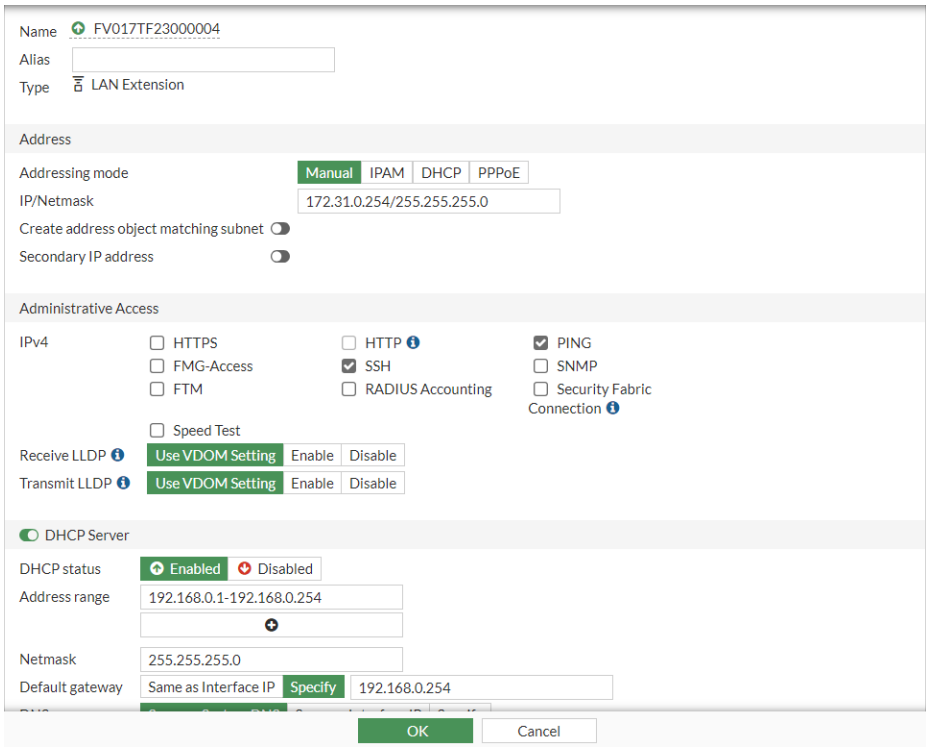
```
config extension-controller extender
    edit "FV017TF23000004"
        set id "FVA22FTF23000004"
        set authorized enable
        set device-id 0
        set extension-type lan-extension
        set profile "FVA22F-lanext-default"
    next
end
```

Configuring the LAN extension interface as a DHCP server

Configure the LAN extension interface as an DHCP server to assign IP addresses to WiFi clients.

To configure the LAN extension interface as a DHCP server in the GUI:

1. Go to *Network* > *Interfaces*, and double-click the LAN extension interface to open it for editing.
2. Enable *DHCP Server*.
3. Set *Address range*, *Netmask*, and *Default gateway*.



4. Set the remaining options as desired, and click *OK*.

To configure the LAN extension interface as a DHCP server in the CLI:

1. Assign an IP address to the LAN extension interface:

```
config system interface
    edit "FV017TF23000004"
        set vdom "root"
        set ip 172.31.0.254 255.255.255.0
        set allowaccess ping ssh
        set type lan-extension
        set role lan
        set snmp-index 27
        set ip-managed-by-fortiipam enable
        config ipv6
            set ip6-send-adv enable
            set ip6-other-flag enable
        end
        set interface "fext-ipsec-wiUx"
    next
end
```

2. Configure the DHCP server on the LAN extension interface:

```
config system dhcp server
    edit 3
        set dns-service default
        set default-gateway 172.31.0.254
```

```
        set netmask 255.255.255.0
        set interface "FV017TF23000004"
        config ip-range
            edit 1
                set start-ip 172.31.0.1
                set end-ip 172.31.0.254
            next
        end
        set dhcp-settings-from-fortiipam enable
        config exclude-range
            edit 1
                set start-ip 172.31.0.254
                set end-ip 172.31.0.254
            next
        end
    next
end
```

3. Confirm that the DHCP server can assign IP addresses to clients connecting to the FortiExtender Virtual Access Point (VAP).

   In this example, an iPhone connects to the FortiExtender 2.4GHz radio VAP named 2G-lan and receives an IP address of 172.31.0.3 from the LAN extension interface.

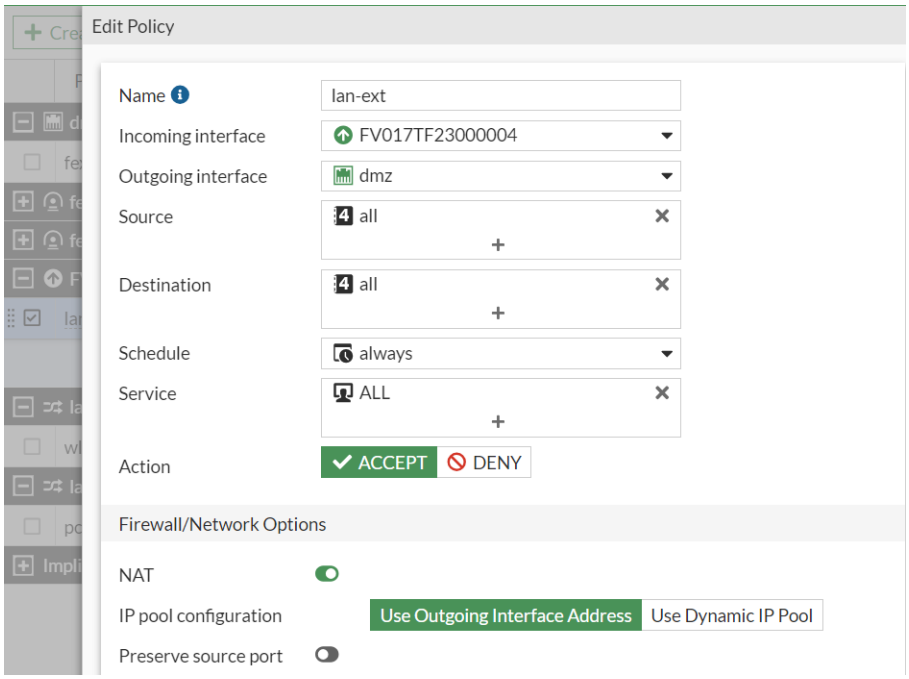
```
execute dhcp lease-list
FV017TF23000004
  IP            MAC-Address             Hostname            VCI                 SSID
     AP                  SERVER-ID           Expiry
  172.31.0.2    74:78:a6:8b:52:ff       FVA22FTF23000004    FortiExtenderVehicl
                        3                   Fri Apr 19 13:30:48 2024
  172.31.0.3    0a:ba:c9:5f:47:4d
```

Configuring a firewall policy

Configure a firewall policy with incoming interface set to the LAN extension interface to allow FortiExtender WiFi clients to reach the internet.

To configure a firewall policy to use the LAN extension interface in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy* and double-click the LAN extension policy to open it for editing.
2. Set *Incoming interface* to the LAN extension interface.
3. Set *Outgoing Interface*.



4. Set the remaining options as desired, and click *OK*.

To configure a firewall policy to use the LAN extension interface in the GUI:

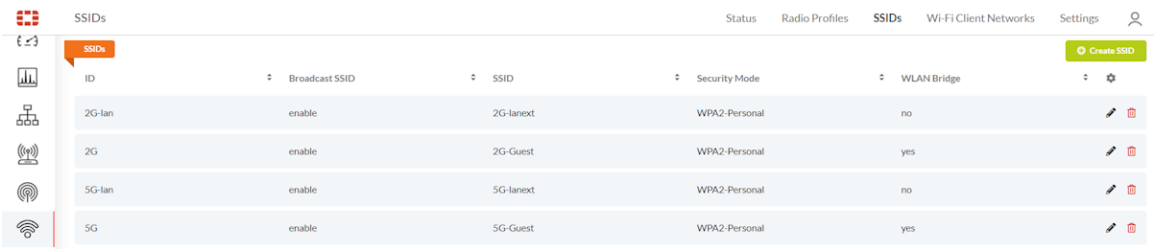
```
config firewall policy
...
    edit 4
        set name "lan-ext"
        set uuid 341c7010-270b-51ec-16b6-309891e3e880
        set srcintf "FV017TF23000004"
        set dstintf "dmz"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Verifying FortiExtender received the configuration

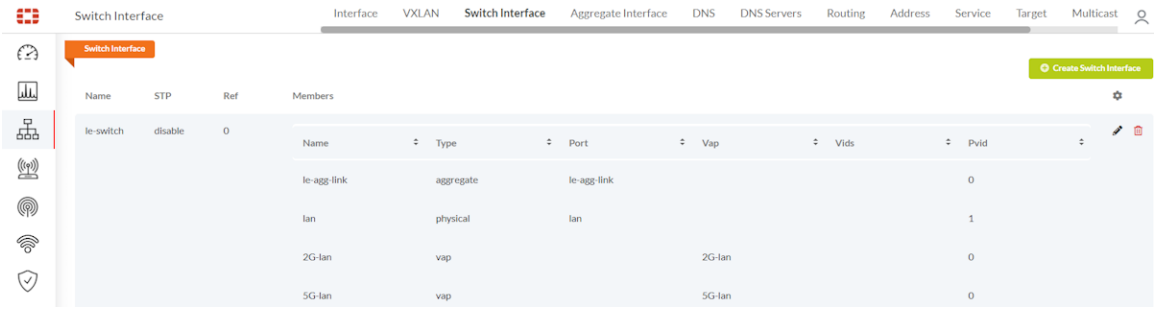
Verify that FortiExtender received the configuration from FortiGate.

To verify FortiExtender received the configuration:

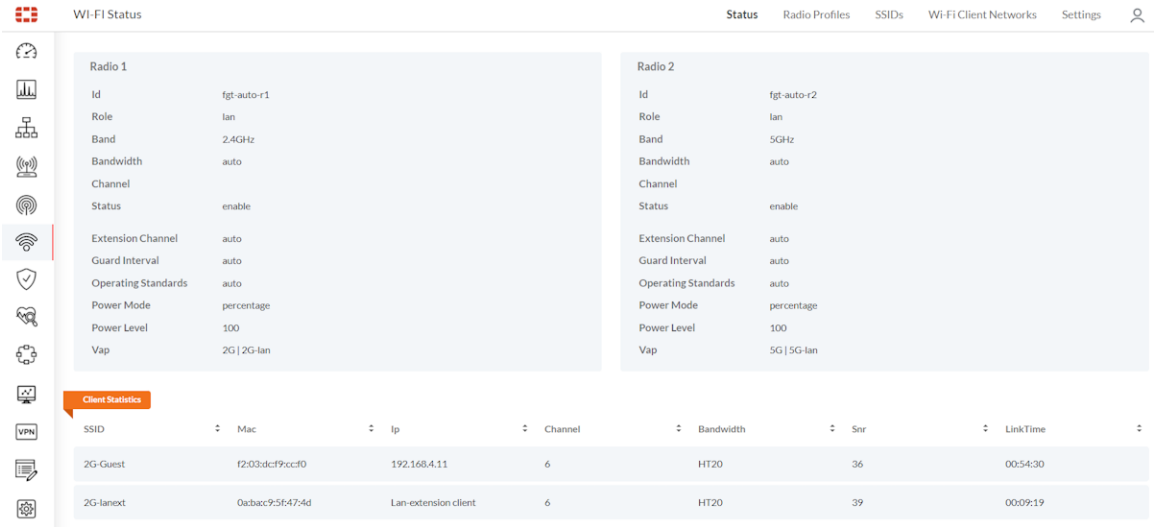
1. On FortiExtender GUI, go to *SSIDs*, and verify that the device received a LAN extension type of SSID. In this example, the LAN extension type of SSID is named *2G-lanext*.



2. Go to *Switch Interface*, and verify that the device received the WiFi interface for the LAN extension. In this example, the WiFi interface is named *2G-lan*.



3. Go to *Wi-Fi Status*, and verify that the WiFi client is connected to the LAN extension SSID. In this example, the client is connected to *2G-lanext*.



4. Confirm the FortiExtender WiFi client can reach the internet.

SCTP packets with zero checksum on the NP7 platform

The `sctp-csum-err` command provides flexibility to discard or permit IPv4 SCTP packets with zero checksum on the NP7 platform.

```
config system npu
    config fp-anomaly
        set sctp-csum-err {allow | drop | trap-to-host}
    end
end
```

`allow`	The NP7 platform will forward all SCTP packets with zero checksum.
`drop`	The NP7 platform will drop all SCTP packets with zero checksum. This is the default value.
`trap-to-host`	NP7 anomaly protection for SCTP will be disabled and SCTP packets with zero checksum will be forwarded. This option can also be used with a DoS policy to configure anomaly protection. If `policy-offload-level` is set to `dos-offload`, DoS policy anomaly protection is offloaded to the NP7 platform.

Industrial Connectivity

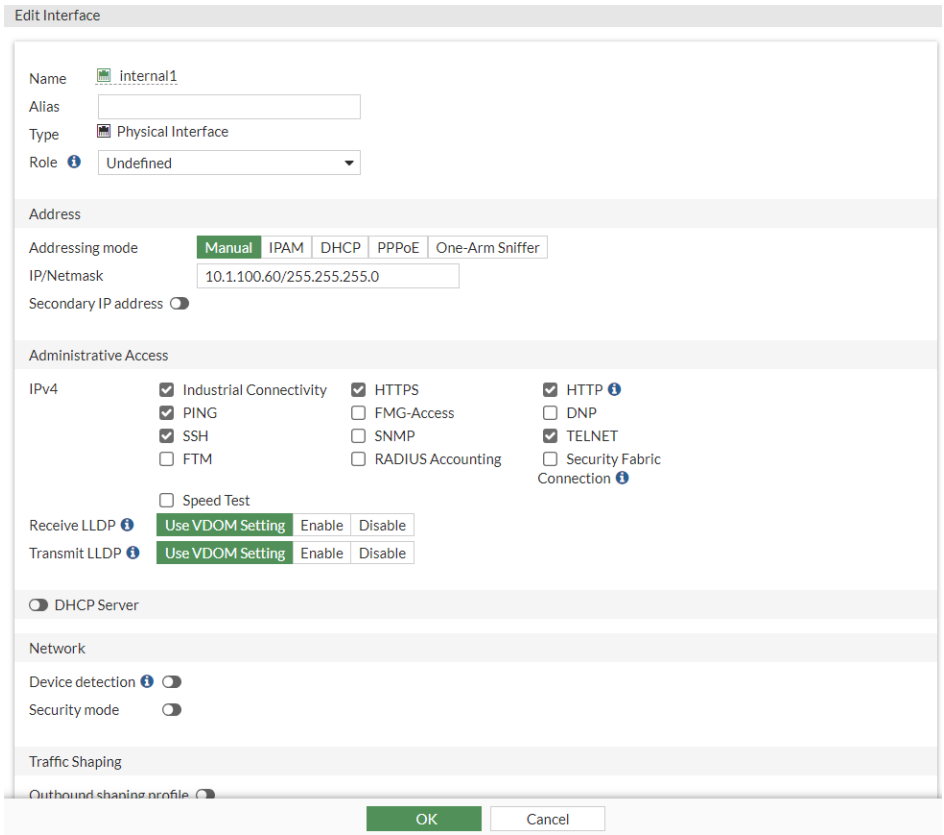
The industrial connectivity daemon (icond) and Industrial Connectivity service are available for FortiGate Rugged models equipped with a serial RS-232 (DB9/RJ45) interface to:

- Receive data in IEC 60870-5-101 serial protocol and convert it to IEC 60870-5-104 TCP/IP. See Sample configuration to convert IEC 60870-5-101 serial to IEC 60870-5-104 TCP/IP transport on page 882.
- Receive data in Modbus serial (RTU/ASCII) protocol and convert it to Modbus TCP. See Sample configuration to convert Modbus serial to Modbus TCP on page 883.

You can allow Industrial Connectivity access to an interface in the GUI and CLI.

To enable Industrial Connectivity for an interface in the GUI:

1. Go to *Network* > *Interfaces*.
2. Click *Create New* > *Interface*, or double-click an interface to open in for editing.
3. Set *Role* to *Undefined* or *WAN*
   Only internal and WAN interfaces support *Industrial Connectivity* administrative access.
4. In the *Administrative Access* section, select *Industrial Connectivity*.



5. Set the remaining options as desired, and click *OK*.

To enable Industrial Connectivity for an interface in the CLI:

```
config system interface
    edit <name>
        set allowaccess icond
        ...
    next
end
```

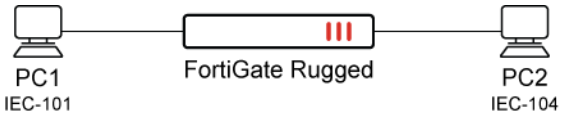
`set allowaccess icond`	Specify what types of management protocols can access the interface: • `icond`: Industrial Connectivity service access to proxy traffic between serial port and TCP/IP.

Use the `config system icond` command to configure the Industrial Connectivity service provided by the Industrial Connectivity daemon (icond).

Sample configuration to convert IEC 60870-5-101 serial to IEC 60870-5-104 TCP/IP transport

After the Industrial Connectivity service is enabled and configured for an interface, supported FortiGate Rugged devices can receive data from Supervisory Control and Data Acquisition (SCADA) systems in serial format and convert it to TCP/IP formats.

In the following topology, PC1 uses the IEC 60870-5-101 (shortened to IEC-101) protocol to transmit data from SCADA systems to FortiGate Rugged, where the data is converted to the IEC 60870-5-104 (shortened to IEC-104) protocol, and sent to PC2.



The data is converted as follows:

- FortiGate Rugged transmits data over TCP port 502.
- Protocols IEC 60870-5-101 and IEC 60870-5-104 are both used to transmit the data.

  While IEC-101 is based on a serial transmission of data (for example, using RS-232 and FSK-based modems), IEC-104 is packet oriented and based on TCP/IP transmission.

To enable Industrial Connectivity for an interface in the CLI:

```
config system interface
    edit "internal1"
        set vdom "root"
        set ip 10.1.100.60 255.255.255.0
        set allowaccess ping https ssh http telnet icond
        set type physical
        set snmp-index 3
    next
end
```

To configure the Industrial Connectivity service in the CLI:

1. Configure the Industrial Connectivity service

   ```
   config system icond
       set status enable
       set type iec101-104
       set tty-device "serial0"
   end
   ```

2. Get the default status:

   ```
   get system icond
   status              : enable
   type                : iec101-104
   tty-device          : serial0
   ```

```
tty-baudrate        : 9600
tty-parity          : even
tty-databits        : 8
tty-stopbits        : 1
tty-flowcontrol     : none
iec101-mode         : unbalanced
iec101-laddr-size   : 1
iec101-laddr-local  : 1
iec101-laddr-remote : 2
iec101-use-ack-char : disable
iec101-keepalive    : enable

Sample configuration to convert Modbus serial to Modbus TCP

After the Industrial Connectivity service is enabled and configured for an interface, supported FortiGate Rugged devices can receive data from Modbus networks in serial format and convert it to TCP.

In the following topology, the Modbus controller uses Modbus serial to transmit data to FortiGate Rugged, where the data is converted to the Modbus TCP, and sent to the Modbus Remote Terminal Unit (RTU).

To enable Industrial Connectivity for an interface in the CLI:

```
config system interface
    edit "internal1"
        set vdom "root"
        set ip 10.1.100.60 255.255.255.0
        set allowaccess ping https http telnet icond
        set type physical
        set description "link to modbus server"
        set snmp-index 3
    next
end
```

To configure the Industrial Connectivity service in the CLI:

1. Configure the Industrial Connectivity service

```
config system icond
    set status enable
    set type modbus-serial-tcp
    set tty-device "serial0"
end
```

2. Get the default status:

```
get system icond
status              : enable
type                : modbus-serial-tcp
tty-device          : serial0
tty-baudrate        : 9600
tty-parity          : even
tty-databits        : 8
tty-stopbits        : 1
tty-flowcontrol     : none
modbus-serial-mode  : RTU/ASCII
modbus-serial-addr  : 1
modbus-serial-timeout-resp: 500
modbus-tcp-unit-id  : 255
```

Diagnostics

Administrators can use the *Diagnostics* page to access the following tools:

Capture packet	Captures packet streams in real-time to let you view header and payload information. See Using the packet capture tool on page 884.
Debug flow	Traces packet flow through FortiOS to help you diagnose and debug issues. See Using the debug flow tool on page 889.

See also Performing a sniffer trace or packet capture on page 4325 and Debugging the packet flow on page 4327.

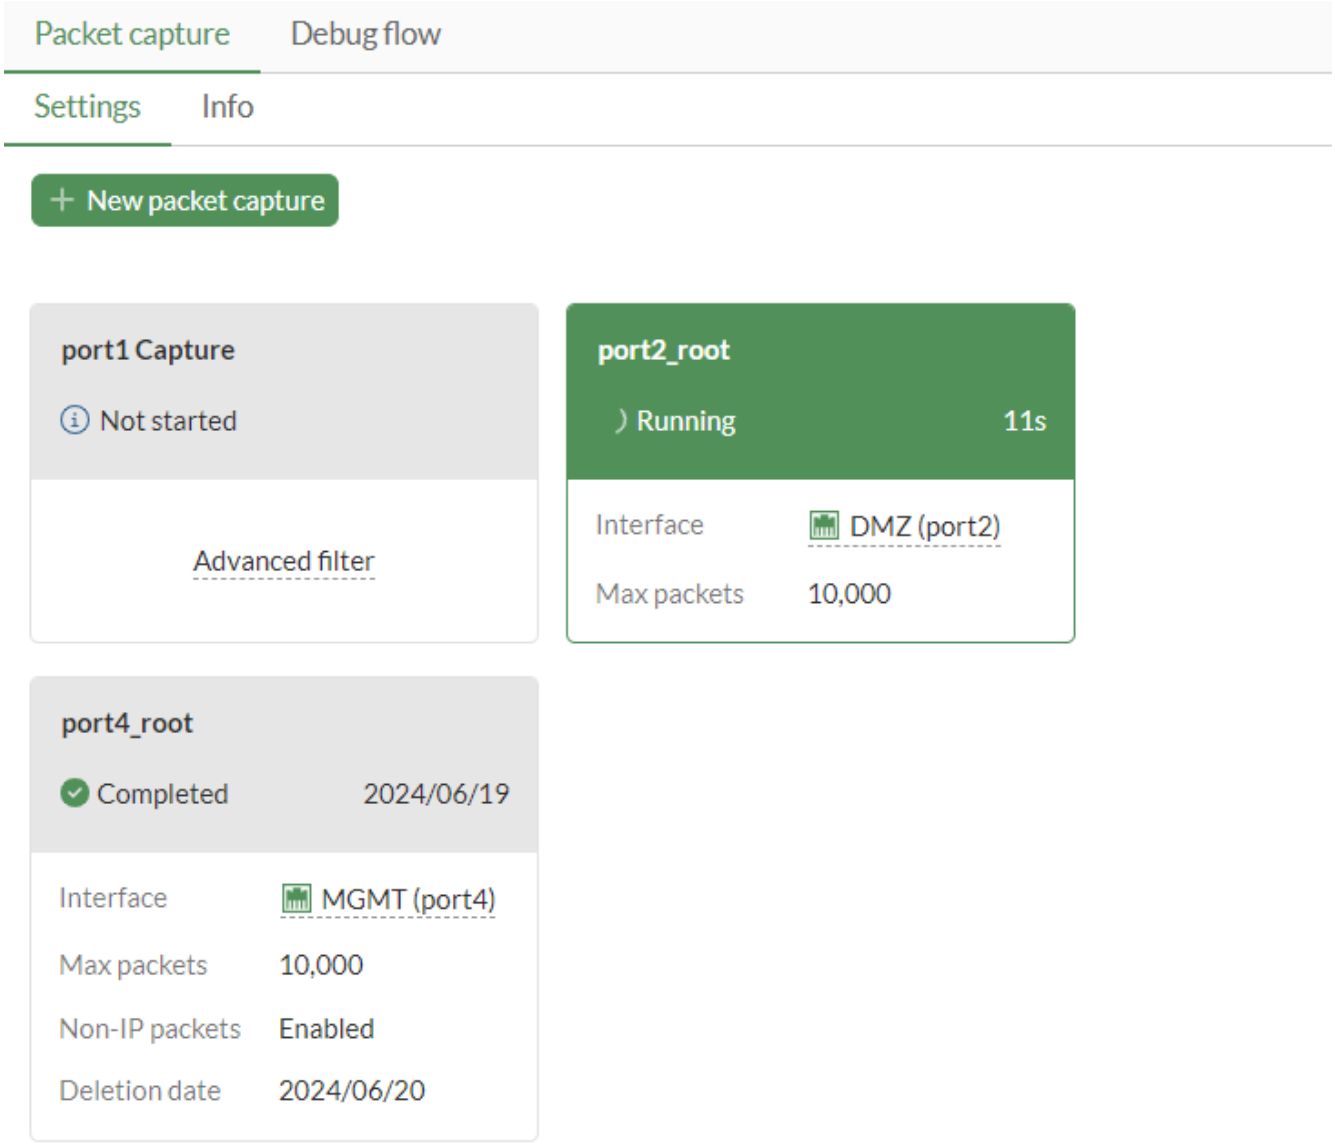
Using the packet capture tool

Administrators can use the packet capture tool to select a packet and view its header and payload information in real-time. Once completed, packets can be filtered by various fields or through the search bar. The capture can be saved as a PCAP file that you can use with a third-party application, such as Wireshark, for further analysis.

Packet capture criteria can be stored for the re-initiation of packet captures multiple times using the same parameters, such as interface, filters, and so on.

Packet capture criteria can be created and stored in order to re-initiate packet captures in the GUI with the same parameters. Capture cards in the *Network* > *Diagnostics* page are sorted in alphabetical order of the configured name and colored depending on state:

- Green: The packet capture is running.
- Gray: The packet capture has not started yet, has completed, or the capture files have been deleted.



When creating the packet capture:

- The *Name* field must be a unique name for the packet capture criteria being configured.
- Enabling *Include non-IP packets* allows non-IP address packets to be captured when enabled. Supported non-IP address packet types include ARP, RARP, LLC, LLDP, VLAN, and LACPDU. When the packet capture is complete, non-IP address packets will include header information, however, unsupported types will display as *Unknown*.
- After configuring the packet capture criteria, you can choose to *Start capture*, *Save settings for later*, or *Close*. Starting a packet capture or saving the configured settings will both store criteria for future use.

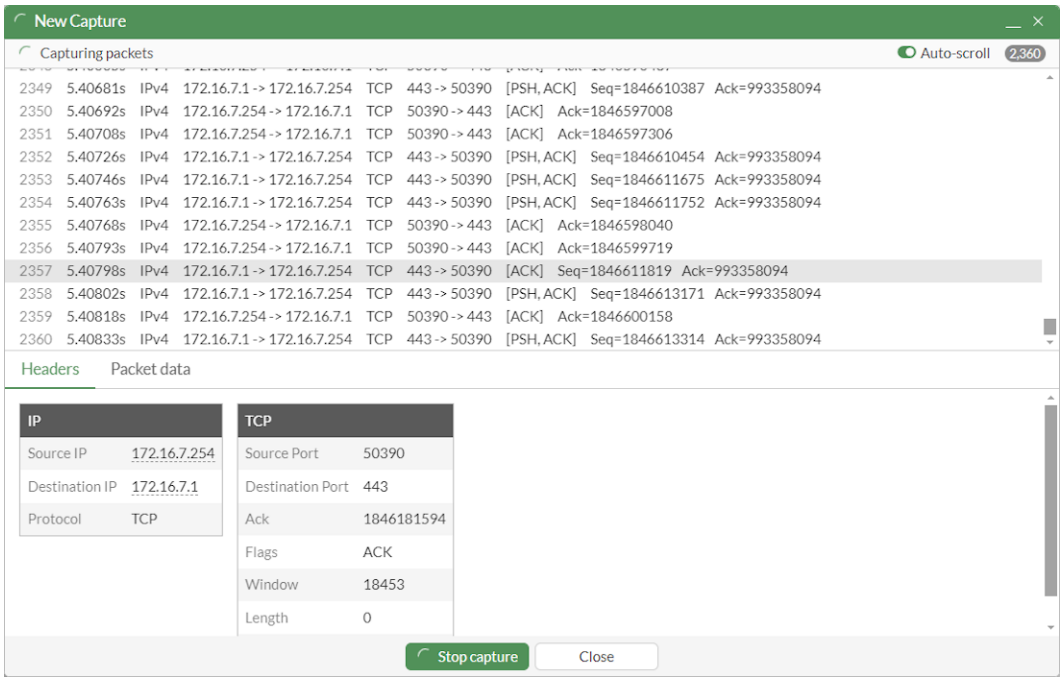
System event logs are generated when a packet capture is started or stopped in the GUI.

To use the packet capture tool in the GUI:

1. Go to *Network* > *Diagnostics* and select the *Packet Capture* tab.
2. Optionally, select an *Interface* (*any* is the default).
3. Optionally, enable *Filters* and select a *Filtering syntax*:
   a. *Basic*: enter criteria for the *Host*, *Port*, and *Protocol number*.

   b. *Advanced*: enter a string, such as *src host 172.16.200.254 and dst host 172.16.200.1 and dst port 443*.
4. Click *Start capture*. The capture is visible in real-time.
5. While the capture is running, select a packet, then click the *Headers* or *Packet data* tabs to view more information.

When the packet capture is running, disable *Auto-scroll* to stop automatic scrolling behavior when new packets arrive.



6. When the capture is finished, click *Save as pcap*. The PCAP file is automatically downloaded.
7. Optionally, use the *Search* bar or the column headers to filter the results further.

Multiple packet captures

Multiple packet captures can be run simultaneously for when many packet captures are needed for one situation. For example, ingress and egress interfaces can be captured at the same time to compare traffic or the physical interface and VPN interface can be captured using different filters to see if packets are leaving the VPN.

The packet capture dialog can be docked and minimized to run in the background. The minimized dialog aligns with other CLI terminals that are minimized.

How many packet captures and the number of packets that can be captured depend on the device model.

Whether the device model has disk storage affects when packet captures are deleted. Without disk storage, packet captures are deleted 24 hours after completion or immediately after reboot. With disk storage, packet captures are deleted after 7 days.

To find the limit on the number of packet captures supported for a specific device model, use the Maximum Values Table, and search for the object `firewall.on-demand-sniffer`.

To run multiple packet captures at the same time:

1. Go to *Network* > *Diagnostics*.
2. Configure the first packet capture:

   a. Click *New packet capture*.
   b. Select the *Interface* and configure other settings as needed.
   c. Click *Start capture*. The first packet capture begins.
3. Minimize the packet capture. The packet capture continues to run.
4. Configure the second packet capture:
   a. Click *New packet capture*.
   b. Select the *Interface* and configure other settings as needed.
   c. Click *Start capture*. The second packet capture begins.
5. When the captures are complete, expand the dialog and select *Save as pcap* for each packet capture.

Controlling GUI packet captures in the CLI

GUI packet captures can be controlled in the CLI using the `on-demand-sniffer` commands.

To control GUI packet captures in the CLI:

1. Add a new firewall on-demand sniffer table to store the GUI packet capture settings and filters:

```
config firewall on-demand-sniffer
    edit "port1 Capture"
        set interface "port1"
        set max-packet-count 10000
        set advanced-filter "net 172.16.200.0/24 and port 443 and port 49257"
    next
end
```

2. Run packet capture commands:
   a. List all of the packet captures:

```
# diagnose on-demand-sniffer list
mkey: port1 Capture
interface: port1
status: not_started
start time:
end time:
```

   b. Start a packet capture:

```
# diagnose on-demand-sniffer start "port1 Capture"
```

   c. Stop a packet capture:

```
# diagnose on-demand-sniffer stop "port1 Capture"
```

   d. Delete the result of a packet capture:

```
# diagnose on-demand-sniffer delete-results "port1 Capture"
```

For more information about running a packet capture in the CLI, see Performing a sniffer trace or packet capture on page 4325.

Using the debug flow tool

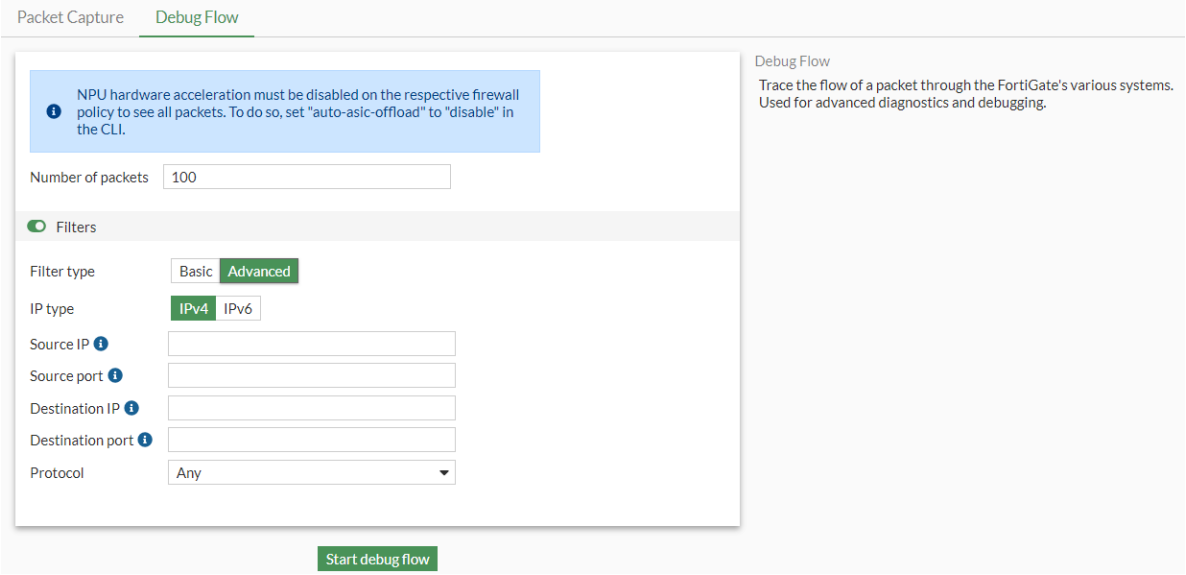
Administrators can use the debug flow tool to display debug flow output in real-time until it is stopped. The completed output can be filtered by time, message, or function. The output can be exported as a CSV file.

For information about using the debug flow tool in the CLI, see Debugging the packet flow on page 4327.

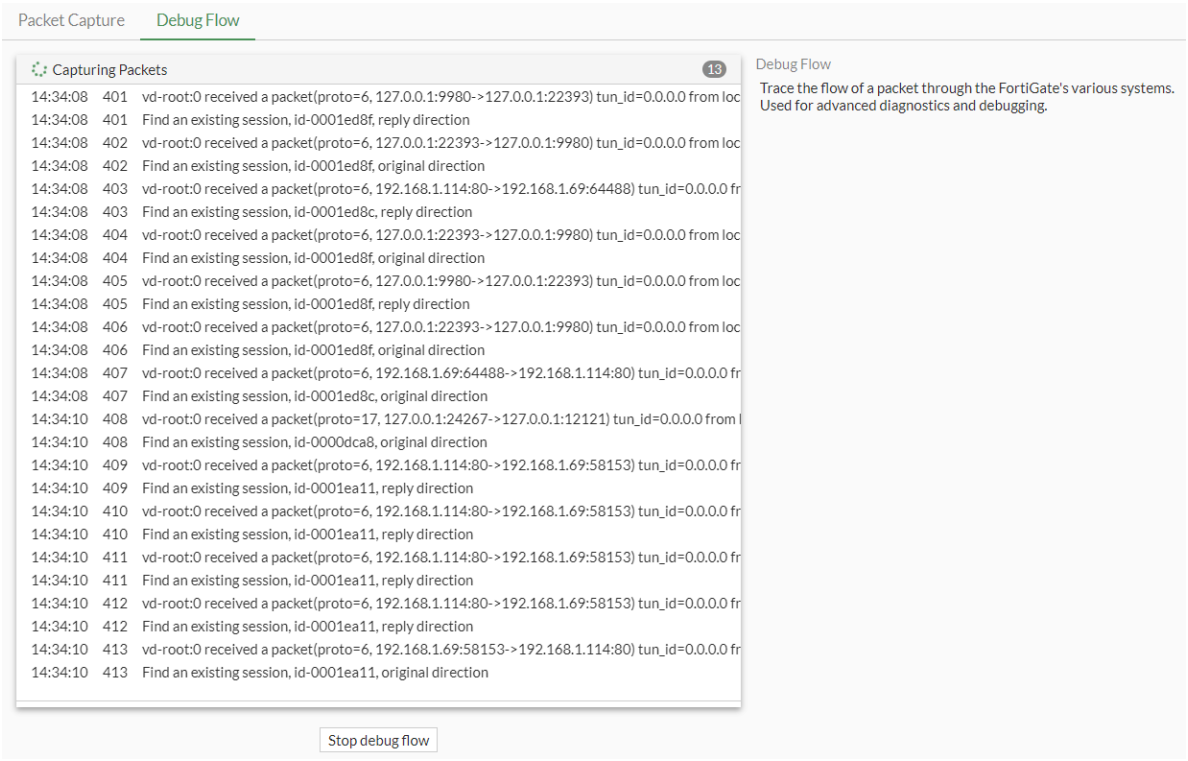
To run a debug flow:

1. Go to *Network* > *Diagnostics* and select the *Debug Flow* tab.
2. Optionally, enable *Filters* and select a *Filter type*:
   a. *Basic*: filter by *IP address*, *Port*, and *Protocol*, which is the equivalent of:
      - `# diagnose debug flow filter addr <addr/range>`
      - `# diagnose debug flow filter port <port/range>`
      - `# diagnose debug flow filter proto <protocol>`

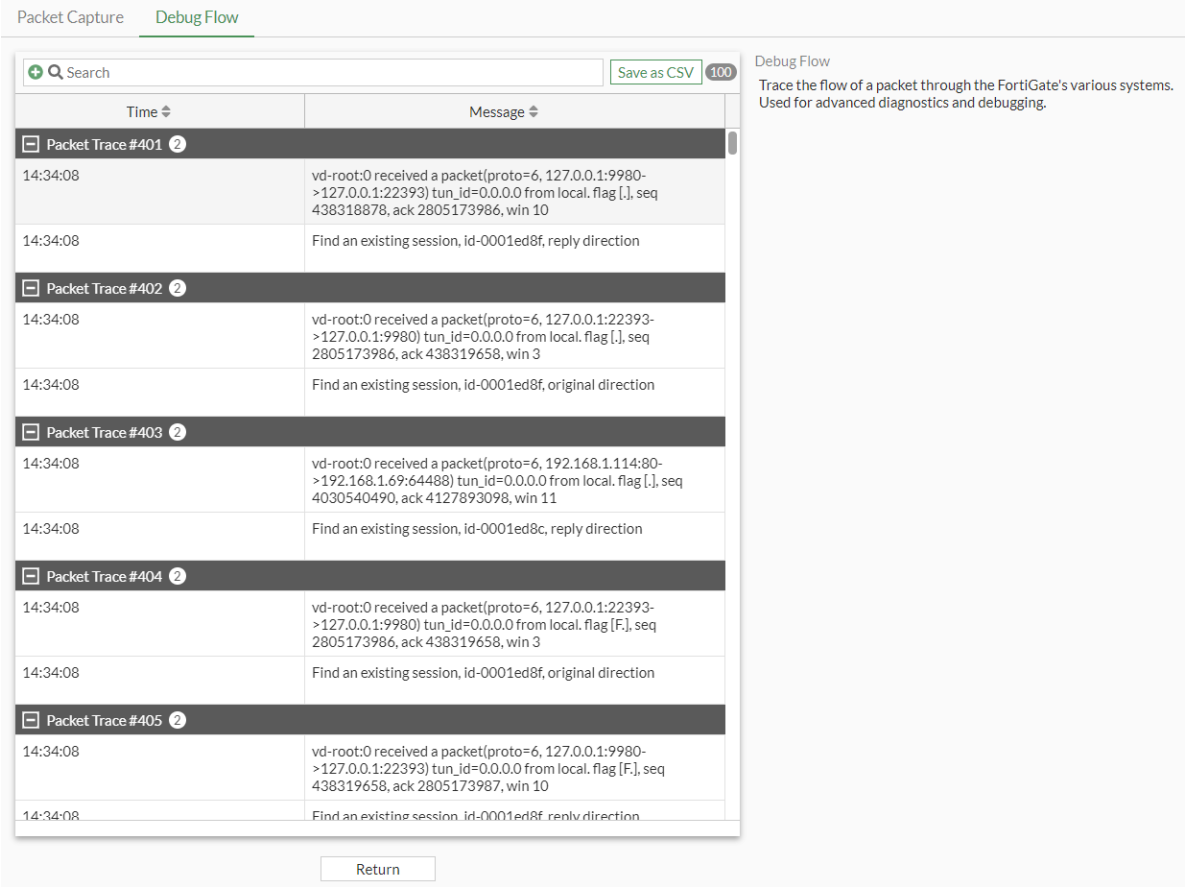
   b. *Advanced*: filter by *Source IP*, *Source port*, *Destination IP*, *Destination port*, and *Protocol*, which is the equivalent of:
      - `# diagnose debug flow filter saddr <addr/range>`
      - `# diagnose debug flow filter sport <port/range>`
      - `# diagnose debug flow filter daddr <addr/range>`
      - `# diagnose debug flow filter dport <port/range>`
      - `# diagnose debug flow filter proto <protocol>`



3. Click *Start debug flow*. The debug messages are visible in real-time.



4. When the debug flow is finished (or you click *Stop debug flow*), click *Save as CSV*. The CSV file is automatically downloaded.



The current output can be filtered by *Time* and *Message*. The *Function* field can be added.

5. Hover over the table header and click the gear icon (*Configure Table*).
6. Select *Function* and click *Apply*. The *Function* column is displayed and can be used to filter the output for further analysis.

SD-WAN

The following topics provide information about SD-WAN:

- SD-WAN overview on page 893
- SD-WAN quick start on page 897
- SD-WAN members and zones on page 908
- Performance SLA on page 931
- SD-WAN rules on page 1017
- Advanced routing on page 1125
- VPN overlay on page 1158
- Advanced configuration on page 1278
- SD-WAN cloud on-ramp on page 1332
- SD-WAN Network Monitor service on page 1355
- Troubleshooting SD-WAN on page 1386

SD-WAN overview

SD-WAN is a software-defined approach to managing Wide-Area Networks (WAN). It consolidates the physical transport connections, or underlays, and monitors and load-balances traffic across the links. VPN overlay networks can be built on top of the underlays to control traffic across different sites.

Health checks and SD-WAN rules define the expected performance and business priorities, allowing the FortiGate to automatically and intelligently route traffic based on the application, internet service, or health of a particular connection.

WAN security and intelligence can be extended into the LAN by incorporating wired and wireless networks under the same domain. FortiSwitch and FortiAP devices integrate seamlessly with the FortiGate to form the foundation of an SD-Branch.

Some of the key benefits of SD-WAN include:

- Reduced cost with transport independence across MPLS, 4G/5G LTE, and others.
- Reduced complexity with a single vendor and single-pane-of-glass management.
- Improve business application performance thanks to increased availability and agility.
- Optimized user experience and efficiency with SaaS and public cloud applications.

SD-WAN components and design principles

SD-WAN can be broken down into three layers:

- Management and orchestration
- Control, data plane, and security
- Network access

The control, data plane, and security layer can only be deployed on a FortiGate. The other two layers can help to scale and enhance the solution. For large deployments, FortiManager and FortiAnalyzer provide the management and orchestration capabilities FortiSwitch and FortiAP provide the components to deploy an SD-Branch.

Layer	Functions	Devices	
Management and orchestration	• Unified management • Template based solution • Zero touch provisioning • Logging, monitoring, and analysis • Automated orchestration using the REST API	FortiManager	FortiAnalyzer

Control, data plane, and security	• Consolidation of underlays and overlays into SD-WAN zones
	  • Underlay and Overlay
	• Scalable VPN solutions using ADVPN
	  • Overlay
	• Static and dynamic routing definition
	  • Routing
	• NGFW firewalling
	  • Security
	• SD-WAN health-checks and monitoring
	  • SD-WAN
	• Application-aware steering and intelligence
	  • SD-WAN
		FortiGate	

Network access	• Wired and wireless network segmentation • Built-in network access control	FortiSwitch	FortiAP

Design principles

The Five-pillar approach, described in the SD-WAN / SD-Branch Architecture for MSSPs guide, is recommended when designing a secure SD-WAN solution.

Underlay

Determine the WAN links that will be used for the underlay network, such as your broadband link, MPLS, 4G/5G LTE connection, and others.

For each link, determine the bandwidth, quality and reliability (packet loss, latency, and jitter), and cost. Use this information to determine which link to prefer, what type of traffic to send across the each link, and to help you the baselines for health-checks.

Overlay

VPN overlays are needed when traffic must travel across multiple sites. These are usually site-to-site IPsec tunnels that interconnect branches, datacenters, and the cloud, forming a hub-and-spoke topology.

The management and maintenance of the tunnels should be considered when determining the overlay network requirements. Manual tunnel configuration might be sufficient in a small environment, but could become unmanageable as the environment size increases. ADVPN can be used to help scale the solution; see ADVPN on page 2623 for more information.

Routing

Traditional routing designs manipulate routes to steer traffic to different links. SD-WAN uses traditional routing to build the basic routing table to reach different destinations, but uses SD-WAN rules to steer traffic. This allows the steering to be based on criteria such as destination, internet service, application, route tag, and the health of the link. Routing in an SD-WAN solution is used to identify all possible routes across the underlays and overlays, which the FortiGate balances using ECMP.

In the most basic configuration, static gateways that are configured on an SD-WAN member interface automatically provide the basic routing needed for the FortiGate to balance traffic across the links. As the number of sites and destinations increases, manually maintaining routes to each destination becomes difficult. Using dynamic routing to advertise routes across overlay tunnels should be considered when you have many sites to interconnect.

Security

Security involves defining policies for access control and applying the appropriate protection using the FortiGate's NGFW features. Efficiently grouping SD-WAN members into SD-WAN zones must also be considered. Typically, underlays provide direct internet access and overlays provide remote internet or network access. Grouping the underlays together into one zone, and the overlays into one or more zones could be an effective method.

SD-WAN

The SD-WAN pillar is the intelligence that is applied to traffic steering decisions. It is comprised of four primary elements:

- **SD-WAN zones**

  SD-WAN is divided into zones. SD-WAN member interfaces are assigned to zones, and zones are used in policies as source and destination interfaces. You can define multiple zones to group SD-WAN interfaces together, allowing logical groupings for overlay and underlay interfaces. Routing can be configured per zone.

See SD-WAN members and zones on page 908.

- **SD-WAN members**

  Also called interfaces, SD-WAN members are the ports and interfaces that are used to run traffic. At least one interface must be configured for SD-WAN to function.

  See Configuring the SD-WAN interface on page 898.

- **Performance SLAs**

  Also called health-checks, performance SLAs are used to monitor member interface link quality, and to detect link failures. When the SLA falls below a configured threshold, the route can be removed, and traffic can be steered to different links in the SD-WAN rule.

  SLA health-checks use active or passive probing:

  - Active probing requires manually defining the server to be probed, and generates consistent probing traffic.
  - Passive probing uses active sessions that are passing through firewall policies used by the related SD-WAN interfaces to derive health measurements. It reduces the amount of configuration, and eliminates probing traffic. See Passive WAN health measurement on page 944 for details.

  See Performance SLA on page 931.

- **SD-WAN rules**

  Also called services, SD-WAN rules control path selection. Specific traffic can be dynamically sent to the best link, or use a specific route.

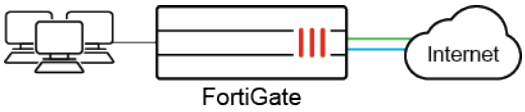
  Rules control the strategy that the FortiGate uses when selecting the outbound traffic interface, the SLAs that are monitored when selecting the outgoing interface, and the criteria for selecting the traffic that adheres to the rule. When no SD-WAN rules match the traffic, the implicit rule applies.

  See SD-WAN rules on page 1017.

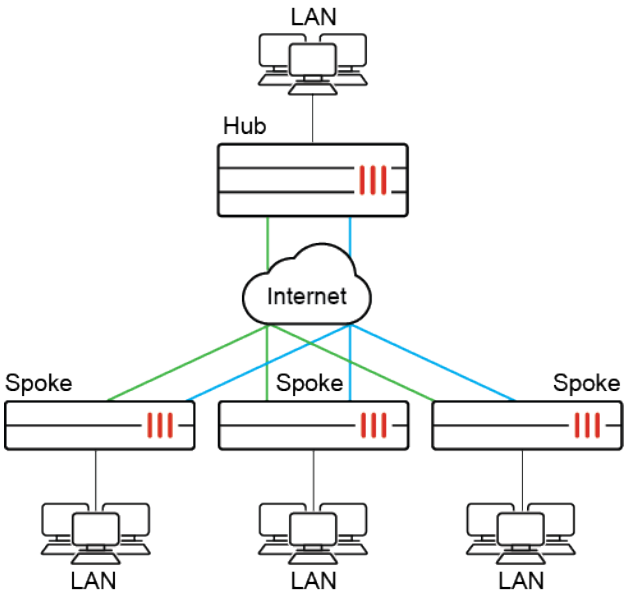
SD-WAN designs and architectures

The core functionalities of Fortinet's SD-WAN solution are built into the FortiGate. Whether the environment contains one FortiGate, or one hundred, you can use SD-WAN by enabling it on the individual FortiGates.

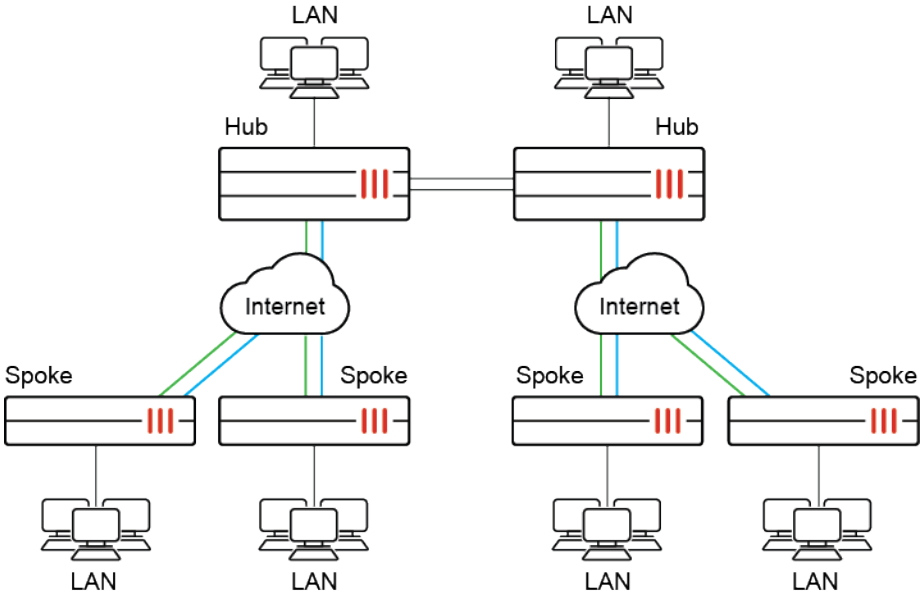
At a basic level, SD-WAN can be deployed on a single device in a single site environment:



At a more advanced level, SD-WAN can be deployed in a multi-site, hub and spoke environment:



At an enterprise or MSSP level, the network can include multiple hubs, possibly across multiple regions:

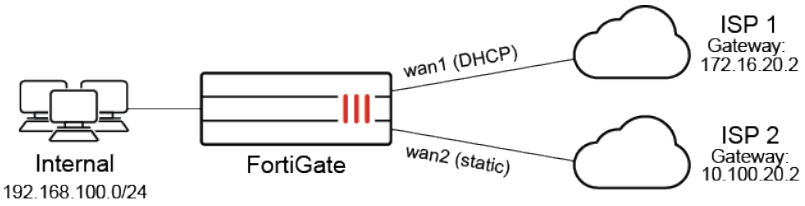


For more details, see the SD-WAN / SD-Branch Architecture for MSSPs guide.

SD-WAN quick start

This section provides an example of how to start using SD-WAN for load balancing and redundancy.

In this example, two ISP internet connections, wan1 (DHCP) and wan2 (static), use SD-WAN to balance traffic between them at 50% each.



1. Configuring the SD-WAN interface on page 898
2. Adding a static route on page 899
3. Selecting the implicit SD-WAN algorithm on page 900
4. Configuring firewall policies for SD-WAN on page 900
5. Link monitoring and failover on page 901
6. Results on page 902
7. Configuring SD-WAN in the CLI on page 905

Configuring the SD-WAN interface

First, SD-WAN must be enabled and member interfaces must be selected and added to a zone. The selected FortiGate interfaces can be of any type (physical, aggregate, VLAN, IPsec, and others), but must be removed from any other configurations on the FortiGate.

In this step, two interfaces are configured and added to the default SD-WAN zone (virtual-wan-link) as SD-WAN member interfaces. This example uses a mix of static and dynamic IP addresses; your deployment could also use only one or the other.

Once the SD-WAN members are created and added to a zone, the zone can be used in firewall policies, and the whole SD-WAN can be used in static routes.

To configure SD-WAN members:

1. Configure the wan1 and wan2 interfaces. See Interface settings on page 173 for details.
   a. Set the wan1 interface *Addressing mode* to *DHCP* and *Distance* to *10*.

   By default, *Retrieve default gateway from server* (`defaultgw` in the CLI) is enabled for DHCP interfaces. This enables using the default gateway information that is retrieved from the DHCP server to create a default route through the DHCP interface with the default administrative distance.

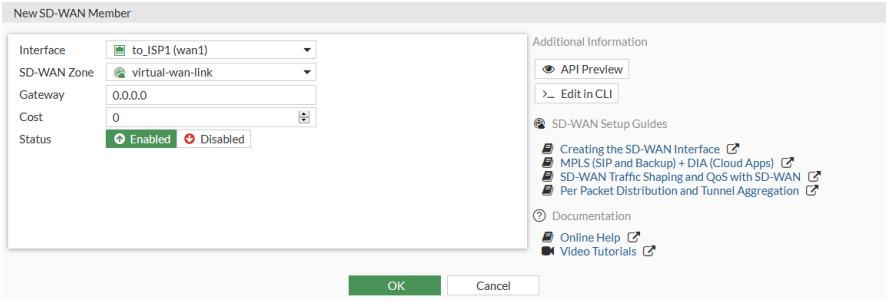
   The default administrative distance for DHCP interfaces is *5*, and for static routes it is *10*. It is important to account for this when configuring your SD-WAN for 50/50 load balancing by setting the DHCP interface's distance to *10*.

   b. Set the wan2 interface *IP/Netmask* to *10.100.20.1 255.255.255.0*.
2. Go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
3. Set the *Interface* to *wan1*.
4. Leave *SD-WAN Zone* as *virtual-wan-link*.
5. As wan1 uses DHCP, leave *Gateway* set to *0.0.0.0*.

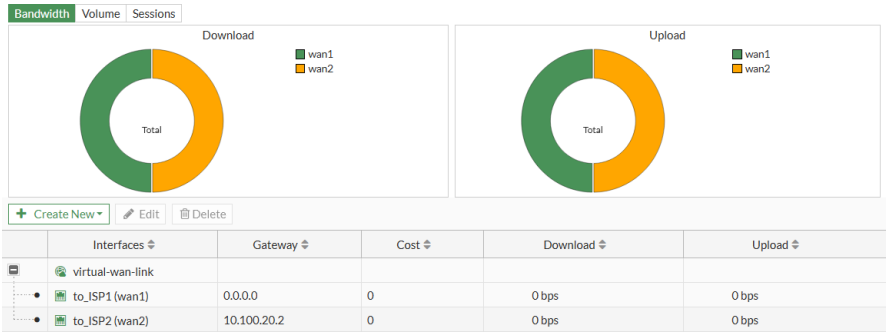
If IPv6 visibility is enabled in the GUI, an IPv6 gateway can also be added for each member. See Feature visibility on page 3595 for details.

6. Leave *Cost* as *0*.

   The *Cost* field is used by the Lowest Cost (SLA) strategy. The link with the lowest cost is chosen to pass traffic. The lowest possible *Cost* is *0*.



7. Set *Status* to *Enable*, and click *OK*.
8. Repeat the above steps for wan2, setting *Gateway* to the ISP's gateway: *10.100.20.2*.

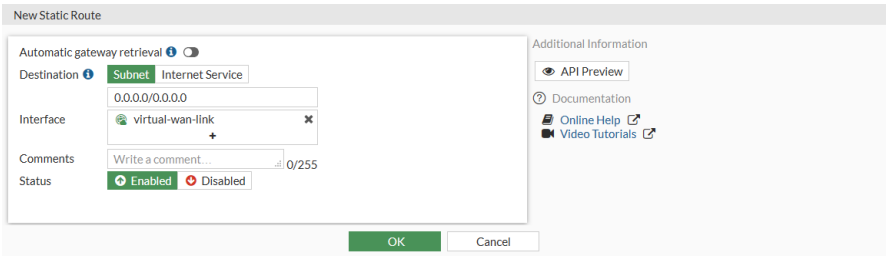


Adding a static route

You must configure a default route for the SD-WAN. The default gateways for each SD-WAN member interface do not need to be defined in the static routes table. FortiGate will decide what route or routes are preferred using Equal Cost Multi-Path (ECMP) based on distance and priority.

To create a static route for SD-WAN:

1. Go to *Network* > *Static Routes*.
2. Click *Create New*. The *New Static Route* page opens.
3. Set *Destination* to *Subnet*, and leave the IP address and subnet mask as *0.0.0.0/0.0.0.0*.
4. In the *Interface* field select an SD-WAN zone.



5. Ensure that *Status* is *Enabled*.
6. Click *OK*.

By default, a static route or the default route outgoing through an SD-WAN zone have an administrative distance of *1*.

To change the default distance in the CLI:

```
config router static
    edit <static-route-entry>
        set distance <AD>
    next
end
```

Selecting the implicit SD-WAN algorithm

SD-WAN rules define specific routing options to route traffic to an SD-WAN member.

If no routing rules are defined, the default *Implicit* rule is used. It can be configured to use one of five different load balancing algorithms. See Implicit rule on page 1026 for more details and examples.

This example shows four methods to equally balance traffic between the two WAN connections. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and edit the *sd-wan* rule to select the method that is appropriate for your requirements.

- *Source IP* (CLI command: `source-ip-based`):
  Select this option to balance traffic equally between the SD-WAN members according to a hash algorithm based on the source IP addresses.
- *Session* (`weight-based`):
  Select this option to balance traffic equally between the SD-WAN members by the session numbers ratio among its members. Use weight 50 for each of the 2 members.
- *Source-Destination IP* (`source-dest-ip-based`):
  Select this option to balance traffic equally between the SD-WAN members according to a hash algorithm based on the source and destination IP addresses.
- *Volume* (`measured-volume-based`):
  Select this option to balance traffic equally between the SD-WAN members according to the bandwidth ratio among its members.

Configuring firewall policies for SD-WAN

SD-WAN zones can be used in policies as source and destination interfaces. Individual SD-WAN members cannot be used in policies.

You must configure a policy that allows traffic from your organization's internal network to the SD-WAN zone. Policies configured with the SD-WAN zone apply to all SD-WAN interface members in that zone.

To create a firewall policy for SD-WAN:

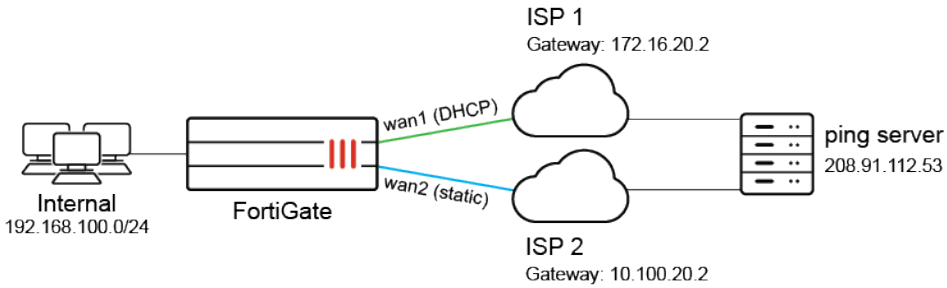
1. Go to *Policy & Objects* > *Firewall Policy*.
2. Click *Create New*. The *New Policy* page opens.
3. Configure the following:

Name	Enter a name for the policy.
Incoming Interface	*internal*
Outgoing Interface	*virtual-wan-link*
Source	*all*
Destination	*all*
Schedule	*always*
Service	*ALL*
Action	*ACCEPT*
Firewall / Network Options	Enable *NAT* and set *IP Pool Configuration* to *Use Outgoing Interface Address*.
Security Profiles	Apply profiles as required.
Logging Options	Enable *Log Allowed Traffic* and select *All Sessions*. This allows you to verify results later.

4. Enable the policy, then click *OK*.

Link monitoring and failover

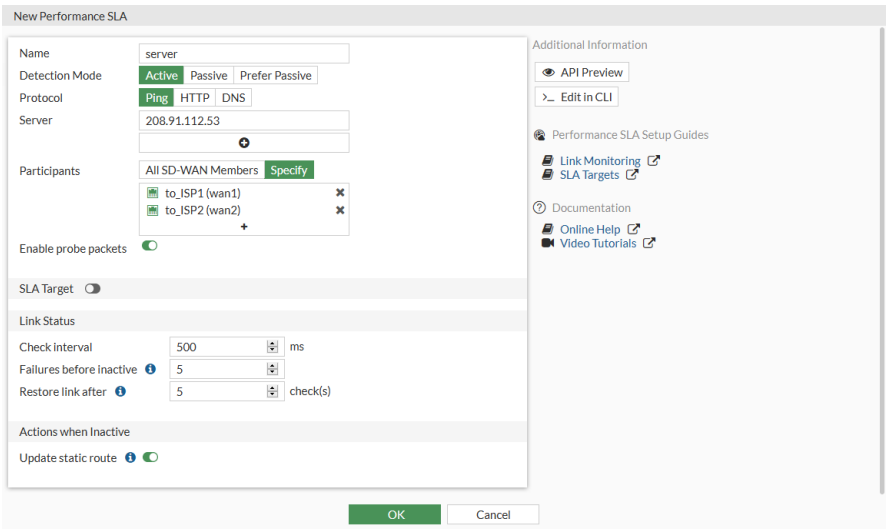
Performance SLA link monitoring measures the health of links that are connected to SD-WAN member interfaces by sending probing signals through each link to a server, and then measuring the link quality based on latency, jitter, and packet loss. If a link is broken, the routes on that link are removed and traffic is routed through other links. When the link is working again, the routes are re-enabled. This prevents traffic being sent to a broken link and lost.



In this example, the detection server IP address is 208.91.112.53. A performance SLA is created so that, if ping fails per the metrics defined, the routes to that interface are removed and traffic is detoured to the other interface. The ping protocol is used, but other protocols could also be selected as required.

To configure a performance SLA:

1. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Enter a name for the SLA and set *Protocol* to *Ping*.
3. In the *Server* field, enter the detection server IP address (208.91.112.53 in this example).
4. In the *Participants* field, select *Specify* and add wan1 and wan2.



SLA targets are not required for link monitoring.

5. Configure the required metrics in *Link Status*.
6. Ensure that *Update static route* is enabled. This disables static routes for the inactive interface and restores routes on recovery.
7. Click *OK*.

Results

The following GUI pages show the function of the SD-WAN and can be used to confirm that it is setup and running correctly:

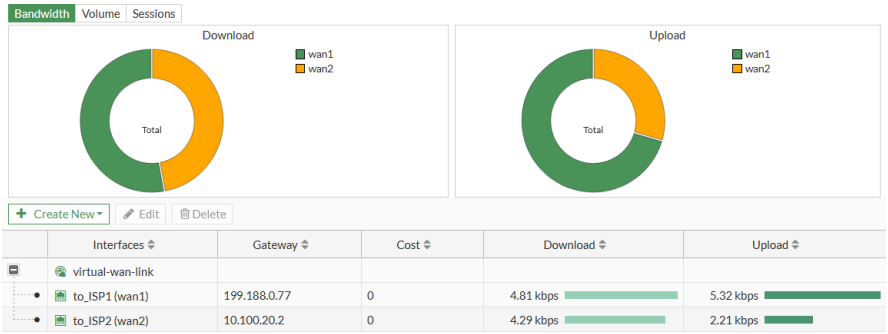
- Interface usage on page 902
- Performance SLA on page 903
- Routing table on page 905
- Firewall policy on page 905

Interface usage

Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab to review the SD-WAN interfaces' usage.

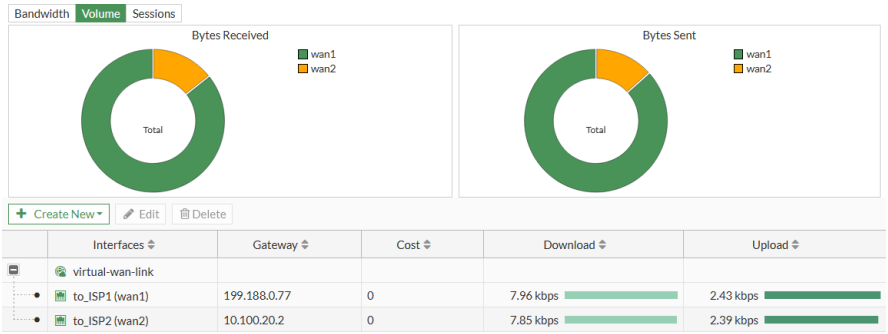
Bandwidth

Select *Bandwidth* to view the amount of downloaded and uploaded data for each interface.



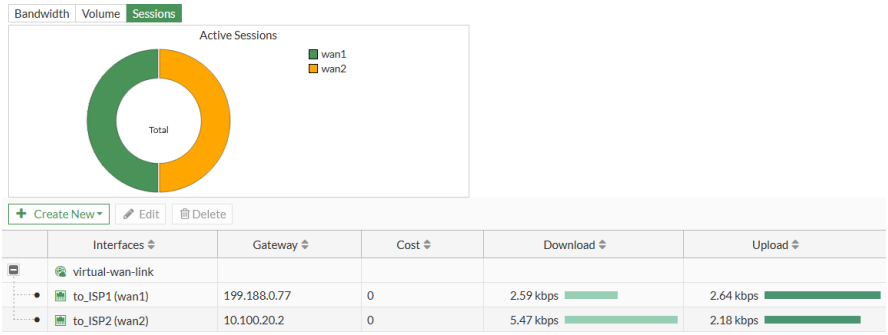
Volume

Select *Volume* to see donut charts of the received and sent bytes on the interfaces.



Sessions

Select *Sessions* to see a donut chart of the number of active sessions on each interface.

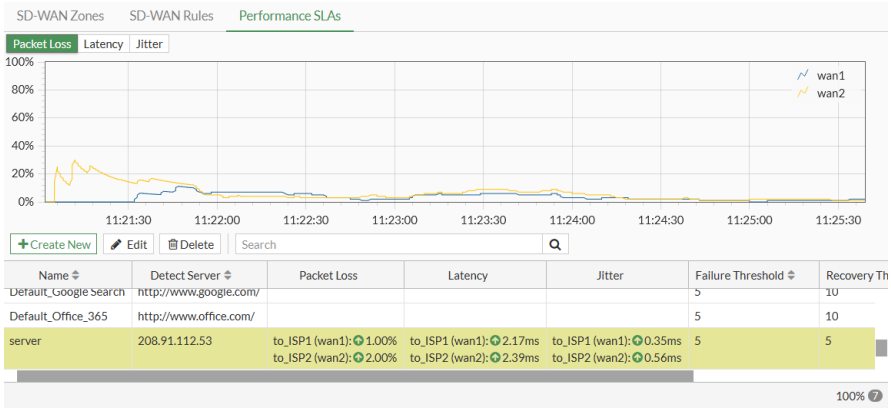


Performance SLA

Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and select the SLA from the table (*server* in this example) to view the packet loss, latency, and jitter on each SD-WAN member in the health check server.

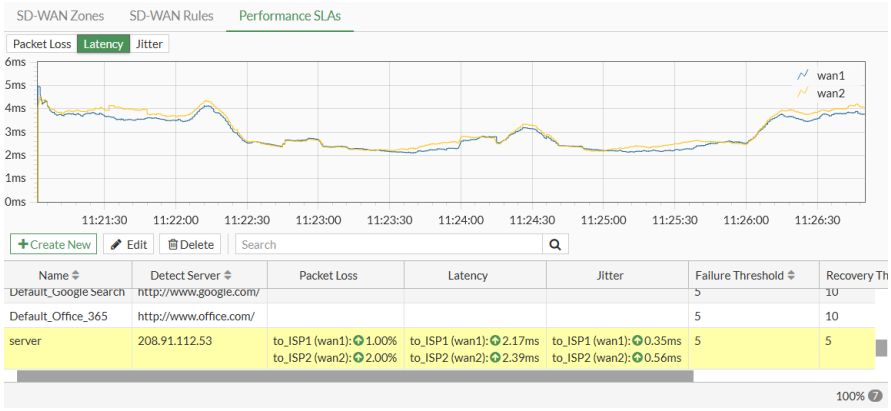
Packet loss

Select *Packet Loss* to see the percentage of packets lost for each member.



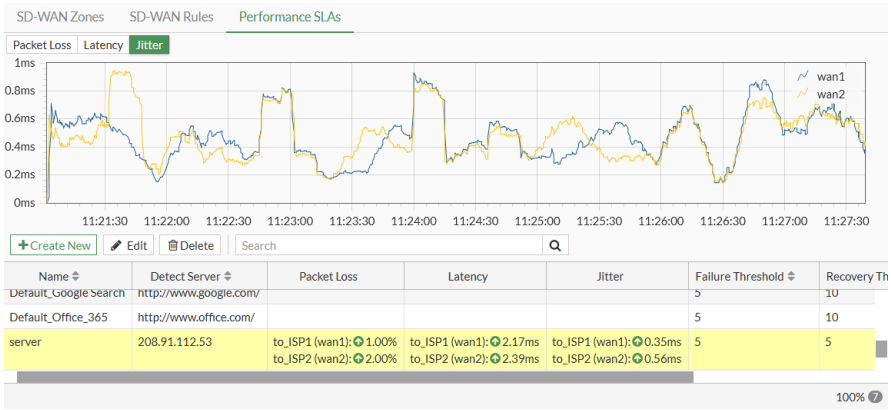
Latency

Select *Latency* to see the current latency, in milliseconds, for each member.



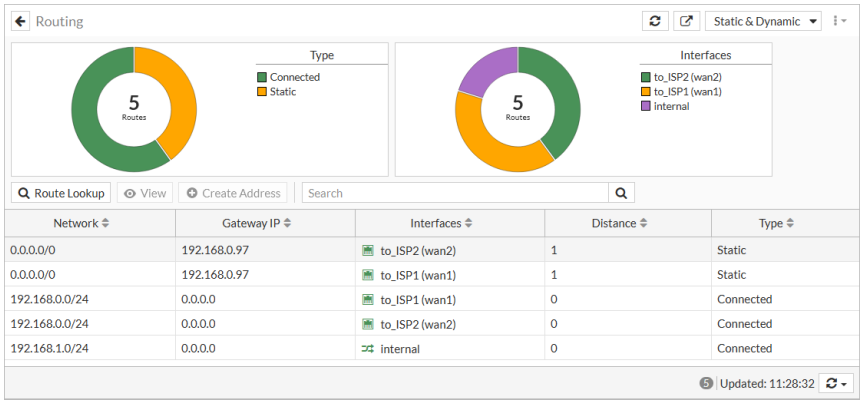
Jitter

Select *Jitter* to see the jitter, in milliseconds, for each member.



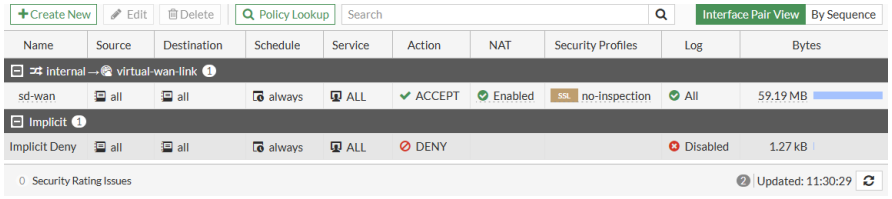
Routing table

Go to *Dashboard* > *Network*, expand the *Routing* widget, and select *Static & Dynamic* to review all static and dynamic routes. For more information about the widget, see Static & Dynamic Routing monitor on page 117.



Firewall policy

Go to *Policy & Objects* > *Firewall Policy* to review the SD-WAN policy.



Configuring SD-WAN in the CLI

This example can be entirely configured using the CLI.

To configure SD-WAN in the CLI:

1. Configure the wan1 and wan2 interfaces:

```
config system interface
    edit "wan1"
        set alias to_ISP1
        set mode dhcp
        set distance 10
    next
    edit "wan2"
        set alias to_ISP2
        set ip 10.100.20.1 255.255.255.0
    next
end
```

2. Enable SD-WAN and add the interfaces as members:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "wan1"
        next
        edit 2
            set interface "wan2"
            set gateway 10.100.20.2
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

3. Create a static route for SD-WAN:

```
config router static
    edit 1
        set sdwan-zone "virtual-wan-link"
    next
end
```

4. Select the implicit SD-WAN algorithm:

```
config system sdwan
    set load-balance-mode {source-ip-based | weight-based | source-dest-ip-based | measured-
volume-based}
end
```

5. Create a firewall policy for SD-WAN:

```
config firewall policy
    edit <policy_id>
        set name <policy_name>
        set srcintf "internal"
        set dstintf "virtual-wan-link"
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set utm-status enable
        set ssl-ssh-profile <profile_name>
        set av-profile <profile_name>
        set webfilter-profile <profile_name>
        set dnsfilter-profile <profile_name>
        set emailfilter-profile <profile_name>
```

```
        set ips_sensor <sensor_name>
        set application-list <app_list>
        set voip-profile <profile_name>
        set logtraffic all
        set nat enable
        set status enable
    next
end
```

6. Configure a performance SLA:

```
config system sdwan
    config health-check
        edit "server"
            set server "208.91.112.53"
            set update-static-route enable
            set members 1 2
        next
    end
end
```

Results

To view the routing table:

```
# get router info routing-table all

Routing table for VRF=0
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

S*      0.0.0.0/0 [1/0] via 172.16.20.2, wan1
                  [1/0] via 10.100.20.2, wan2
C       10.100.20.0/24 is directly connected, wan2
C       172.16.20.2/24 is directly connected, wan1
C       192.168.0.0/24 is directly connected, internal
```

To diagnose the Performance SLA status:

```
FGT # diagnose sys sdwan health-check
Health Check(server):
Seq(1): state(alive), packet-loss(0.000%) latency(15.247), jitter(5.231) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(13.621), jitter(6.905) sla_map=0x0
```

SD-WAN members and zones

SD-WAN bundles interfaces together into zones. Interfaces are first configured as SD-WAN members. This does not change the interface, it just allows SD-WAN to reference the interface as a member. SD-WAN member interfaces can be any interface supported by FortiGates, such as physical ports, VLAN interfaces, LAGs, IPsec tunnels, GRE tunnels, IPIP tunnels, and FortiExtender interfaces. Once SD-WAN members are configured, they can be assigned to a zone. Zones are used in policies as source and destination interfaces, in static routes, and in SD-WAN rules.

Multiple zones can be used to group SD-WAN interfaces for logical scenarios, such as overlay and underlay interfaces. Using multiple zones in policies allows for more granular control over functions like resource access and UTM access. Individual SD-WAN member interfaces cannot be used directly in policies, but they can be moved between SD-WAN zones at any time. If a member interface requires a special SD-WAN consideration, it can be put into an SD-WAN zone by itself.

SD-WAN zones and members can be used in IPv4 and IPv6 static routes to make route configurations more flexible. SD-WAN zones and members can be used in SD-WAN rules to simplify the rule configuration. See Specify an SD-WAN zone in static routes and SD-WAN rules on page 914 for more information.

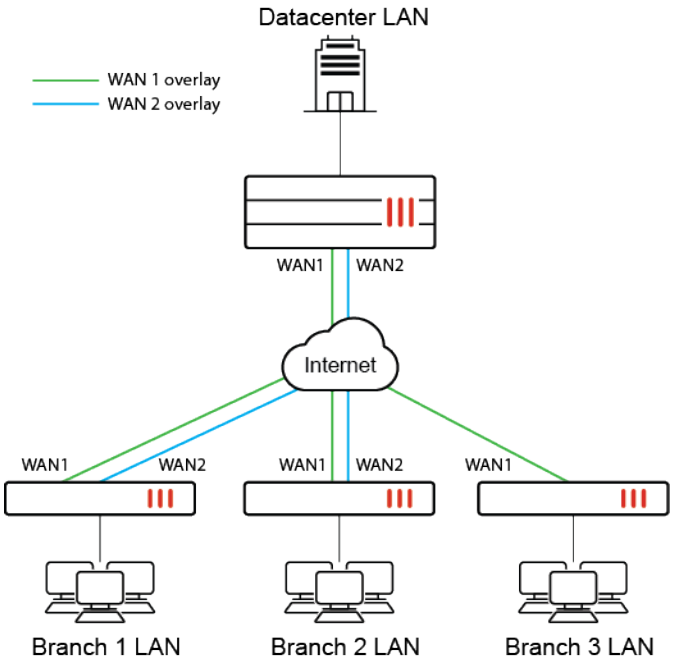
SD-WAN zones can also be specified as interfaces in Local In policies, DoS policies, Multicast policies, TTL policies, and central SNAT maps. See Specify SD-WAN zones in some policies on page 921 for more information.

When the Security Fabric is configured, SD-WAN zones are included in the Security Fabric topology views.

Topology

This topology is used in the following procedures:

- Configuring SD-WAN member interfaces
- Configuring SD-WAN zones
- Using SD-WAN zones



Configuring SD-WAN member interfaces

When configuring SD-WAN zones and members, it does not matter what order they are defined. In this example, the members are defined first, and they will be placed temporarily in the default zone called virtual-wan-link. A zone must be defined when creating a member, and the overlay and underlay zones will created in the next procedure. It is standard practice to create SD-WAN members for each underlay and overlay interface, as most SD-WAN implementations apply SD-WAN intelligence to both underlay and overlay networks.

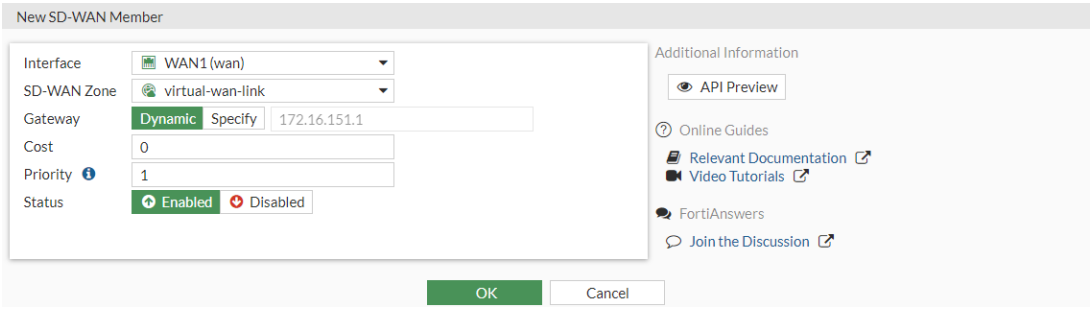
The following options can be configured for SD-WAN members:

GUI option	CLI option	Description
Interface	`interface`	Select the interface to use as an SD-WAN member. Optionally, select *None* in the GUI to not use an interface yet.
SD-WAN Zone	`zone`	Select the destination zone if it exists at the time of member creation. Otherwise, the default virtual-wan-link zone is applied. A new zone can be created within the GUI dropdown field.
Gateway/IPv6 Gateway	`gateway/gateway6`	Enter the default gateway for the interface. For interfaces that already have a default gateway, such as those configured using DHCP, this field is pre-populated in the GUI.

GUI option	CLI option	Description
Cost	`cost`	Enter the cost of the interface for services in SLA mode (0 - 4294967295, default = 0). A lower cost has a higher preference.
Fallback priority	`priority`	Enter the priority of the interface for IPv4 (1 - 65535, default = 1). The priority is used in the static route created for the SD-WAN member interface and in SD-WAN rules (including the implicit rule). When priority is used to determine the best route, the lower value takes precedence.
Status	`status`	Enable or disable the interface in SD-WAN.
n/a	`source/source6`	Set the source IP address used in the health check packet to the server.

To configure the SD-WAN members and add them to the default zone in the GUI:

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
2. Set the *Interface* to *WAN1*.
3. Leave the *SD-WAN Zone* as *virtual-wan-link*.



4. Click *OK*.
5. Repeat these steps to create SD-WAN members for the WAN2, VPN1, and VPN2 interfaces.

To configure the SD-WAN members and add them to the default zone in the CLI:

```
config system sdwan
    config members
        edit 1
            set interface "WAN1"
            set zone "virtual-wan-link"
        next
        edit 2
            set interface "WAN2"
            set zone "virtual-wan-link"
        next
```

```
        edit 3
            set interface "VPN1"
            set zone "virtual-wan-link"
        next
        edit 4
            set interface "VPN2"
            set zone "virtual-wan-link"
        next
    end
end
```

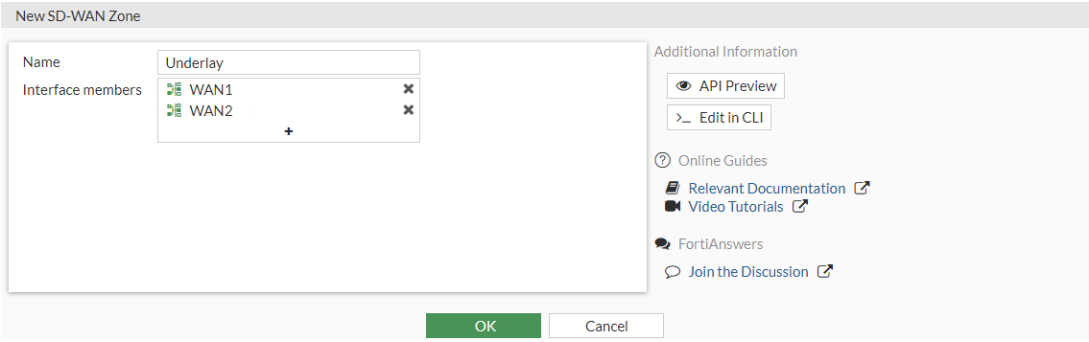
Configuring SD-WAN zones

While SD-WAN zones are primarily used to logically group interfaces that are often used for the same purpose (such as WAN1 and WAN2), sometimes an SD-WAN zone can have a single member. This is due to the constraint that SD-WAN members may not be referenced directly in policies; however, SD-WAN members can be referenced directly in SD-WAN rules.

In this example, two zones named Overlay and Underlay are configured, and the member interfaces are added to their respective zones.

To configure the SD-WAN zones in the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab.
2. Click *Create New* > *SD-WAN Zone*.
3. Enter the *Name*, *Underlay*.
4. Set the *Interface members* to *WAN1* and *WAN2*.



5. Click *OK*.
6. Repeat these steps to configure the *Overlay* zone with members VPN1 and VPN2.

To configure the SD-WAN zones in the CLI:

1. Configure the SD-WAN zones:

```
config system sdwan
    config zone
        edit "Overlay"
```

```
        next
        edit "Underlay"
        next
    end
end
```

2. Add the member interfaces to their respective zones:

```
config system sdwan
    config members
        edit 1
            set interface WAN1
            set zone "Underlay"
        next
        edit 2
            set interface WAN2
            set zone "Underlay"
        next
        edit 3
            set interface VPN1
            set zone "Overlay"
        next
        edit 4
            set interface VPN2
            set zone "Overlay"
        next
    end
end
```

In the `config zone` settings, there is a `service-sla-tie-break` parameter that includes three options for the tie-break method used when multiple interfaces in a zone are eligible for traffic:

- `cfg-order`: members that meet the SLA are selected in the order they are configured (default).
- `fib-best-match`: members that meet the SLA are selected that match the longest prefix in the routing table.
- `input-device`: members that meet the SLA are selected by matching the input device.

See Overlay stickiness on page 1299 for more information.

Using SD-WAN zones

Once SD-WAN zones are defined, they can be used in firewall policies. This section covers three policy scenarios:

- Datacenter resource access
- Direct internet access
- Remote internet access

SD-WAN zones are a critical component of SD-WAN rules. See Fields for configuring WAN intelligence on page 1022 for more information.

Datacenter resource access

Datacenter resources are made available through the VPN branches or overlay. In this example, there are two SD-WAN members in the overlay zone that the branch FortiGate can use to route traffic to and from the datacenter resource. The overlay zone is used as the destination in the firewall policy.

To configure the firewall policy:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	*DC_Access*
Incoming Interface	*LAN*
Outgoing Interface	*Overlay*
Source	*Branch_LAN*
Destination	*DC_LAN*
Action	*ACCEPT*

3. Configure the other settings as needed.
4. Click *OK*.

This firewall policy allows traffic to any interfaces included in the zone. The SD-WAN rules contain the intelligence used to select which members in the zone to use.

Direct internet access

Direct internet access (DIA) is how a branch may access resources contained on the public internet. This can be non-business resources (such as video streaming sites), or publically available business resources (such as vendor portals).

To configure the firewall policy:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	*DIA*

Incoming Interface	*LAN*
Outgoing Interface	*Underlay*
Source	*Branch_LAN*
Destination	*all*
Action	*ACCEPT*

3. Configure the other settings as needed.
4. Click *OK*.

Remote internet access

Remote internet access (RIA) is the ability for a branch location to route public internet access requests across the overlay and out one of the hub's (or datacenter's) WAN interfaces. This option is effective when a branch has a WAN circuit with a local ISP and a second circuit that is private, such as MPLS. When the WAN circuit goes down, it is possible to send traffic through the hub using the MPLS overlay.

To configure the firewall policy:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	*RIA*
Incoming Interface	*LAN*
Outgoing Interface	*Overlay*
Source	*Branch_LAN*
Destination	*all*
Action	*ACCEPT*

3. Configure the other settings as needed.
4. Click *OK*.

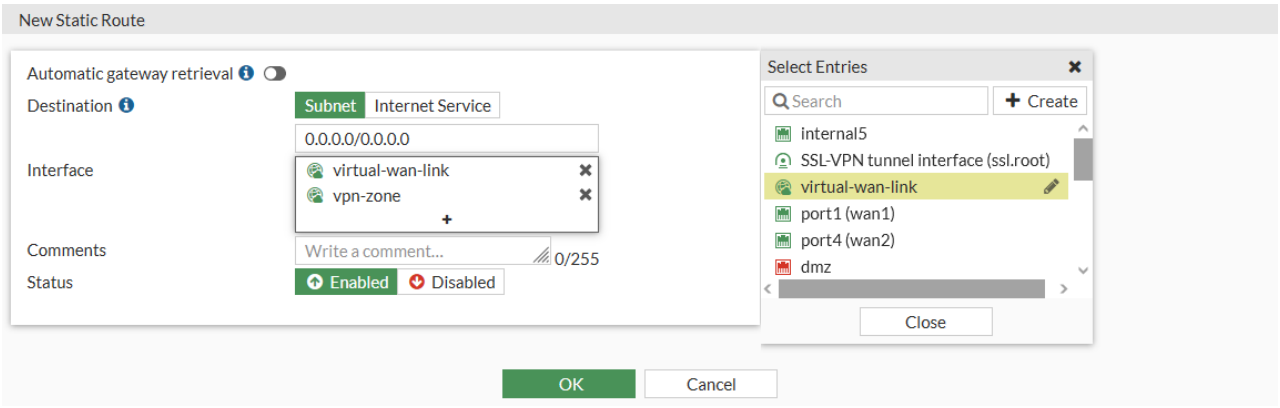
Specify an SD-WAN zone in static routes and SD-WAN rules

SD-WAN zones can be used in IPv4 and IPv6 static routes, and in SD-WAN service rules. This makes route configuration more flexible, and simplifies SD-WAN rule configuration.

To configure an SD-WAN zone in a static route in the GUI:

1. Go to *Network* > *Static Routes*
2. Edit an existing static route, or click *Create New* to create a new route.

3. Set *Interface* to one or more SD-WAN zones.



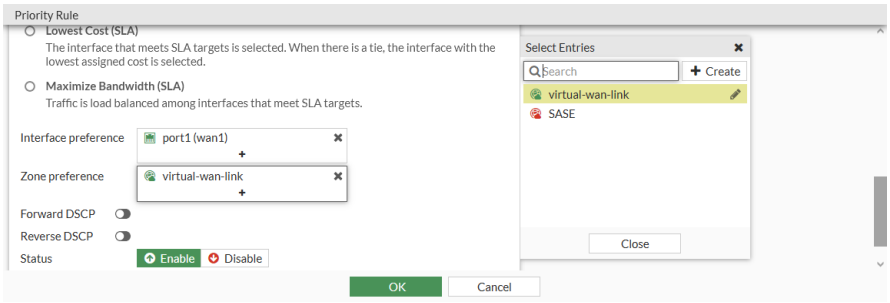
4. Configure the remaining settings are required.
5. Click *OK*.

To configure an SD-WAN zone in a static route in the CLI:

```
config router {static | static6}
    edit 1
        set sdwan-zone <zone> <zone> ...
    next
end
```

To configure an SD-WAN zone in an SD-WAN rule in the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab
2. Edit an existing rule, or click *Create New* to create a new rule.
3. In the *Zone preference* field add one or more SD-WAN zones.



4. Configure the remaining settings are needed.
5. Click *OK*.

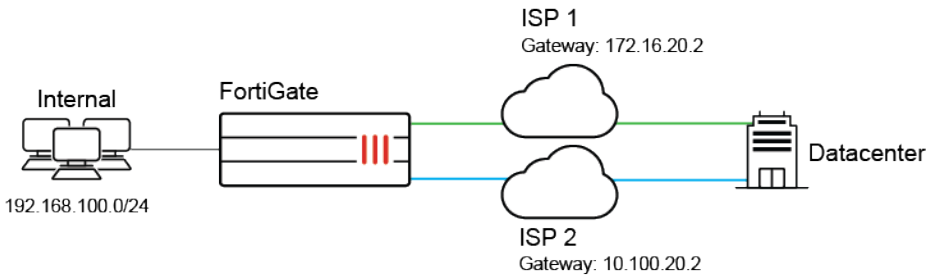
To configure an SD-WAN zone in an SD-WAN rule in the CLI:

```
config system sdwan
    config service
        edit 1
            set priority-zone <zone>
        next
```

```
    end
end
```

Examples

In these two examples, three SD-WAN members are created. Two members, port13 and port15, are in the default zone (*virtual-wan-link*), and the third member, to_FG_B_root, is in the *SASE* zone.



Example 1

In this example:

- Two service rules are created. Rule 1 uses the *virtual-wan-link* zone, and rule 2 uses the *SASE* zone.
- Two IPv4 static routes are created. The first route uses the *virtual-wan-link* zone, and the second route uses the *SASE* zone.

To configure the SD-WAN:

1. Assign port13 and port15 to the *virtual-wan-link* zone and to_FG_B_root to the *SASE* zone:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "port13"
            set zone "virtual-wan-link"
            set gateway 10.100.1.1
        next
        edit 2
            set interface "port15"
            set zone "virtual-wan-link"
            set gateway 10.100.1.5
        next
        edit 3
            set interface "to_FG_B_root"
            set zone "SASE"
        next
    end
end
```

2. Create two service rules, one for each SD-WAN zone:

```
config system sdwan
    config service
        edit 1
            set dst "10.100.20.0"
            set priority-zone "virtual-wan-link"
        next
        edit 2
            set internet-service enable
            set internet-service-name "Fortinet-FortiGuard"
            set priority-zone "SASE"
        next
    end
end
```

3. Configure static routes for each of the SD-WAN zones:

```
config router static
    edit 1
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
    edit 2
        set dst 172.16.109.0 255.255.255.0
        set distance 1
        set sdwan-zone "SASE"
    next
end
```

To verify the results:

1. Check the service rule 1 diagnostics:

```
# diagnose sys sdwan service4 1

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Members(2):
    1: Seq_num(1 port13), alive, selected
    2: Seq_num(2 port15), alive, selected
  Dst address(1):
        10.100.20.0-10.100.20.255
```

Both members of the *virtual-wan-link* zone are selected. In manual mode, the interface members are selected based on the member configuration order. In SLA and priority mode, the order depends on the link status. If all of the link statuses pass, then the members are selected based on the member configuration order.

2. Check the service rule 2 diagnostics:

```
# diagnose sys sdwan service4 2

Service(2): Address Mode(IPV4) flags=0x200 use-shortcut-sla
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
```

```
  Members(1):
    1: Seq_num(3 to_FG_B_root), alive, selected
  Internet Service(1): Fortinet-FortiGuard(1245324,0,0,0)
```

The member of the *SASE* zone is selected.

3. Review the routing table:

```
# get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 10.100.1.1, port13
                  [1/0] via 10.100.1.5, port15
S       172.16.109.0/24 [1/0] via 172.16.206.2, to_FG_B_root
```

The default gateway has the members from the *virtual-wan-link* zone, and the route to 172.16.10.9.0/24 has the single member from the *SASE* zone.

Example 2

In this example, two IPv6 static routes are created. The first route uses the *virtual-wan-link* zone, and the second route uses the *SASE* zone.

To configure the SD-WAN:

1. Configure port13 and port15 with IPv6 addresses and assign them to the *virtual-wan-link* zone, and assign to_FG_B_root to the *SASE* zone:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "port13"
            set zone "virtual-wan-link"
            set gateway6 2004:10:100:1::1
            set source6 2004:10:100:1::2
        next
        edit 2
            set interface "port15"
            set zone "virtual-wan-link"
            set gateway6 2004:10:100:1::5
            set source6 2004:10:100:1::6
        next
        edit 3
            set interface "to_FG_B_root"
            set zone "SASE"
        next
    end
end
```

2. Configure IPv6 static routes for each of the SD-WAN zones:

```
config router static6
    edit 1
```

```
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
    edit 2
        set dst 2003:172:16:109::/64
        set distance 1
        set sdwan-zone "SASE"
    next
end
```

To verify the results:

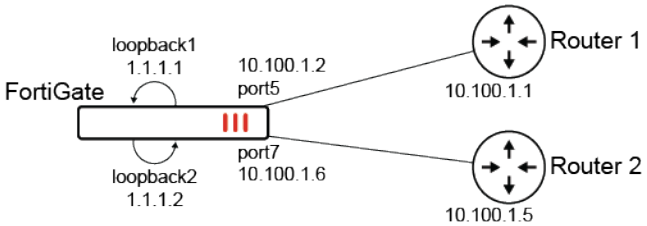
1. Review the routing table:

```
# get router info6 routing-table static
Routing table for VRF=0
S*      ::/0 [1/0] via 2004:10:100:1::1, port13, 00:20:51, [1024/0]
             [1/0] via 2004:10:100:1::5, port15, 00:20:51, [1024/0]
S       2003:172:16:109::/64 [1/0] via ::ac10:ce02, to_FG_B_root, 00:20:51, [1024/0]
S       2003:172:16:209::/64 [5/0] via ::ac10:ce02, to_FG_B_root, 14:40:14, [1024/0]
```

The IPv6 default route includes the members from the *virtual-wan-link* zone, and the route to 2003:172:16:109::/64 has the single member from the *SASE* zone.

Defining a preferred source IP for local-out egress interfaces on SD-WAN members

The preferred source IP can be configured on SD-WAN members so that local-out traffic is sourced from that IP. In the following example, two SD-WAN members (port5 and port7) will use loopback1 and loopback2 as sources instead of their physical interface address. A static route is created for destination 200.0.0.0/24 to use the virtual-wan-link. In turn, the FortiGate will create two ECMP routes to the member gateways and source the traffic from the loopback IPs.



To configure preferred source IPs for SD-WAN members:

1. Configure the SD-WAN members and other settings:

```
config system sdwan
    set status enable
    config zone
```

```
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "port5"
            set gateway 10.100.1.1
            set preferred-source 1.1.1.1
            set source 1.1.1.1
        next
        edit 2
            set interface "port7"
            set gateway 10.100.1.5
            set preferred-source 1.1.1.2
            set source 1.1.1.2
        next
    end
end
```

In the SD-WAN `config members` settings, configuring the `source` for the health check probes is still required. SD-WAN adds dedicated kernel routes (proto=17) for the health checks using the interface IP or source IP when specified. To view the kernel routes, use `diagnose ip route list`.

2. Configure the static route:

```
config router static
    edit 2000
        set dst 200.0.0.0 255.255.255.0
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
end
```

To verify the configuration:

1. Verify the kernel routing table for 200.0.0.0/24:

```
# get router info kernel | grep -A 2 200.0.0.0/24
tab=254 vf=0 scope=0 type=1 proto=11 prio=1 0.0.0.0/0.0.0.0/0->200.0.0.0/24 pref=0.0.0.0
        gwy=10.100.1.1 flag=14 hops=255 oif=13(port5) pref=1.1.1.1
        gwy=10.100.1.5 flag=14 hops=254 oif=15(port7) pref=1.1.1.2
```

2. Verify the routing table for 200.0.0.0/24:

```
# get router info routing-table details 200.0.0.0/24
Routing table for VRF=0
Routing entry for 200.0.0.0/24
  Known via "static", distance 1, metric 0, best
  * vrf 0 10.100.1.1, via port5, prefsrc 1.1.1.1
  * vrf 0 10.100.1.5, via port7, prefsrc 1.1.1.2
```

3. Run a sniffer trace after some traffic passes.
   a. When traffic leaves port5:

```
# diagnose sniffer packet any "host 200.0.0.1" 4
interfaces=[any]
filters=[host 200.0.0.1]
6.592488 port5 out 1.1.1.1 -> 200.0.0.1: icmp: echo request
7.592516 port5 out 1.1.1.1 -> 200.0.0.1: icmp: echo request
8.592532 port5 out 1.1.1.1 -> 200.0.0.1: icmp: echo request
```

   b. When traffic leaves port7:

```
# diagnose sniffer packet any "host 200.0.0.1" 4
interfaces=[any]
filters=[host 200.0.0.1]
75.664173 port7 out 1.1.1.2 -> 200.0.0.1: icmp: echo request
76.664194 port7 out 1.1.1.2 -> 200.0.0.1: icmp: echo request
```

   Traffic exiting each interface is sourced from the corresponding loopback IP.

Specify SD-WAN zones in some policies

SD-WAN zones can be specified as interfaces in Local In policies, DoS policies, Multicast policies, TTL policies, and central SNAT maps. This simplifies policy management and improves operational efficiency.

```
config firewall local-in-policy
    edit <id>
        set intf <SD-WAN zone>
    next
end
config firewall DoS-policy
    edit <id>
        set interface <SD-WAN zone>
    next
end
config firewall interface-policy
    edit <id>
        set interface <SD-WAN zone>
    next
end
config firewall multicast-policy
    edit <id>
        set srcintf <SD-WAN zone>
        set dstintf <SD-WAN zone>
    next
end
config firewall ttl-policy
    edit <id>
        set srcintf <SD-WAN zone>
    next
end
```

```
config firewall central-snat-map
    edit <id>
        set srcintf <SD-WAN zone>
        set dstintf <SD-WAN zone>
    next
end
```

Example

To configure a use an SD-WAN zone as an interface in some policies:

1. Configure an SD-WAN zone:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "test"
        next
    end
    config members
        edit 1
            set interface "agg1"
            set zone "test"
            set gateway 172.16.203.2
        next
        edit 2
            set interface "vlan100"
            set zone "test"
            set gateway 172.16.206.2
        next
    end
end
```

2. Use that SD-WAN zone as an interface in policies:

```
config firewall local-in-policy
    edit 1
        set intf "test"
        set srcaddr "172.16.205.0"
        set dstaddr "all"
        set service "ALL"
        set schedule "always"
    next
end
```

```
config firewall DoS-policy
    edit 1
        set interface "test"
```

```
        set srcaddr "172.16.205.0"
        set dstaddr "all"
        set service "ALL"
        config anomaly
            edit "tcp_syn_flood"
                set threshold 2000
            next
            edit "tcp_port_scan"
                set threshold 1000
            next
            edit "tcp_src_session"
                set threshold 5000
            next
            ...
        end
    next
end
```

```
config firewall interface-policy
    edit 1
        set interface "test"
        set srcaddr "172.16.205.0"
        set dstaddr "all"
        set service "ALL"
    next
end
```

```
config firewall multicast-policy
    edit 1
        set srcintf "test"
        set dstintf "any"
        set srcaddr "172.16.205.0"
        set dstaddr "all"
    next
end
```

```
config firewall ttl-policy
    edit 1
        set srcintf "test"
        set srcaddr "172.16.205.0"
        set service "ALL"
        set schedule "always"
        set ttl 5
    next
end
```

```
config firewall central-snat-map
    edit 1
        set srcintf any
        set dstintf "test"
        set orig-addr "all"
```

```
        set dst-addr "172.16.205.0"
    next
end
```

SD-WAN Setup wizard

The *SD-WAN Setup* wizard helps you configure the following settings for a simple SD-WAN setup:

- Interface
  The wizard supports a maximum of two interfaces.
- Networking
- Performance SLA
- SD-WAN Rule

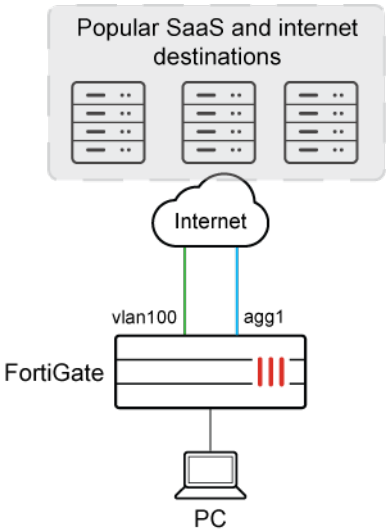
After completing the wizard, configure a default static route for the newly created SD-WAN interface.

FortiGate requires a valid SD-WAN Network Monitor (SWNM) entitlement before the SD-WAN Setup wizard is visible.

See also FortiGuard SLA database for SD-WAN performance SLA on page 1012.

Example

This example describes how to use the SD-WAN Setup wizard to create an SD-WAN configuration with one SD-WAN zone (named *Test*) and two SD-WAN members (*agg1* and *vlan100*). The wizard also guides you to complete the networking, performance SLA, and SD-WAN rule. After the wizard completes, configure a default static route for the SD-WAN interface.



To use the SD-WAN Setup wizard to configure SD-WAN:

1. Go to the *Network* > *SD-WAN* > *SD-WAN Zones* page to access the wizard:
   - When no SD-WAN configuration exists, the following message is displayed. Click *Begin SD-WAN setup wizard* to access the wizard.

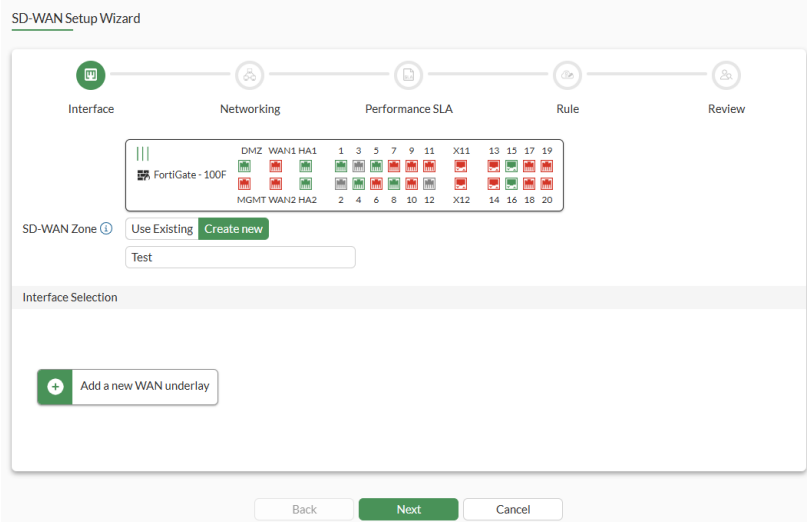
   - When an SD-WAN configuration exists, click *Create New* > *SD-WAN Wizard* to access the wizard.

   The *SD-WAN Setup* wizard opens on the *Interface* step.
2. For the *Interface* step, identify a zone, and select one or two interfaces for the underlay:

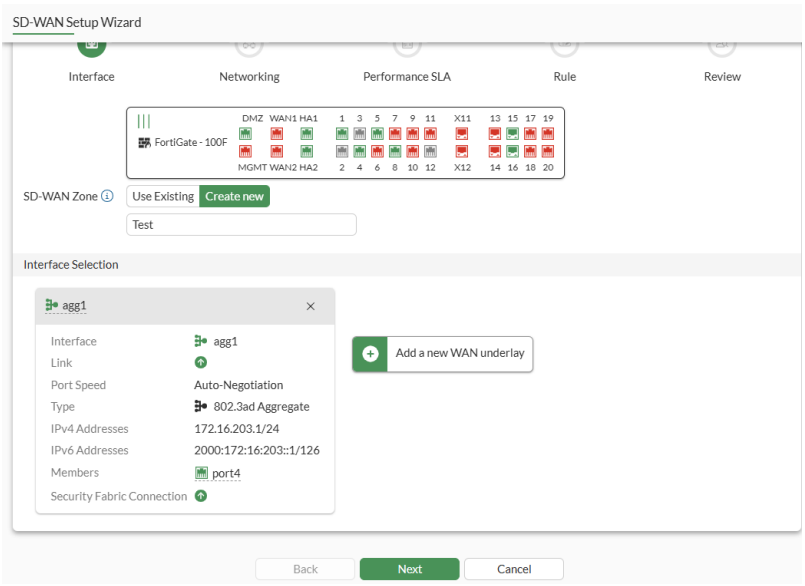
   The selected interfaces become members of the SD-WAN zone. This example creates a zone named *Test* and uses two interfaces (*agg1* and *vlan100*).

   a. Set *SD-WAN Zone* to:
      - *Use Existing* and select an existing SD-WAN zone.

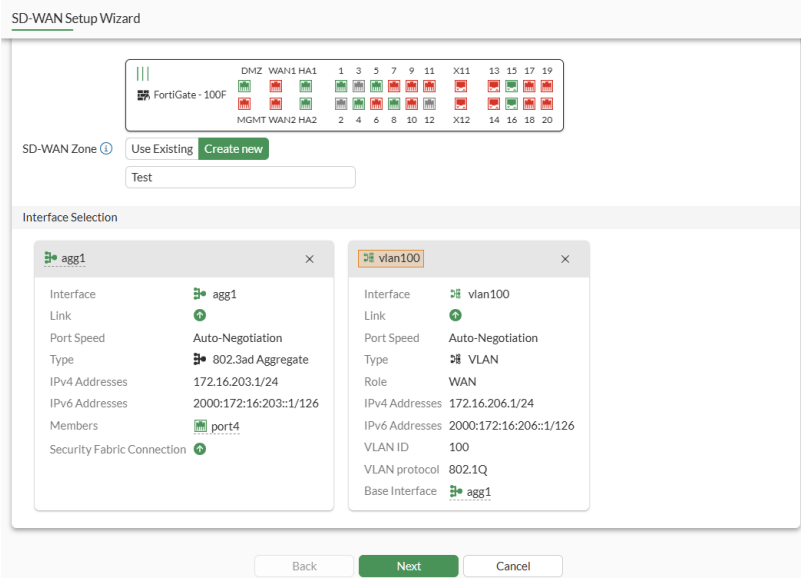
        Or:
      - *Create New* and type a name for the new SD-WAN zone. In this example, a new zone named *Test* is created.



b. Click *Add a new WAN underlay*, select an interface, and click *Apply*.



c. Click *Add a new WAN underlay* again, select an interface, and click *Apply*.

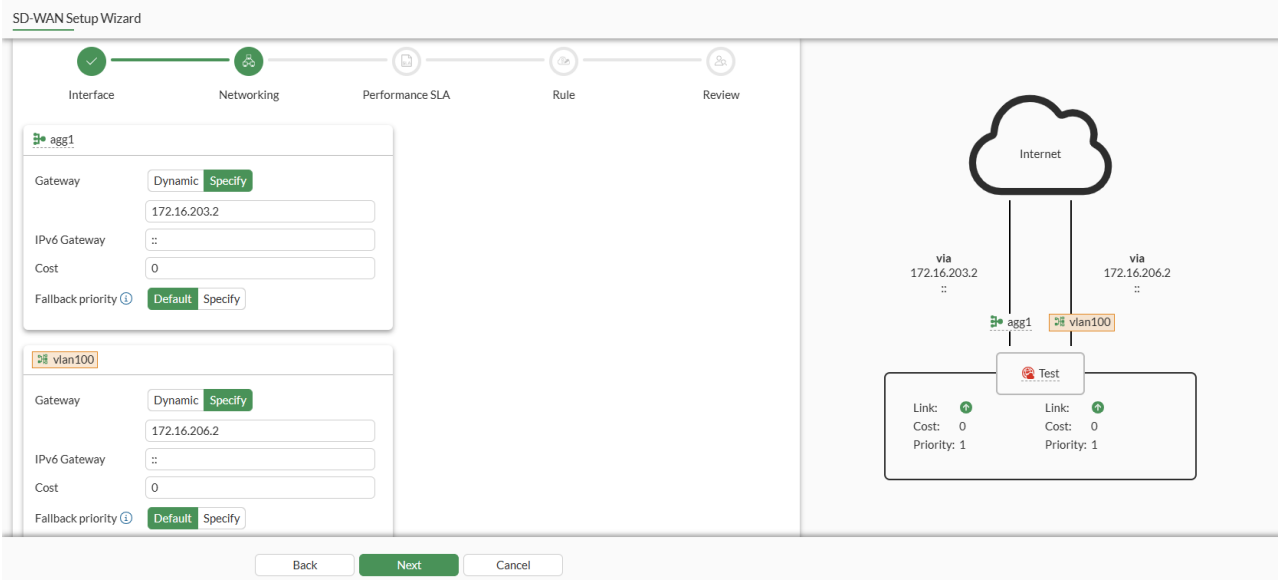


You have added two interfaces to the SD-WAN zone.

d. Click *Next* to proceed to the *Networking* step.

3. For the *Networking* step, set the gateway and priority for each interface, and click *Next*:

Gateway	Select one of the following methods to assign a gateway IP address to the interface: • *Dynamic*: Select to leave the gateway undefined and proceed to the next screen. Can be used with interfaces set to use DHCP as a client. • *Specify*: Select to specify an IPv4 or IPv6 address for the gateway.
Cost	Used by the lowest-cost SLA strategy. The link with the lowest cost is chosen to pass traffic. The lowest possible cost is 0
Fallback priority	Select one of the following methods to define the priority of SD-WAN members: • *Default*: Select to use the default, which is the same priority for all SD-WAN members. • *Specify*: Select to specify a priority for the SD-WAN member in the *Priority* box. The priority is used in the static route created for the SD-WAN member interface and in SD-WAN rules (including the implicit rule). When priority is used to determine the best route, the lower value takes precedence.
Priority	Available when *Fallback priority* is set to *Specify*. Specify a priority for the SD-WAN member (1 - 65535, default = 1).

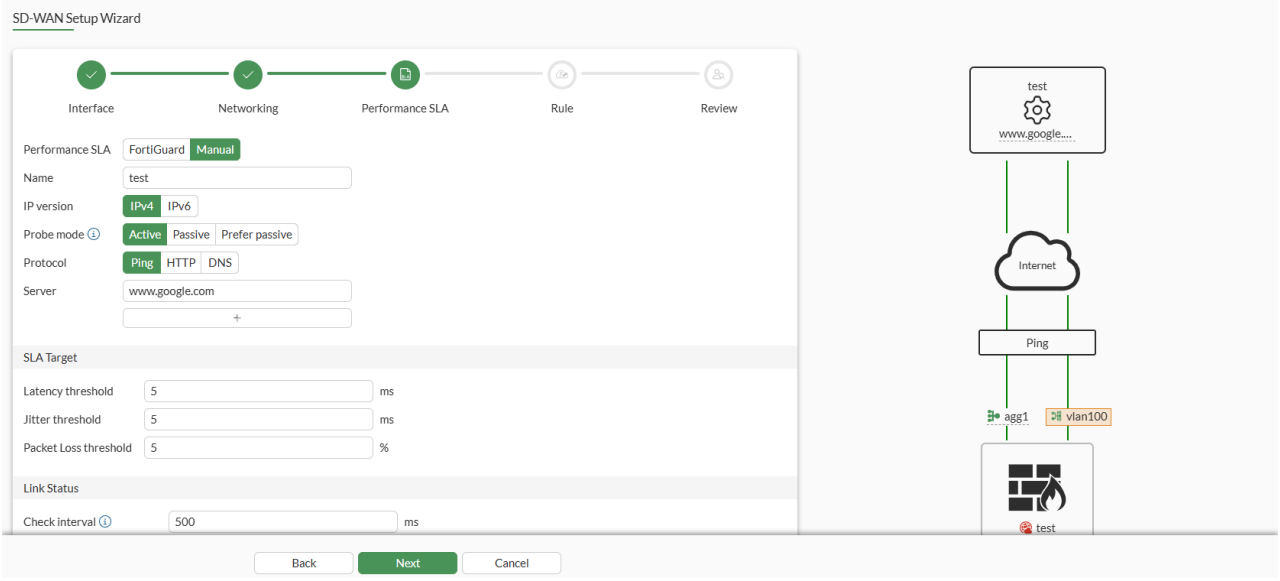


The wizard moves to the *Performance SLA* step.

4. For the *Performance SLA* step, configure health-check for SD-WAN members, and click *Next*:

Only the fields that you must set before you can proceed are described.

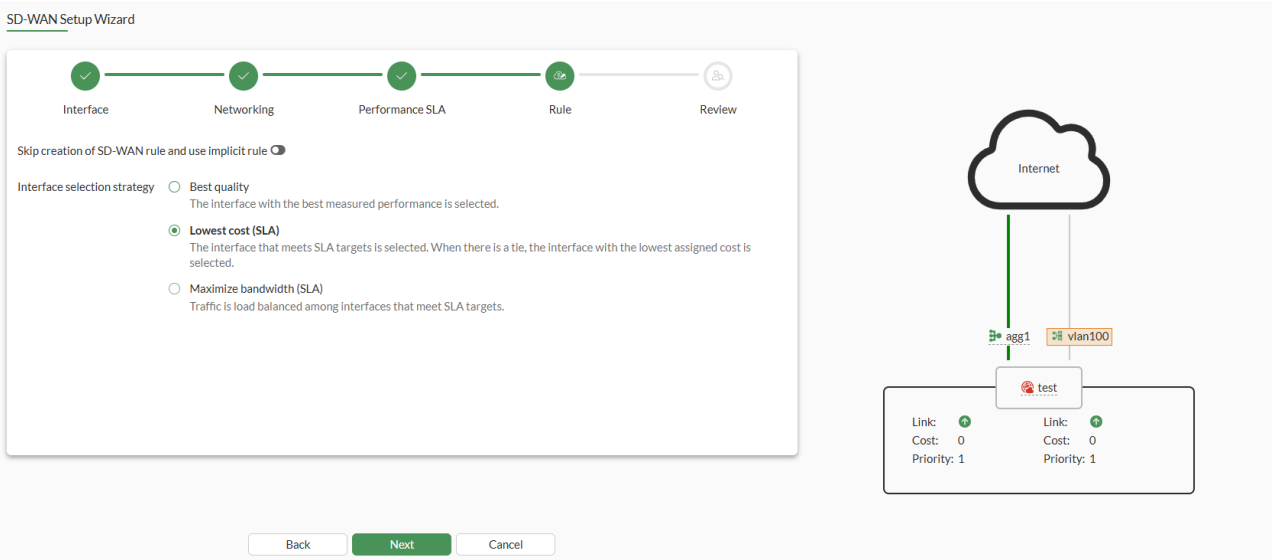
Performance SLA	Select one of the following to choose how to define performance SLA: • *FortiGuard*: Select to use the FortiGuard SLA database. Select a predefined server from the *Server* list, and specify the protocol to use. • *Manual*: Select to manually define a server for the SLA.



The wizard moves to the *Rule* step.

5. For the *Rule* step, create a service rule, and click *Next*:

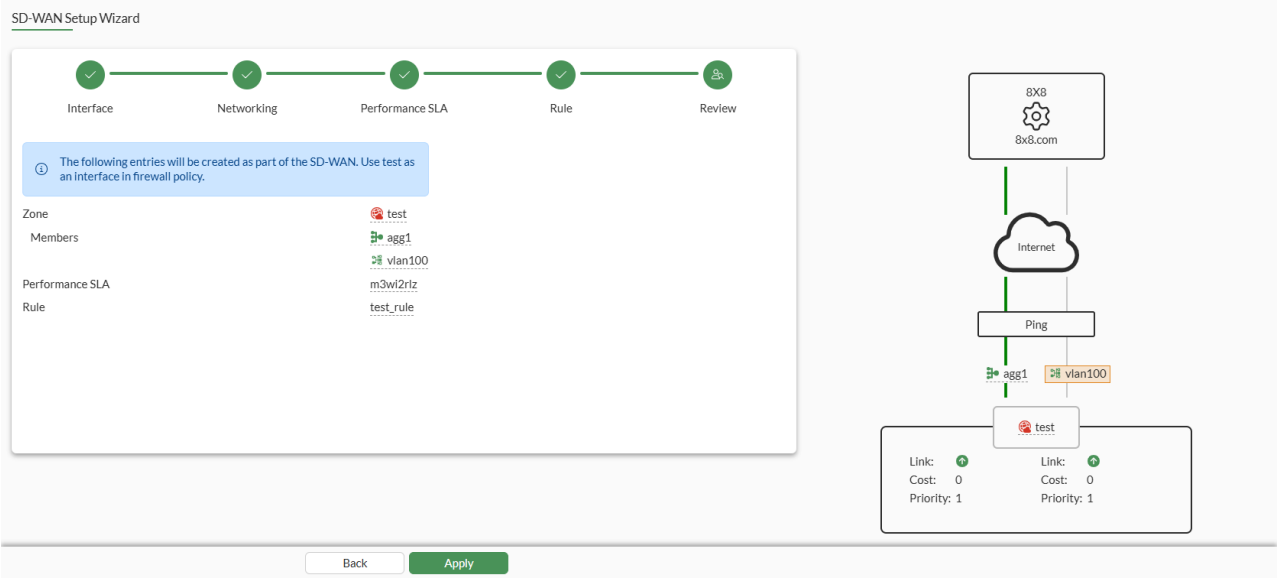
Skip creation of SD-WAN rule and use implicit rule	Enable to use the implicit rule instead of creating an SD-WAN rule.
Interface selection strategy	Available when *Skip creation of SD-WAN rule and use implicit rule* is disabled. Specify how SD-WAN should select an interface: • *Best quality*: Select to use the interface with the best measured performance. • *Lowest cost (SLA)*: Select to use the interface that meets the defined performance SLA targets. When a tie occurs, the interface with the lowest assigned cost is selected. • *Maximize bandwidth*: Traffic is load balanced among interfaces that meet SLA targets.



The wizard moves to the *Review* step.

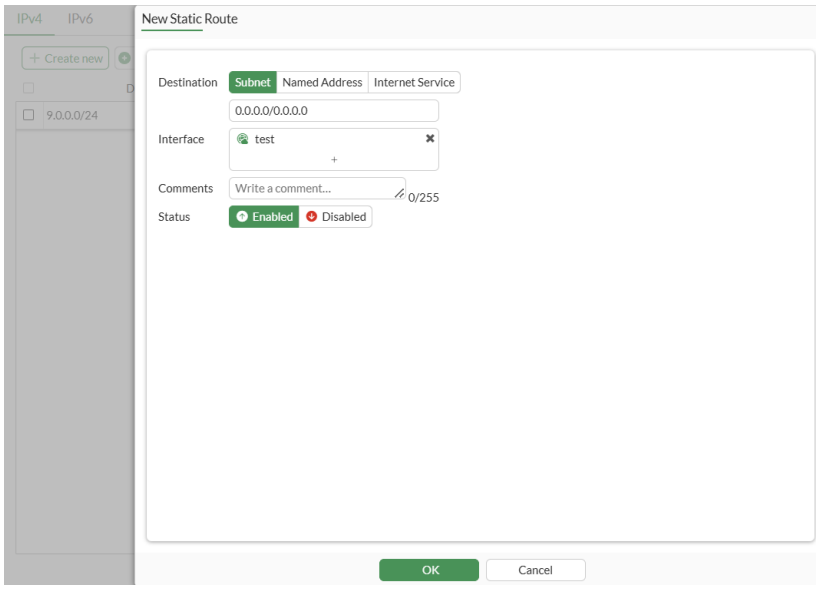
6. For the *Review* step, review the entries, and click *Apply* to create them:

Zone	Displays the name of the SD-WAN zone that will be created.
Members	Displays the name of the interface members that will be added to the SD-WAN zone.
Performance SLA	Displays the name of the performance SLA configuration that will be used for the SD-WAN configuration.
Rule	Displays the name of the SD-WAN rule that will be used for the SD-WAN configuration



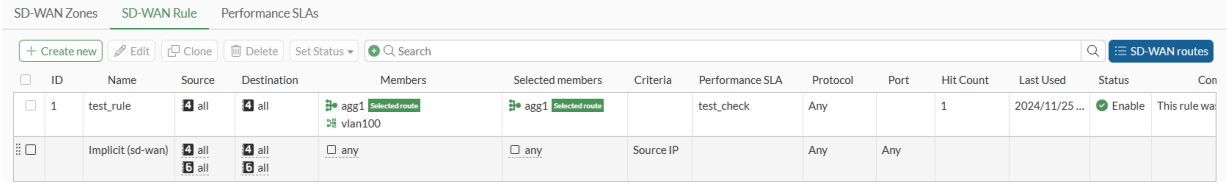
The entries are created, and the wizard completes.

7. Create a static route for the SD-WAN interface (that is the SD-WAN zone):
   a. Go to *Network* > *Static Routes*, and click *Create new*.
   b. Complete the options, and click *OK*.

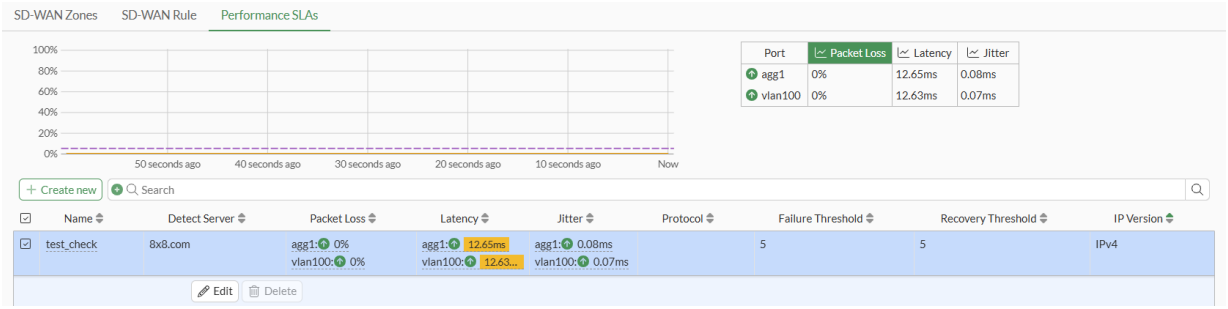


8. Review the SD-WAN configuration:
   a. Go to *Network* > *SD-WAN* > *SD-WAN Zones*, and view the zone and members that you created.

   b. On the *SD-WAN Rule* tab, view the rule that you created.



c. On the *Performance SLAs* tab, view the SLA configuration that you created.



Performance SLA

Performance SLAs are used to measure the health of links that are connected to SD-WAN member interfaces by either sending probing signals through each link to a server, or using session information that is captured by firewall policies (see Passive WAN health measurement on page 944 for information), and measuring the link quality based on latency, jitter, and packet loss. If a link fails all of the health checks, the routes on that link are removed from the SD-WAN link load balancing group, and traffic is routed through other links. When the link passes SLA, the routes are reestablished. This prevents traffic from being sent to a broken link and getting lost.

The following topics provide instructions on configuring performance SLA:

- Performance SLA overview on page 932
- Link health monitor on page 937
- Monitoring performance SLA on page 940
- Passive WAN health measurement on page 944
- Passive monitoring of TCP metrics on page 950
- Passive health-check measurement by internet service and application on page 954
- Mean opinion score calculation and logging in performance SLA health checks on page 959
- Embedded SD-WAN SLA information in ICMP probes on page 962
  - Embedded SD-WAN SLA priorities in ICMP probes on page 971
  - Embedded SD-WAN SLA status in ICMP probes on page 984
  - Map SD-WAN member priorities to BGP MED attribute when spoke advertises routes using iBGP to hub on page 996
- SD-WAN application monitor using FortiMonitor on page 1002
- Classifying SLA probes for traffic prioritization on page 1007
- FortiGuard SLA database for SD-WAN performance SLA on page 1012

Performance SLA overview

Performance SLAs consist of three parts:

- Health checks
- SLA targets
- Link status

Health checks

A health check is defined by a probe mode, protocol, and server. These three options specify what resource is being evaluated and how the evaluation is done. Each health check should be configured specifically for that resource, so the probe mode, protocol and server should be tailored for the particular service. For example, the health check for a VoIP service will differ than one for a database replication service.

Performance SLA participants are the interfaces that will be evaluated for a given health check. They must be SD-WAN member interfaces, but do not have to belong to the same zone. When selecting participants, only select participants that you expect the service communications to use. For example, a health check for a corporate resource might only use the overlay to access the service. Therefore, you would only add the VPN interfaces as participants.

There are five predefined performance SLA profiles for newly created VDOMs or factory reset FortiGate devices: DNS, FortiGuard, Gmail, Google Search, and Office 365. These performance SLA profiles provide Fortinet recommended settings for common services. To complete the performance SLA configuration, add the participants for the service. You can adjust the default settings to suit your needs.

Bandwidth limits and traffic prioritization can be enabled using SLA probe classification. The `class-id` command can be used to assign a class ID to SLA probes. Class IDs then guarantee that assigned bandwidth is honored when traffic congestion occurs. See Classifying SLA probes for traffic prioritization on page 1007.

Probe mode

The probe mode can be set to active, passive, or prefer passive.

In active mode, the FortiGate sends a packet of the type specified by the protocol setting towards the defined server. This allows you to evaluate the path to the destination server using the protocol that matches the service provided by the server. Active probing does add some overhead in the form of health check probes (and additional configurations to define the probe type and server), but it has the benefit of constantly measuring the performance of the path to the server. This can be beneficial when reviewing historical data.

In passive mode, session information captured by firewall policies is used to determine latency, jitter, and packet loss. This has the added benefit of not generating additional traffic, and does not require the performance SLA to define a specific server for measurement. Instead, the SD-WAN rule must define the traffic to evaluate, and the firewall policy permitting the traffic must have a setting enabled. See Passive WAN health measurement on page 944 and Passive health-check measurement by internet service and application on page 954 for more information.

Prefer passive mode is a combination of active and passive modes. Health is measured using traffic when there is traffic, and using probes when there is no traffic. A protocol and server must be configured.

Protocol

Health checks support a variety of protocols and protocol specific options. The most commonly used protocols (ping, HTTP, and DNS) can be configured in the GUI when creating a new performance SLA on the *Network > SD-WAN > Performance SLAs* page. The following protocols and options can be configured in the CLI using the `set protocol <option>` parameter:

`ping`	Use PING to test the link with the server.
`tcp-echo`	Use TCP echo to test the link with the server.
`udp-echo`	Use UDP echo to test the link with the server.
`http`	Use HTTP-GET to test the link with the server.
`https`	Use HTTPS-GET to test the link with the server.
`twamp`	Use TWAMP to test the link with the server.
`dns`	Use DNS query to test the link with the server. The FortiGate sends a DNS query for an A Record and the response matches the expected IP address.
`tcp-connect`	Use a full TCP connection to test the link with the server. The method to measure the quality of the TCP connection can be: • `half-open`: FortiGate sends SYN and gets SYN-ACK. The latency is based on the round trip between SYN and SYN-ACK (default). • `half-close`: FortiGate sends FIN and gets FIN-ACK. The latency is based on the round trip between FIN and FIN-ACK.
`ftp`	Use FTP to test the link with the server. The FTP mode can be: • `passive`: The FTP health-check initiates and establishes the data connection (default). • `port`: The FTP server initiates and establishes the data connection.

SD-WAN health checks can generate traffic that becomes quite high as deployments grow. Take this into consideration when setting DoS policy thresholds. For details on setting DoS policy thresholds, refer to DoS policy on page 1621.

The default FortiGuard, Google Search, and Office 365 performance SLA profiles use HTTPS.

To use UDP-echo and TCP-echo as health checks:

```
config system sdwan
    set status enable
    config health-check
        edit "h4_udp1"
```

```
            set protocol udp-echo
            set port 7
            set server <server>
        next
        edit "h4_tcp1"
            set protocol tcp-echo
            set port 7
            set server <server>
        next
        edit "h6_udp1"
            set addr-mode ipv6
            set server "2032::12"
            set protocol udp-echo
            set port 7
        next
    end
end
```

To use DNS as a health check, and define the IP address that the response must match:

```
config system sdwan
    set status enable
    config health-check
        edit "h4_dns1"
            set protocol dns
            set dns-request-domain "ip41.forti2.com"
            set dns-match-ip 1.1.1.1
        next
        edit "h6_dns1"
            set addr-mode ipv6
            set server "2000::15.1.1.4"
            set protocol dns
            set port 53
            set dns-request-domain "ip61.xxx.com"
        next
    end
end
```

To use TCP Open (SYN/SYN-ACK) and TCP Close (FIN/FIN-ACK) to verify connections:

```
config system sdwan
    set status enable
    config health-check
        edit "h4_tcpconnect1"
            set protocol tcp-connect
            set port 443
            set quality-measured-method {half-open | half-close}
            set server <server>
        next
        edit "h6_tcpconnect1"
            set addr-mode ipv6
```

```
            set server "2032::13"
            set protocol tcp-connect
            set port 444
            set quality-measured-method {half-open | half-close}
        next
    end
end
```

To use active or passive mode FTP to verify connections:

```
config system sdwan
    set status enable
    config health-check
        edit "h4_ftp1"
            set protocol ftp
            set port 21
            set user "root"
            set password ***********
            set ftp-mode {passive | port}
            set ftp-file "1.txt"
            set server <server>
        next
        edit "h6_ftp1"
            set addr-mode ipv6
            set server "2032::11"
            set protocol ftp
            set port 21
            set user "root"
            set password ***********
            set ftp-mode {passive | port}
            set ftp-file "2.txt"
        next
    end
end
```

Health check probe packets support DSCP markers for accurate link performance evaluation for high priority applications. This allows the probe packet to match the real traffic it is providing measurements for, including how that traffic is shaped by upstream devices based on the DSCP markers.

To mark health check packets with DSCP:

```
config system sdwan
    config health-check
        edit <name>
            set diffservcode <6-bits_binary, 000000-111111>
            set protocol <option>
        next
    end
end
```

Server

An IP address or FQDN can be defined as the server that the probe packets will be sent to. Up to two servers can be defined this way. When two servers are provided, both must fail in order for the health check to fail. This is to avoid a scenario where one remote server is down and causes a false positive that the link is down. The FortiGate can still use the interface associated with this health check to reach the remaining healthy server.

The purpose of the server is not simply to measure the health of the link, but rather the health of the path to a resource. It is highly recommended to use an IP address or FQDN that reflects the resource so the traffic path is considered.

A server can only be used in one performance SLA at any given time.

SLA targets

SLA targets are a set of constraints that are used in SD-WAN rules to control the paths that traffic takes. The constraints are:

- Latency threshold: latency for SLA to make a decision, in milliseconds (0 - 10000000, default = 5).
- Jitter threshold: jitter for SLA to make a decision, in milliseconds (0 - 10000000, default = 5).
- Packet loss threshold: packet loss for SLA to make a decision, in percentage (0 - 100, default = 0).

These settings should be specific to the service whose performance is being considered. You should attempt to configure the constraints to be just under the maximum values for the application or service to function well. For example, if your application requires less than 100 ms latency, then you should configure the SLA target to be 90 ms. Misconfiguring these settings will cause the performance SLA to lose value. If the values are too tight, then you may have traffic flipping between links before necessary. If the values are too loose, then performance may be impacted and the FortiGate will do nothing about it.

In the GUI, one SLA target can be configured, but additional targets can be configured in the CLI. Once a second target is configured in the CLI, additional targets can be configured from the GUI. Multiple SLA targets can be configured where a server provides multiple services that have different values for acceptable performance. For example, Google provides a DNS service and entertainment services (YouTube), so it is necessary to configure multiple SLA targets in this case since you can only configure a server in one performance SLA.

Link status

The *Link Status* section of the performance SLA configuration consists of three settings that determine the frequency that the link is evaluated, and the requirements to be considered valid or invalid:

- *Check interval*: the interval in which the FortiGate checks the interface, in milliseconds (20 - 3600000, default = 500).
- *Failures before inactive*: the number of failed status checks before the interface shows as inactive (1 - 3600, default =5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links.
- *Restore link after*: the number of successful status checks before the interface shows as active (1 - 3600, default = 5). This setting also helps prevent flapping.

When a participant becomes inactive, the performance SLA causes the FortiGate to withdraw all static routes associated with that interface. If there are multiple static routes using the same interface, they will all be withdrawn when the link monitor is failing.

Link health monitor

Performance SLA link health monitoring measures the health of links that are connected to SD-WAN member interfaces by either sending probing signals through each link to a server, or using session information that is captured on firewall policies (see Passive WAN health measurement on page 944 for information), and measuring the link quality based on latency, jitter, and packet loss. If a link fails all of the health checks, the routes on that link are removed from the SD-WAN link load balancing group, and traffic is routed through other links. When the link is working again the routes are reestablished. This prevents traffic being sent to a broken link and lost.

When an SD-WAN member has multiple health checks configured, all of the checks must fail for the routes on that link to be removed from the SD-WAN link load balancing group.

Two health check servers can be configured to ensure that, if there is a connectivity issue, the interface is at fault and not the server. A server can only be used in one health check.

The FortiGate uses the first server configured in the health check server list to perform the health check. If the first server is unavailable, then the second server is used. The second server continues to be used until it becomes unavailable, and then the FortiGate returns to the first server, if it is available. If both servers are unavailable, then the health check fails.

You can configure the protocol that is used for status checks, including: Ping, HTTP, HTTPS. DNS, TCP echo, UDP echo, two-way active measurement protocol (TWAMP), TCP connect, and FTP. In the GUI, only Ping, HTTP, and DNS are available.

You can view link quality measurements by going to *Network > SD-WAN* and selecting the *Performance SLAs* tab. The table shows the default health checks, the health checks that you configured, and information about each health check. The values shown in the *Packet Loss*, *Latency*, and *Jitter* columns are for the health check server that the FortiGate is currently using. The green up arrows indicate that the server is responding, and does not indicate if the health checks are being met. See Results on page 902 for more information.

To configure a link health monitor in the GUI:

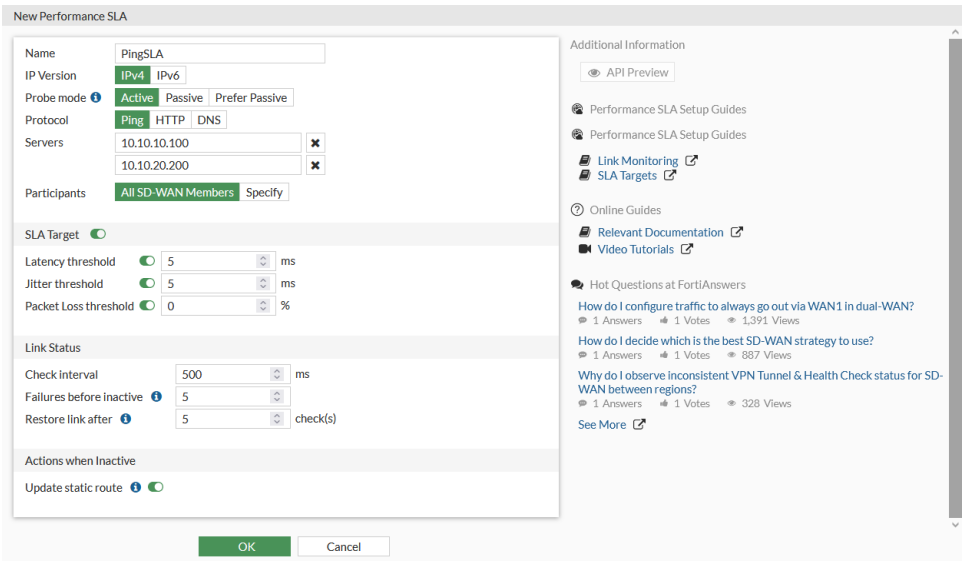
1. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Set a *Name* for the SLA.
3. If enabled in Feature Visibility, set the *IP Version*. *IPv6* does not support all of the protocols.
4. Set the *Probe mode*:
   - *Active*: Send probes to determine link quality.
   - *Passive*: Use traffic to determine link quality. Enable passive health checks in policies to allow measurement.
   - *Prefer Passive*: Same as passive mode, but send probes when there is no traffic.
5. Set the *Protocol* that you need to use for status checks: *Ping*, *HTTP*, or *DNS*.
6. Set *Server* to the IP addresses of up to two servers that all of the SD-WAN members in the performance SLA can reach. If the *Protocol* is *DNS*, set the *DNS Server* to either the same as the system DNS, or specify the primary and secondary DNS servers.

7. Set *Participants* to *All SD-WAN Members*, or select *Specify* to choose specific SD-WAN members.
8. Set *Enable probe packets* to enable or disable sending probe packets.
9. Configure *SLA Target*:

   If the health check is used in an SD-WAN rule that uses *Manual* or *Best Quality* strategies, enabling *SLA Target* is optional. If the health check is used in an SD-WAN rule that uses *Lowest Cost (SLA)* or *Maximum Bandwidth (SLA)* strategies, then *SLA Target* is enabled.

   When *SLA Target* is enabled, configure the following:

   - *Latency threshold*: Calculated based on last 30 probes (default = 5ms).
   - *Jitter threshold*: Calculated based on last 30 probes (default = 5ms).
   - *Packet Loss threshold*: Calculated based on last 100 probes (default = 0%).
10. In the *Link Status* section configure the following:
    - *Check interval*: the interval in which the FortiGate checks the interface, in milliseconds (20 - 3600000, default = 500).
    - *Failures before inactive*: The number of failed status checks before the interface shows as inactive (1 - 3600, default =5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links
    - *Restore link after*: The number of successful status checks before the interface shows as active (1 - 3600, default = 5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links
11. In the *Actions when Inactive* section, enable *Update static route* to disable static routes for inactive interfaces and restore routes when interfaces recover.



12. Click *OK*.

To configure a link health monitor in the CLI:

```
config system sdwan
    config health-check
        edit "PingSLA"
            set addr-mode {ipv4 | ipv6}
            set server <server1_IP_address> <server2_IP_address>
```

```
            set detect-mode {active | passive | prefer-passive}
            set protocol {ping | tcp-echo | udp-echo | http | https| twamp | dns | tcp-connect |
ftp}
            set ha-priority <integer>
            set probe-timeout <integer>
            set probe-count <integer>
            set probe-packets {enable | disable}
            set interval <integer>
            set failtime <integer>
            set recoverytime <integer>
            set diffservcode <binary>
            set update-static-route {enable | disable}
            set update-cascade-interface {enable | disable}
            set sla-fail-log-period <integer>
            set sla-pass-log-period <integer>
            set threshold-warning-packetloss <integer>
            set threshold-alert-packetloss <integer>
            set threshold-warning-latency <integer>
            set threshold-alert-latency <integer>
            set threshold-warning-jitter <integer>
            set threshold-alert-jitter <integer>
            set vrf <integer>
            set source <ip address>
            set members <member_number> ... <member_number>
            config sla
                edit 1
                    set link-cost-factor {latency jitter packet-loss}
                    set latency-threshold <integer>
                    set jitter-threshold <integer>
                    set packetloss-threshold <integer>
                next
            end
        next
    end
end
```

Additional settings are available for some of the protocols:

Protocol	Additional options

http, https	`port <port_number>`
	`http-get <url>`
	`http-agent <string>`
	`http-match <response_string>`

twamp	`port <port_number>`
	`security mode {none | authentication}`
	`password <password>`
	`packet-size <size>`

ftp	`ftp-mode {passive | port}` `ftp-file <path>`

For more examples see Protocol.

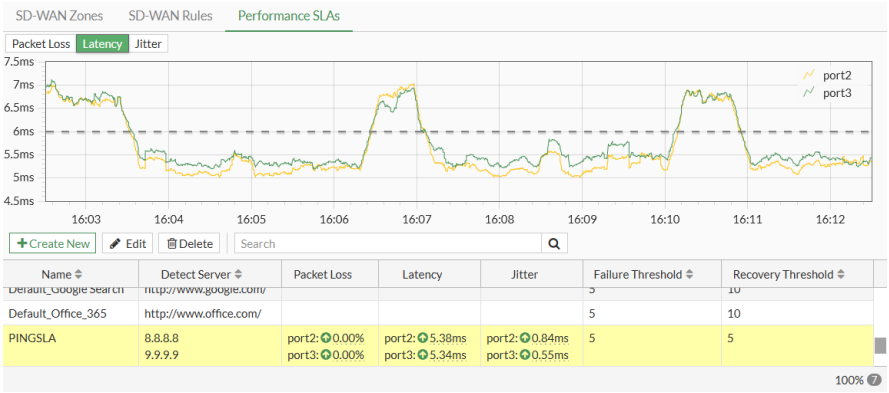
Monitoring performance SLA

SD-WAN diagnostics can be used to help maintain your SD-WAN solution.

Monitoring SD-WAN link quality status

Link quality plays a significant role in link selection for SD-WAN. Investigate any prolonged issues with packet loss, latency, or jitter to ensure that your network does not experience degraded performance or an outage.

You can monitor the link quality status of SD-WAN interface members by going to *Network* > *SD-WAN* and selecting the *Performance SLAs* tab.



The live charts show the packet loss, latency, or jitter for the selected health check. Hover the cursor over a line in the chart to see the specific value for that interface at that specific time.

The table shows information about each health check, including the configured servers, link quality data, and thresholds. The colored arrow indicates the status of the interface when the last status check was performed: green means that the interface was active, and red means that the interface was inactive. Hover the cursor over the arrow for additional information.

Monitoring system event logs

The features adds an SD-WAN daemon function to keep a short, 10 minute history of SLA that can be viewed in the CLI.

Performance SLA results related to interface selection, session failover, and other information, can be logged. These logs can then be used for long-term monitoring of traffic issues at remote sites, and for reports and views in FortiAnalyzer.

The time intervals that Performance SLA fail and pass logs are generated in can be configured.

To configure the fail and pass logs' generation time interval:

```
config system sdwan
    config health-check
        edit "PingSLA"
            set sla-fail-log-period 30
            set sla-pass-log-period 60
        next
    end
end
```

To view the 10 minute Performance SLA link status history:

```
FGDocs # diagnose sys sdwan sla-log PingSLA 1
Timestamp: Fri Sep  4 10:32:37 2020, vdom root, health-check PingSLA, interface: wan2, status: up,

In the FortiAnalyzer GUI:

Monitoring using the REST API

SLA log and interface information can be monitored using the REST API. This feature is also used by FortiManager as part of its detailed SLA monitoring and drilldown features.

API call	URL
Interface log	`https://172.172.172.9/api/v2/monitor/virtual-wan/interface-log`
SLA log	`https://172.172.172.9/api/v2/monitor/virtual-wan/sla-log`
Health check log	`https://172.172.172.9/api/v2/monitor/virtual-wan/health-check`

A comprehensive list of API calls with sample output is available on the Fortinet Developer Network.

CLI diagnose commands:

```
# diagnose sys sdwan intf-sla-log port13

map=0x1
```

Passive WAN health measurement

SD-WAN passive WAN health measurement determines the health check measurements (jitter, latency, and packet loss) using session information captured from the firewall policies that have *Passive Health Check* (`passive-wan-health-measurement`) enabled. Passive measurements analyze session information that is gathered from various TCP sessions can be viewed using the command `diagnose sys link-monitor-passive admin list by-interface`.

Using passive WAN health measurement reduces the amount of configuration required and decreases the traffic that is produced by health check monitor probes doing active measurements. Passive WAN health measurement analyzes real-life traffic; active WAN health measurement using a detection server might not reflect the real-life traffic.

By default, active WAN health measurement is enabled when a new health check is created. It can be changed to passive or prefer passive:

passive	Health is measured using live traffic passing through an SD-WAN link to determine link metrics (jitter, latency, and packet loss) of participating SD-WAN links. No link health monitor needs to be configured.
prefer-passive	Health is measured using live traffic when there is traffic passing though an SD-WAN link to determine link metrics (jitter, latency, and packet loss). If there is no live traffic flowing through an SD-WAN link for three continuous minutes, then the FortiGate sends out active probes to the configured health check server (`set server`) to calculate the link metrics. A link health monitor must be configured, see Link health monitor for details.

When `passive-wan-health-measurement` is enabled, `auto-asic-offload` will be disabled.

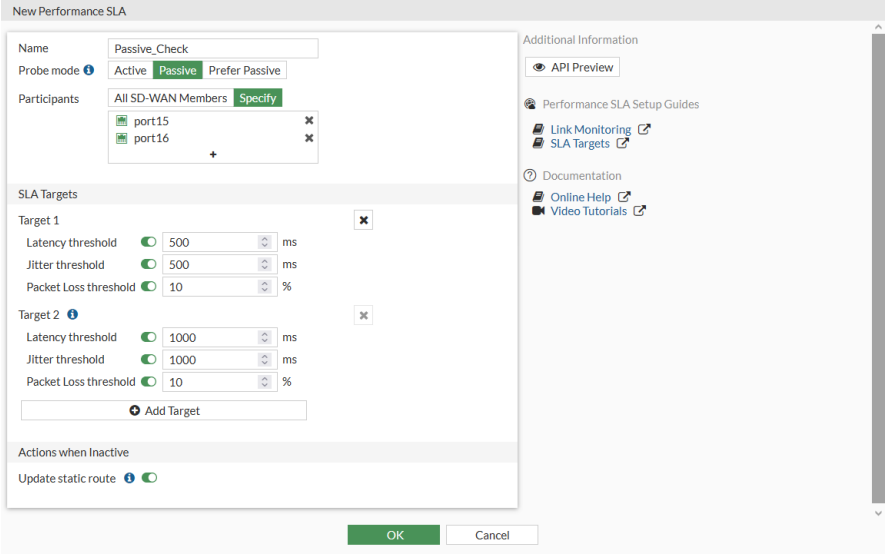
Example

In this example, the FortiGate is configured to load-balance between two WAN interfaces, port15 and port16. A health check is configured in passive mode, and SLA thresholds are set. Passive WAN health measurement is enabled on the SD-WAN policy.

Measurements are taken from YouTube traffic generated by the PC. When latency is introduced to the traffic on port15, the passive health check trigger threshold is exceeded and traffic is rerouted to port16.

To configure the SD-WAN in the GUI:

1. Create the SD-WAN zone:
   a. Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab.
   b. Click *Create New* > *SD-WAN Zone*.
   c. Enter a name for the zone, such as *SD-WAN*.
   d. Click *OK*.
2. Create the SD-WAN members:
   a. Go to *Network* > *SD-WAN* and select the *SD-WAN Zones* tab.
   b. Click *Create New* > *SD-WAN Member*.
   c. Set *Interface* to *port15*, *SD-WAN Zone* to *SD-WAN*, and *Gateway* set to *172.16.209.2*.
   d. Click *OK*.
   e. Click *Create New* > *SD-WAN Member* again.
   f. Set *Interface* to *port16*, *SD-WAN Zone* to *SD-WAN*, and *Gateway* set to *172.16.210.2*.
   g. Click *OK*.
3. Create a performance SLA:
   a. Go to *Network* > *SD-WAN* and select the *Performance SLAs* tab.
   b. Edit an existing health check, or create a new one.
   c. Set *Probe mode* to *Passive*.
   d. Set *Participants* to *Specify* and add *port15* and *port16*.
   e. Configure two SLA targets. Note that the second SLA target must be configured in the CLI.



f. Configure the remaining settings as needed.

g. Click *OK*.

The SLA list shows the probe mode in the *Detect Server* column, if the probe mode is passive or prefer passive.

Probe packets can only be disabled in the CLI and when the probe mode is not passive.

4. Create SD-WAN rules:

a. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.

b. Configure the first rule:

Name	Background_Traffic
Source address	172.16.205.0
Application	Click in the field, and in the *Select Entries* pane search for *YouTube* and select all of the entries
Strategy	Maximize Bandwidth (SLA)
Interface preference	port15 and port16
Required SLA target	Passive_Check#2

c. Click *OK*.

d. Click *Create New* again and configure the second rule:

Name	Foreground_Traffic
Source address	172.16.205.0
Address	all

Protocol number	Specify - 1
Strategy	Lowest Cost (SLA)
Interface preference	port15 and port16
Required SLA target	Passive_Check#1

e. Click *OK*.

To configure the firewall policy in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the policy:

Name	SD-WAN-HC-policy
Incoming Interface	port5
Outgoing Interface	SD-WAN
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT
Passive Health Check	Enabled Passive health check can only be enabled in a policy when the outgoing interface is an SD-WAN zone.

3. Click *OK*.

To configure the SD-WAN in the CLI:

```
config system sdwan
    set status enable
    config zone
        edit "SD-WAN"
        next
    end
    config members
        edit 1
            set zone "SD-WAN"
            set interface "port15"
            set gateway 172.16.209.2
        next
        edit 2
            set zone "SD-WAN"
            set interface "port16"
            set gateway 172.16.210.2
```

```
        next
    end
    config health-check
        edit "Passive_Check"
            set detect-mode passive
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 500
                    set jitter-threshold 500
                    set packetloss-threshold 10
                next
                edit 2
                    set latency-threshold 1000
                    set jitter-threshold 1000
                    set packetloss-threshold 10
                next
            end
        next
    end
    config service
        edit 1
            set name "Background_Traffic"
            set mode sla
            set load-balance enable
            set src "172.16.205.0"
            set internet-service enable
            set internet-service-app-ctrl 31077 33321 41598 31076 33104 23397 30201 16420 17396
38569 25564
            config sla
                edit "Passive_Check"
                    set id 2
                next
            end
            set priority-member 1 2
        next
        edit 2
            set name "Foreground_Traffic"
            set mode sla
            set src "172.16.205.0"
            set protocol 1
            set dst "all"
            config sla
                edit "Passive_Check"
                    set id 1
                next
            end
            set priority-member 1 2
        next
    end
end
```

To configure the firewall policy in the CLI:

```
config firewall policy
    edit 1
        set name "SD-WAN-HC-policy"
        set srcintf "port5"
        set dstintf "SD-WAN"
        set nat enable
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set passive-wan-health-measurement enable
        set auto-asic-offload disable
    next
end
```

Results

When both links pass the SLA:

```
# diagnose sys link-monitor-passive admin list by-interface
Interface port16 (28):
  Default(0x00000000): latency=10.0    15:46:36, jitter=5.0    15:46:37, pktloss=0.0  % 10:09:21

Interface port15 (27):
  Default(0x00000000): latency=60.0    15:46:36, jitter=0.0    15:46:37, pktloss=0.0  % 10:39:24
```

```
# diagnose sys sdwan health-check
Health Check(Passive_Check):
Seq(1 port15): state(alive), packet-loss(0.000%) latency(60.000), jitter(0.750) sla_map=0x3
Seq(2 port16): state(alive), packet-loss(0.000%) latency(10.000), jitter(5.000) sla_map=0x3
```

```
# diagnose sys sdwan service4 2

Service(2): Address Mode(IPV4) flags=0x200

  Dst address(1):
        8.8.8.8-8.8.8.8
```

Passive measurement

Passive measurement allows SLA information per internet service/application to be differentiated and collected when internet services/applications are defined in an SD-WAN rule that uses passive or prefer passive SLA. The SLA metrics (jitter, latency, and packet loss) on each SD-WAN member in the rule are calculated based on the relevant internet services/applications SLA information. These metrics help analyze the performance of different applications using the same WAN link. See Passive health-check measurement by internet service and application on page 954 for more information.

Passive monitoring of TCP metrics

FortiGate can now perform passive monitoring of TCP metrics by measuring and logging the following for each TCP session:

- Network response time
- Server response time
- Original retransmits
- Reply retransmits
- SYN retransmits
- SYN-ACK retransmits
- Original or reply resets

Passive monitoring of TCP sessions is configured in firewall policies with the SD-WAN zone as the destination interface using the following CLI command:

```
config firewall policy
    edit <entry>
```

```
        set app-monitor {enable | disable}
    next
end
```

When `set app-monitor` is enabled in a firewall policy, NPU offloading for the firewall policy is automatically disabled.

The following metrics for each TCP session are logged:

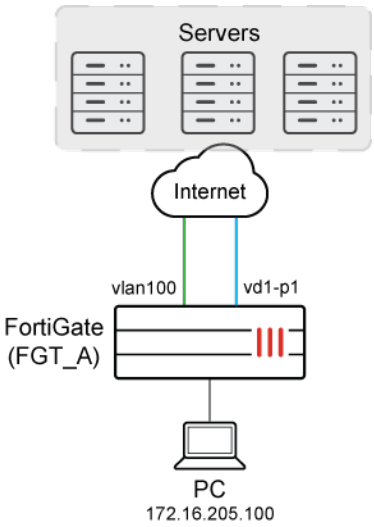
tcpnrt	Represents TCP Network Response Time and the time between `SYN_ACK` to `ACK` in milliseconds.
tcpsrt	Represents TCP Server Response Time and the time between `SYN` to `SYN_ACK` in milliseconds.
tcporgrtrs	Represents TCP Original Retransmit and the number of retransmissions in the original direction.
tcprplrtrs	Represents TCP Reply Retransmit and the number of retransmissions in the reply direction.
tcpsynrtrs	Represents TCP SYN Retransmit and number of `SYN` retransmissions.
tcpsynackrtrs	Represents TCP SYN ACK Retransmit and number of `SYN_ACK` retransmissions.
tcprst	Represents TCP Reset and values are `none`, `origin`, and `reply`.

This feature helps monitor performance of TCP traffic and locate potential network issues. You can display TCP metrics using the `diagnose sys session list` command, or you can view traffic logs in either the CLI or the GUI.

SD-WAN traffic steering remains independent from the measured TCP session metrics.

Example

In this example, SD-WAN is configured with a zone named virtual-wan-link, and it contains two members (vlan100 and vd1-p1). A firewall policy is configured for the SD-WAN zone to passively monitor TCP metrics from the PC to a server.



To configure SD-WAN:

1. Configure SD-WAN:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "vd1-p1"
        next
        edit 2
            set interface "vlan100"
            set gateway 172.16.206.2
        next
    end
    config service
        edit 1
            set name "1"
            set dst "all"
            set src "172.16.205.0"
            set priority-members 1 2
        next
    end
end
```

2. Identify the preferred interface:
   In this example `vd1-p1` is the preferred SD-WAN member.

```
# diagnose sys sdwan service4

Service(1): Address Mode(IPV4) flags=0x4200 use-shortcut-sla use-shortcut
```

```
 Tie break: cfg
 Shortcut priority: 2
  Gen(1), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(manual)
  Members(2):
    1: Seq_num(1 vd1-p1 virtual-wan-link), alive, selected
    2: Seq_num(2 vlan100 virtual-wan-link), alive, selected
  Src address(1):
        172.16.205.0-172.16.205.255
  Dst address(1):
        0.0.0.0-255.255.255.255
```

3. Configure a firewall policy for the SD-WAN zone to monitor traffic from the PC:

   In this example, the `dstintf` option is set to the SD-WAN zone (`virtual-wan-link`), the `srcaddr` option identifies the PC (172.16.205.0), and passive monitoring and logging of TCP metrics is enabled.

```
config firewall policy
    edit 1
        set name "TCP-Metrics"
        set srcintf "any"
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr "172.16.205.0"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set app-monitor enable
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "g-default"
        set logtraffic all
        set auto-asic-offload disable
    next
end
```

4. As traffic passes from the PC through FortiGate to the server, TCP traffic is measured and logged, and you can view the results:
   - View a session list:

```
# diagnose sys session list

session info: proto=6 proto_state=11 duration=172 expire=3577 timeout=3600 refresh_
dir=both flags=00000000 socktype=0 sockport=0 av_idx=0 use=3

Passive health-check measurement by internet service and application

Active probing relies on checking the performance metrics of underlying infrastructure using layer 3 probes (ping) and layer 4 probes (tcp-echo, http, dns, and others) to provide limited information about an application's true performance.

Passive WAN health measurement uses passive probing to provide more realistic application performance information by collecting the performance metrics (jitter, latency, and packet loss) of live traffic that is passing through the firewall policies. See Passive WAN health measurement on page 944.

Different applications can have different performance on the same WAN link, depending on the application's implementation. Passive measurement can be used to measure the performance of different internet services/applications that use the same WAN link.

The following is required:

1. Firewall policy configuration:
   - Enable passive WAN health measurement (`set passive-wan-health-measurement enable`).
   - Disable hardware offloading (`set auto-asic-offload disable`).
   - Use an application control security profile to identify applications.

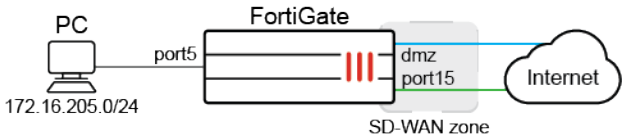
2. SD-WAN rule configuration:
   - Use passive or prefer passive performance SLA.
   - Use ISDB/application signatures or ISDB/application signature groups to identify applications.
   - Enable passive measurement (`set passive-measurement enable`).

If internet services or applications are defined in an SD-WAN rule with passive or prefer passive performance SLA , SLA information for each service or application will be differentiated and collected. SLA metrics (jitter, latency, and packet loss) on each SD-WAN member in the rule are then calculated based on the relevant internet service's or application's SLA information.

In this example, three SD-WAN rules are created:

- Rule 1: Best quality (latency) using passive SLA for the internet services Alibaba and Amazon.
- Rule 2: Best quality (latency) using passive SLA for the applications Netflix and YouTube.
- Rule 3: Best quality (latency) using passive SLA for all other traffic.

After passive application measurement is enabled for rules one and two, the SLA metric of rule one is the average latency of the internet services Alibaba and Amazon, and the SLA metric of rule two is the average latency of the applications Netflix and YouTube.



To configure the SD-WAN:

1. Configure the SD-WAN members:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 2
            set interface "port15"
            set gateway 172.16.209.2
        next
    end
end
```

2. Configure the passive mode health check:

```
config health-check
    edit "Passive_HC"
        set detect-mode passive
        set members 1 2
```

```
    next
end
```

3. Configure SD-WAN service rules:

```
config service
    edit 1
        set name "1"
        set mode priority
        set src "172.16.205.0"
        set internet-service enable
        set internet-service-name "Alibaba-Web" "Amazon-Web"
        set health-check "Passive_HC"
        set priority-members 1 2
        set passive-measurement enable    //Enable "passive application measurement", it is a
new command which is introduced in this project.
    next
    edit 2
        set name "2"
        set mode priority
        set src "172.16.205.0"
        set internet-service enable
        set internet-service-app-ctrl 18155 31077
        set health-check "Passive_HC"
        set priority-members 1 2
        set passive-measurement enable    ////Enable "passive application measurement"
    next
    edit 3
        set name "3"
        set mode priority
        set dst "all"
        set src "172.16.205.0"
        set health-check "Passive_HC"
        set priority-members 1 2
    next
end
```

4. Configure SD-WAN routes:

```
config router static
    edit 1
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
end
```

5. Configure the firewall policy with passive WAN health measurement enabled:

```
config firewall policy
    edit 1
        set uuid 972345c6-1595-51ec-66c5-d705d266f712
        set srcintf "port5"
```

```
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr "172.16.205.0"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set passive-wan-health-measurement enable
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "g-default"
        set auto-asic-offload disable
    next
end
```

To verify the results:

1. On the PC, open the browser and visit the internet services and applications.
2. On the FortiGate, check the collected SLA information to confirm that each server or application on the SD-WAN members was measured individually:

```
# diagnose sys link-monitor-passive admin list by-interface

Interface dmz (5):
       Default(0x00000000): latency=3080.0  11:57:54, jitter=5.0     11:58:08, pktloss=0.0  %
NA
   Alibaba-Web(0x00690001): latency=30.0    11:30:06, jitter=25.0    11:29:13, pktloss=0.0  %
NA
       YouTube(0x00007965): latency=100.0   12:00:35, jitter=2.5     12:00:30, pktloss=0.0  %
NA
       Netflix(0x000046eb): latency=10.0    11:31:24, jitter=10.0    11:30:30, pktloss=0.0  %
NA
    Amazon-Web(0x00060001): latency=80.0    11:31:52, jitter=35.0    11:32:07, pktloss=0.0  %
NA

Interface port15 (27):
       Default(0x00000000): latency=100.0   12:00:42, jitter=0.0     12:00:42, pktloss=0.0  %
NA
    Amazon-Web(0x00060001): latency=30.0    11:56:05, jitter=0.0     11:55:21, pktloss=0.0  %
NA
   Alibaba-Web(0x00690001): latency=0.0     11:26:08, jitter=35.0    11:27:08, pktloss=0.0  %
NA
       YouTube(0x00007965): latency=100.0   11:33:34, jitter=0.0     11:33:50, pktloss=0.0  %
NA
       Netflix(0x000046eb): latency=0.0     11:26:29, jitter=0.0     11:29:03, pktloss=0.0  %
NA
```

The `Default(0x00000000)` applications are other, unidentified applications that do not have ISDB or application signatures configured in SD-WAN rules. The latency of default/application is taken into account in per SD-WAN rule calculations only if `passive-measurement` is disabled in any one of the SD-WAN rules.

3. Verify that the SLA metrics on the members are calculated as expected:

```
# diagnose sys sdwan service4

Service(1): Address Mode(IPV4) flags=0x600 use-shortcut-sla
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(priority), link-cost-factor(latency),

  Src address(1):
        172.16.205.0-172.16.205.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

The latency on each member interface per SD-WAN rule is the average of the latency of the application identified by respective SD-WAN rules.

The SLA metrics listed for each member interface per SD-WAN rule shown by the `diagnose sys sdwan service4` and `diagnose sys sdwan service6` commands are derived from the output of the SLA information for the applications shown in the output of the `diagnose sys link-monitor-passive admin list by-interface` command.

Until the applications are identified, their SLA metrics are not used to calculate SLA metrics for each member per SD-WAN rule. Applications are identified only when there is (or was) any application traffic passing through a member interface.

Mean opinion score calculation and logging in performance SLA health checks

The mean opinion score (MOS) is a method of measuring voice quality using a formula that takes latency, jitter, packet loss, and the codec into account to produce a score from one to five (1 - 5). The G.711, G.729, and G.722 codecs can be selected in the health check configurations, and an MOS threshold can be entered to indicate the minimum MOS score for the SLA to pass. The maximum MOS score will depend on which codec is used, since each codec has a theoretical maximum limit.

```
config system sdwan
    config health-check
          edit <name>
            set mos-codec {g711 | g729 | g722}
            config sla
                edit <id>
                    set link-cost-factor {latency jitter packet-loss mos}
                    set mos-threshold <value>
                next
            end
        next
    end
end
```

`mos-codec {g711 | g729 | g722}`	Set the VoIP codec to use for the MOS calculation (default = g711).
`link-cost-factor {latency jitter packet-loss mos}`	Set the criteria to base the link selection on.
`mos-threshold <value>`	Set the minimum MOS for the SLA to be marked as pass (1.0 - 5.0, default = 3.6).

To configure a health check to calculate the MOS:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 2
            set interface "port15"
            set gateway 172.16.209.2
        next
    end
```

```
    config health-check
        edit "Test_MOS"
            set server "2.2.2.2"
            set sla-fail-log-period 30
            set sla-pass-log-period 30
            set members 0
            set mos-codec g729
            config sla
                edit 1
                    set link-cost-factor mos
                    set mos-threshold "4.0"
                next
            end
        next
    end
end
```

To use an MOS SLA to steer traffic in an SD-WAN rule:

```
config system sdwan
    config service
        edit 1
            set name "MOS_traffic_steering"
            set mode sla
            set dst "HQ_LAN"
            set src "Branch_LAN"
            config sla
                edit "Test_MOS"
                    set id 1
                next
            end
            set priority-members 0
        next
    end
end
```

The MOS currently cannot be used to steer traffic when the `mode` is set to `priority`.

To verify the MOS calculation results:

1. Verify the health check diagnostics:

```
# diagnose sys sdwan health-check
Health Check(Test_MOS):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.114), jitter(0.026), mos(4.123),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
```

```
Seq(2 port15): state(alive), packet-loss(0.000%) latency(0.100), jitter(0.008), mos(4.123),
bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
```

```
# diagnose sys sdwan sla-log Test_MOS 1
Timestamp: Tue Jan  4 11:23:06 2022, vdom root, health-check Test_MOS, interface: dmz, status:
up, latency: 0.151, jitter: 0.040, packet loss: 0.000%, mos: 4.123.
Timestamp: Tue Jan  4 11:23:07 2022, vdom root, health-check Test_MOS, interface: dmz, status:
up, latency: 0.149, jitter: 0.041, packet loss: 0.000%, mos: 4.123.
```

```
# diagnose sys sdwan sla-log Test_MOS 2
Timestamp: Tue Jan  4 11:25:09 2022, vdom root, health-check Test_MOS, interface: port15,
status: up, latency: 0.097, jitter: 0.009, packet loss: 0.000%, mos: 4.123.
Timestamp: Tue Jan  4 11:25:10 2022, vdom root, health-check Test_MOS, interface: port15,
status: up, latency: 0.097, jitter: 0.008, packet loss: 0.000%, mos: 4.123.
```

2. Change the `mos-codec` to `g722`. The diagnostics will now display different MOS values:

```
# diagnose sys sdwan health-check
Health Check(Test_MOS):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.150), jitter(0.031), mos(4.453),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
Seq(2 port15): state(alive), packet-loss(0.000%) latency(0.104), jitter(0.008), mos(4.453),
bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
```

3. Increase the latency on the link in port15. The calculated MOS value will decrease accordingly. In this example, port15 is out of SLA since its MOS value is now less than the 4.0 minimum:

```
# diagnose sys sdwan  health-check
Health Check(Test_MOS):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.106), jitter(0.022), mos(4.453),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
Seq(2 port15): state(alive), packet-loss(0.000%) latency(300.119), jitter(0.012), mos(3.905),
bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x0
```

Sample logs

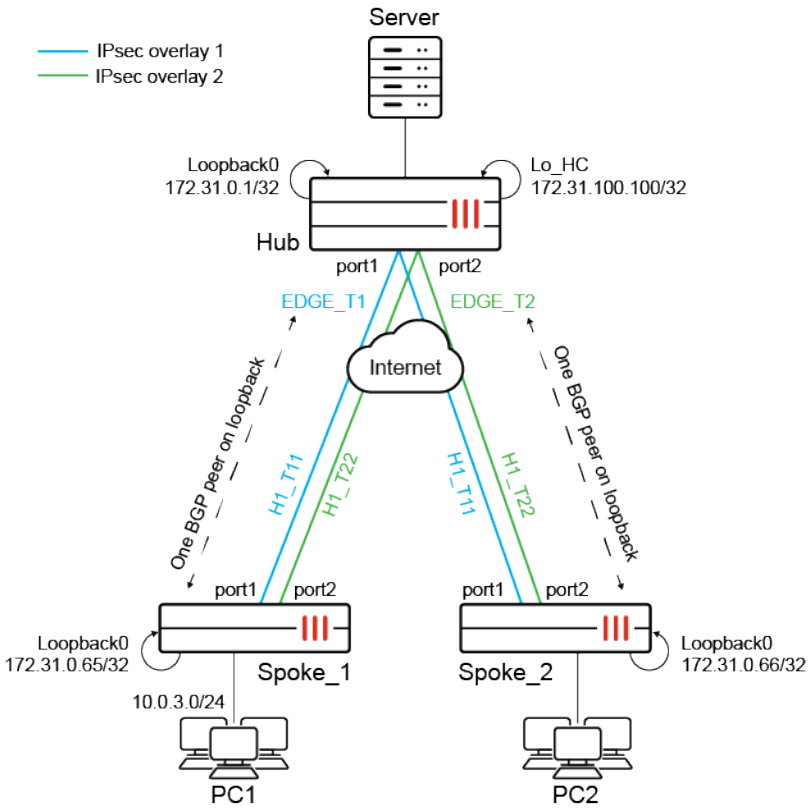
Embedded SD-WAN SLA information in ICMP probes

In the hub and spoke SD-WAN design, in order for traffic to pass symmetrically from spoke to hub and hub to spoke, it is essential for the hub to know which IPsec overlay is in SLA and out of SLA. Prior to introducing embedded SLA information in ICMP probes, it is common practice for spokes to use the SD-WAN neighbor feature and `route-map-out-preferable` setting to signal the health of each overlay to the hub. However, this requires BGP to be configured per overlay, and to manipulate BGP routes using custom BGP communities.

With embedded SLA information in ICMP probes, spokes can communicate their SLA for each overlay directly through ICMP probes to the hub. The hub learns these SLAs and maps the status for each spoke and its corresponding overlays.

The hub uses the SLA status to apply priorities to the IKE routes, giving routes over IPsec overlays that are within SLAs a lower priority value and routes over overlays out of SLAs a higher priority value. If BGP is used, recursively resolved BGP routes can inherit the priority from its parent.

Embedded SLA information in ICMP probes allows hub and spoke SD-WAN to be designed with a BGP on loopback topology, or without BGP at all. The following topology outlines an example of the BGP on loopback design where each spoke is peered with the hub and route reflector on the loopback interface.



In this topology, each FortiGate's BGP router ID is based on its Loopback0 interface. Each spoke has SLA health checks defined to send ICMP probes to the server's Lo_HC interface on 172.31.100.100. The ICMP probes include embedded SLA information for each SD-WAN overlay member.

Related SD-WAN settings:

```
config system sdwan
    config health-check
        edit <name>
            set detect-mode {active | passive | prefer-passive | remote}
            set embed-measured-health {enable | disable}
            config sla
                edit <id>
                    set priority-in-sla <integer>
                    set priority-out-sla <integer>
                next
            end
            set sla-id-redistribute <id>
        next
    end
end
```

`detect-mode {active | passive | prefer-passive | remote}`	Set the mode that determines how to detect the server: • `active`: the probes are sent actively (default). • `passive`: the traffic measures health without probes.

	• `prefer-passive`: the probes are sent in case of no new traffic. • `remote`: the link health is obtained from remote peers.
`embed-measured-health {enable | disable}`	Enable/disable embedding SLA information in ICMP probes (default = disable).
`set priority-in-sla <integer>`	Set the priority that will be set to the IKE route when the corresponding overlay is in SLA (0 - 65535).
`set priority-out-sla <integer>`	Set the priority that will be set to the IKE route when the corresponding overlay is out of SLA (0 - 65535).
`sla-id-redistribute <id>`	Set the SLA entry (ID) that will be applied to the IKE routes (0 - 32, default = 0).

Related BGP setting:

```
config router bgp
    set recursive-inherit-priority {enable | disable}
end
```

`recursive-inherit-priority {enable | disable}`	Enable/disable allowing recursive resolved BGP routes to inherit priority from its parent (default = disable).

Example with BGP on loopback SD-WAN

This example demonstrates the configurations needed to configure the SD-WAN and BGP settings for the preceding topology. It is assumed that IPsec VPN overlays are already configured per the topology, and that loopback interfaces are already configured on each FortiGate.

Configuring the Spoke_1 FortiGate

In the SD-WAN settings, note the following requirements:

1. Configure the SD-WAN zones and members. For each SD-WAN member, define the source of its probes to be the Loopback0 interface IP.
2. Configure the SLA health check to point to the Hub's Lo_HC interface and IP. Enable `embed-measured-health`.
3. Configure an SD-WAN service rule to route traffic based on the maximize bandwidth (SLA) algorithm to prefer member H1_T11 over H1_T22.
4. Configure `set exchange-interface-ip enable` and `set exchange-ip-addr4` to the Loopback0 interface IP. The `exchange-interface-ip option` is automatically turned on when ADVPN has already been configured. If ADVPN has not been configured, then `set exchange-interface-ip enable` must be configured before `set exchange-ip-addr4` can be configured.

To configure the SD-WAN settings:

```
config system sdwan
    set status enable
```

```
    config zone
        edit "virtual-wan-link"
        next
        edit "overlay"
        next
    end
    config members
        edit 1
            set interface "H1_T11"
            set zone "overlay"
            set source 172.31.0.65
        next
        edit 4
            set interface "H1_T22"
            set zone "overlay"
            set source 172.31.0.65
        next
    end
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set embed-measured-health enable
            set members 0
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
            end
        next
    end
    config service
        edit 1
            set mode sla
            set dst "CORP_LAN"
            set src "CORP_LAN"
            config sla
                edit "HUB"
                    set id 1
                next
            end
            set priority-members 1 4
        next
    end
end
```

To configure the BGP settings:

```
config router bgp
    set as 65001
    set router-id 172.31.0.65
    config neighbor
```

```
        edit "172.31.0.1"
            set remote-as 65001
            set update-source "Loopback0"
        next
    end
    config network
        edit 1
            set prefix 10.0.3.0 255.255.255.0
        next
    end
end
```

To add the loopback IP to the IPsec interface settings:

```
config vpn ipsec phase1-interface
    edit "H1_T11"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.65
    next
    edit "H1_T22"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.65
    next
end
```

Configuring the hub FortiGate

In the SD-WAN settings, note the following requirements:

1. Configure the SD-WAN zone and members.
2. Configure the SLA health checks to detect SLAs based on the remote site (spoke). This must be defined for each SD-WAN member:
   a. For the SLA, specify the same link cost factor and metric as the spoke (100).
   b. Define the IKE route priority for in and out of SLA. Lower priority values have higher priority than higher priority values.
3. Define the SLA entry ID that will be applied to the IKE routes.
4. Configure `set exchange-interface-ip enable` and `set exchange-ip-addr4` to the Loopback0 interface IP. The `exchange-interface-ip option` is automatically turned on when ADVPN has already been configured. If ADVPN has not been configured, then `set exchange-interface-ip enable` must be configured before `set exchange-ip-addr4` can be configured.

To configure the SD-WAN settings:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
```

```
    config members
        edit 1
            set interface "EDGE_T1"
        next
        edit 2
            set interface "EDGE_T2"
        next
    end
    config health-check
        edit "1"
            set detect-mode remote
            set sla-id-redistribute 1
            set members 1
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                    set priority-in-sla 10
                    set priority-out-sla 20
                next
            end
        next
        edit "2"
            set detect-mode remote
            set sla-id-redistribute 1
            set members 2
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                    set priority-in-sla 15
                    set priority-out-sla 25
                next
            end
        next
    end
end
```

In the BGP settings, note the following requirements:

1. Enable `recursive-inherit-priority` to inherit the route priority from its parent, which is the priority defined in the health check SLA settings.
2. Configure the other BGP settings similar to a regular BGP hub.

To configure the BGP settings:

```
config router bgp
    set as 65001
    set router-id 172.31.0.1
    set recursive-inherit-priority enable
    config neighbor-group
        edit "EDGE"
```

```
            set remote-as 65001
            set update-source "Loopback0"
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 172.31.0.64 255.255.255.192
            set neighbor-group "EDGE"
        next
    end
end
```

To add the loopback IP to the IPsec interface settings:

```
config vpn ipsec phase1-interface
    edit "EDGE_T1"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.1
    next
    edit "EDGE_T2"
        set exchange-interface-ip enable
        set exchange-ip-addr4 172.31.0.1
    next
end
```

Testing and verification

Once the hub and spokes are configured, verify that SLA statuses are passed from the spoke to the hub.

To verify that the SLA statuses are passed from the spoke to the hub:

1. On Spoke_1, display the status of the health-checks for H1_T11 and H1_T22:

```
# diagnose sys sdwan  health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(0.228), jitter(0.018), mos(4.404),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x1
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.205), jitter(0.007), mos(4.404),
bandwidth-up(999998), bandwidth-dw(1000000), bandwidth-bi(1999998) sla_map=0x1
```

2. On Spoke_1, display the status and order of the overlays in the SD-WAN service rule:

```
# diagnose sys sdwan service4
Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
 Tie break: cfg
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(2):
    1: Seq_num(1 H1_T11), alive, sla(0x1), gid(0), cfg_order(0), local cost(0), selected
```

```
    2: Seq_num(4 H1_T22), alive, sla(0x1), gid(0), cfg_order(3), local cost(0), selected

Src address(1):
      10.0.0.0-10.255.255.255
Dst address(1):
      10.0.0.0-10.255.255.255
```

Both overlays are within SLA, so H1_T11 is preferred due to its `cfg-order`.

Spoke_1's SLA information for H1_T11 and H1_T22 is embedded into the ICMP probes destined for the hub's Lo_HC interface. The hub receives this information and maps the SLAs correspondingly per spoke and overlay based on the same SLA targets.

As a result, since all SLAs are within target, the hub sets the routes over each overlay as follows:

Hub SD-WAN member	Overlay	SLA status	Priority for IKE routes
1	EDGE_T1	0x1 – within SLA	10
2	EDGE_T2	0x1 – within SLA	15

3. Verify that the spoke has sent its health check result to hub.
   a. On the hub, display the status of the health checks for EDGE_T1 and EDGE_T2:

```
# diagnose sys sdwan health-check remote
Remote Health Check: 2(2)
  Passive remote statistics of EDGE_T2(22):
EDGE_T2_0(172.31.3.5): timestamp=02-09 16:19:11, latency=1.056, jitter=0.582,
pktloss=0.000%
Remote Health Check: 1(1)
  Passive remote statistics of EDGE_T1(21):
EDGE_T1_0(172.31.3.1): timestamp=02-09 16:19:11, latency=1.269, jitter=0.675,
pktloss=0.000%
```

4. When there are multiple spokes, additional options can be used to filter a spoke by health check name, or health check name and the member's sequence number (`diagnose system sdwan health-check remote <hc_name> <seq_num>`).
   a. To filter the health check by health check name:

```
# diagnose sys sdwan health-check remote 1
Remote Health Check: 1(1)
  Passive remote statistics of EDGE_T1(21):
EDGE_T1_0(172.31.3.1): timestamp=02-09 16:43:37, latency=1.114, jitter=0.473,
pktloss=0.000%
```

   When this method is used, the output displays all the members of the specified health check name.

   b. To filter the health check by health check name and the member's sequence number:

```
# diagnose sys sdwan health-check remote 1 1
Remote Health Check: 1(1)
  Passive remote statistics of EDGE_T1(21):
```

```
EDGE_T1_0(172.31.3.1): timestamp=02-09 16:43:41, latency=1.178, jitter=0.497,
pktloss=0.000%
```

When this method is used, the output displays the specified member of the specified health check name.

If the `detect-mode` is set to `remote`, use `diagnose sys sdwan health-check remote` in lieu of `diagnose sys sdwan health-check`.

5. Simultaneously, BGP recursive routes inherit the priority based on the parent IKE routes. The recursively resolved BGP routes that pass through EDGE_T1 will have a priority of 10, and routes that pass through EDGE_T2 will have a priority of 15. Therefore, traffic from the hub to the spoke will be routed to EDGE_T1.

   Verify the routing tables.

   a. Static:

```
# get router info routing-table static
Routing table for VRF=0
S       172.31.0.65/32 [15/0] via EDGE_T1 tunnel 10.0.0.69 vrf 0, [10/0]
                              [15/0] via EDGE_T2 tunnel 172.31.0.65 vrf 0, [15/0]
```

   b. BGP:

```
# get router info routing-table bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T1 tunnel 10.0.0.69 vrf 0
[10]), 04:32:53
                                           (recursive via EDGE_T2 tunnel 172.31.0.65 vrf
0 [15]), 04:32:53, [1/0]
```

Next, test by making the health checks over the spokes' H1_T11 tunnel out of SLA. This should trigger traffic to start flowing from the spokes' H1_T22 tunnel. Consequently, the SLA statuses are passed from the spoke to the hub, and the hub will start routing traffic to EDGE_T2.

To verify that the hub will start routing traffic to EDGE_T2 when the spoke H1_T11 tunnel is out of SLA:

1. On Spoke_1, display the status of the health checks for H1_T11 and H1_T22:

```
# diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(120.228), jitter(0.013), mos(4.338),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x0
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.220), jitter(0.008), mos(4.404),
bandwidth-up(999998), bandwidth-dw(1000000), bandwidth-bi(1999998) sla_map=0x1
```

2. Verify the routing tables.

   a. Static:

```
# get router info routing-table static
Routing table for VRF=0
```

```
S       172.31.0.65/32 [15/0] via EDGE_T2 tunnel 172.31.0.65 vrf 0, [15/0]
                       [15/0] via EDGE_T1 tunnel 10.0.0.69 vrf 0, [20/0]
```

The priority for EDGE_T1 has changed from 10 to 20.

b. BGP:

```
# get router info routing-table bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T2 tunnel 172.31.0.65 vrf
0 [15]), 00:01:19
                                            (recursive via EDGE_T1 tunnel 10.0.0.69 vrf 0
[20]), 00:01:19, [1/0]
```

EDGE_T2 is now preferred. The priority for EDGE_T1 has changed from 10 to 20.

Spoke_1's SLA information for H1_T11 embedded into the ICMP probes has now changed.

As a result, the hub sets the routes over each overlay as follows:

Hub SD-WAN member	Overlay	SLA status	Priority for IKE routes
1	EDGE_T1	0x0 – out of SLA	20
2	EDGE_T2	0x1 – within SLA	15

The BGP recursive routes inherit the priority based on the parent IKE routes. Since priority for IKE routes on EDGE_T1 has changed to 20, recursively resolved BGP routes passing through EDGE_T1 has also dropped to 20. As a result, hub to spoke_1 traffic will go over EDGE_T2.

Embedded SD-WAN SLA priorities in ICMP probes

In SD-WAN hub-and-spoke topologies, each spoke can embed an SLA priority (`priority-in-sla` and `priority-out-sla`) in ICMP probes and send them to the hub. The hub can use the received SLA priorities from each spoke to manage route priority for hub-to-spoke traffic.

SLA status can also be embedded in ICMP probes. See Embedded SD-WAN SLA status in ICMP probes on page 984 for more information.

Spoke-initiated speed tests can also use the embedded information. When a spoke continually embeds an out-of SLA priority into ICMP probes on the overlay, the hub can use the received out-of SLA priority information to manage route priorities and detour hub-to-spoke user traffic to other tunnels.

For configuration on a spoke, the `config system sdwan` command includes these options:

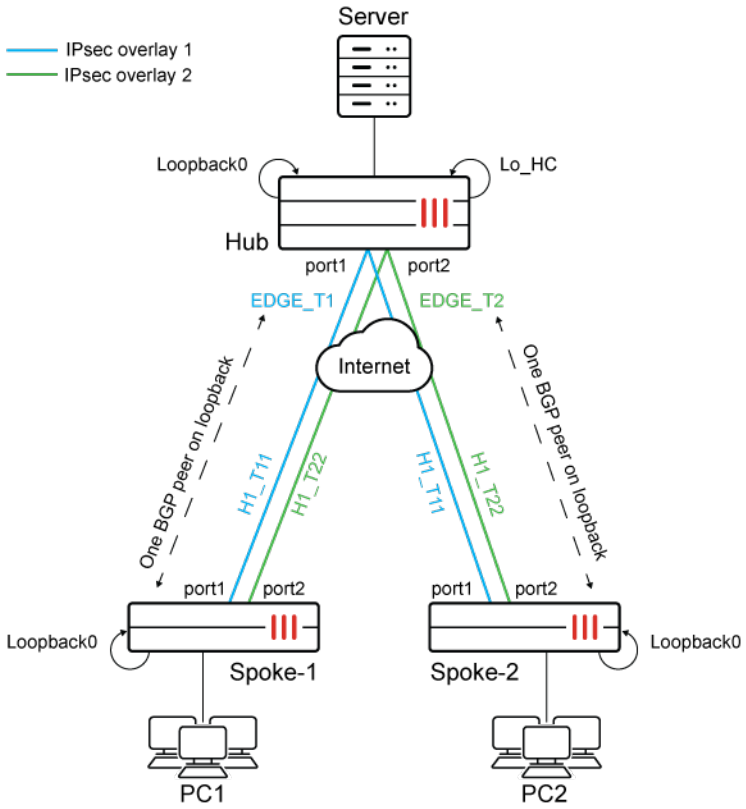
```
config system sdwan
    config members
        edit <entry>
          set priority-in-sla <integer>
          set priority-out-sla <integer>
        next
    end
end
```

`set priority-in-sla <integer>`	Preferred priority of routes to this member when this member is in SLA (0 - 65535, default = 0).
`set priority-out-sla <integer>`	Preferred priority of routes to this member when this member is out of SLA (0 - 65535, default = 0).

Examples

The SD-WAN topology with ADVPN and BGP neighbor on loopback is used for the following two examples:

- Path selection based on embedded SLA priorities on page 973
- Speed test rerouting based on embedded SLA priorities on page 980



The examples use the following SD-WAN settings on the spoke:

SD-WAN settings on the spoke relevant to the examples:

```
config system sdwan
    set speedtest-bypass-routing enable
    config members
        edit <id>
            set priority-in-sla <value>
            set priority-out-sla <value>
        next
    end
    config health-check
```

```
        edit <name>
            set embed-measured-health enable
            set sla-id-redistribute <id>
            config sla
                edit 1
                   <desired SLA thresholds>
                next
            end
        next
    end
end
```

SD-WAN settings on the hub relevant to the examples:

```
config system sdwan
    config health-check
        edit <name>
            set detect-mode remote
            set sla-id-redistribute <id>
                config sla
                    edit <id>
                        set link-cost-factor remote
                    next
                end
            next
        end
    next
end
```

Path selection based on embedded SLA priorities

In this example, spokes are configured to embed the SLA priority in ICMP probes, and the hub is configured to use the information. With this configuration:

- The spoke's overlay priority on each overlay is embedded in the ICMP probes and transported to the hub.
- The hub sets priorities on IKE routes over different overlays based on the received overlay priorities.
- On the hub, BGP routes, which are used to guide hub-to-spoke traffic, rely on IKE routes to be resolved to tunnels and inherit the priorities from the IKE routes.
- The hub can steer traffic to spokes by resolved BGP routes with different inherited priorities.

To embed SD-WAN SLA status and priorities in ICMP probes:

1. Configure SD-WAN and BGP on Spoke-1 (Branch1_A_FGT):
   a. Configure SD-WAN:

```
config system sdwan
    set status enable
    set speedtest-bypass-routing enable
    config zone
        edit "overlay"
```

```
        next
    end
    config members
        edit 4
            set interface "H1_T11"
            set zone "overlay"
            set source 172.31.0.65
            set priority 10
            set priority-in-sla 10
            set priority-out-sla 20
        next
        edit 5
            set interface "H1_T22"
            set zone "overlay"
            set source 172.31.0.65
            set priority 10
            set priority-in-sla 15
            set priority-out-sla 25
        next
    end
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set embed-measured-health enable
            set sla-id-redistribute 1
            set members 4 5
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 50
                next
            end
        next
    end
end
```

b. Configure BGP:

```
config router bgp
    set as 65001
    set router-id 172.31.0.65
    ......
    config neighbor
        edit "172.31.0.1"
            ......
            set remote-as 65001
            set update-source "Loopback0"
        next
    end
    config network
        edit 1
            set prefix 10.0.3.0 255.255.255.0
```

```
        next
    end
 ......
end
```

c. View the health-check settings:

```
# diagnose sys sdwan health-check
Health Check(HUB):
Seq(4 H1_T11): state(alive), packet-loss(0.000%) latency(0.246), jitter(0.015), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999996), bandwidth-bi(1999994) sla_map=0x1
Seq(5 H1_T22): state(alive), packet-loss(0.000%) latency(0.197), jitter(0.005), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999997), bandwidth-bi(1999995) sla_map=0x1
```

2. Configure SD-WAN and BGP on Spoke-2 (Branch2_FGT):

a. Configure SD-WAN:

```
config system sdwan
    set status enable
    set speedtest-bypass-routing enable
    config zone
        edit "overlay"
        next
    end
    config members
        edit 4
            set interface "H1_T11"
            set zone "overlay"
            set source 172.31.0.66
            set priority 10
            set priority-in-sla 30
            set priority-out-sla 40
        next
        edit 5
            set interface "H1_T22"
            set zone "overlay"
            set source 172.31.0.66
            set priority 10
            set priority-in-sla 35
            set priority-out-sla 45
        next
    end
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set embed-measured-health enable
            set sla-id-redistribute 1
            set members 4 5
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 70
```

```
                next
            end
        next
    end
end
```

b. Configure BGP:

```
config router bgp
    set as 65001
    set router-id 172.31.0.66
    ......
    config neighbor
        edit "172.31.0.1"
            ......
            set remote-as 65001
            set update-source "Loopback0"
        next
    end
    config network
        edit 1
            set prefix 10.0.4.0 255.255.255.0
        next
    end
    ......
end
```

c. View the health-check settings:

```
# diagnose sys sdwan health-check
Health Check(HUB):
Seq(4 H1_T11): state(alive), packet-loss(0.000%) latency(0.230), jitter(0.040), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999996), bandwidth-bi(1999994) sla_map=0x1
Seq(5 H1_T22): state(alive), packet-loss(0.000%) latency(0.188), jitter(0.007), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999996), bandwidth-bi(1999994) sla_map=0x1
```

3. Configure SD-WAN and BGP on the Hub (DC1_A_FGT):

a. Configure SD-WAN:

```
config system sdwan
    set status enable
    config zone
        edit "overlay"
        next
    end
    config members
        edit 1
            set interface "EDGE_T1"
            set zone "overlay"
        next
        edit 2
            set interface "EDGE_T2"
```

```
            set zone "overlay"
        next
    end
    config health-check
        edit "Remote_HC"
            set detect-mode remote
            set sla-id-redistribute 1
            set members 1 2
            config sla
                edit 1
                    set link-cost-factor remote
                next
            end
        next
    end
end
```

b. Configure BGP:

```
config router bgp
    set as 65001
    set router-id 172.31.0.1
    set recursive-inherit-priority enable
    ......
    config neighbor-group
        edit "EDGE"
            set remote-as 65001
            set update-source "Loopback0"
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 172.31.0.64 255.255.255.192
            set neighbor-group "EDGE"
        next
    end
......
end
```

c. View the health-check settings:

The following example shows:

- `rmt_ver=2` indicates that SLA information, SLA status, and overlay priority have been received.
- `rmt_sla=out` indicates that received SLA status is out of SLA.
- `rmt_sla=in` indicates that received SLA status is in SLA.
- `rmt_prio` indicates the received overlay priority value.
- `EDGE_T1_0` is to `H1_T11` on Spoke-1, and `EDGE_T1_1` is to `H1_T11` on Spoke-2.
- `EDGE_T2_1` is to `H1_T22` on Spoke-1, and `EDGE_T1_0` is to `H1_T22` on Spoke-2.

```
# diagnose sys sdwan health-check remote
```

```
Remote Health Check: Remote_HC(1)
  Passive remote statistics of EDGE_T1(46):
    EDGE_T1_0(10.0.0.20): timestamp=06-12 14:04:29, src=172.31.0.65, latency=0.247,
jitter=0.028, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=2, rmt_sla=in, rmt_
prio=10
    EDGE_T1_1(172.31.0.66): timestamp=06-12 14:04:30, src=172.31.0.66, latency=0.246,
jitter=0.031, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=2, rmt_sla=in, rmt_
prio=30

Remote Health Check: Remote_HC(2)
  Passive remote statistics of EDGE_T2(47):
    EDGE_T2_0(10.0.0.15): timestamp=06-12 14:04:30, src=172.31.0.66, latency=0.191,
jitter=0.008, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=2, rmt_sla=in, rmt_
prio=35
    EDGE_T2_1(172.31.0.65): timestamp=06-12 14:04:29, src=172.31.0.65, latency=0.201,
jitter=0.008, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=2, rmt_sla=in, rmt_
prio=15
```

4. After the spokes' overlay priorities are embedded in ICMP probes and transported to the hub, view the routing tables on the hub.

   The hub sets overlay priorities on IKE routes over EDGE_T1 and EDGE_T2. Meanwhile, recursively resolved BGP routes inherit the priorities from those IKE routes.

   a. On the hub, get the static routing table:

```
# get router info routing-table static
Routing table for VRF=0
S       172.31.0.65/32 [15/0] via EDGE_T1 tunnel 10.0.0.20, [10/0]
                       [15/0] via EDGE_T2 tunnel 172.31.0.65, [15/0]
S       172.31.0.66/32 [15/0] via EDGE_T1 tunnel 172.31.0.66, [30/0]
                       [15/0] via EDGE_T2 tunnel 10.0.0.15, [35/0]
```

   b. On the hub, get the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T1 tunnel 10.0.0.20 [10]),
01:15:46
                                            (recursive via EDGE_T2 tunnel 172.31.0.65
[15]), 01:15:46, [1/0]
B       10.0.4.0/24 [200/0] via 172.31.0.66 (recursive via EDGE_T1 tunnel 172.31.0.66
[30]), 01:13:46
                                            (recursive via EDGE_T2 tunnel 10.0.0.15 [35]),
01:13:46, [1/0]
```

5. Change the latency on Spoke-1 and Spoke-2, and view the results.
   a. On Spoke-1, increase H1_T11's latency to 60 to make it out of SLA.
   b. On Spoke-2, increase H1_T11's latency to 80 to make it out of SLA.
   c. On Spoke-1, run a health check:

```
Branch1_A_FGT (root) (Interim)# diagnose sys sdwan  health-check
Health Check(HUB):
```

```
Seq(4 H1_T11): state(alive), packet-loss(0.000%) latency(60.247), jitter(0.036), mos
(4.373), bandwidth-up(999998), bandwidth-dw(999997), bandwidth-bi(1999995) sla_map=0x0
Seq(5 H1_T22): state(alive), packet-loss(0.000%) latency(0.218), jitter(0.016), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999998), bandwidth-bi(1999996) sla_map=0x
```

d. On Spoke-2, run a health check:

```
Branch2_FGT (root) (Interim)# diagnose sys sdwan  health-check
Health Check(HUB):
Seq(4 H1_T11): state(alive), packet-loss(0.000%) latency(80.217), jitter(0.022), mos
(4.361), bandwidth-up(999998), bandwidth-dw(999998), bandwidth-bi(1999996) sla_map=0x0
Seq(5 H1_T22): state(alive), packet-loss(0.000%) latency(0.202), jitter(0.016), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999997), bandwidth-bi(1999995) sla_map=0x1
```

6. After the hub receives the updated overlay priorities, run a health check on the hub and view the routing tables.

The hub has updated the route priorities.

a. Run a health check:

```
# diagnose sys sdwan health-check remote

Remote Health Check: Remote_HC(1)
  Passive remote statistics of EDGE_T1(46):
  EDGE_T1_0(10.0.0.20): timestamp=06-12 14:19:26, src=172.31.0.65, latency=60.249,
jitter=0.031, pktloss=0.000%, mos=4.373, SLA id=1(remote), rmt_ver=2, rmt_sla=out, rmt_
prio=20
EDGE_T1_1(172.31.0.66): timestamp=06-12 14:19:26, src=172.31.0.66, latency=80.222,
jitter=0.021, pktloss=0.000%, mos=4.361, SLA id=1(remote), rmt_ver=2, rmt_sla=out, rmt_
prio=40

Remote Health Check: Remote_HC(2)
  Passive remote statistics of EDGE_T2(47):
  EDGE_T2_0(10.0.0.15): timestamp=06-12 14:19:26, src=172.31.0.66, latency=0.205,
jitter=0.011, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=2, rmt_sla=in, rmt_
prio=35
  EDGE_T2_1(172.31.0.65): timestamp=06-12 14:19:26, src=172.31.0.65, latency=0.215,
jitter=0.009, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=2, rmt_sla=in, rmt_
prio=15
```

b. View the static routing table:

For `EDGE_T1`, the priority changed from `10` to `20` and from `30` to `40` because it is out of SLA.

```
DC1_A_FGT (root) (Interim)# get router info routing-table static
Routing table for VRF=0
S       172.31.0.65/32 [15/0] via EDGE_T2 tunnel 172.31.0.65, [15/0]
                              [15/0] via EDGE_T1 tunnel 10.0.0.20, [20/0]
S       172.31.0.66/32 [15/0] via EDGE_T2 tunnel 10.0.0.15, [35/0]
                              [15/0] via EDGE_T1 tunnel 172.31.0.66, [40/0]
```

c. View the BGP routing table:

- For 10.0.3.0/24, EDGE_T2 is preferred. Priority for EDGE_T1 changed from 10 to 20.
- For 10.0.4.0/24, EDGE_T2 is preferred. Priority for EDGE_T1 changed from 30 to 40.

```
DC1_A_FGT (root) (Interim)# get router info routing-table  bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T2 tunnel 172.31.0.65
[15]), 00:07:28
                                            (recursive via EDGE_T1 tunnel 10.0.0.20 [20]),
00:07:28, [1/0]
B       10.0.4.0/24 [200/0] via 172.31.0.66 (recursive via EDGE_T2 tunnel 10.0.0.15 [35]),
00:07:28                                                          (recursive via EDGE_T1
tunnel 172.31.0.66 [40]), 00:07:28, [1/0]
```

Speed test rerouting based on embedded SLA priorities

When spoke-initiated speed tests are enabled for this configuration, the out-of SLA priority is used by the hub to choose other routes during the speed test.

To configure speed tests:

1. On the hub, enable speed tests and allow them on the underlays and overlays.
   a. Enable speed tests:

```
config system global
    set speedtest-server enable
    set speedtestd-ctrl-port 6000
    set speedtestd-server-port 7000
end
```

   b. Allow speed tests on the underlay:

```
config system interface
    edit "port1"
       ...
        set allowaccess ping speed-test
      ...
    next
end
```

   c. Allow speed tests on the underlay:

```
config system interface
    edit "port2"
        ...
        set allowaccess ping speed-test
       ...
    next
end
```

   d. Allow speed tests on the overlay, and specify a shaping profile:

```
config system interface
    edit "EDGE_T1"
        ...
        set allowaccess ping speed-test
        set type tunnel
        set egress-shaping-profile "profile_1"
        ...
        set interface "port1"
    next
end
```

e. Allow speed tests on the overlay, and specify a shaping profile:

```
config system interface
    edit "EDGE_T2"
        ...
        set allowaccess ping speed-test
        set type tunnel
        set egress-shaping-profile "profile_1"
        ...
        set interface "port2"
    next
end
```

f. View the shaping profile:

```
config firewall shaping-profile
    edit "profile_1"
        set default-class-id 2
        config shaping-entries
            edit 1
                set class-id 2
                set priority low
                set guaranteed-bandwidth-percentage 10
                set maximum-bandwidth-percentage 10
            next
            edit 2
                set class-id 3
                set priority medium
                set guaranteed-bandwidth-percentage 30
                set maximum-bandwidth-percentage 40
            next
            edit 3
                set class-id 4
                set guaranteed-bandwidth-percentage 20
                set maximum-bandwidth-percentage 50
            next
        end
    next
end
```

2. On Spoke-1, schedule speed tests:

```
config system speed-test-schedule
    edit "H1_T11"
        set mode TCP
        set schedules "speed-test"
        set dynamic-server enable
        set ctrl-port 6000
        set server-port 7000
        set update-shaper remote
    next
    edit "H1_T22"
        set mode UDP
        set schedules "speed-test"
        set dynamic-server enable
        set ctrl-port 6000
        set server-port 7000
        set update-shaper remote
    next
end
```

Before starting the speed test on Spoke-1, route priorities are based on the received overlay priorities on both H1_T11 and H1_T22

```
DC1_A_FGT (root) (Interim)# get router info routing-table bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T1 tunnel 10.0.0.20 [10]),
00:11:56
                                            (recursive via EDGE_T2 tunnel 172.31.0.65 [15]),
00:11:56, [1/0]
```

While the speed test is running on H1_T11 of Spoke-1, Spoke-1 will constantly embed out-of SLA overlay priority into probes on H1_T11 and send them to the hub. Then the Hub updates route priorities accordingly and detours hub-to-spoke traffic to H1_T22 to avoid the impact on speed test of H1_T11. EDGE_T2 is preferred, and the EDGE_T1 priority changed from 10 to 20.

```
DC1_A_FGT (root) (Interim)# get router info routing-table  bgp
Routing table for VRF=0Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T2 tunnel 172.31.0.65 [15]),
00:03:49
                                            (recursive via EDGE_T1 tunnel 10.0.0.20 [20]),
00:03:49, [1/0]
```

During the speed test on H1_T22 of Spoke-1, Spoke-1 constantly embeds out-of SLA overlay priority into probes on H1_T22 and sends them to the hub. Then the Hub updates route priorities accordingly and detours hub-to-spoke traffic to H1_T11 to avoid the impact on speed test of H1_T22. EDGE_T1 is preferred, and the EDGE_T2 priority changed from 15 to 25.

```
DC1_A_FGT (root) (Interim)# get router info routing-table  bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T1 tunnel 10.0.0.20 [10]),
00:04:06
```

```
                                                                (recursive via EDGE_T2 tunnel
172.31.0.65 [25]), 00:04:06, [1/0]
```

Once speed test completes, the results are applied on child tunnels as egress-shaping-profile on the hub.

```
DC1_A_FGT (root) (Interim)# diagnose vpn tunnel  list
list all ipsec tunnel in vd 0

```

Embedded SD-WAN SLA status in ICMP probes

In SD-WAN hub-and-spoke topologies, each spoke can embed in ICMP probes sent to the hub the SLA status decided by the spoke. The SLA status is either in SLA or out of SLA. The hub uses the received SLA status from each spoke to manage route priority for hub-to-spoke traffic.

SLA priority can also be embedded in ICMP probes. See Embedded SD-WAN SLA priorities in ICMP probes on page 971 for more information.

Spoke-initiated speed tests can also use the embedded information. When a spoke continually embeds an out-of SLA status into ICMP probes—regardless of the SLA calculation—the hub can use the received out-of SLA status information to manage route priorities and detour hub-to-spoke user traffic to other tunnels.

For configuration on a hub, the `config system sdwan` command includes these options:

```
config system sdwan
    config health-check
        edit <entry>
            set sla-id-redistribute <ID>
            config sla
                edit <entry>
                    set link-cost-factor remote {latency | jitter | packet-loss | mos | remote}
                next
            end
        next
    end
end
```

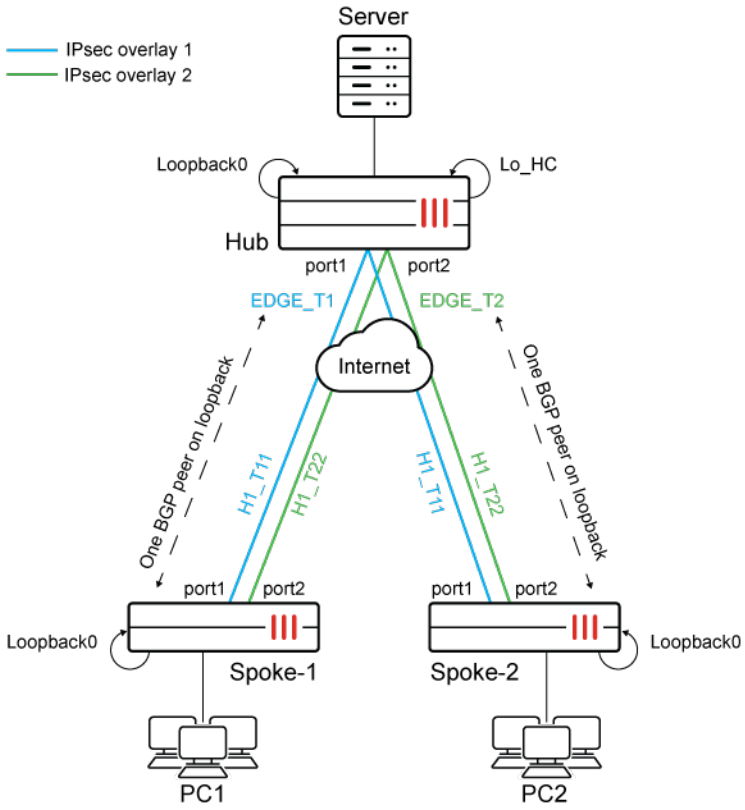
`set sla-id-redistribute <ID>`	Select the ID from the SLA subtable. The selected SLA's priority value will be distributed into the routing table (0 - 32, default = 0).
`set link-cost-factor {latency | jitter | packet-loss | mos | remote}`	Criteria on which to base link selection. • `remote`: Select link based on available remote SLA status.

The hub can also work in a hybrid mode. If `set sla-id-redistribute` is not configured on the spoke, the hub can use its own SLA settings to determine the route priority.

Examples

The SD-WAN topology with ADVPN and BGP neighbor on loopback is used for the following two examples:

- Path selection based on embedded SLA status on page 986
- Speed test rerouting based on embedded SLA status on page 992



The examples use the following SD-WAN settings on the spoke:

SD-WAN settings on the spoke relevant to the examples:

```
config system sdwan
    set speedtest-bypass-routing enable
        config health-check
            edit <name>
                set embed-measured-health enable
                set sla-id-redistribute <id>
                config sla
                    edit 1
                       <desired SLA thresholds>
                    next
               end
           next
        end
    next
end
```

SD-WAN settings on the hub relevant to the examples:

```
config system sdwan
    config health-check
        edit <name>
            set detect-mode remote
            set sla-id-redistribute <num>
                config sla
                    edit <num>
                        set link-cost-factor remote
                        set priority-in-sla <value>
                        set priority-out-sla <value>
                    next
                end
            next
        end
    next
end
```

Path selection based on embedded SLA status

In this example, spokes are configured to embed the SLA status in ICMP probes, and the hub is configured to use the information. With this configuration:

- The spoke's SLA information (packet-loss, latency, jitter, and mos) and SLA status (in SLA or out of SLA) on each overlay are embedded into ICMP probes and transported to the hub;
- The hub sets priorities on IKE routes over different overlays based on the received SLA status on overlays
- On the hub, BGP routes, which are used to guide hub-to-spoke traffic, rely on IKE routes to be resolved to tunnels and inherit the priorities from the IKE routes
- The hub can steer traffic to spokes by resolved BGP routes with different inherited priorities

To embed SD-WAN SLA status and priorities in ICMP probes:

1. Configure SD-WAN and BGP on Spoke-1 (Branch1_A_FGT):
   a. Configure SD-WAN:

```
config system sdwan
    set status enable
    set speedtest-bypass-routing enable
    config zone
        edit "overlay"
        next
    end
    config members
        edit 4
            set interface "H1_T11"
            set zone "overlay"
            set source 172.31.0.65
            set priority 10
        next
```

```
        edit 5
            set interface "H1_T22"
            set zone "overlay"
            set source 172.31.0.65
            set priority 10
        next
    end
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set embed-measured-health enable
            set sla-id-redistribute 1
            set members 4 5
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 50
                next
            end
        next
    end
end
```

b. Configure BGP:

```
config router bgp
    set as 65001
    set router-id 172.31.0.65
    ......
    config neighbor
        edit "172.31.0.1"
            ......
            set remote-as 65001
            set update-source "Loopback0"
        next
    end
    config network
        edit 1
            set prefix 10.0.3.0 255.255.255.0
        next
    end
 ......
end
```

c. View the health-check settings:
All overlays on Spoke-1 are in SLA.

```
# diagnose sys sdwan  health-check
Health Check(HUB):
Seq(4 H1_T11): state(alive), packet-loss(0.000%) latency(0.252), jitter(0.025), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999998), bandwidth-bi(1999996) sla_map=0x1
```

```
Seq(5 H1_T22): state(alive), packet-loss(0.000%) latency(0.199), jitter(0.008), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999997), bandwidth-bi(1999995) sla_map=0x1
```

2. Configure SD-WAN and BGP on Spoke-2 (Branch2_FGT):
   a. Configure SD-WAN:

```
config system sdwan
    set status enable
    set speedtest-bypass-routing enable
    config zone
        edit "overlay"
        next
    end
    config members
        edit 4
            set interface "H1_T11"
            set zone "overlay"
            set source 172.31.0.66
            set priority 10
        next
        edit 5
            set interface "H1_T22"
            set zone "overlay"
            set source 172.31.0.66
            set priority 10
        next
    end
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set embed-measured-health enable
            set sla-id-redistribute 1
            set members 4 5
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 70
                next
            end
        next
    end
end
```

   b. Configure BGP:

```
config router bgp
    set as 65001
    set router-id 172.31.0.66
    ......
    config neighbor
        edit "172.31.0.1"
            ......
```

```
            set remote-as 65001
            set update-source "Loopback0"
        next
    end
    config network
        edit 1
            set prefix 10.0.4.0 255.255.255.0
        next
    end
    ......
end
```

c. View the health-check settings:
All overlays on Spoke-2 are in SLA.

```
# diagnose sys sdwan  health-check
Health Check(HUB):
Seq(4 H1_T11): state(alive), packet-loss(0.000%) latency(0.245), jitter(0.034), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999996), bandwidth-bi(1999994) sla_map=0x1
Seq(5 H1_T22): state(alive), packet-loss(0.000%) latency(0.191), jitter(0.007), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999997), bandwidth-bi(1999995) sla_map=0x1
```

3. Configure SD-WAN and BGP on the Hub (DC1_A_FGT):

a. Configure SD-WAN:

```
config system sdwan
    set status enable
    config zone
        edit "overlay"
        next
    end
    config members
        edit 1
            set interface "EDGE_T1"
            set zone "overlay"
        next
        edit 2
            set interface "EDGE_T2"
            set zone "overlay"
        next
    end
    config health-check
        edit "Remote_HC"
            set detect-mode remote
            set sla-id-redistribute 1
            set members 1 2
            config sla
                edit 1
                    set link-cost-factor remote
                    set priority-in-sla 100
                    set priority-out-sla 200
```

```
                next
            end
        next
    end
end
```

b. Configure BGP:

```
config router bgp
    set as 65001
    set router-id 172.31.0.1
    set recursive-inherit-priority enable
    ......
    config neighbor-group
        edit "EDGE"
            set remote-as 65001
            set update-source "Loopback0"
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 172.31.0.64 255.255.255.192
            set neighbor-group "EDGE"
        next
    end
......
end
```

c. View the health-check settings:

The following example shows:

- `rmt_ver=0` indicates that only SLA information has been received.
- `rmt_ver=1` indicates that SLA information and SLA status have been received.
- `rmt_sla=out` indicates that received SLA status is out of SLA.
- `rmt_sla=in` indicates that received SLA status is in SLA.
- `EDGE_T1_0` is to `H1_T11` on Spoke-1, and `EDGE_T1_1` is to `H1_T11` on Spoke-2.
- `EDGE_T2_1` is to `H1_T22` on Spoke-1, and `EDGE_T1_0` is to `H1_T22` on Spoke-2.

```
# diagnose sys sdwan  health-check remote

Remote Health Check: Remote_HC(1)
  Passive remote statistics of EDGE_T1(46):
    EDGE_T1_0(10.0.0.20): timestamp=06-11 14:50:33, src=172.31.0.65, latency=0.261,
jitter=0.043, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=1, rmt_sla=in, rmt_prio=0
    EDGE_T1_1(172.31.0.66): timestamp=06-11 14:50:33, src=172.31.0.66, latency=0.285,
jitter=0.038, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=1, rmt_sla=in, rmt_prio=0

Remote Health Check: Remote_HC(2)
  Passive remote statistics of EDGE_T2(47):
    EDGE_T2_0(10.0.0.15): timestamp=06-11 14:50:33, src=172.31.0.66, latency=0.195,
jitter=0.008, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=1, rmt_sla=in, rmt_prio=0
```

```
    EDGE_T2_1(172.31.0.65): timestamp=06-11 14:50:33, src=172.31.0.65, latency=0.202,
jitter=0.009, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=1, rmt_sla=in, rmt_prio=0
```

4. After the spokes' SLA status on overlays are embedded in ICMP probes and transported to the hub, view the routing tables on the hub.

   Based on the received in-SLA status, the hub sets a predefined priority of 100 on IKE routes over EDGE_T1 and EDGE_T2. Meanwhile, recursively resolved BGP routes inherit the priorities from those IKE routes.

   a. On the hub, get the static routing table:

```
# get router info routing-table static
Routing table for VRF=0
S       172.31.0.65/32 [15/0] via EDGE_T2 tunnel 172.31.0.65, [100/0]
                              [15/0] via EDGE_T1 tunnel 10.0.0.20, [100/0]
S       172.31.0.66/32 [15/0] via EDGE_T1 tunnel 172.31.0.66, [100/0]
                              [15/0] via EDGE_T2 tunnel 10.0.0.15, [100/0]
```

   b. On the hub, get the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T2 tunnel 172.31.0.65
[100]), 22:15:50
                                            (recursive via EDGE_T1 tunnel 10.0.0.20
[100]), 22:15:50, [1/0]
B       10.0.4.0/24 [200/0] via 172.31.0.66 (recursive via EDGE_T1 tunnel 172.31.0.66
[100]), 00:01:50
                                            (recursive via EDGE_T2 tunnel 10.0.0.15
[100]), 00:01:50, [1/0]
```

5. Change the latency on Spoke-1 and Spoke-2, and view the results.
   a. On Spoke-1, increase H1_T11's latency to 60 to make it out of SLA.
   b. On Spoke-2, increase H1_T11's latency to 80 to make it out of SLA.
   c. On Spoke-1, run a health check:

```
Branch1_A_FGT (root) (Interim)# diagnose sys sdwan  health-check
Health Check(HUB):
Seq(4 H1_T11): state(alive), packet-loss(0.000%) latency(60.229), jitter(0.021), mos
(4.373), bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x0
Seq(5 H1_T22): state(alive), packet-loss(0.000%) latency(0.210), jitter(0.012), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999997), bandwidth-bi(1999995) sla_map=0x1
```

   d. On Spoke-2, run a health check:

```
Branch2_FGT (root) (Interim)# diagnose sys sdwan  health-check
Health Check(HUB):
Seq(4 H1_T11): state(alive), packet-loss(0.000%) latency(80.227), jitter(0.024), mos
(4.361), bandwidth-up(999998), bandwidth-dw(999998), bandwidth-bi(1999996) sla_map=0x0
Seq(5 H1_T22): state(alive), packet-loss(0.000%) latency(0.202), jitter(0.012), mos
(4.404), bandwidth-up(999998), bandwidth-dw(999997), bandwidth-bi(1999995) sla_map=0x1
```

6. After the hub receives the updated SLA status, run a health check on the hub and view the routing tables.

The hub has updated the route priorities based on predefined priority settings (`set priority-in-sla 100` and `set priority-out-sla 200`).

a. Run a health check:

```
# diagnose sys sdwan health-check remote

Remote Health Check: Remote_HC(1)
  Passive remote statistics of EDGE_T1(46):
   EDGE_T1_0(10.0.0.20): timestamp=06-11 15:35:29, src=172.31.0.65, latency=60.244,
jitter=0.017, pktloss=0.000%, mos=4.373, SLA id=1(remote), rmt_ver=1, rmt_sla=out, rmt_
prio=0
   EDGE_T1_1(172.31.0.66): timestamp=06-11 15:35:29, src=172.31.0.66, latency=80.234,
jitter=0.036, pktloss=0.000%, mos=4.361, SLA id=1(remote), rmt_ver=1, rmt_sla=out, rmt_
prio=0

Remote Health Check: Remote_HC(2)
  Passive remote statistics of EDGE_T2(47):
   EDGE_T2_0(10.0.0.15): timestamp=06-11 15:35:29, src=172.31.0.66, latency=0.201,
jitter=0.008, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=1, rmt_sla=in, rmt_prio=0
   EDGE_T2_1(172.31.0.65): timestamp=06-11 15:35:29, src=172.31.0.65, latency=0.215,
jitter=0.010, pktloss=0.000%, mos=4.404, SLA id=1(pass), rmt_ver=1, rmt_sla=in, rmt_prio=0
```

b. View the static routing table:

For `EDGE_T1`, the priority changed from `100` to `200` because it is out of SLA.

```
DC1_A_FGT (root) (Interim)# get router info routing-table  static
Routing table for VRF=0
S       172.31.0.65/32 [15/0] via EDGE_T2 tunnel 172.31.0.65, [100/0]
                              [15/0] via EDGE_T1 tunnel 10.0.0.20, [200/0]
S       172.31.0.66/32 [15/0] via EDGE_T2 tunnel 10.0.0.15, [100/0]
                              [15/0] via EDGE_T1 tunnel 172.31.0.66, [200/0]
```

c. View the BGP routing table:

- For 10.0.3.0/24, EDGE_T2 is preferred. Priority for EDGE_T1 changed from 100 to 200.
- For 10.0.4.0/24, EDGE_T2 is preferred. Priority for EDGE_T1 changed from 30 to 40.

```
DC1_A_FGT (root) (Interim)# get router info routing-table  bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T2 tunnel 172.31.0.65
[100]), 22:31:22                                                  (recursive via EDGE_
T1 tunnel 10.0.0.20 [200]), 22:31:22, [1/0]
B       10.0.4.0/24 [200/0] via 172.31.0.66 (recursive via EDGE_T2 tunnel 10.0.0.15
[100]), 00:08:22
                                          (recursive via EDGE_T1 tunnel 172.31.0.66
[200]), 00:08:22, [1/0]
```

Speed test rerouting based on embedded SLA status

When spoke-initiated speed tests are enabled for this configuration, the out-of SLA status is used by the hub to choose other routes during the speed test.

To configure speed tests:

1. On the hub, enable speed tests and allow them on the underlays and overlays.
   a. Enable speed tests:

```
config system global
    set speedtest-server enable
    set speedtestd-ctrl-port 6000
    set speedtestd-server-port 7000
end
```

   b. Allow speed tests on the underlay:

```
config system interface
    edit "port1"
       ...
        set allowaccess ping speed-test
      ...
    next
end
```

   c. Allow speed tests on the underlay:

```
config system interface
    edit "port2"
        ...
        set allowaccess ping speed-test
       ...
    next
end
```

   d. Allow speed tests on the overlay, and specify a shaping profile:

```
config system interface
    edit "EDGE_T1"
        ...
        set allowaccess ping speed-test
        set type tunnel
        set egress-shaping-profile "profile_1"
        ...
        set interface "port1"
    next
end
```

   e. Allow speed tests on the overlay, and specify a shaping profile:

```
config system interface
    edit "EDGE_T2"
        ...
        set allowaccess ping speed-test
        set type tunnel
        set egress-shaping-profile "profile_1"
        ...
```

```
        set interface "port2"
    next
end
```

f. View the shaping profile:

```
config firewall shaping-profile
    edit "profile_1"
        set default-class-id 2
        config shaping-entries
            edit 1
                set class-id 2
                set priority low
                set guaranteed-bandwidth-percentage 10
                set maximum-bandwidth-percentage 10
            next
            edit 2
                set class-id 3
                set priority medium
                set guaranteed-bandwidth-percentage 30
                set maximum-bandwidth-percentage 40
            next
            edit 3
                set class-id 4
                set guaranteed-bandwidth-percentage 20
                set maximum-bandwidth-percentage 50
            next
        end
    next
end
```

2. On Spoke-1, schedule speed tests:

```
config system speed-test-schedule
    edit "H1_T11"
        set mode TCP
        set schedules "speed-test"
        set dynamic-server enable
        set ctrl-port 6000
        set server-port 7000
        set update-shaper remote
    next
    edit "H1_T22"
        set mode UDP
        set schedules "speed-test"
        set dynamic-server enable
        set ctrl-port 6000
        set server-port 7000
        set update-shaper remote
    next
```

```
end
```

Before starting the speed test on Spoke-1, route priorities are based on the received in-SLA status on both H1_T11 and H1_T22

```
DC1_A_FGT (root) (Interim)# get router info routing-table  bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T2 tunnel 172.31.0.65 [100]),
00:24:14
                                            (recursive via EDGE_T1 tunnel 10.0.0.20 [100]),
00:24:14, [1/0]
```

While the speed test is running on H1_T11 of Spoke-1, Spoke-1 will constantly embed `NOK`status into probes on H1_T11 and send them to the hub. Then the Hub updates route priorities accordingly and detours hub-to-spoke traffic to H1_T22 to avoid the impact on speed test of H1_T11. EDGE_T2 is preferred, and the EDGE_T1 priority changed from 100 to 200.

```
DC1_A_FGT (root) (Interim)# get router info routing-table  bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T2 tunnel 172.31.0.65 [100]),
00:04:42
                                            (recursive via EDGE_T1 tunnel 10.0.0.20 [200]),
00:04:42, [1/0]
```

During the speed test on H1_T22 of Spoke-1, Spoke-1 constantly embeds `NOK` status (out of SLA status) into probes on H1_T22 and sends them to the hub. Then the Hub updates route priorities accordingly and detours hub-to-spoke traffic to H1_T11 to avoid the impact on speed test of H1_T22. EDGE_T1 is preferred, and the EDGE_T2 priority changed from 100 to 200.

```
DC1_A_FGT (root) (Interim)# get router info routing-table  bgp
Routing table for VRF=0
B       10.0.3.0/24 [200/0] via 172.31.0.65 (recursive via EDGE_T1 tunnel 10.0.0.20 [100]),
00:00:05
                                            (recursive via EDGE_T2 tunnel 172.31.0.65 [200]),
00:00:05, [1/0]
```

Once speed test completes, the results are applied on child tunnels as egress-shaping-profile on the hub.

```
DC1_A_FGT (root) (Interim)# diagnose vpn  tunnel  list
list all ipsec tunnel in vd 0
------------------------------------------------------
name=EDGE_T1_0 ver=2 serial=22 172.31.1.1:0->172.31.3.1:0 nexthop=172.31.1.2 tun_id=10.0.0.20 tun_

        class-id=4      allocated-bandwidth=194576(kbps)        guaranteed-bandwidth=77830(kbps)
                        max-bandwidth=194576(kbps)      current-bandwidth=0(kbps)
                        priority=high   forwarded_bytes=0
                        dropped_packets=0       dropped_bytes=0
```

Map SD-WAN member priorities to BGP MED attribute when spoke advertises routes using iBGP to hub

When a spoke advertises routes using iBGP to a hub, SD-WAN member priorities are mapped into the BGP multiple exit discriminator (MED) attribute using the following CLI commands:

```
config system sdwan
    config neighbor
```

```
        edit <bgp-peer-IP>
            set member <num_1> ... <num_n>
            set route-metric {preferable | priority}
            set health-check <health-check-name>
        next
    end
end
```

Value	Description
preferable	Select neighbor based on its HC to match BGP preferable/unpreferable route_map.
priority	Select neighbor based on its members' priority-in-sla/priority-out-sla value.

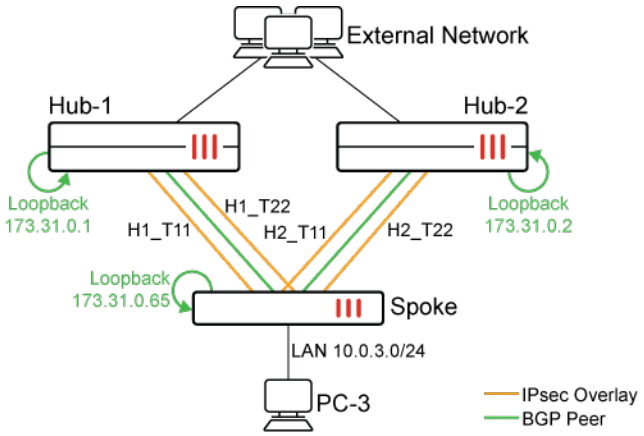
Routes to prefixes behind spokes are advertised by the SD-WAN hub to eBGP peers on an external network. The relative values of the BGP MED attribute for each hub are used to indicate to eBGP peers the more preferred paths, that is, the preferred hub used to route to spoke prefixes.

This feature depends on the spoke SD-WAN configuration defined in Embedded SD-WAN SLA priorities in ICMP probes on page 971 and hub SD-WAN and BGP configuration defined in Embedded SD-WAN SLA status in ICMP probes on page 984.

Example

This example includes one spoke and two hubs:

- The spoke has two overlays to Hub-1 and Hub-2 respectively.
- BGP neighbors between the spoke and hubs are over loopback IP addresses
- SD-WAN is configured on the spoke.



To configure and test the example:

1. Enable recursive inherit priority on the hubs:

```
config router bgp
    set recursive-inherit-priority enable
end
```

See Embedded SD-WAN SLA information in ICMP probes for more information.

2. Configure SD-WAN on the spoke:

```
config system sdwan
    set status enable
    config zone
        edit "overlay"
        next
    end
    config members
        edit 4
            set interface "H1_T11"
            set zone "overlay"
            set source 172.31.0.65
            set priority-in-sla 50
            set priority-out-sla 100
        next
        edit 5
            set interface "H1_T22"
            set zone "overlay"
            set source 172.31.0.65
            set priority-in-sla 70
            set priority-out-sla 120
        next
        edit 7
            set interface "H2_T11"
            set zone "overlay"
            set source 172.31.0.65
            set priority-in-sla 60
            set priority-out-sla 110
        next
        edit 8
            set interface "H2_T22"
            set zone "overlay"
            set source 172.31.0.65
            set priority-in-sla 80
            set priority-out-sla 130
        next
    end
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set embed-measured-health enable
            set sla-id-redistribute 1
            set sla-fail-log-period 10
            set sla-pass-log-period 10
            set members 4 5 7 8
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
```

```
            end
        next
    end
    config neighbor
        edit "172.31.0.1"
            set member 4 5
            set route-metric priority
            set health-check "HUB"
        next
        edit "172.31.0.2"
            set member 7 8
            set route-metric priority
            set health-check "HUB"
        next
    end
end
```

The routes with MEDs are advertised to a router on the external network that establishes a BGP neighbor relationship with Hub-1 and Hub-2. When sending traffic destined for 10.0.3.0/24, the router on the external network will prefer to send traffic to the hub with the lower MED.

3. All overlays are in SLA.

   When sending traffic destined for 10.0.3.0/24, the router on the external network will prefer to send traffic to Hub-1 with lower MED 50 over Hub-2 with higher MED 60.

```
# diagnose sys sdwan health-check

SD-WAN application monitor using FortiMonitor

The agent-based health check detection mode works with FortiMonitor to provide more accurate user level performance statistics. FortiMonitor acts as an agent and sends health check probes on behalf of the monitored FortiGate interface. FortiMonitor mimics a real user, and the probes return a more accurate application level performance. The SLA information collected from FortiMonitor is sent back to the FortiGate as the monitored interface's SLA information. These statistics can be used to gain a deeper insight into the SD-WAN traffic performance.

FortiGate can log statistics when using FortiMonitor to detect advanced SD-WAN application performance metrics. These logs may also be sent to FortiAnalyzer and FortiManager for review and reporting.

```
config system sdwan
    config health-check
        edit <name>
            set detect-mode agent-based
        next
    end
    config service
        edit <id>
            set agent-exclusive {enable | disable}
        next
    end
    set app-perf-log-period <time in seconds>
end
```

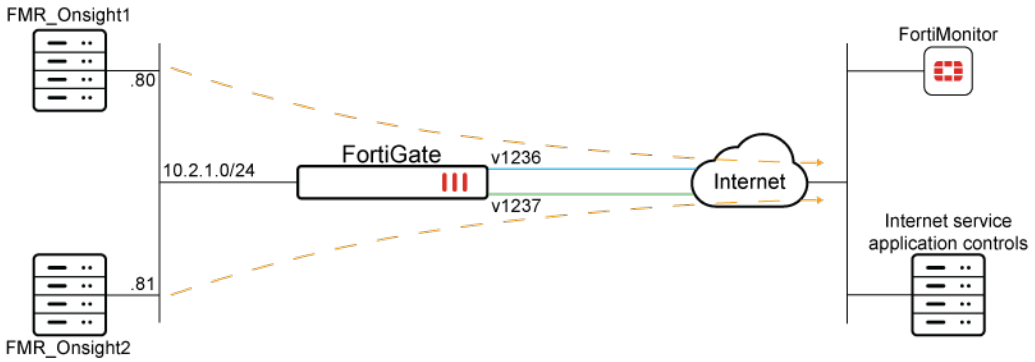
The following diagnostic commands can be used to view agent related metrics:

```
# diagnose sys link-monitor-passive agent <option>
```

`list`	List all the collected reports.
`list-app`	List the details of each application.
`flush`	Flush all the collected reports.
`flush-app`	Flush the details of all the applications.
`agent-oif-map`	List the agent and interface maps.

Example

In this example, routing is achieved through SD-WAN rules. The agent-based health check detection mode creates the FortiMonitor IP address and FortiGate SD-WAN interface map.



This example assumes that the FortiMonitor has already been added to the Security Fabric (see Configuring FortiMonitor on page 3771 for detailed instructions). The FortiMonitor OnSight (client) can be configured for two or more IP addresses, and each IP address is capable of sending application probes to user-specified applications.

Specific routing is implemented on the FortiGate to ensure each FortiMonitor client collects performance statistics for only one SD-WAN member interface. The FortiMonitor is configured to send application-specific probes to measure that application's performance on a given SD-WAN member. The FortiGate uses the FortiMonitor performance statistics to determine link quality based on application performance by mapping the health check. The link quality for a given application can then be used to steer the matching application traffic with greater accuracy.

To configure the FortiGate:

1. Configure the address objects for each FortiMonitor client:

```
config firewall address
    edit "FMR_OnSight1"
        set subnet 10.2.1.80 255.255.255.255
    next
    edit "MR_OnSight2"
        set subnet 10.2.1.81 255.255.255.255
    next
end
```

2. Set the logging frequency:

```
config system sdwan
    set status enable
    set app-perf-log-period 60
end
```

3. Configure the SD-WAN zone and members:

```
config system sdwan
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "v1236"
            set gateway 10.12.36.2
        next
        edit 2
            set interface "v1237"
            set gateway 10.12.37.20
        next
    end
end
```

4. Configure the SD-WAN rules to ensure each OnSight client uses only one SD-WAN member, and map the FortiMonitor IP to an SD-WAN member (interface):

```
config system sdwan
    config service
        edit 1
```

```
            set dst "all"
            set src "FMR_OnSight1"
            set priority-members 1
            set agent-exclusive enable
        next
        edit 2
            set dst "all"
            set src "FMR_OnSight2"
            set priority-members 2
            set agent-exclusive enable
        next
    end
end
```

5. Configure the SD-WAN health check:

```
config health-check
    edit "FMR"
        set detect-mode agent-based
        set members 1 2
        config sla
            edit 1
            next
        end
    next
end
```

To verify the SD-WAN member performance:

1. Verify the health check diagnostics:

```
# diagnose sys sdwan health-check
Health Check(FMR):
Seq(1 v1236): state(alive), packet-loss(0.000%) latency(183.214), jitter(0.124), mos(4.225),
bandwidth-up(999992), bandwidth-dw(999976), bandwidth-bi(1999968) sla_map=0x0
Seq(2 v1237): state(alive), packet-loss(0.000%) latency(182.946), jitter(0.100), mos(4.226),
bandwidth-up(999998), bandwidth-dw(999993), bandwidth-bi(1999991) sla_map=0x0
```

2. Verify the collected reports:

```
# diagnose sys link-monitor-passive agent list
       v1236( 23) | src=10.2.1.80 | latency=183.2   20:27:24 | jitter=0.1     20:27:24 |
pktloss=0.0  % 20:27:24
       v1237( 24) | src=10.2.1.81 | latency=182.9   20:27:24 | jitter=0.1     20:27:24 |
pktloss=0.0  % 20:27:24
```

3. Verify the details of each application:

```
# diagnose sys link-monitor-passive agent list-app
app_id=0x00000000, app=fortinet.com, dev=v1236(23)
        latency=183.2, jitter=0.1, pktloss=0.0,ntt=99.2,srt=384.8,app_err=0.0, 20:28:25
```

```
app_id=0x00000000, app=fortinet.com, dev=v1237(24)
        latency=183.1, jitter=0.5, pktloss=0.0,ntt=104.4,srt=377.8,app_err=0.0, 20:28:25
```

4. Verify the agent and interface maps:

```
# diagnose sys link-monitor-passive agent agent-oif-map
oif=v1236(23), src=10.2.1.80
oif=v1237(24), src=10.2.1.81
```

5. Review the SD-WAN logs:

6.
```
# execute log filter category event
# execute log filter field subtype sdwan
# execute log display

1: date=2023-01-27 time=16:32:15 eventtime=1674865935918381398 tz="-0800" logid="0113022937"

Classifying SLA probes for traffic prioritization

Traffic classification on SLA probes helps to ensure that they are prioritized in times of congestion. This prevents SD-WAN link flapping and unexpected routing behaviors, and stabilizes SD-WAN from unnecessary failovers.

SLA probes can be classified into a specific class ID so that SLA probes assigned to a class ID with higher priority are prioritized over other traffic. SLA probes are assigned using the `class-id` command:

```
config system sdwan
    config health-check
        edit <health-check name>
            set class-id <class name>
        next
    end
end
```

For more information on traffic shaping, see Traffic shaping on page 1798.

Example

In this example, SLA probes are assigned into different class ID. The interfaces dmz and vd1-01 both have outbandwidth of 1000000 Kbps (1 Gbps) configured. Three traffic shaping classes are defined:

Class ID	Name	Definition
2	sla_probe	High priority with a guaranteed 10% of bandwidth (100 Mbps)
3	default	Low priority with a guaranteed 80% of bandwidth (800 Mbps)
4	sla_probe_2	Medium priority with a guaranteed 10% of bandwidth (100 Mbps)

Under this scheme, when congestion occurs, traffic in each class will have their guaranteed bandwidth honored. If there is remaining bandwidth, higher priority traffic will get the bandwidth. On the SD-WAN health check, probes to server 2.2.2.2 are assigned to class 2 (sla_probe). This means it has a guaranteed bandwidth and has the highest priority to use unused bandwidth. This allows SD-WAN health check to function properly even during times of congestion.

To classify SLA probes for traffic prioritization:

1. Configure the firewall traffic class:

```
config firewall traffic-class
    edit 2
        set class-name "sla_probe"
    next
    edit 3
        set class-name "default"
    next
    edit 4
        set class-name "sla_probe_2"
    next
end
```

2. Configure the class ID priority and guaranteed bandwidth:

```
config firewall shaping-profile
    edit "profile-1"
        set default-class-id 3
        config shaping-entries
            edit 2
                set class-id 2
                set priority high
                set guaranteed-bandwidth-percentage 10
                set maximum-bandwidth-percentage 100
            next
            edit 3
                set class-id 3
                set priority low
                set guaranteed-bandwidth-percentage 80
                set maximum-bandwidth-percentage 100
            next
            edit 4
                set class-id 4
                set priority medium
                set guaranteed-bandwidth-percentage 10
                set maximum-bandwidth-percentage 100
            next
        end
    next
end
```

3. Configure the interfaces:

```
config system interface
    edit "dmz"
        set outbandwidth 1000000
        set egress-shaping-profile "profile-1"
        ...
    next
    edit "vd1-p1"
```

```
        set outbandwidth 1000000
        set egress-shaping-profile "profile-1"
        ...
    next
end
```

4. Configure the SD-WAN health check and assign the SLA probes into class 2:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 2
            set interface "vd1-p1"
        next
    end
    config health-check
        edit "1"
            set server "2.2.2.2"
            set members 1 2
            set class-id 2
            config sla
                edit 1
                next
            end
        next
    end
end
```

To verify the SLA probe assignment:

1. Verify the health check diagnostics:

```
# diagnose sys sdwan health-check
Health Check(1):
Seq(1 dmz): state(alive), packet-loss(0.000%) latency(0.247), jitter(0.022), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999997), bandwidth-bi(1999996) sla_map=0x1
Seq(2 vd1-p1): state(alive), packet-loss(0.000%) latency(0.247), jitter(0.018), mos(4.404),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x1
```

2. Verify the SLA probes are assigned into class 2:

```
# diagnose netlink interface list dmz
if=dmz family=00 type=1 index=5 mtu=1500 link=0 master=0
ref=36 state=start present fw_flags=10018000 flags=up broadcast run multicast
```

```
Qdisc=mq hw_addr=e0:23:ff:9d:f9:9e broadcast_addr=ff:ff:ff:ff:ff:ff
egress traffic control:
        bandwidth=1000000(kbps) lock_hit=0 default_class=3 n_active_class=3

(kbps)
                            max-bandwidth=1000000(kbps)     current-bandwidth=0(kbps)
                            priority=low    forwarded_bytes=0
                            dropped_packets=0       dropped_bytes=0
        class-id=4      allocated-bandwidth=100000(kbps)        guaranteed-bandwidth=100000
(kbps)
                            max-bandwidth=1000000(kbps)     current-bandwidth=0(kbps)
                            priority=medium         forwarded_bytes=0
                            dropped_packets=0       dropped_bytes=0
        class-id=2      allocated-bandwidth=100000(kbps)        guaranteed-bandwidth=100000
(kbps)
                            max-bandwidth=1000000(kbps)     current-bandwidth=1(kbps)
                            priority=high   forwarded_bytes=1120
                            dropped_packets=0       dropped_bytes=0
stat: rxp=4097 txp=4586 rxb=540622 txb=221500 rxe=0 txe=19 rxd=0 txd=0 mc=0     collision=0 @
time=1675121742
re: rxl=0 rxo=0 rxc=0 rxf=0 rxfi=0 rxm=0
te: txa=0 txc=0 txfi=0 txh=0 txw=0
misc rxc=0 txc=0
input_type=0 state=3 arp_entry=0 refcnt=20
```

When verifying the class assignment, the counter value should increase.

The example also demonstrates assigning SLA probes to class 4 (sla_probe_2), in which case the probes get medium priority.

To assign the SLA probe to medium priority:

1. Assign SLA probes into class 4:

```
config sys sdwan
    config health-check
        edit 1
            set class-id 4
        next
    end
    set status disable
end
config sys sdwan
    set status enable
end
```

2. Verify the SLA probes are assigned into class 4.

```
# diagnose netlink interface list dmz
if=dmz family=00 type=1 index=5 mtu=1500 link=0 master=0
ref=34 state=start present fw_flags=10018000 flags=up broadcast run multicast
Qdisc=mq hw_addr=e0:23:ff:9d:f9:9e broadcast_addr=ff:ff:ff:ff:ff:ff
egress traffic control:
        bandwidth=1000000(kbps) lock_hit=0 default_class=3 n_active_class=3
        class-id=3      allocated-bandwidth=800000(kbps)        guaranteed-bandwidth=800000
(kbps)
                            max-bandwidth=1000000(kbps)     current-bandwidth=1(kbps)

FortiGuard SLA database for SD-WAN performance SLA

A FortiGuard SLA database includes popular SaaS and Internet destinations as well as recommended settings that you can select as probe servers for SD-WAN Performance SLA configurations in the GUI or CLI.

In the GUI, go to *Network* > *SD-WAN* > *Performance SLA*, and click *Create New* to access the new database.

In the CLI, use the following options:

```
config system sdwan
    config health-check
        edit <health-check name>
            set fortiguard {enable | disable}
            set fortiguard-name <string>
        next
    end
end
```

`set fortiguard {enable | disable}`	Enable/disable use of FortiGuard SLA database.
`set fortiguard-name <string>`	Name of the predefined health-check target from the FortiGuard SLA database.

The FortiGate requires a valid SD-WAN Network Monitor (SWNM) entitlement before the FortiGuard SLA Database can be downloaded or updated.

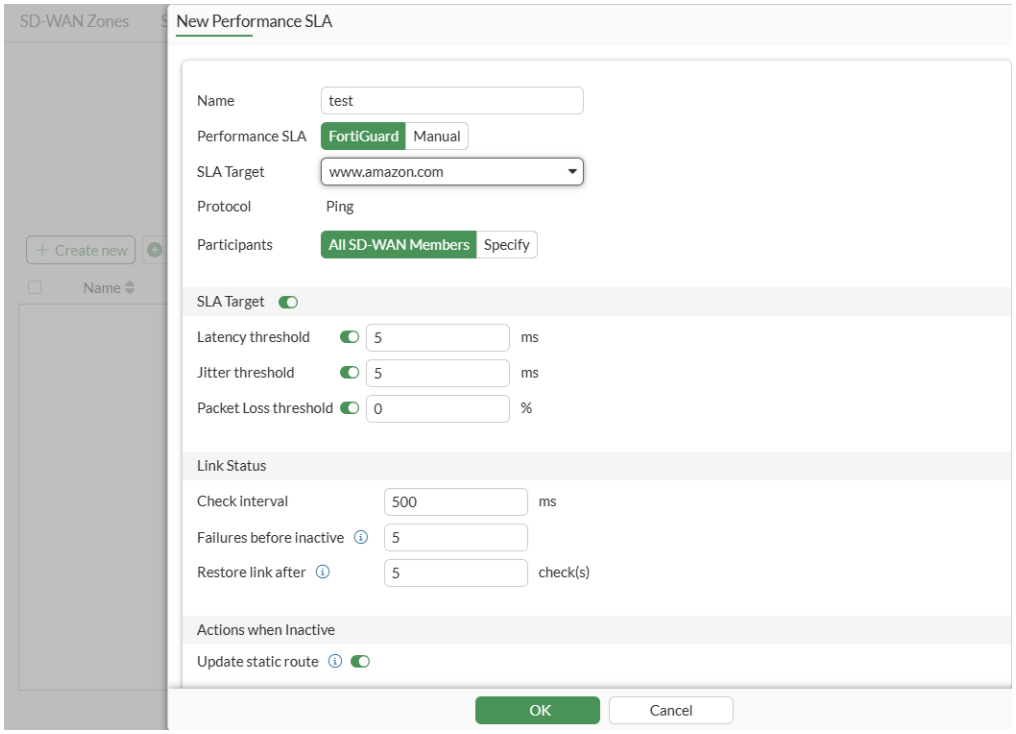
See also SD-WAN Setup wizard on page 924.

Example

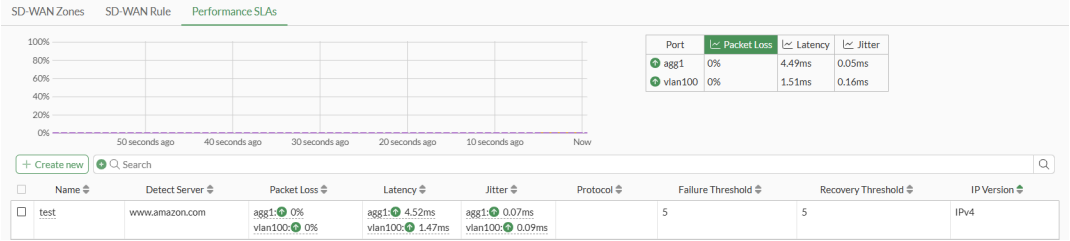
In this example, an SD-WAN performance SLA is configured to use the FortiGuard SLA database and its Amazon target.

To configure a performance SLA in the GUI:

1. Go to *Network* > *SD-WAN* > *Performance SLA*, and click *Create New*. The *New Performance SLA* pane is displayed.
2. Set *Performance SLA* to *FortiGuard* to select the database, and set *SLA Target* to the *www.amazon.com* target from the database.



3. Complete the remaining options, and click *OK*. The configuration is displayed on the *Performance SLAs* pane.
4. On the *Performance SLAs* pane, select the configuration to view the health-check status.



To configure performance SLA in the CLI:

1. Configure an SD-WAN health-check to use the SLA database and its Amazon target:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "agg1"
            set gateway 172.16.203.2
        next
        edit 2
            set interface "vlan100"
            set gateway 172.16.206.2
        next
    end
    config health-check
        edit "test"
            set fortiguard enable
            set fortiguard-name "Amazon"
            set server "www.amazon.com"
            set members 0
            config sla
                edit 1
                next
            end
        next
    end
end
```

2. Check the health status:
   In this example, the SLA database is enabled and Amazon is configured.

```
# diagnose sys sdwan  health-check
Health Check(test):
Seq(1 agg1): state(alive), packet-loss(1.000%), latency(55.557), jitter(1.245), mos(4.373),
bandwidth-up(999993), bandwidth-dw(999982), bandwidth-bi(1999975), sla_map=0x0
Seq(2 vlan100): state(alive), packet-loss(4.000%), latency(55.534), jitter(1.211), mos(4.372),
bandwidth-up(697383), bandwidth-dw(437492), bandwidth-bi(1134875), sla_map=0x0
```

To view the performance SLA database in the CLI:

1. View the SLA database version:

```
# diagnose autoupdate version

...

SLA Database
---------
Version: 1.00003
Contract Expiry Date: Wed Apr 30 2025
Last Updated using scheduled update on Mon Nov 25 09:46:47 2024
Last Update Attempt: Wed Nov 27 14:36:01 2024
Result: No Updates

Timezone Database
---------
Version: 1.0006

...
```

2. List the targets predefined by FortiGuard in the SLA database:

```
# diagnose sladb target-list
target-name:8X8
deprecated:0
sz_domain:6

target-name:ADP
deprecated:0
sz_domain:5

target-name:AOL
deprecated:0
sz_domain:9

target-name:AWS dynamodb
deprecated:0
sz_domain:27

target-name:AWS ec2
deprecated:0
sz_domain:27

target-name:AWS ecs
deprecated:0
sz_domain:27

target-name:AWS es
deprecated:0
sz_domain:27
```

```
target-name:AWS lambda
deprecated:0
sz_domain:27
...
```

3. List the domains under a specific target predefined by FortiGuard in the SLA database:

```
# diagnose sladb  domain-list ADP
domain-name:www.adp.com
desc:ADP (www.adp.com)
deprecated:0
sz_protocol:2

domain-name:ipay.adp.com
desc:Online payroll management and payment platform.
deprecated:0
sz_protocol:2

domain-name:workforcenow.adp.com
desc:Human resource management platform.
deprecated:0
sz_protocol:2

domain-name:globalview.adp.com
desc:Global HR management platform.
deprecated:0
sz_protocol:2

domain-name:mobile.adp.com
desc:Mobile app for ADP services.
deprecated:0
sz_protocol:2
```

4. List the protocols under a specific target and domain predefined by FortiGuard in the SLA database:

```
# diagnose sladb protocol-list ADP www.adp.com
target-name:ADP
domain-name:www.adp.com

        protocol: ping
        protocol: https
```

5. View the communication method between FortiGate and servers predefined by FortiGuard for SD-WAN health-checks.

```
# show system health-check-fortiguard
config system health-check-fortiguard
    edit "8X8"
        set server "www.8x8.com"
        set protocol https
    next
    edit "ADP"
        set server "www.adp.com"
```

```
    next
    edit "AOL"
        set server "www.aol.com"
    next
    edit "AWS dynamodb"
        set server "dynamodb.me-central-1.amazonaws.com"
    next
    edit "AWS ec2"
        set server "ec2.us-east-1.amazonaws.com"
    next
    edit "AWS ecs"
        set server "ecs.me-central-1.amazonaws.com"
    next
    edit "AWS es"
        set server "es.us-east-1.amazonaws.com"
    next
    edit "AWS lambda"
        set server "lambda.us-east-1.amazonaws.com"
    next
...
```

SD-WAN rules

SD-WAN rules, which are sometimes called *service rules*, identify traffic of interest, and then route the traffic based on a strategy and the condition of the route or *link* between two devices. You can use many strategies to select the outgoing interface and many performance service level agreements (SLAs) to evaluate the link conditions.

Use the following topics to learn about and create SD-WAN rules for your needs:

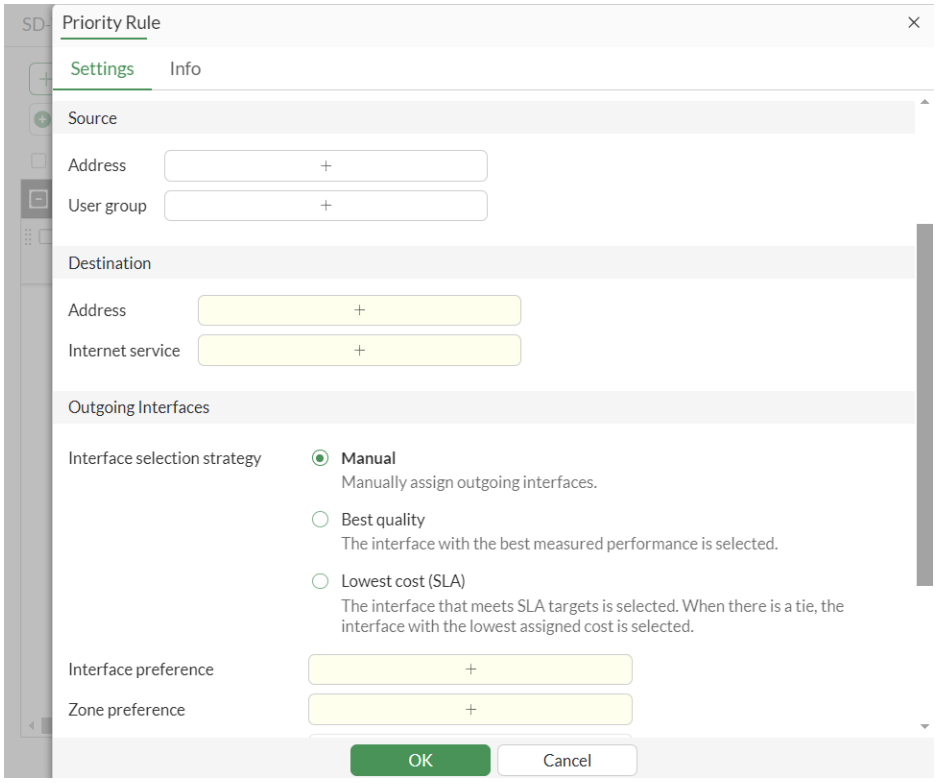
- SD-WAN rules overview on page 1018
- Implicit rule on page 1026
- Automatic strategy on page 1030
- Manual strategy on page 1031
- Best quality strategy on page 1035
- Lowest cost (SLA) strategy on page 1038
- Load balancing strategy on page 1045
- SD-WAN traffic shaping and QoS on page 1045
- SDN dynamic connector addresses in SD-WAN rules on page 1051
- Application steering using SD-WAN rules on page 1053
- DSCP tag-based traffic steering in SD-WAN on page 1066
- ECMP support for the longest match in SD-WAN rule matching on page 1073
- Override quality comparisons in SD-WAN longest match rule matching on page 1076
- Internet service and application control steering on page 1079
- Use maximize bandwidth to load balance traffic between ADVPN shortcuts on page 1089
- Use SD-WAN rules to steer multicast traffic on page 1096

- Use SD-WAN rules for WAN link selection with load balancing on page 1117

SD-WAN rules overview

SD-WAN rules control how sessions are distributed to SD-WAN members. You can configure SD-WAN rules from the GUI and CLI.

From the GUI, go to *Network* > *SD-WAN* > *SD-WAN Rules*. When creating a new SD-WAN rule, or editing an existing SD-WAN rule, use the *Source* and *Destination* sections to identify traffic, and use the *Outgoing interfaces* section to configure WAN intelligence for routing traffic.



From the CLI, use the following command to configure SD-WAN rules:

```
config system sdwan
    config service
        edit <ID>
        set comment <string>
    next
end
```

The following topics describe the fields used to configure SD-WAN rules:

- Fields for identifying traffic on page 1019
- Fields for configuring WAN intelligence on page 1022
- Additional fields for configuring WAN intelligence on page 1024

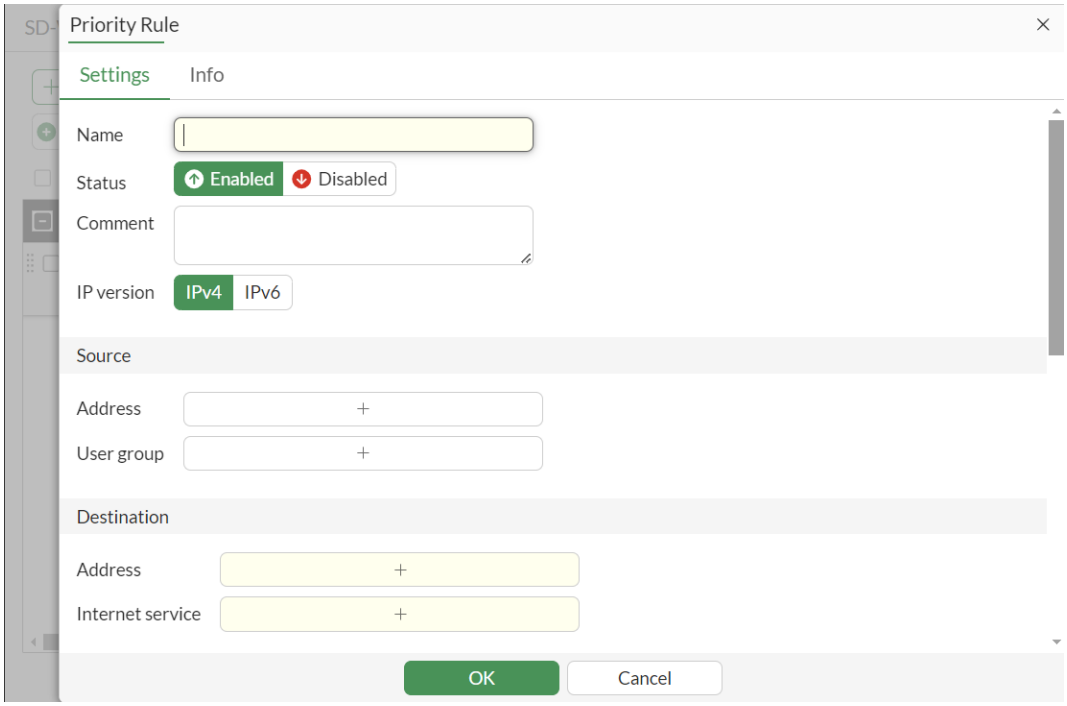
Fields for identifying traffic

This topic describes the fields in an SD-WAN rule used for defining the traffic to which the rule applies. Some fields are available only in the CLI.

SD-WAN rules can identify traffic by a variety of means:

Address type	Source	Destination
IPv4/6	✓	✓
MAC	✓	✓
Group	✓	✓
FABRIC_DEVICE dynamic address	✓	✓
Users	✓	✓
User groups	✓	✓
Application control (application aware routing)		✓
Internet service database (ISDB)		✓
BGP route tags		✓
Differentiated Services Code Point (DSCP) tags		✓

In the GUI, go to *Network* > *SD-WAN* > *SD-WAN Rules*. Click *Create New*, or double-click an existing rule to open it for editing. The *Source* and *Destination* sections are used to identify traffic for the rule:



In the CLI, edit the service definition ID number to identify traffic for the rule:

```
config system sdwan
    config service
        edit <ID>
        set comment <string>
        <CLI commands from the following tables>
        ...
    next
end
```

The following table describes the fields used for the name, ID, and IP version of the SD-WAN rule:

ID, Name, and IP version		
Field	**CLI**	**Description**

ID	`config system sdwan`
	`config service`
	`edit <ID>`
	`set comment <string>`
	`next`
	`end`
		ID is generated when the rule is created. You can only specify the ID from the CLI.

Name	`set name <string>`	The name does not need to relate to the traffic being matched, but it is good practice to have intuitive rule names.
IP version	`set addr-mode <ipv4 | ipv6>`	The addressing mode can be IPv4 or IPv6. To configure in the GUI, IPv6 must be enabled from *System* > *Feature Visibility* page.

The following table describes the fields used for source section of the SD-WAN rule:

Source		
Field	**CLI**	**Description**

Source address	`set src <object>`
	`set start-src-port <integer>`
	`set end-src-port <integer>`
	Use `set src-negate enable` to negate the address object.
		One or more address objects.
		Start source port number. CLI only.
		End source port number. CLI only.

User group	`set users <user object>` `set groups <group object>`	Individual users or user groups
Source interface	`set input-device <interface name>` Can be negated with `set input-device-negate enable`.	Select one or more source interfaces. CLI only.

The following table describes the fields used for the destination section of the SD-WAN rule:

Destination		
Field	**CLI**	**Description**

Address	`set dst <object>`
	`set protocol <integer>`
	`set start-port <integer>`
	`set end-port <integer>`
	Use `set dst-negate enable` to negate the address object.
		One or more address objects.
		One protocol and one port range can be combined with the address object.
		If it is necessary for an SD-WAN rule to match multiple protocols or multiple port ranges, you can create a custom Internet Service.

Internet Service	`set internet-service enable`
	`set internet-service-custom <name_1> <name_2> ... <name_n>`
	`set internet-service-custom-group <name_1> <name_2> ... <name_n>`
	`set internet-service-name <name_1> <name_2> ... <name_n>`
	`set internet-service-group <name_1> <name_2> ... <name_n>`
		One or more internet services or service groups.

Application	`set internet-service-app-ctrl <id_1> <id_2> ... <id_n>`
	`set internet-service-app-ctrl-group <name_1> <name_2> ... <name_n>`
	`set internet-service-app-ctrl-category <id_1> <id_2> ... <id_n>`
		One or more applications or application groups.
		Can be used with internet services or service group.

Route tag (`route-tag`)	`set route-tag <integer>`	CLI only. This replaces the `dst` field (if previously configured) and matches a BGP route tag configured in a route map. See Using BGP tags with SD-WAN rules on page 1132.
TOS mask (`tos-mask`)	`set tos-mask <8-bit hex value>`	CLI only. In order to leverage type of service (TOS) matching or DSCP matching on the IP header, the SD-WAN rule must specify the bit mask of the byte holding the TOS value. For example, a TOS mask of 0xe0 (11100000) matches the upper 3 bits.
TOS (`tos`)	`set tos <8 bit hex value>`	CLI only. The value specified here is matched after the `tos-mask` is applied.

Destination		
Field	**CLI**	**Description**
		For example, the FortiGate receives DSCP values 110000 and 111011. (DSCP is the upper 6 bits of the TOS field – 11000000 and 11101100 respectively). Using the TOS value 0xe0 (11100000), only the second DSCP value is matched.

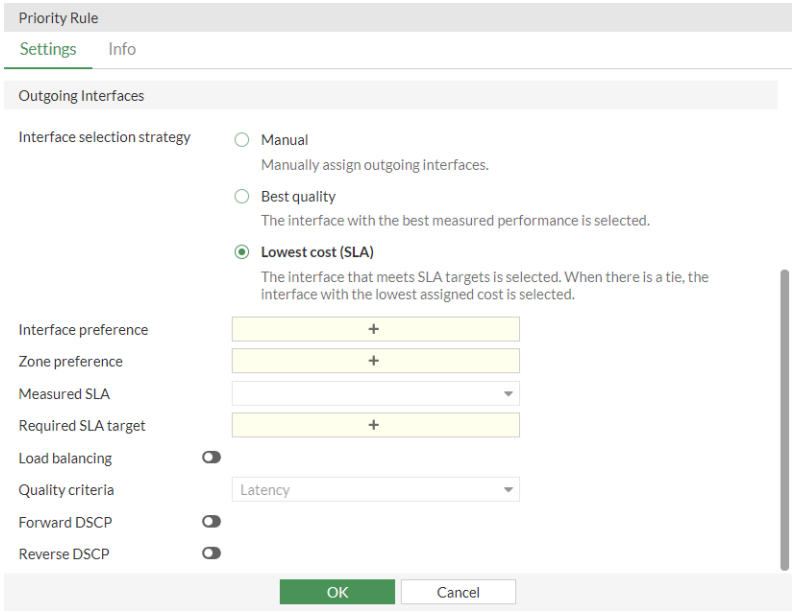
By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System > Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
    set gui-app-detection-sdwan enable
end
```

Fields for configuring WAN intelligence

This topic describes the fields in an SD-WAN rule used for configuring WAN intelligence, which processes and routes traffic that matches the SD-WAN rule.

In the GUI, go to *Network > SD-WAN > SD-WAN Rules*. Click *Create New*, or double-click an existing rule to open it for editing. The *Outgoing Interfaces* section is used to configure WAN intelligence for the rule:



WAN intelligence is comprised of the following parts:

- Interface or zone preference on page 1023
- Strategy on page 1023

- Performance SLA on page 1024

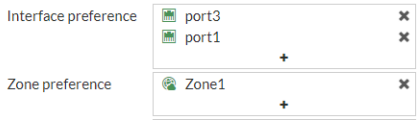
Interface or zone preference

By default, the configured order of interfaces and/or zones in a rule are used. Interfaces and zones that are selected first have precedence over interfaces selected second and so on.

You can specify both interfaces and zones. When a zone is specified in the *Zone preference* field, it is equivalent to selecting each of the contained interface members in the *Interface preference* section. Interface members in a zone have lower priority than interfaces configured in the *Interface preference* section.

For example:

- There are 3 interfaces: port1, port2 and port3.
  - Port2 is in Zone1
  - Port1 and port3 belong to the default *virtual-wan-link* zone.
- An SD-WAN rule is created with *Interface preference* set to *port3* and *port1*, and *Zone preference* set to *Zone1*.



The SD-WAN rule prefers the interfaces in the following order:

1. port3
2. port1
3. port2

You can configure the interface and zone preference in the CLI:

```
config system sdwan
    config service
        edit <ID>
            set priority-members <integer>
            set priority-zone <interface>
        next
    end
end
```

Strategy

Strategy dictates how the interface and/or zone order changes as link conditions change. You can use the following strategies:

- Automatic (`auto`): interfaces are assigned a priority based on quality. See Automatic strategy on page 1030.
- Manual (`manual`): interfaces are manually assigned a priority. See Manual strategy on page 1031.
- Best Quality (`priority`): interfaces are assigned a priority based on the `link-cost-factor` of the interface. See Best quality strategy on page 1035.
- Lowest cost (SLA) (`sla`): interfaces are assigned a priority based on selected SLA settings. See Lowest cost (SLA) strategy on page 1038.

Performance SLA

The best quality, lowest cost, and maximize bandwidth strategies are the most intelligent modes, and they leverage SLA health checks to provide meaningful metrics for a given link. FortiGate uses the metrics to make intelligent decisions to route traffic.

Automatic and manual strategies have pre-configured logic that do not leverage SLA health checks.

The goal of the performance SLA is to measure the quality of each SD-WAN member link. The following methods can be used to measure the quality of a link:

- Active measurement
  - Health-check traffic is sent to a server with a variety of protocols options.
  - The following SLA metrics are measured on this probe traffic:
    - Latency
    - Jitter
    - Packet loss
- Passive measurement
  - SLA metrics are measured on real or live traffic, reducing the amount of probe traffic that is sent and received.
  - There is the option (prefer passive) to initiate probe traffic when no live traffic is present.

Performance SLA is utilized by `auto`, *Lowest Cost (SLA)*, *Maximize Bandwidth (SLA)*, and *Best Quality* strategies. *Lowest Cost (SLA)* and *Maximize Bandwidth SLA* use SLA targets in a pass or fail style to evaluate whether a link is considered for traffic. *Best Quality* compares a specific metric of the SLA to pick the best result.

Therefore it is integral to select or create an SLA target(s) that relates to the traffic targeted by the rule. It does not make sense to evaluate a public resource, such as YouTube, when the rule matches Azure traffic.

See Performance SLA on page 931 for more details.

Additional fields for configuring WAN intelligence

This topic describes the fields in an SD-WAN rule used for configuring WAN intelligence for egress traffic:

- Forward and/or reverse differentiated services code point (DSCP) on page 1024
- Default and gateway options on page 1025

For information about accessing fields for configuring WAN intelligence, see Fields for configuring WAN intelligence on page 1022.

Forward and/or reverse differentiated services code point (DSCP)

The FortiGate differentiated services feature can be used to change the DSCP value for all packets accepted by a policy.

The packet's `DSCP` field for traffic initiating a session (forward) or for reply traffic (reverse) can be changed and enabled in each direction separately by configuring it in the firewall policy using the *Forward DSCP* and *Reverse DSCP* fields.

From the CLI:

```
config system sdwan
    config service
        edit <ID>
            ...
            set dscp-forward enable
            ...
        next
    end
end
```

`set dscp-forward enable`	Enable use of forward DSCP tag.
`set dscp-forward-tag 000000`	Forward traffic DSCP tag.
`set dscp-reverse enable`	Enable use of reverse DSCP tag.
`set dscp-reverse-tag 000000`	Reverse traffic DSCP tag.

Default and gateway options

Following are additional gateway options that can be set only in the CLI:

```
config system sdwan
    config service
        edit <ID>
            ...
            set default enable
            ...
        next
    end
end
```

`set default [enable|disable]`	Enable or disable use of SD-WAN as default service.
`set gateway [enable|disable]`	Enable or disable SD-WAN service gateway.

By default, these settings are set to `disable`.

These two commands help adjust FortiGate route selection by affecting how the FortiGate consults the Forward Information Base (FIB).

In order to decide whether an SD-WAN policy-route can be matched, FortiGate performs the following FIB lookups:

- FIB best match for the destination must return an SD-WAN member.
- FIB route to the destination must exist over the desired SD-WAN member.

When `set default enable` is used with `set gateway enable`, FortiGate bypasses the FIB checks, and instead routes any matching traffic of the SD-WAN rule to the chosen SD-WAN member using the member's configured gateway. SD-WAN members must have a gateway configured.

When `set default disable` is used with `set gateway enable`, FortiGate keeps the first rule in effect but causes the second rule to change to:

- FIB route to the gateway IP address must exist over any interface.

See also Fields for configuring WAN intelligence on page 1022.

Implicit rule

SD-WAN rules define specific policy routing options to route traffic to an SD-WAN member. When no explicit SD-WAN rules are defined, or if none of the rules are matched, then the default implicit rule is used.

In an SD-WAN configuration, the default route usually points to the SD-WAN interface, so each active member's gateway is added to the routing table's default route. FortiOS uses equal-cost multipath (ECMP) to balance traffic between the interfaces. One of five load balancing algorithms can be selected:

Source IP (`source-ip-based`)	Traffic is divided equally between the interfaces, including the SD-WAN interface. Sessions that start at the same source IP address use the same path. This is the default selection.
Sessions (`weight-based`)	The workload is distributing based on the number of sessions that are connected through the interface. The weight that you assign to each interface is used to calculate the percentage of the total sessions that are allowed to connect through an interface, and the sessions are distributed to the interfaces accordingly. The sessions with the same source and destination IP are forwarded to the same path if the device model and kernel version supports route cache. However, it is not guaranteed and the route cache could be refreshed in case network events take place. In most cases where route cache is not supported, the sessions with the same source and destination IP will be load balanced between SD-WAN member interfaces. An interface's weight value cannot be zero.
Spillover (`usage-based`)	The interface is used until the traffic bandwidth exceeds the ingress and egress thresholds that you set for that interface. Additional traffic is then sent through the next SD-WAN interface member.
Source-Destination IP (`source-dest-ip-based`)	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address and go to the same destination IP address use the same path.
Volume (`measured-volume-based`)	The workload is distributing based on the number of packets that are going through the interface. The volume weight that you assign to each interface is used to calculate the percentage of the total bandwidth that is allowed to go through an interface, and the bandwidth is distributed to the interfaces accordingly. An interface's volume value cannot be zero.

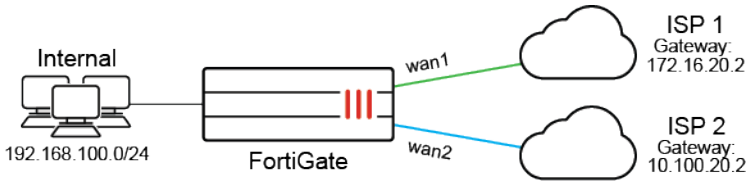
You cannot exclude an interface from participating in load balancing using the implicit rule. If the weight or volume were set to zero in a previous FortiOS version, the value is treated as a one.

When using dynamic routes for routing, sessions are distributed equally regardless of weight.

Interfaces with static routes can be excluded from ECMP if they are configured with a lower priority than other static routes.

Examples

The following four examples demonstrate how to use the implicit rules (load-balance mode).



If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

Example 1

Outgoing traffic is equally balanced between wan1 and wan2, using *source-ip-based* or *source-dest-ip-based* mode.

Using the GUI:

1. On the FortiGate, enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 897 for details.
2. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab.
3. Edit the *sd-wan* rule (the last default rule).
4. For the *Load Balancing Algorithm*, select either *Source IP* or *Source-Destination IP*.
5. Click *OK*.

Using the CLI:

1. Enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 897 for details.
2. Set the load balancing algorithm:
   Source IP based:

```
config system sdwan
    set load-balance-mode source-ip-based
end
```

Source-Destination IP based:

```
config system sdwan
    set load-balance-mode source-dest-ip-based
end
```

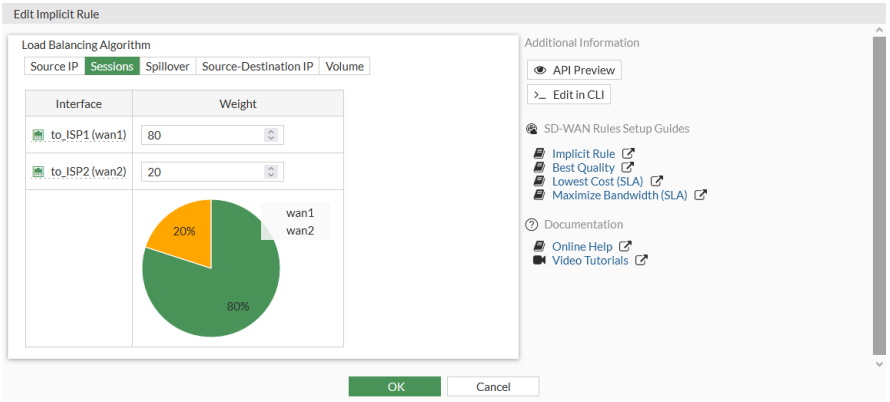
Example 2

Outgoing traffic is balanced between wan1 and wan2 with a customized ratio, using *weight-based* mode: wan1 runs 80% of the sessions, and wan2 runs 20% of the sessions.

Sessions with the same source and destination IP addresses (`src-ip` and `dst-ip`) will be forwarded to the same path, but will still be considered in later session ratio calculations.

Using the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab.
2. Edit the *sd-wan* rule (the last default rule).
3. For the *Load Balancing Algorithm*, select *Sessions*.
4. Enter 80 in the *wan1* field, and 20 in the *wan2* field.



5. Click *OK*.

Using the CLI:

```
config system sdwan
    set load-balance-mode weight-based
    config members
        edit 1
            set interface "wan1"
            set weight 80
        next
        edit 2
            set interface "wan2"
            set weight 20
```

```
        next
    end
end
```

Example 3

Outgoing traffic is balanced between wan1 and wan2 with a customized ratio, using *measured-volume-based* mode: wan1 runs 80% of the volume, and wan2 runs 20% of the volume.

Using the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab.
2. Edit the *sd-wan* rule (the last default rule).
3. For the *Load Balancing Algorithm*, select *Volume*.
4. Enter 80 in the *wan1* field, and 20 in the *wan2* field.
5. Click *OK*.

Using the CLI:

```
config system sdwan
    set load-balance-mode measured-volume-based
    config members
        edit 1
            set interface "wan1"
            set volume-ratio 80
        next
        edit 2
            set interface "wan2"
            set volume-ratio 20
        next
    end
end
```

Example 4

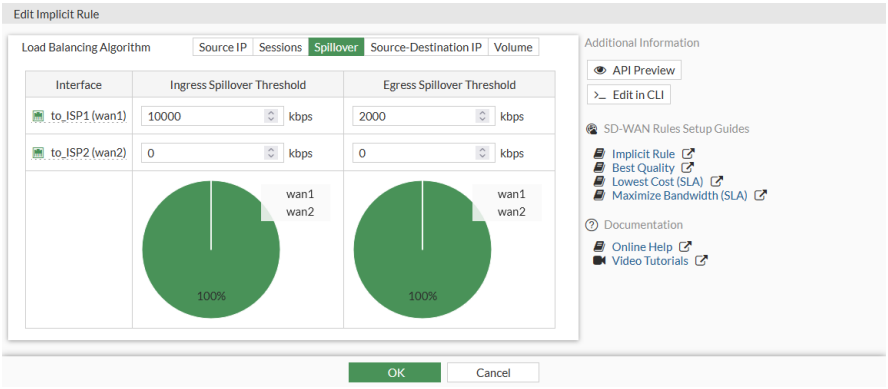
Load balancing can be used to reduce costs when internet connections are charged at different rates. For example, if wan2 charges based on volume usage and wan1 charges a fixed monthly fee, we can use wan1 at its maximum bandwidth, and use wan2 for overflow.

In this example, wan1's bandwidth is 10Mbps down and 2Mbps up. Traffic will use wan1 until it reaches its spillover limit, then it will start to use wan2. Note that `auto-asic-offload` must be disabled in the firewall policy.

Using the GUI:

1. On the FortiGate, enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 897 for details.
2. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab.
3. Edit the *sd-wan* rule (the last default rule).
4. For the *Load Balancing Algorithm*, select *Spillover*.

5. Enter 10000 in the *wan1 Ingress Spillover Threshold* field, and 2000 in the *wan1 Egress Spillover Threshold* field.



6. Click *OK*.

Using the CLI:

```
config system sdwan
    set load-balance-mode usage-based
    config members
        edit 1
            set interface "wan1"
            set spillover-threshold 2000
            set ingress-spillover-threshold 10000
        next
    end
end
```

Automatic strategy

The automatic strategy is a legacy rule that lets you select an outgoing interface based on its performance ranking compared to the other SD-WAN interfaces. This is achieved by applying a performance SLA to rank the interfaces, and then selecting the desired rank.

In this example, you have three SD-WAN interfaces to three different ISPs that all go to the public internet. WAN1 is your highest quality link and should be reserved for business critical traffic. WAN2 and WAN3 are redundant backup links. You noticed one non-critical application is taking up a lot of bandwidth and want to prioritize it to the lowest quality link at any given time.

To configure automatic SD-WAN rules from the CLI:

```
config system sdwan
    config members
        edit 1
            set interface "wan1"
        next
        edit 2
            set interface "wan2"
```

```
        next
        edit 3
            set interface "wan3"
        next
    end
    config health-check
        edit "non-critical application"
            set server "noncritical.application.com"
            set members 1 2 3
            config sla
                edit 1
                    set latency-threshold 250
                    set jitter-threshold 50
                    set packletloss-threshold 3
                next
            end
        next
    end
    config service
        edit 1
            set name "non-critical application"
            set mode auto
            set quality-link 3
            set dst "non-critical-app-address-object"
            set health-check "non-critical application"
        next
    end
end
```

The `auto` option is only available in the CLI. If you use the GUI to edit the rule, the `auto` option will be overwritten because you cannot select *auto* in the GUI.

Manual strategy

In manual mode, no health checks are used. As a result, the decision making closer resembles logic than intelligence. SD-WAN manual rules are similar to regular policy-based routes, but have the added features of application-aware routing and BGP-tag routing. A manual strategy rule is comprised of the following parts:

- Defining the interfaces to be used
- Ordering the interfaces based on preference, or load balancing traffic out of the specified interfaces using a load balancing algorithm

The maximize bandwidth (`load-balance`) strategy used prior to FortiOS 7.4.1 is now known as the load balancing strategy. This strategy can be configured under the manual mode and the lowest cost (SLA) strategies.

- When the load balancing strategy is configured under the manual mode strategy, SLA targets are not used.
- When the load balancing strategy is configured under the lowest cost (SLA) strategy, SLA targets are used.

To configure manual SD-WAN rules from the GUI:

1. Go to *Network* > *SD-WAN*.
2. Select the *SD-WAN Rules* tab, and click *Create New*.
3. Set the following options to create a manual rule:

Name	Type a name for the rule.
Source	(Optional) Specify a *Source address* and/or *User group*.
Destination	Specify the destination using an *Address* object or an *Internet Service* or an *Application*.
Zone preference	Specify one or more SD-WAN interfaces or zones. The order in which the interfaces or zones are specified determines their priority when the rule is matched.

4. Set the remaining options as desired, and click *OK* to create the rule.

To configure manual SD-WAN rules from the CLI:

```
config system sdwan
    config members
        edit 1
            set interface "wan1"
        next
        edit 2
            set interface "wan2"
        next
    end
    config service
        edit 1
            set name "manual"
            set mode manual
            set priority-members 2 1
            set dst "DC_net"
            set hold-down-time 60
        next
    end
end
```

- The command `set mode manual` will not appear in the configuration because it is the default mode.
- The command `set hold-down-time <integer>` is an optional command that controls how long to wait before switching back to the primary interface in the event of a failover.

Load balancing strategy without SLA targets

The load balancing strategy known as maximize bandwidth (`load-balance`) prior FortiOS 7.4.1 is now configured within manual mode SD-WAN rules to achieve load balancing but without the need to configure SLA targets.

By enabling load balancing mode (`set load-balance enable`) inside the manual SD-WAN rule, SD-WAN will start to load balance traffic out of all the specified interfaces based on the configured load balancing algorithm. There is no explicit need to configure SLA targets to achieve load balancing. The load balancing algorithm, or hash method, can be one of the following:

`round-robin`	All traffic is distributed to selected interfaces in equal portions and circular order. This is the default method, and the only option available when using the GUI.
`source-ip-based`	All traffic from a source IP is sent to the same interface.
`source-dest-ip-based`	All traffic from a source IP to a destination IP is sent to the same interface.
`inbandwidth`	All traffic is distributed to a selected interface with most available bandwidth for incoming traffic.
`outbandwidth`	All traffic is distributed to a selected interface with most available bandwidth for outgoing traffic.
`bibandwidth`	All traffic is distributed to a selected interface with most available bandwidth for both incoming and outgoing traffic.

When the `inbandwidth`, `outbandwidth`, or `bibandwidth` load balancing algorithm is used, the FortiGate will compare the bandwidth based on the configured upstream and downstream bandwidth values.

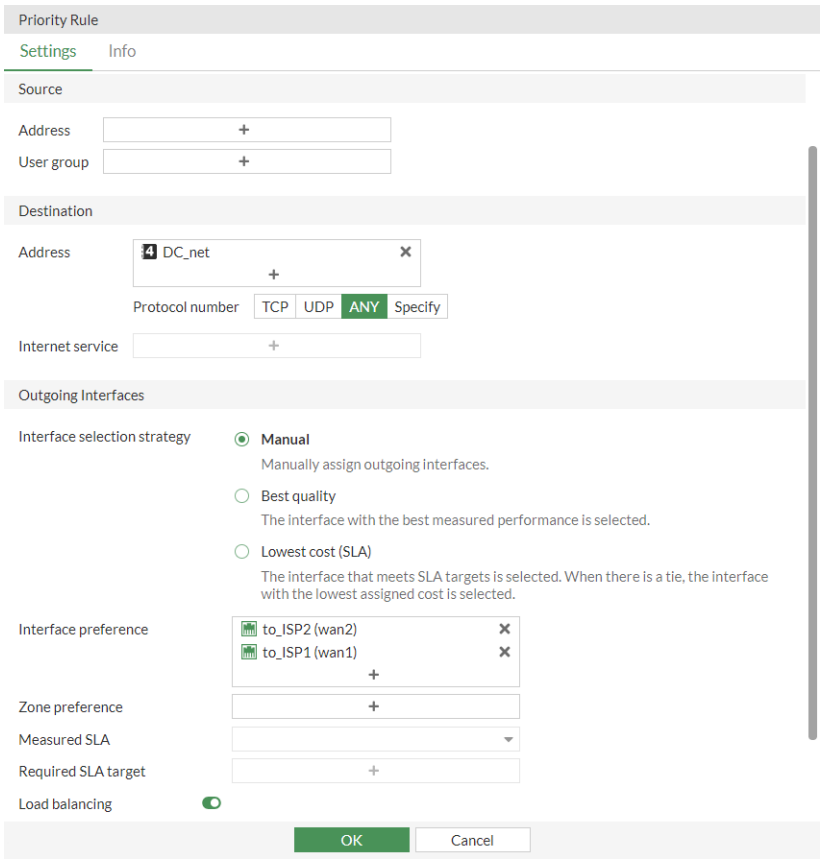
The interface speedtest can be used to populate the bandwidth values based on the speedtest results. See GUI speed test on page 1357 for details.

To manually configure the upstream and downstream bandwidth values:

```
config system interface
    edit <interface>
        set estimated-upstream-bandwidth <speed in kbps>
        set estimated-downstream-bandwidth <speed in kbps>
    next
end
```

To enable the load balancing strategy for manual mode in the GUI:

1. Go to *Network* > *SD-WAN*.
2. Select the *SD-WAN Rules* tab, and click *Create New*.
3. Set the *Interface selection strategy* to *Manual*.
4. Enable *Load balancing*.



5. Set the remaining options as desired, and click *OK* to create the rule.

To enable the load balancing strategy for manual mode in the CLI:

```
config system sdwan
    ...
    config service
        edit 1
            set name "manual"
            set mode manual
            set load-balance enable
            set hash-mode round-robin
            set priority-members 2 1
            set dst "DC_net"
            set hold-down-time 60
        next
    end
end
```

Best quality strategy

When using *Best Quality* mode, SD-WAN will choose the best link to forward traffic by comparing the *link-cost-factor*. A link-cost factor is a specific metric of participating link(s) (such as, latency, packet loss, and so on) evaluated against a target that you define (such as a health-check server), for example, the latency of WAN1 and WAN2 to your datacenter. Below is a list of link-cost factors available to you:

GUI	CLI	Description
Latency	`latency`	Select a link based on latency.
Jitter	`jitter`	Select a link based on jitter.
Packet Loss	`packet-loss`	Select a link based on packet loss.
Downstream	`inbandwidth`	Select a link based on available bandwidth of incoming traffic.
Upstream	`outbandwidth`	Select a link based on available bandwidth of outgoing traffic.
Bandwidth	`bibandwidth`	Select a link based on available bandwidth of bidirectional traffic.
Customized profile	`custom-profile-1`	Select link based on customized profile. If selected, set the following weights: • packet-loss-weight: Coefficient of packet-loss. • latency-weight: Coefficient of latency. • jitter-weight: Coefficient of jitter. • bandwidth-weight: Coefficient of reciprocal of available bidirectional bandwidth.

Although SD-WAN intelligence selects the best quality link according to the selected metric, by default a preference or advantage is given to the first configured SD-WAN member. This default is 10% and may be configured with the CLI command `set link-cost-threshold 10`.

Example of how `link-cost-threshold` works:

```
config system sdwan
    config members
        edit 1
            set interface "wan1"
        next
        edit 2
            set interface "wan2"
        next
    end
    config service
        edit 1
            set name "Best_Quality"
            set mode priority
            set priority-members 2 1
            set dst "DC_net"
            set health-check “DC_HealthCheck”
            set link-cost-factor latency
```

```
            set link-cost-threshold 10
        next
    end
end
```

In this example both WAN1 and WAN2 are assumed to have 200ms latency to the health-check server named `DC_HealthCheck`. Because WAN2 is specified before WAN1 in priority-members, SD-WAN parses the two interfaces metric as follows:

- WAN1: 200ms
- WAN2: 200ms / (1+10%) = ~182ms

As a result, WAN2 is selected because the latency is lower.

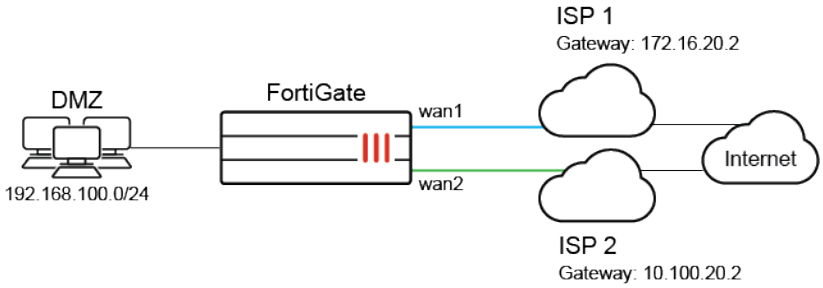
If the *Downstream* (`inbandwidth`), *Upstream* (`outbandwidth`), or *Bandwidth* (`bibandwidth`) quality criteria is used, the FortiGate uses the upstream and downstream bandwidth values configured on the member interfaces to calculate bandwidth.

The interface bandwidth configuration can be done manually, or the interface speedtest can be used to populate the bandwidth values based on the speedtest results. See GUI speed test on page 1357 for details.

To manually configure the upstream and downstream interface bandwidth values:

```
config system interface
    edit <interface>
        set estimated-upstream-bandwidth <speed in kbps>
        set estimated-downstream-bandwidth <speed in kbps>
    next
end
```

Example

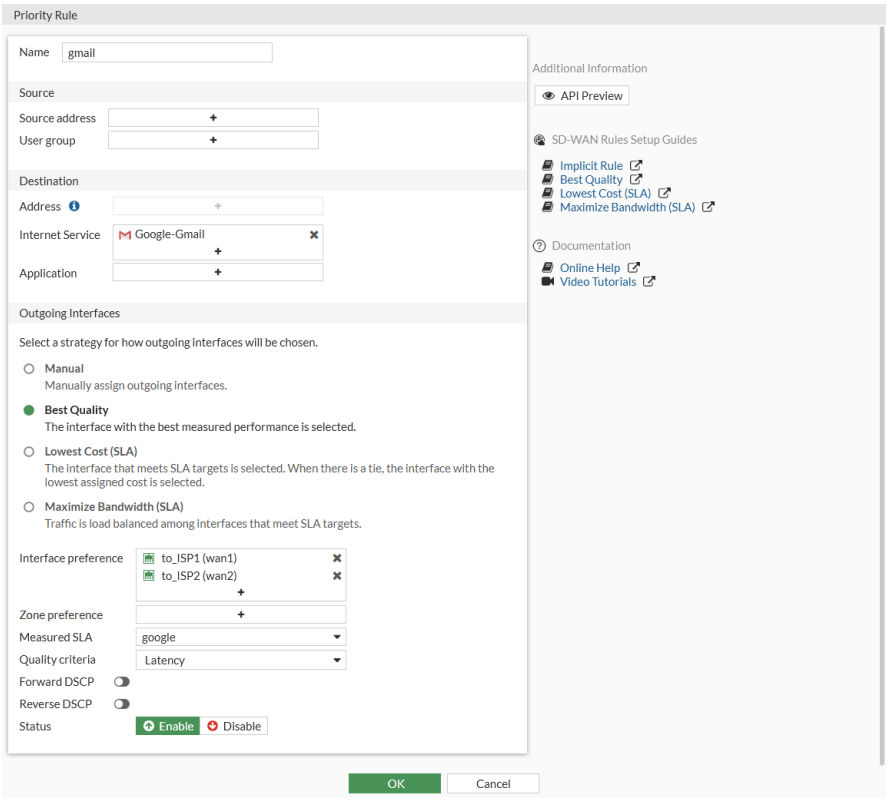


In this example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet, and you want Gmail services to use the link with the least latency.

To configure an SD-WAN rule to use Best Quality:

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 897 for more details.
2. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.

3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*. See Health checks for more details.
4. Click *OK*.
5. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
6. Enter a name for the rule, such as *gmail*.
7. Configure the following settings:



Internet Service	Google-Gmail
Strategy	Best Quality
Interface preference	wan1 and wan2
Measured SLA	google
Quality criteria	Latency

8. Click *OK*.

To configure an SD-WAN rule to use priority:

```
config system sdwan
    config health-check
        edit "google"
            set server "google.com"
            set members 1 2
```

```
        next
    end
    config service
        edit 1
            set name "gmail"
            set mode priority
            set internet-service enable
            set internet-service-id 65646
            set health-check "google"
            set link-cost-factor latency
            set priority-members 1 2
        next
    end
end
```

To diagnose the Performance SLA status:

```
FGT # diagnose sys sdwan health-check google
Health Check(google):
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0

FGT # diagnose sys sdwan service4 1
Service(1):

    TOS(0x0/0x0), protocol(0: 1->65535), Mode(priority), link-cost-facotr(latency), link-cost-
threshold(10), health-check(google) Members:

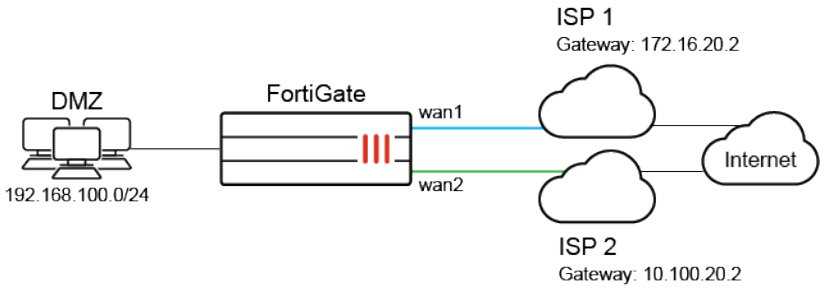
        1: Seq_num(2), alive, latency: 12.633, selected
        2: Seq_num(1), alive, latency: 14.563, selected

    Internet Service: Google-Gmail(65646)
```

As wan2 has a smaller latency, SD-WAN will put Seq_num(2) on top of Seq_num(1) and wan2 will be used to forward Gmail traffic.

Lowest cost (SLA) strategy

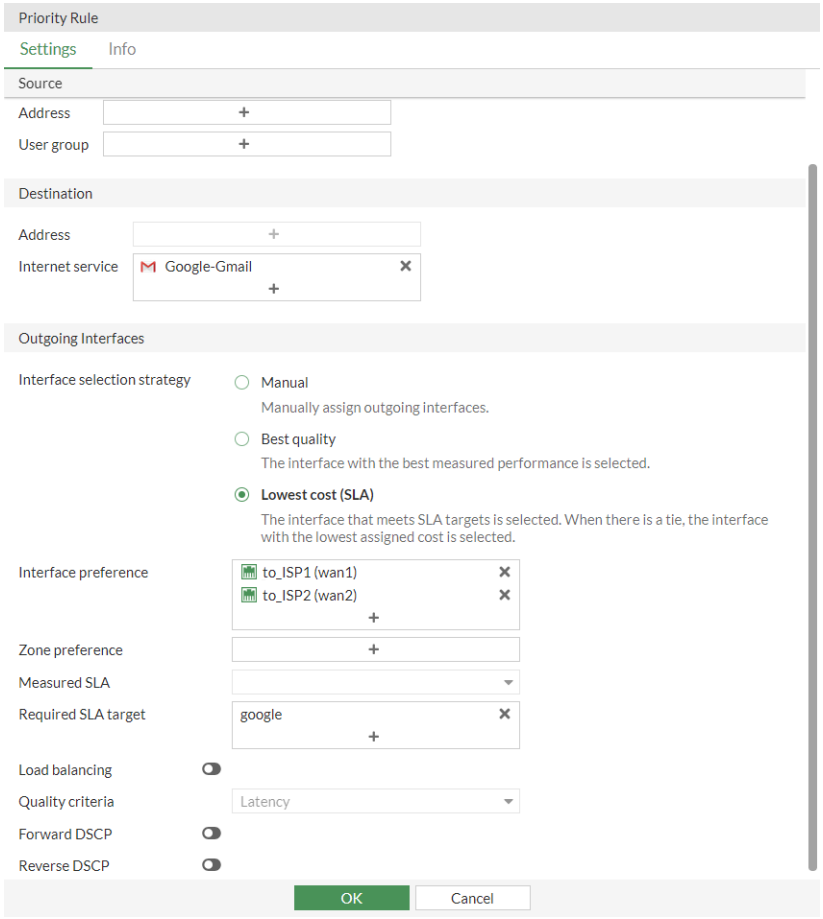
When using *Lowest Cost (SLA)* mode (`sla` in the CLI), SD-WAN will choose the lowest cost link that satisfies SLA to forward traffic. The lowest possible cost is `0`. If multiple eligible links have the same cost, the *Interface preference* order will be used to select a link.



In this example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet. The cost of wan2 is less than that of wan1. You want to configure Gmail services to use the lowest cost interface, but the link quality must meet a standard of latency: 10ms, and jitter: 5ms.

To configure an SD-WAN rule to use Lowest Cost (SLA):

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 897 for details.
2. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*.
4. Enable *SLA Target*. Set the *Latency threshold* to *10 ms*, and the *Jitter threshold* to *5 ms*. See Health checks for more details.
5. Click *OK*.
6. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
7. Enter a name for the rule, such as *gmail*.
8. Configure the following settings:



Internet Service	Google-Gmail
Strategy	Lowest Cost (SLA)

Interface preference	wan1 and wan2
Required SLA target	google

9. Click *OK*.

To configure an SD-WAN rule to use SLA:

```
config system sdwan
    config members
        edit 1
            set interface "wan1"
            set cost 10
        next
        edit 2
            set interface "wan2"
            set cost 5
        next
    end
    config health-check
        edit "google"
            set server "google.com"
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 10
                    set jitter-threshold 5
                next
            end
        next
    end
    config service
        edit 1
            set name "gmail"
            set mode sla
            set internet-service enable
            set internet-service-id 65646
            config sla
                edit "google"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

The CLI command `set minimum-sla-meet-members` allows you to specify the number of links that must meet SLA for the rule to take effect. If the number of members is less than the minimum set with this command, the rule will not take effect.

To diagnose the performance SLA status:

```
FGT # diagnose sys sdwan health-check status
Health Check(google):
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0

FGT # diagnose sys sdwan service4 1
Service(1): Address Mode(IPV4) flags=0x0

    TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla)
    Members:<<BR>>

        1: Seq_num(2), alive, sla(0x1), cfg_order(1), selected
        2: Seq_num(1), alive, sla(0x1), cfg_order(0), selected

    Internet Service: Google.Gmail(65646)
```

When both wan1 and wan2 meet the SLA requirements, Gmail traffic will only use wan2. If only wan1 meets the SLA requirements, Gmail traffic will only use wan1, even though it has a higher cost. If neither interface meets the requirements, wan2 will be used.

If both interface had the same cost and both met the SLA requirements, the first link configured in `set priority-members` would be used.

Load balancing strategy with SLA targets

SD-WAN rules can be configured to load balance traffic out of all the interfaces that satisfy the SLA target.

The load balancing strategy known as maximize bandwidth (`load-balance`) prior FortiOS 7.4.1 is now configured within *Lowest Cost (SLA)* mode (`sla`) SD-WAN rules.

By enabling load balancing mode (`set load-balance enable`) inside the lowest cost SD-WAN rule, SD-WAN will choose all of the links that satisfy the SLA target to forward traffic based on a load balancing algorithm. The load balancing algorithm, or hash method, can be one of the following:

`round-robin`	All traffic is distributed to selected interfaces in equal portions and circular order. This is the default method, and the only option available when using the GUI.
`source-ip-based`	All traffic from a source IP is sent to the same interface.
`source-dest-ip-based`	All traffic from a source IP to a destination IP is sent to the same interface.
`inbandwidth`	All traffic is distributed to a selected interface with most available bandwidth for incoming traffic.

`outbandwidth`	All traffic is distributed to a selected interface with most available bandwidth for outgoing traffic.
`bibandwidth`	All traffic is distributed to a selected interface with most available bandwidth for both incoming and outgoing traffic.

When the `inbandwidth`, `outbandwidth`, or `bibandwidth` load balancing algorithm is used, the FortiGate will compare the bandwidth based on the configured upstream and downstream bandwidth values.

The interface speedtest can be used to populate the bandwidth values based on the speedtest results. See GUI speed test on page 1357 for details.

To manually configure the upstream and downstream bandwidth values:

```
config system interface
    edit <interface>
        set estimated-upstream-bandwidth <speed in kbps>
        set estimated-downstream-bandwidth <speed in kbps>
    next
end
```

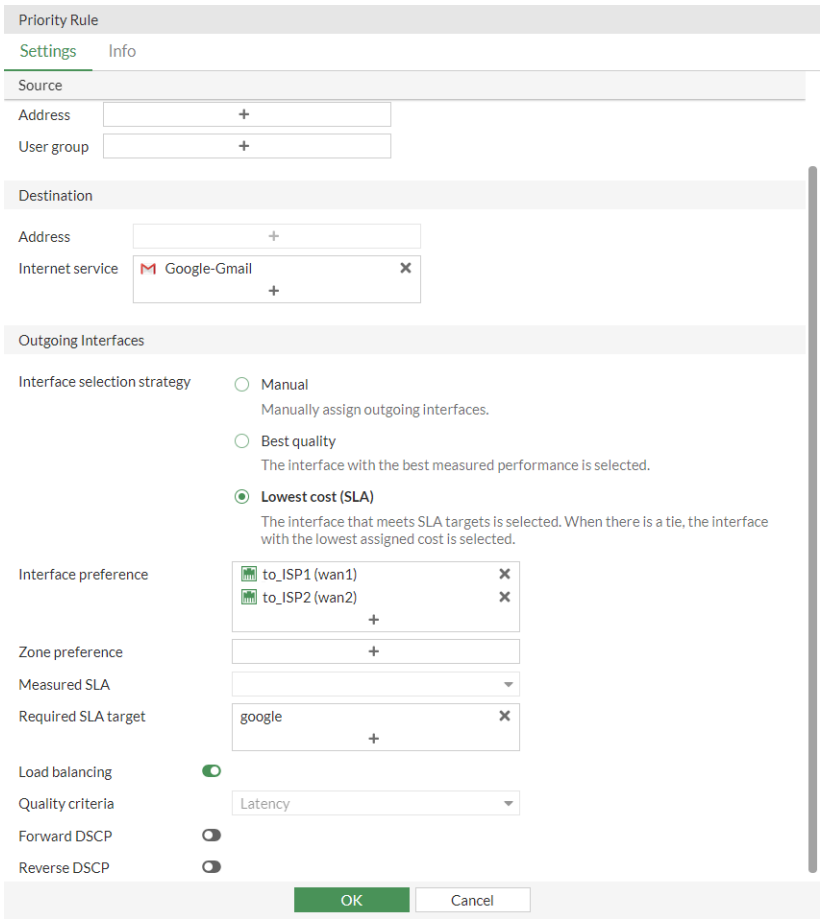
Example

Based on the same topology as the preceding example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet. You want to configure Gmail services to use both of the interface, but the link quality must meet a standard of latency: 10ms, and jitter: 5ms. This can maximize the bandwidth usage by using load balancing.

To configure an SD-WAN rule to use load balancing with SLA targets in the GUI:

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 897 for details.
2. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*.
4. Enable *SLA Target*. Set the *Latency threshold* to *10 ms*, and the *Jitter threshold* to *5 ms*. See Health checks for more details.
5. Click *OK*.
6. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
7. Enter a name for the rule, such as *gmail*.

8. Configure the following settings:



Internet Service	Google-Gmail
Strategy	Lowest Cost (SLA)
Interface preference	wan1 and wan2
Required SLA target	google
Load balancing	Enable this setting

9. Click *OK*.

To configure an SD-WAN rule to use load balancing with SLA targets in the CLI:

```
config system sdwan
   config members
        edit 1
            set interface "wan1"
            set cost 10
        next
        edit 2
```

```
            set interface "wan2"
            set cost 5
        next
    end
    config health-check
        edit "google"
            set server "google.com"
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 10
                    set jitter-threshold 5
                next
            end
        next
    end
   config service
        edit 1
            set name "gmail"
            set load-balance enable
            set mode sla
            set internet-service enable
            set internet-service-name "Google-Gmail"
            config sla
                edit "google"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

To diagnose the performance SLA status:

```
FGT # diagnose sys sdwan health-check status
Health Check(google):
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0

FGT # diagnose sys sdwan service4 1
Service(1): Address Mode(IPV4) flags=0x0

    TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance)
    Members:<<BR>>

        1: Seq_num(1), alive, sla(0x1), num of pass(1), selected
        2: Seq_num(2), alive, sla(0x1), num of pass(1), selected

    Internet Service: Google.Gmail(65646)
```

When both wan1 and wan2 meet the SLA requirements, Gmail traffic will use both wan1 and wan2. If only one of the interfaces meets the SLA requirements, Gmail traffic will only use that interface.

If neither interface meets the requirements but the `health-check` is still alive, then wan1 and wan2 tie. The traffic will try to balance between wan1 and wan2, using both interfaces to forward traffic.

The maximize bandwidth (`load-balance`) strategy used prior to FortiOS 7.4.1 is now known as the load balancing strategy. This strategy can be configured under the manual mode and the lowest cost (SLA) strategies.

- When the load balancing strategy is configured under the manual mode strategy, SLA targets are not used.
- When the load balancing strategy is configured under the lowest cost (SLA) strategy, SLA targets are used.

  The load balancing strategy functionality remains the same as the maximum bandwidth (SLA) strategy when it is configured inside the lowest cost (SLA) strategy: load balance traffic out of all the interfaces that satisfy the SLA targets. Interface cost is not considered when selecting the best path when the load balancing strategy is used.

Load balancing strategy

The maximize bandwidth (`load-balance`) strategy used prior to FortiOS 7.4.1 is now known as the load balancing strategy. This strategy can be configured under the manual mode and the lowest cost (SLA) strategies.

- When the load balancing strategy is configured under the manual mode strategy, SLA targets are not used (see Load balancing strategy without SLA targets for an example configuration).
- When the load balancing strategy is configured under the lowest cost (SLA) strategy, SLA targets are used (see Load balancing strategy with SLA targets for an example configuration).

The load balancing strategy functionality remains the same as the maximum bandwidth (SLA) strategy when it is configured inside the lowest cost (SLA) strategy: load balance traffic out of all the interfaces that satisfy the SLA targets. Interface cost is not considered when selecting the best path when the load balancing strategy is used.

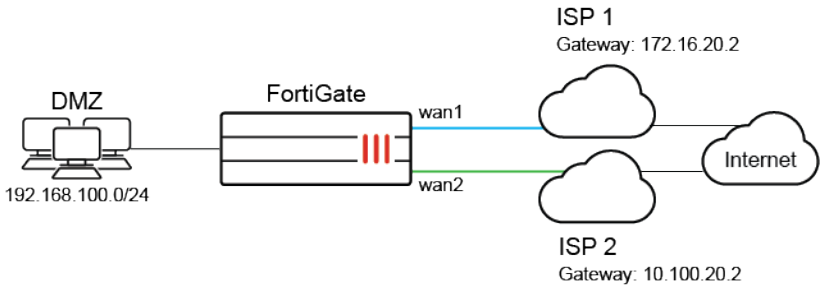
SD-WAN traffic shaping and QoS

Use a traffic shaper in a firewall shaping policy to control traffic flow. You can use it to control maximum and guaranteed bandwidth, or put certain traffic to one of the three different traffic priorities: high, medium, or low.

An advanced shaping policy can classify traffic into 30 groups. Use a shaping profile to define the percentage of the interface bandwidth that is allocated to each group. Each group of traffic is shaped to the assigned speed limit based on the outgoing bandwidth limit configured on the interface.

For more information, see Traffic shaping on page 1798.

Sample topology



Sample configuration

This example shows a typical customer usage where the customer's SD-WAN uses the default zone, and has two member: wan1 and wan2, each set to 10Mb/s.

An overview of the procedures to configure SD-WAN traffic shaping and QoS with SD-WAN includes:

1. Give HTTP/HTTPS traffic high priority and give FTP low priority so that if there are conflicts, FortiGate will forward HTTP/HTTPS traffic first.
2. Even though FTP has low priority, configure FortiGate to give it a 1Mb/s guaranteed bandwidth on each SD-WAN member so that if there is no FTP traffic, other traffic can use all the bandwidth. If there is heavy FTP traffic, it can still be guaranteed a 1Mb/s bandwidth.
3. Traffic going to specific destinations such as a VOIP server uses wan1 to forward, and SD-WAN forwards with an Expedited Forwarding (EF) DSCP tag 101110.

To configure SD-WAN traffic shaping and QoS with SD-WAN in the GUI:

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See SD-WAN quick start on page 897.
2. Add a firewall policy with *Application Control* enabled. See Configuring firewall policies for SD-WAN on page 900.
3. Go to *Policy & Objects* > *Traffic Shaping*, select the *Traffic Shaper* tab, and edit *low-priority*.
   a. Enable *Guaranteed Bandwidth* and set it to *1000* kbps.
4. Go to *Policy & Objects* > *Traffic Shaping*, select the *Traffic Shaping Policy* tab, and click *Create New*.
   a. Name the traffic shaping policy, for example, *HTTP-HTTPS*.
   b. Set the following:

Source	*all*
Destination	*all*
Service	*HTTP* and *HTTPS*
Outgoing interface	*virtual-wan-link*
Shared Shaper	Enable and set to *high-priority*
Reverse Shaper	Enable and set to *high-priority*

   c. Click *OK*.

5. Go to *Policy & Objects* > *Traffic Shaping*, select the *Traffic Shaping Policy* tab, and click *Create New*.
   a. Name the traffic shaping policy, for example, *FTP*.
   b. Set the following:

Source	*all*
Destination	*all*
Service	*FTP*, *FTP_GET*, and *FTP_PUT*
Outgoing interface	*virtual-wan-link*
Shared Shaper	Enable and set to *low-priority*
Reverse Shaper	Enable and set to *low-priority*

   c. Click *OK*
6. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
   a. Enter a name for the rule, such as *Internet*.
   b. In the *Destination* section, click *Address* and select the VoIP server that you created in the firewall address.
   c. Under *Outgoing Interfaces* select *Manual*.
   d. For *Interface preference* select *wan1*.
   e. Click *OK*.
7. Use CLI commands to modify DSCP settings. See the DSCP CLI commands below.

To configure the firewall policy using the CLI:

```
config firewall policy
    edit 1
        set name "1"
        set srcintf "dmz"
        set dstintf "virtual-wan-link"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "default"
        set nat enable
    next
end
```

To configure the firewall traffic shaper priority using the CLI:

```
config firewall shaper traffic-shaper
    edit "high-priority"
        set maximum-bandwidth 1048576
        set per-policy enable
```

```
    next
    edit "low-priority"
        set guaranteed-bandwidth 1000
        set maximum-bandwidth 1048576
        set priority low
        set per-policy enable
    next
end
```

To configure the firewall traffic shaping policy using the CLI:

```
config firewall shaping-policy
    edit 1
        set name "http-https"
        set service "HTTP" "HTTPS"
        set dstintf "virtual-wan-link"
        set traffic-shaper "high-priority"
        set traffic-shaper-reverse "high-priority"
        set srcaddr "all"
        set dstaddr "all"
    next
    edit 2
        set name "FTP"
        set service "FTP" "FTP_GET" "FTP_PUT"
        set dstintf "virtual-wan-link"
        set traffic-shaper "low-priority"
        set traffic-shaper-reverse "low-priority"
        set srcaddr "all"
        set dstaddr "all"
    next
end
```

To configure SD-WAN traffic shaping and QoS with SD-WAN in the CLI:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "wan1"
            set gateway 172.16.20.2
        next
        edit 2
            set interface "wan2"
            set gateway 10.100.20.2
        next
    end
    config service
        edit 1
            set name "SIP"
            set priority-members 1
            set dst "voip-server"
```

```
            set dscp-forward enable
            set dscp-forward-tag 101110
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To use the diagnose command to check if specific traffic is attached to the correct traffic shaper:

```
# diagnose firewall iprope list 100015

policy index=1 uuid_idx=0 action=accept
flag (0):
shapers: orig=high-priority(2/0/134217728) reply=high-priority(2/0/134217728)
cos_fwd=0  cos_rev=0
group=00100015 av=00000000 au=00000000 split=00000000
host=0 chk_client_info=0x0 app_list=0 ips_view=0
misc=0 dd_type=0 dd_mode=0
zone(1): 0 -> zone(2): 36 38
source(1): 0.0.0.0-255.255.255.255, uuid_idx=6,
dest(1): 0.0.0.0-255.255.255.255, uuid_idx=6,
service(2):
        [6:0x0:0/(1,65535)->(80,80)] helper:auto
        [6:0x0:0/(1,65535)->(443,443)] helper:auto

policy index=2 uuid_idx=0 action=accept
flag (0):
shapers: orig=low-priority(4/128000/134217728) reply=low-priority(4/128000/134217728)
cos_fwd=0  cos_rev=0
group=00100015 av=00000000 au=00000000 split=00000000
host=0 chk_client_info=0x0 app_list=0 ips_view=0
misc=0 dd_type=0 dd_mode=0
zone(1): 0 -> zone(2): 36 38
source(1): 0.0.0.0-255.255.255.255, uuid_idx=6,
dest(1): 0.0.0.0-255.255.255.255, uuid_idx=6,
service(3):
        [6:0x0:0/(1,65535)->(21,21)] helper:auto
        [6:0x0:0/(1,65535)->(21,21)] helper:auto
        [6:0x0:0/(1,65535)->(21,21)] helper:auto
```

To use the diagnose command to check if the correct traffic shaper is applied to the session:

```
# diagnose sys session list
session info: proto=6 proto_state=01 duration=11 expire=3599 timeout=3600 flags=00000000
sockflag=00000000 sockport=0 av_idx=0 use=5
origin-shaper=low-priority prio=4 guarantee 128000Bps max 1280000Bps traffic 1050Bps drops 0B
reply-shaper=
```

```
per_ip_shaper=
class_id=0 shaping_policy_id=2 ha_id=0 policy_dir=0 tunnel=/ helper=ftp vlan_cos=0/255
state=may_dirty npu npd os mif route_preserve
statistic(bytes/packets/allow_err): org=868/15/1 reply=752/10/1 tuples=2

current-bandwidth 0 B/sec
priority 2
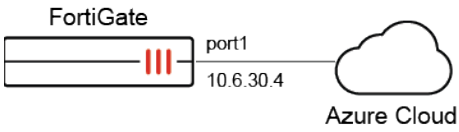
policy 1
tos ff
packets dropped 0
bytes dropped 0
```

```
name low-priority
maximum-bandwidth 131072 KB/sec
guaranteed-bandwidth 125 KB/sec
current-bandwidth 0 B/sec
priority 4
policy 2
tos ff
packets dropped 0
bytes dropped 0
```

SDN dynamic connector addresses in SD-WAN rules

SDN dynamic connector addresses can be used in SD-WAN rules. FortiGate supports both public (AWS, Azure, GCP, OCI, AliCloud) and private (Kubernetes, VMware ESXi and NSX, OpenStack, ACI, Nuage) SDN connectors.

The configuration procedure for all of the supported SDN connector types is the same. This example uses an Azure public SDN connector.



There are four steps to create and use an SDN connector address in an SD-WAN rule:

1. Configure the FortiGate IP address and network gateway so that it can reach the Internet.
2. Create an Azure SDN connector.
3. Create a firewall address to associate with the configured SDN connector.
4. Use the firewall address in an SD-WAN service rule.

To create an Azure SDN connector:

1. Go to *Security Fabric > External Connectors*.
2. Click *Create New*.
3. In the *Public SDN* section, click *Microsoft Azure*.
4. Enter the following:

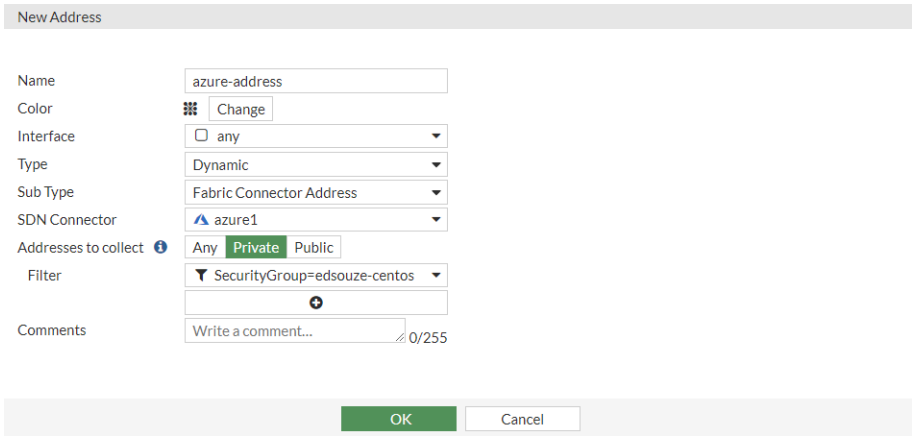
Name	azure1
Status	Enabled
Update Interval	Use Default
Server region	Global
Directory ID	942b80cd-1b14-42a1-8dcf-4b21dece61ba
Application ID	14dbd5c5-307e-4ea4-8133-68738141feb1
Client secret	xxxxxx
Resource path	disabled

5. Click *OK*.

To create a firewall address to associate with the configured SDN connector:

1. Go to *Policy & Objects* > *Addresses* and select *Address*.
2. Click *Create new*.
3. Enter the following:

Name	azure-address
Type	Dynamic
Sub Type	Fabric Connector Address
SDN Connector	azure1
Addresses to collect	Private
Filter	SecurityGroup=edsouza-centos
Interface	Any



4. Click *OK*.

To use the firewall address in an SD-WAN service rule:

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Set the *Name* to *Azure1*.
3. For the *Destination Address* select *azure-address*.
4. Configure the remaining settings as needed. See SD-WAN rules on page 1017 for details.
5. Click *OK*.

Diagnostics

Use the following CLI commands to check the status of and troubleshoot the connector.

To see the status of the SDN connector:

```
# diagnose sys sdn status
SDN Connector          Type        Status          Updating        Last update
-------------------------------------------------------------------------------
azure1                 azure       connected       no              n/a
```

To debug the SDN connector to resolve the firewall address:

```
# diagnose debug application azd -1
    Debug messages will be on for 30 minutes.

    ...
    azd sdn connector azure1 start updating IP addresses
    azd checking firewall address object azure-address-1, vd 0
     IP address change, new list:
      10.18.0.4
      10.18.0.12
      ...
      ...
```

```
# diagnose sys sdwan service4

    Service(2): Address Mode(IPV4) flags=0x0
      TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
      Service role: standalone
      Member sub interface:
      Members:
        1: Seq_num(1), alive, selected
      Dst address:
            10.18.0.4 - 10.18.0.4
            10.18.0.12 - 10.18.0.12
             ... ...
             ... ...
             ... ...
```

Application steering using SD-WAN rules

This topic covers how to use application steering in a topology with multiple WAN links. The following examples illustrate how to use different strategies to perform application steering to accommodate different business needs:

- Application matching on page 1054
- Static application steering with a manual strategy on page 1055
- Dynamic application steering with lowest cost and best quality strategies on page 1057

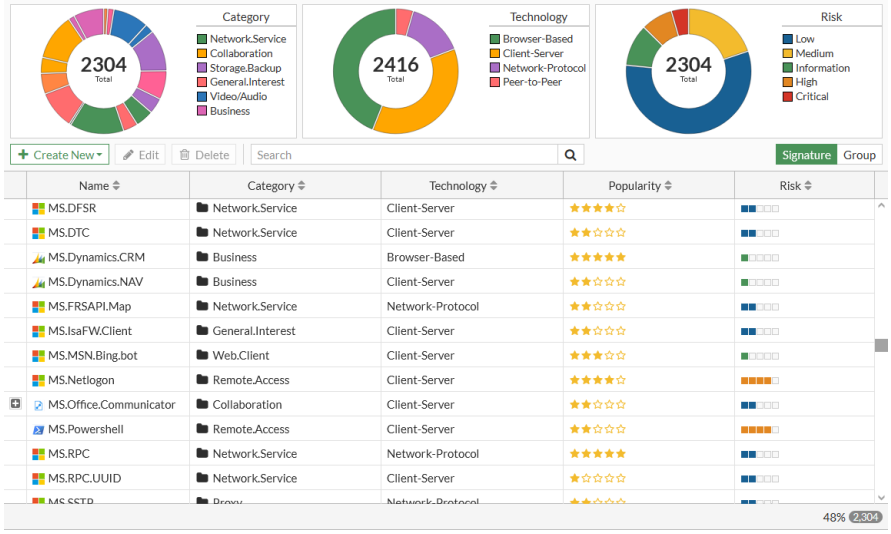
By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System > Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
    set gui-app-detection-sdwan enable
end
```

For application based steering to work, application control must be enabled in a policy. See Application control on page 2077.

Application matching

To apply application steering, SD-WAN service rules match traffic based on the applications that are in the application signature database. To view the signatures, go to *Security Profiles* > *Application Signatures* and select *Signature*.



On the first session that passes through, the IPS engine processes the traffic in the application layer to match it to a signature in the application signature database. The first session does not match any SD-WAN rules because the signature has not been recognized yet. When the IPS engine recognizes the application, it records the 3-tuple IP address, protocol, and port in the application control Internet Service ID list. To view the application and corresponding 3-tuple:

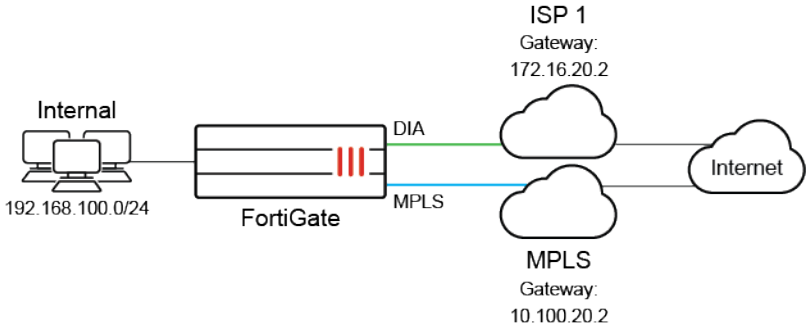
```
# diagnose sys sdwan internet-service-app-ctrl-list [app ID]
52.114.142.254
Microsoft.Teams(43541 4294837333): 52.114.142.254 6 443 Fri Jun 18 13:52:18 2021
```

The recognized application and 3-tuple stay in the application control list for future matches to occur. If there are no hits on the entry for eight hours, the entry is deleted.

For services with multiple IP addresses, traffic might not match the expected SD-WAN rule because the traffic is destined for an IP address that hat no previously been recognized by the FortiGate. The `diagnose sys sdwan internet-service-app-ctrl-list` command can be used to help troubleshoot such situations.

Static application steering with a manual strategy

This example covers a typical usage scenario where the SD-WAN has two members: MPLS and DIA. DIA is primarily used for direct internet access to internet applications, such as Office365, Google applications, Amazon, and Dropbox. MPLS is primarily used for SIP, and works as a backup when DIA is not working.



This example configures all SIP traffic to use MPLS while all other traffic uses DIA. If DIA is not working, the traffic will use MPLS.

By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System > Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
    set gui-app-detection-sdwan enable
end
```

To configure an SD-WAN rule to use SIP and DIA in the GUI:

1. Add port1 (DIA) and port2 (MPLS) as SD-WAN members, and configure a static route. See Configuring the SD-WAN interface on page 898 for details.
2. Create a firewall policy with an *Application Control* profile configured. See Configuring firewall policies for SD-WAN on page 900 for details.
3. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
4. Enter a name for the rule, such as *SIP*.
5. Click the *Application* field and select the applicable SIP applications from the *Select Entries* panel.
6. Under *Outgoing Interfaces*, select *Manual*.
7. For *Interface preference*, select *MPLS*.
8. Click *OK*.
9. Click *Create New* to create another rule.
10. Enter a name for the rule, such as *Internet*.
11. Click the *Address* field and select *all* from the panel.
12. Under *Outgoing Interfaces*, select *Manual*.
13. For *Interface preference*, select *DIA*.
14. Click *OK*.

To configure the firewall policy using the CLI:

```
config firewall policy
    edit 1
        set name "1"
        set srcintf "dmz"
        set dstintf "virtual-wan-link"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set fsso disable
        set application-list "default"
        set ssl-ssh-profile "certificate-inspection"
        set nat enable
    next
end
```

To configure an SD-WAN rule to use SIP and DIA using the CLI:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "MPLS"
        next
        edit 2
            set interface "DIA"
        next
    end
    config service
        edit 1
            set name "SIP"
            set internet-service enable
            set internet-service-app-ctrl 34640 152305677 38938 26180 26179 30251
            set priority-members 2
        next
        edit 2
            set name "Internet"
            set dst "all"
            set priority-members 1
        next
    end
end
```

All SIP traffic uses MPLS. All other traffic goes to DIA. If DIA is broken, the traffic uses MPLS. If you use VPN instead of MPLS to run SIP traffic, you must configure a VPN interface, for example vpn1, and then replace member 1 from MPLS to vpn1 for SD-WAN member.

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To use the diagnose command to check performance SLA status using the CLI:

```
# diagnose sys sdwan service4 1

Service(1): Address Mode(IPV4) flags=0x0

TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members:<<BR>>

1: Seq_num(1), alive, selected

Internet Service: SIP(4294836224 34640) SIP.Method(4294836225 152305677) SIP.Via.NAT(4294836226
38938) SIP_Media.Type.Application(4294836227 26180) SIP_Message(4294836228 26179) SIP_Voice
(4294836229 30251)
```

```
# diagnose sys sdwan service4 2

Service(2): Address Mode(IPV4) flags=0x0

TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members:<<BR>>

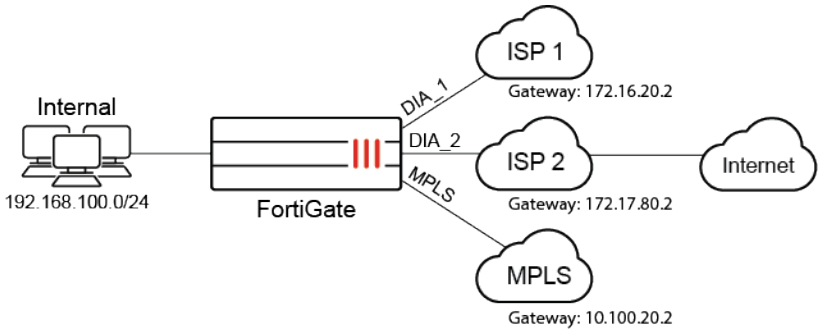
1: Seq_num(2), alive, selected

Dst address: 0.0.0.0-255.255.255.255
```

```
# diagnose sys sdwan internet-service-app-ctrl-list
Ctrl application(SIP 34640):Internet Service ID(4294836224)
Ctrl application(SIP.Method 152305677):Internet Service ID(4294836225)
Ctrl application(SIP.Via.NAT 38938):Internet Service ID(4294836226)
Ctrl application(SIP_Media.Type.Application 26180):Internet Service ID(4294836227)
Ctrl application(SIP_Message 26179):Internet Service ID(4294836228)
Ctrl application(SIP_Voice 30251):Internet Service ID(4294836229)
```

Dynamic application steering with lowest cost and best quality strategies

In this example, the SD-WAN has three members: two ISPs (DIA_1 and DIA_2) that are used for access to internet applications, and an MPLS link that is used exclusively as a backup for business critical applications.



Business applications, such as Office365, Google, Dropbox, and SIP, use the *Lowest Cost (SLA)* strategy to provide application steering, and traffic falls back to MPLS only if both ISP1 and ISP2 are down. Non-business applications, such as Facebook and Youtube, use the *Best Quality* strategy to choose between the ISPs.

By default, individual applications and application groups cannot be selected in SD-WAN rules. To enable this functionality in the GUI, go to *System > Feature Visibility* and enable *Application Detection Based SD-WAN*. In the CLI, enter:

```
config system global
    set gui-app-detection-sdwan enable
end
```

To configure the SD-WAN members, static route, and firewall policy in the GUI:

1. Add port1 (DIA_1), port2 (DIA_2), and port3 (MPLS) as SD-WAN members. Set the cost of DIA_1 and DIA_2 to *0*, and MPLS to *20*. See Configuring the SD-WAN interface on page 898 for details.
2. Configure a static route. See Adding a static route on page 899 for details.
3. Create a firewall policy to allow traffic out on SD-WAN, with an *Application Control* profile configured. See Configuring firewall policies for SD-WAN on page 900 for details.

To configure the SD-WAN rule and performance SLA checks for business critical application in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Set the name to *BusinessCriticalApps*.

   This rule will steer your business critical traffic to the appropriate link based on the *Lowest Cost (SLA)*.
3. Set *Source address* to *all*.
4. Under *Destination*, set *Application* to your required applications. In this example: *Microsoft.Office.365*, *Microsoft.Office.Online*, *Google.Docs*, *Dropbox*, and *SIP*.
5. Under *Outgoing Interfaces*, select *Lowest Cost (SLA)*.

   The lowest cost is defined in the SD-WAN member interface settings (see Configuring the SD-WAN interface on page 898). The lowest possible cost is *0*, which represents the most preferred link. In this example, DIA_1 and DIA_2 both have a cost of *0*, while MPLS has a cost of *20* because it is used for backup.
6. In *Interface preference*, add the interfaces in order of preference when the cost of the links is tied. In this example, DIA_1, DIA_2, then MPLS.

   MPLS will always be chosen last, because it has the highest cost. DIA_1 and DIA_2 have the same cost, so an interface is selected based on their order in the *Interface preference* list.
7. Set *Required SLA target* to ensure that only links that pass your SLA target are chosen in this SD-WAN rule:

a. Click in the *Required SLA target* field.

b. In the *Select Entries* pane, click *Create*. The *New Performace SLA* pane opens.

c. Set *Name* to *BusinessCriticalApps_HC*.

This health check is used for business critical applications in your SD-WAN rule.

d. Leave *Protocol* set to *Ping*, and add up to two servers, such as *office.com* and *google.com*.

e. Set *Participants* to *Specify*, and add all three interfaces: DIA_1, DIA_2, and MPLS.

f. Enable *SLA Target*.

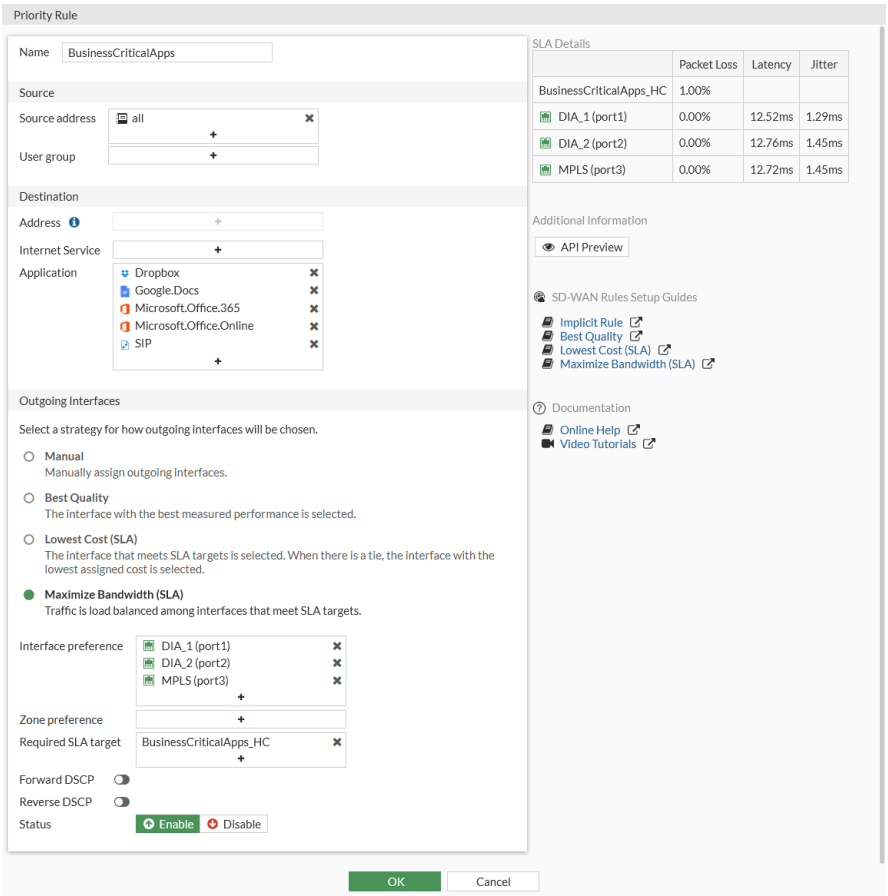
The attributes in your target determine the quality of your link. The SLA target of each link is compared when determining which link to use based on the lowest cost. Links that meet the SLA target are preferred over links that fail, and move to the next step of selection based on cost. If no links meet the SLA target, then they all move to the next step.

In this example, disable *Latency threshold* and *Jitter threshold*, and set *Packet loss threshold* to *1*.

g. Click *OK*.

h. Select the new performance SLA to set it as the *Required SLA target*.

When multiple SLA targets are added, you can choose which target to use in the SD-WAN rule.



8. Click *OK* to create the SD-WAN rule.

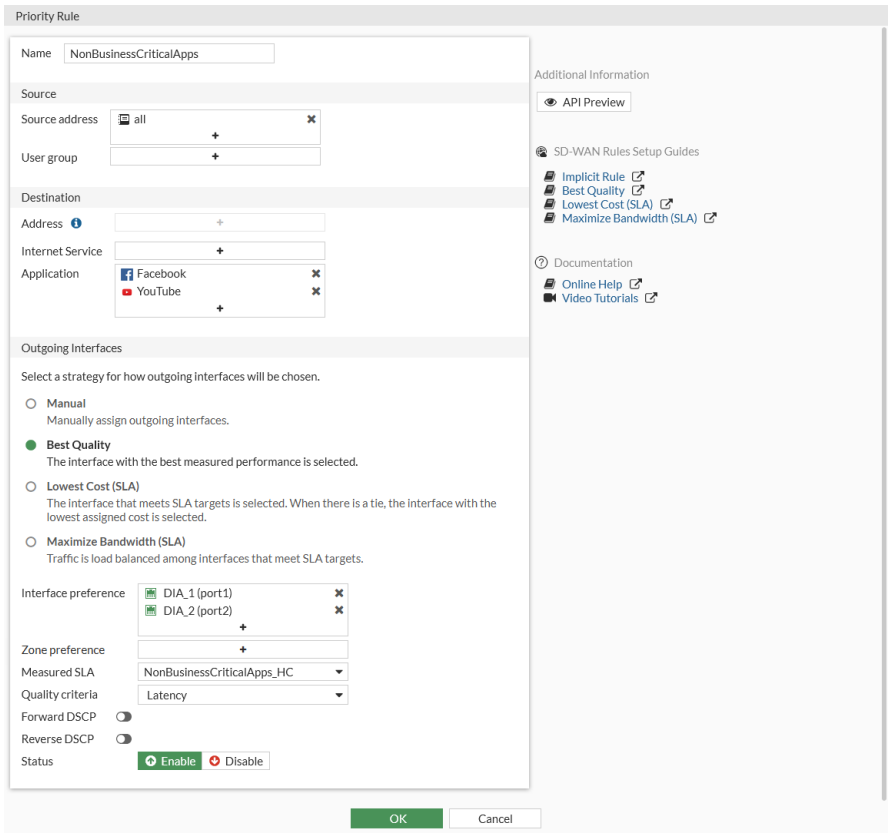
To configure the SD-WAN rule and performance SLA checks for non-business critical application in the GUI:

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Set the name to *NonBusinessCriticalApps*.
   This rule will steer your non-business critical traffic to the appropriate link based on the *Best Quality*. No SLA target must be met, as the best link is selected based on the configured quality criteria and interface preference order.
3. Set *Source address* to *all*.
4. Under *Destination*, set *Application* to your required applications. In this example: *Facebook*, and *Youtube*.
5. Under *Outgoing Interfaces*, select *Best Quality*.
6. In *Interface preference*, add the interfaces in order of preference.
   By default, a more preferred link has an advantage of 10% over a less preferred link. For example, when latency is used, the preferred link's calculated latency = real latency / (1+10%).

The preferred link advantage can be customized in the CLI when the mode is `priority` (*Best Quality*) or `auto`:

```
config system sdwan
    config service
        edit <id>
            set link-cost-threshold <integer>
        next
    end
end
```

7. Create and apply a new performance SLA profile:
   a. Click in the *Measured SLA* field.
   b. In the drop-down list, click *Create*. The *New Performace SLA* pane opens.
   c. Set *Name* to *NonBusinessCritical_HC*.
      This health check is used for non-business critical applications in your SD-WAN rule.
   d. Leave *Protocol* set to *Ping*, and add up to two servers, such as *youtube.com* and *facebook.com*.
   e. Set *Participants* to *Specify*, and add the DIA_1 and DIA_2 interfaces. In this example, MPLS is not used for non-business critical applications.
   f. Leave *SLA Target* disabled.
   g. Click *OK*.
   h. Select the new performance SLA from the list to set it as the *Measured SLA*.
8. Set *Quality criteria* as required. In this example, *Latency* is selected.
   For bandwidth related criteria, such as *Downstream*, *Upstream*, and *Bandwidth* (bi-directional), the selection is based on available bandwidth. An estimated bandwidth should be configured on the interface to provide a baseline, maximum available bandwidth.



9. Click *OK* to create the SD-WAN rule.

To configure the SD-WAN members, static route, and firewall policy in the CLI:

1. Configure the interfaces:

```
config system interface
    edit "port1"
        set ip <class_ip&net_netmask>
        set alias "DIA_1"
        set role wan
    next
    edit "port2"
        set ip <class_ip&net_netmask>
        set alias "DIA_2"
        set role wan
    next
    edit "port3"
        set ip <class_ip&net_netmask>
        set alias "MPLS"
        set role wan
    next
end
```

2. Configure the SD-WAN members:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "port1"
            set gateway 172.16.20.2
        next
        edit 2
            set interface "port2"
            set gateway 172.17.80.2
        next
        edit 3
            set interface "port3"
            set gateway 10.100.20.2
            set cost 20
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

3. Configure a static route. See Adding a static route on page 899 for details.
4. Create a firewall policy to allow traffic out on SD-WAN, with an *Application Control* profile configured. See Configuring firewall policies for SD-WAN on page 900 for details.

To configure the SD-WAN rule and performance SLA checks for business critical application in the CLI:

1. Configure the *BusinessCriticalApps_HC* health-check:

```
config system sdwan
    config health-check
        edit "BusinessCriticalApps_HC"
            set server "office.com" "google.com"
            set members 1 2 3
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 1
                next
            end
        next
    end
end
```

2. Configure the *BusinessCriticalApps* service to use *Lowest Cost (SLA)*:

```
config system sdwan
    config service
```

```
        edit 1
            set name "BusinessCriticalApps"
            set mode sla
            set src "all"
            set internet-service enable
            set internet-service-app-ctrl 17459 16541 33182 16177 34640
            config sla
                edit "BusinessCriticalApps_HC"
                    set id 1
                next
            end
            set priority-members 1 2 3
        next
    end
end
```

To configure the SD-WAN rule and performance SLA checks for non-business critical application in the CLI:

1. Configure the *nonBusinessCriticalApps_HC* health-check:

```
config system sdwan
    config health-check
        edit "NonBusinessCriticalApps_HC"
            set server "youtube.com" "facebook.com"
            set members 1 2
        next
    end
end
```

2. Configure the *NonBusinessCriticalApps* service to use *Lowest Cost (SLA)*:

```
config system sdwan
    config service
        edit 4
            set name "NonBusinessCriticalApps"
            set mode priority
            set src "all"
            set internet-service enable
            set internet-service-app-ctrl 15832 31077
            set health-check "NonBusinessCriticalApps_HC"
            set priority-members 1 2
        next
    end
end
```

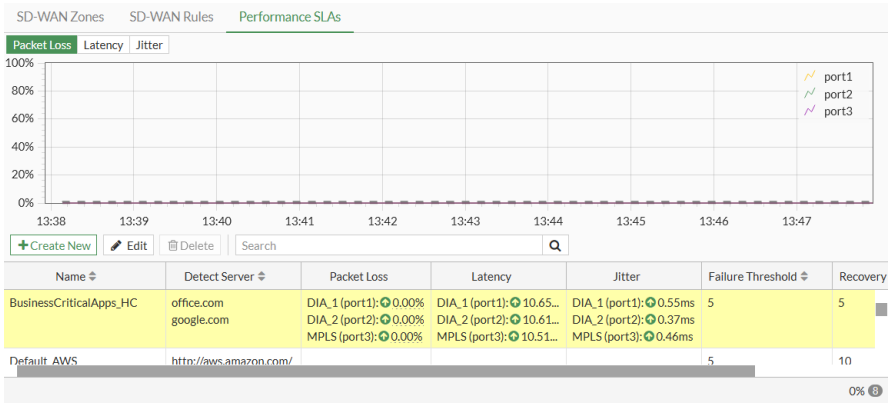
Verification

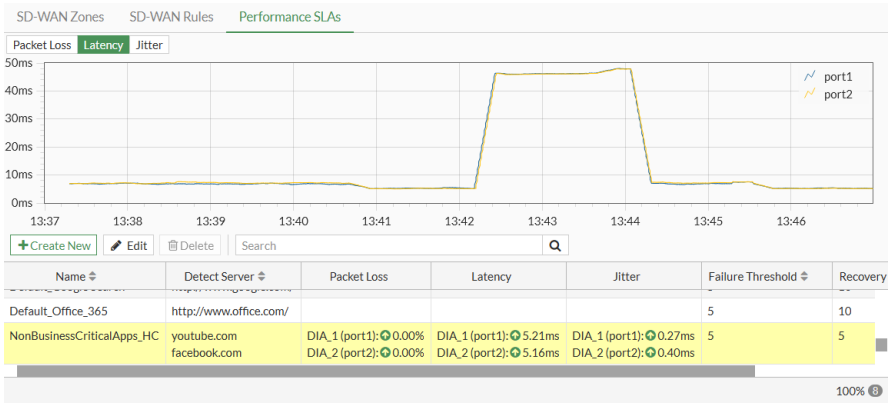
Check the following GUI pages, and run the following CLI commands to confirm that your traffic is being steered by the SD-WAN rules.

Health checks

To verify the status of each of the health checks in the GUI:

1. Go to *Network* > *SD-WAN*, select the *Performance SLAs* tab, and select each of the health checks from the list.





To verify the status of each of the health checks in the CLI:

```
# diagnose sys sdwan health-check
Health Check(BusinessCritical_HC):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(12.884), jitter(0.919) sla_map=0x1
Seq(2 port2): state(alive), packet-loss(0.000%) latency(13.018), jitter(0.723) sla_map=0x1
Seq(3 port3): state(alive), packet-loss(0.000%) latency(13.018), jitter(0.923) sla_map=0x1
Health Check(NonBusinessCritical_HC):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(6.888), jitter(0.953) sla_map=0x0
Seq(2 port2): state(alive), packet-loss(0.000%) latency(6.805), jitter(0.830) sla_map=0x0
```

Rule members and hit count

To verify the active members and hit count of the SD-WAN rule in the GUI:

1. Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab.

   The interface that is currently selected by the rule has a checkmark next to its name in the *Members* column. Hover the cursor over the checkmark to open a tooltip that gives the reason why that member is selected. If multiple members are selected, only the highest ranked member is highlighted (unless the mode is *Maximize Bandwidth (SLA)*).

To verify the active members and hit count of the SD-WAN rule in the CLI:

```
# diagnose sys sdwan service4

Service(3): Address Mode(IPV4) flags=0x0
  Gen(13), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members:
    1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
    2: Seq_num(2 port2), alive, sla(0x1), cfg_order(1), cost(0), selected
    3: Seq_num(3 port3), alive, sla(0x1), cfg_order(2), cost(20), selected

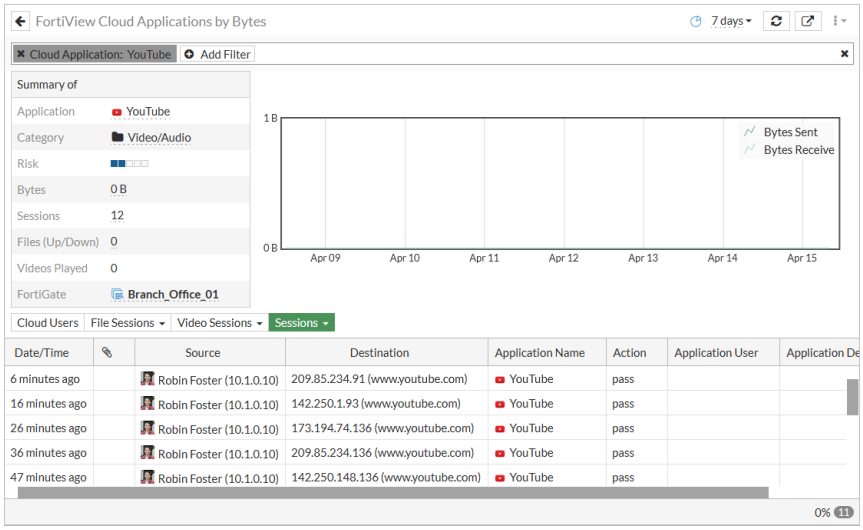
```

Applications and sessions

To verify sessions in FortiView:

1. Go to a dashboard and add the *FortiView Cloud Applications* widget sorted by bytes. See Cloud application view on page 159 for details.
2. Drill down on an application, such as *YouTube*, then select the *Sessions* tab.



To verify applications identified by Application Control in SD-WAN:

```
# diagnose sys sdwan internet-service-app-ctrl-list

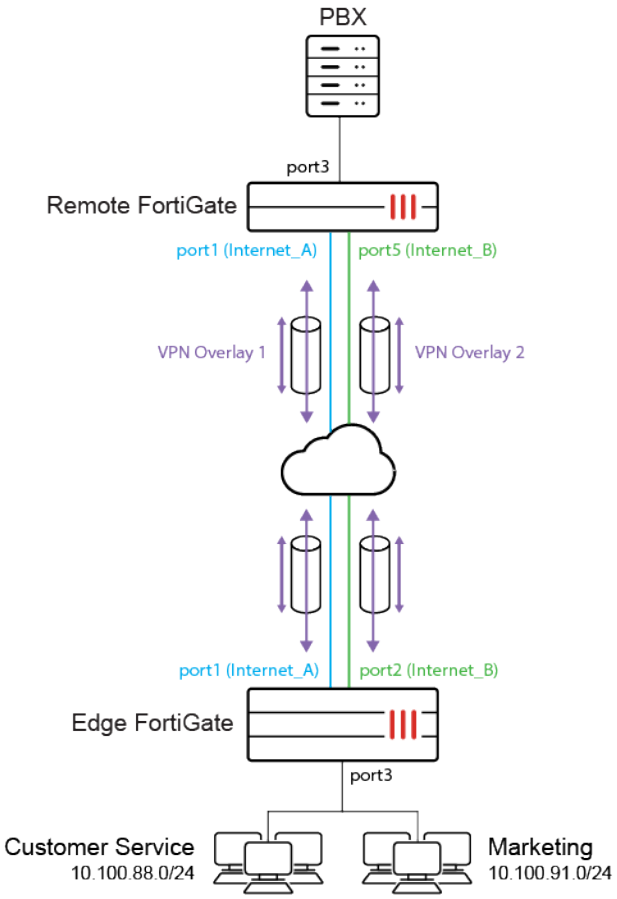
DSCP tag-based traffic steering in SD-WAN

Differentiated Services Code Point (DSCP) tags can be used to categorize traffic for quality of service (QoS). SD-WAN traffic steering on an edge device can be provided based on the DSCP tags.

This section provides an example of using DSCP tag-based traffic steering using secure SD-WAN. Traffic from the customer service and marketing departments at a headquarters are marked with separate DSCP tags by the core switch and passed to the edge FortiGate. The edge FortiGate reads the tags, then steers traffic to the preferred interfaces based on the defined SD-WAN rules.



VoIP and social media traffic are steered. VoIP traffic from the customer service department is more important than social media traffic. The edge FortiGate identifies the tagged traffic based on SD-WAN rules then steers the traffic:

- VoIP traffic is marked with DSCP tag 011100 and steered to the VPN overlay with the lowest jitter, to provide the best quality voice communication with the remote PBX server.
- Social media traffic is marked with the DSCP tag 001100 and steered to the internet connection with the lowest cost.

The following is assumed to be already configured:

- Two IPsec tunnels (IPsec VPN on page 2369):
  - Branch-HQ-A on Internet_A (port 1)
  - Branch-HQ-B on Internet_B (port 5)
- Four SD-WAN members in two zones (Configuring the SD-WAN interface on page 898):
  - Overlay zone includes members Branch-HQ-A and Branch-HQ-B
  - virtual-wan-link zone includes members Internet_A and Internet_B

    Internet_A has a cost of 0 and Internet_B has a cost of 10. When using the lowest cost strategy, Internet_A will be preferred. Both members are participants in the Default_DNS performance SLA.
- A static route that points to the SD-WAN interface (Adding a static route on page 899).
- Two firewall policies:

Name	SD-WAN-OUT	Overlay-OUT

From	port3	port3
To	virtual-wan-link	Overlay
Source	all	all
Destination	all	all
Schedule	always	always
Service	all	all
Action	Accept	Accept
NAT	enabled	enabled

After the topology is configured, you can proceed with the configuration of the edge FortiGate:

- Configuring SD-WAN rules on page 1068
- Results on page 1070

Configuring SD-WAN rules

Configure SD-WAN rules to govern the steering of DSCP tag-based traffic to the appropriate interfaces. Traffic is steered based on the criteria that are configured in the SD-WAN rules.

In this example, three SD-WAN rules are configured to govern DSCP tagged traffic:

- *VoIP-Steer* for VoIP traffic.
- *Facebook-DSCP-steer* for Social media traffic.
- *All-traffic* for all of the Other web traffic.

After configuring the rules, go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab to check the rules.

VoIP traffic

VoIP traffic is steered to the *Overlay* zone.

DSCP values are usually 6-bit binary numbers that are padded with zeros at the end. VoIP traffic with DSCP tag 011100 will become 01110000. This 8-bit binary number is represented in its hexadecimal form, 0x70, as the type of service bit pattern (`tos`) value. The type of service evaluated bits (`tos-mask`) hexadecimal value of 0xf0 (11110000 in binary) is used to check the four most significant bits in the `tos` value. The four most significant bits of the `tos` (0111) are used to match the first four bits of the DSCP tag. Only the non-zero bit positions in the `tos-mask` are used for comparison; the zero bit positions are ignored.

The *Best quality* (`priority` mode) strategy is used to select the preferred interface, with the *Quality criteria* (`link-cost-members`) set to *Jitter*. The interface with the lowest amount of jitter is selected. For more information about configuring SD-WAN rules with the *Best Quality* strategy, see Best quality strategy on page 1035.

To configure the rule for DSCP tagged VoIP traffic using the CLI:

```
config sys sdwan
    config service
```

```
        edit 5
            set name "VoIP-Steer"
            set mode priority
            set tos 0x70
            set tos-mask 0xf0
            set dst "all"
            set health-check "Default_DNS"
            set link-cost-factor jitter
            set priority-members 4 3
        next
    end
end
```

Social media traffic

Social media traffic is steered to the *virtual-wan-link* zone.

DSCP values are usually 6-bit binary numbers that are padded with zeros at the end. Social media traffic traffic with DSCP tag 001100 will become 00110000. This 8-bit binary number is represented in its hexadecimal form, 0x30, as the `tos` value. The `tos-mask` hexadecimal value of 0xf0 (11110000 in binary) is used to check the four most significant bits in the tos value. The four most significant bits of the `tos` (0011) are used to match the first four bits of the DSCP tag. Only the non-zero bit positions in the `tos-mask` are used for comparison; the zero bit positions are ignored.

The *Manual* (`manual` mode) strategy is used to select the preferred interface. Internet_B (port5, priority member 2) is set as the preferred interface to steer all social media traffic to. For more information about configuring SD-WAN rules with the manual strategy, see Manual strategy on page 1031.

To configure SD-WAN rule for DSCP tagged social media traffic using the CLI:

```
config system sdwan
    config service
        edit 3
            set name "Facebook-DSCP-steer"
            set mode manual
            set tos 0x30
            set tos-mask 0xf0
            set dst "all"
            set priority-members 2 1
        next
    end
end
```

Other web traffic

Other web traffic is steered to the *virtual-wan-link* zone.

The *Lowest Cost (SLA)* strategy (`sla` mode) is used to select the preferred interface. The interface that meets the defined SLA targets (*Default_DNS* in this case) is selected. If there is a tie, the interface with the lowest cost is selected, Internet_A (port1) in this case.

For more information about configuring SD-WAN rules with the *Lowest Cost (SLA)* strategy, see Lowest cost (SLA) strategy on page 1038.

To configure SD-WAN rule for all other web traffic using the CLI:

```
config system sdwan
    config service
        edit 2
            set name "All-traffic"
            set mode sla
            set dst "all"
            config sla
                edit "Default_DNS"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

Results

These sections show the function of SD-WAN with respect to DSCP tagged traffic steering, and can help confirm that it is running as expected:

- Verifying the DSCP tagged traffic on FortiGate on page 1070
- Verifying the service rules on page 1071
- Verifying traffic steering on the SD-WAN rules on page 1072
- Verifying that steered traffic is leaving from the expected interface on page 1072

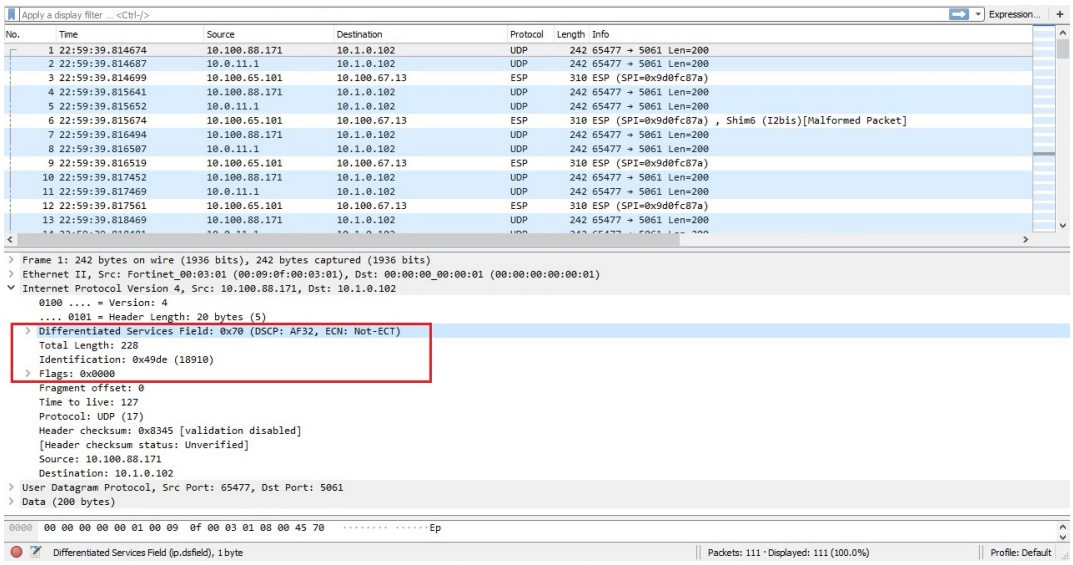
Verifying the DSCP tagged traffic on FortiGate

Packet sniffing is used to verify the incoming DSCP tagged traffic. See Using the FortiOS built-in packet sniffer for more information.

Wireshark is used to verify that VoIP traffic is tagged with the expected DSCP tag, 0x70 or 0x30.

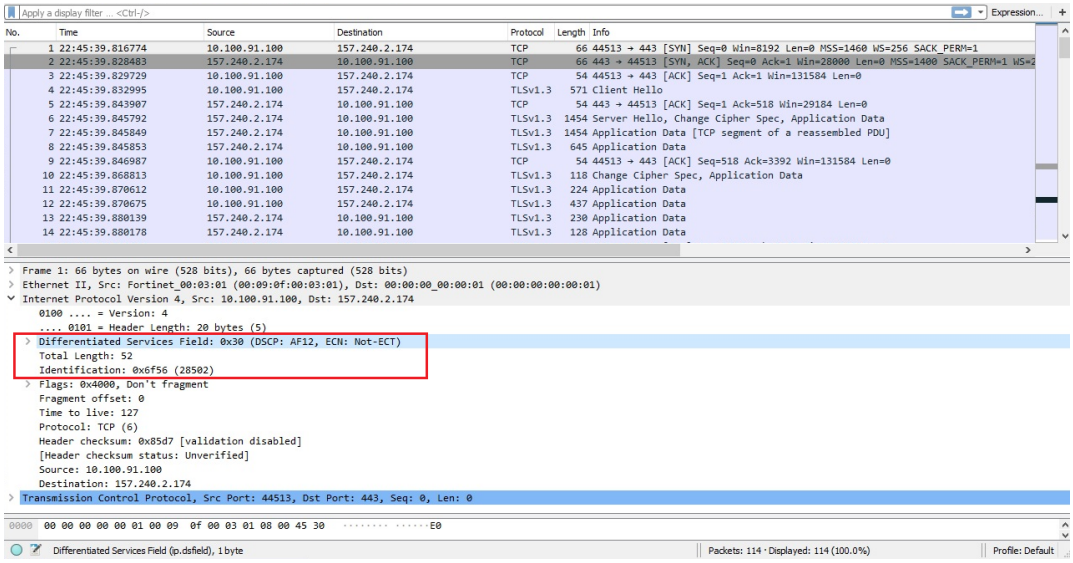
VoIP traffic marked with DSCP tag 0x70:

```
# diagnose sniffer packet any '(ip and ip[1] & 0xfc == 0x70)' 6 0 l
```



Web traffic marked with DSCP tag 0x30:

```
# diagnose sniffer packet any '(ip and ip[1] & 0xfc == 0x30)' 6 0 l
```



Verifying the service rules

To check that the expected DSCP tags and corresponding interfaces are used by the SD-WAN rules to steer traffic:

```
# diagnose sys sdwan service4

Service(5): Address Mode(IPV4) flags=0x0
   Gen(1), TOS(0x70/0xf0), Protocol(0: 1->65535), Mode(manual)
   Members:
      1: Seq_num(4 Branch-HQ-B), alive, selected
   Dst address:
```

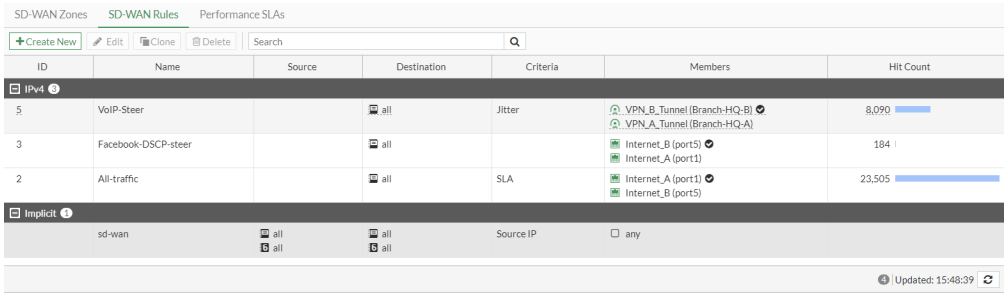
```
        0.0.0.0-255.255.255.255

Service(3): Address Mode(IPV4) flags=0x0
   Gen(1), TOS(0x30/0xf0), Protocol(0: 1->65535), Mode(manual)
   Members:
      1: Seq_num(2 port5), alive, selected
   Dst address:
        0.0.0.0-255.255.255.255

Service(2): Address Mode(IPV4) flags=0x0
   Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
   Members:
      1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
      2: Seq_num(2 port5), alive, sla(0x1), cfg_order(1), cost(10), selected
   Dst address:
        0.0.0.0-255.255.255.255
```

Verifying traffic steering on the SD-WAN rules

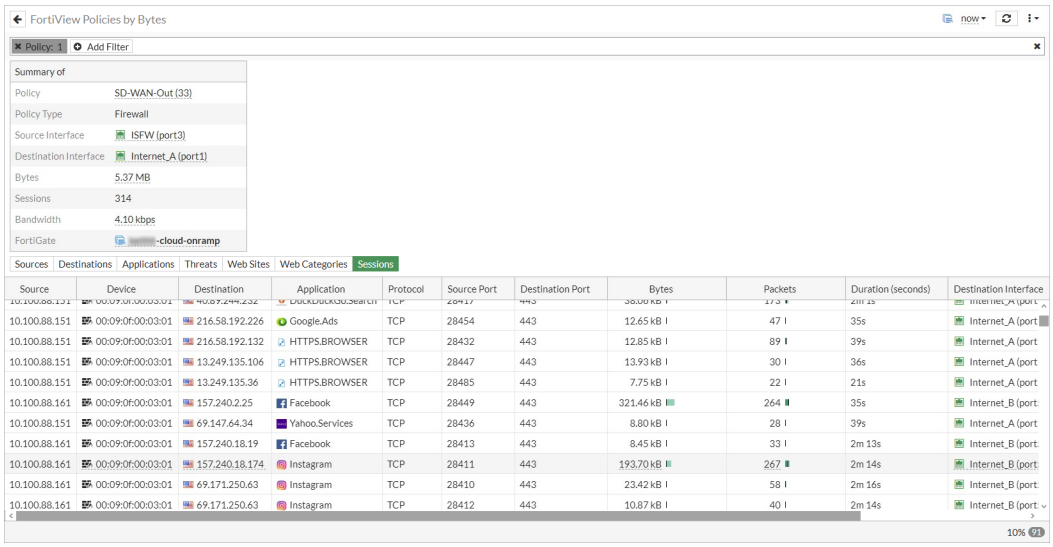
Go to *Network* > *SD-WAN* and select the *SD-WAN Rules* tab to check the *Hit Count* on the SD-WAN interfaces.



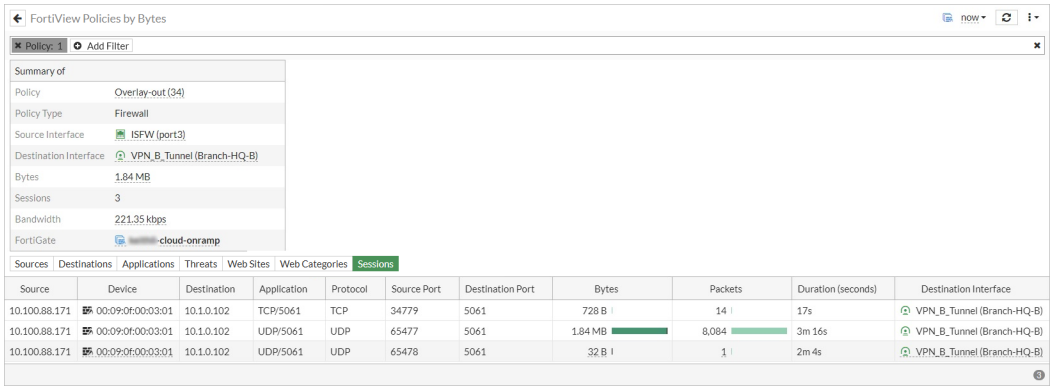
Verifying that steered traffic is leaving from the expected interface

To confirm that web traffic (port 443) flows through the correct underlay interface members, and VoIP traffic flows through the correct overlay interface members, go to *Dashboard* > *FortiView Policies* and double click on the policy name.

Web traffic is expected to leave on *Interface_A (port1)* or *Interface_B (port5)*:



VoIP traffic is expected to leave on the preferred *VPN_B_Tunnel (Branch-HQ-B)* interface:



ECMP support for the longest match in SD-WAN rule matching

The longest match SD-WAN rule can match ECMP best routes. The rule will select the egress ports on ECMP specific routes, and not the less specific routes, to transport traffic.

The service mode determines which egress port on the ECMP specific routes is selected to forward traffic:

- Manual (`manual`): The first configured alive port is selected.
- Best Quality (`priority`): The best quality port is selected.
- Lowest Cost (`sla`): The first configured or lower cost port in SLA is selected.

Example

By default, SD-WAN selects the outgoing interface from all of the links that have valid routes to the destination. In some cases, it is required that only the links that have the best (or longest match) routes (single or ECMP) to

the destination are considered.

In this example, four SD-WAN members in two zones are configured. The remote PC (PC_2 - 10.1.100.22) is accessible on port15 and port16, even though there are valid routes for all of the SD-WAN members. A single SD-WAN service rule is configured that allows traffic to balanced between all four of the members, but only chooses between port15 and port16 for the specific 10.1.100.22 address.

A performance SLA health check is configured to monitor 10.1.100.2. An SD-WAN service rule in Lowest Cost (SLA) mode is configured to select the best interface to steer the traffic. In the rule, the method of selecting a member if more than one meets the SLA (`tie-break`) is configured to select members that meet the SLA and match the longest prefix in the routing table (`fib-best-match`). If there are multiple ECMP routes with the same destination, the FortiGate will take the longest (or best) match in the routing table, and choose from those interface members.

To configure the SD-WAN:

```
config system sdwan
    config zone
        edit "virtual-wan-link"
        next
        edit "z1"
        next
    end
    config members
        edit 1
            set interface "port1"
            set gateway 172.16.200.2
        next
        edit 2
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 3
            set interface "port15"
            set zone "z1"
            set gateway 172.16.209.2
        next
        edit 4
            set interface "port16"
            set zone "z1"
            set gateway 172.16.210.2
        next
    end
    config health-check
        edit "1"
            set server "10.1.100.2"
```

```
            set members 0
            config sla
                edit 1
                next
            end
        next
    end
    config service
        edit 1
            set name "1"
            set mode sla
            set dst "all"
            set src "172.16.205.0"
            config sla
                edit "1"
                    set id 1
                next
            end
            set priority-members 1 2 3 4
            set tie-break fib-best-match
        next
    end
end
```

To check the results:

1. The debug shows the SD-WAN service rule. All of the members meet SLA, and because no specific costs are attached to the members, the egress interface is selected based on the interface priority order that is configured in the rule:

```
FGT_A (root) # diagnose sys sdwan service4

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
  Gen(4), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(4):
    1: Seq_num(1 port1), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
    2: Seq_num(2 dmz), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
    3: Seq_num(3 port15), alive, sla(0x1), gid(0), cfg_order(2), cost(0), selected
    4: Seq_num(4 port16), alive, sla(0x1), gid(0), cfg_order(3), cost(0), selected
  Src address(1):
        172.16.205.0-172.16.205.255
  Dst address(1):
        0.0.0.0-255.255.255.255
```

2. The routing table shows that there are ECMP default routes on all of the members, and ECMP specific (or best) routes only on port15 and port16:

```
FGT_A (root) # get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 172.16.200.2, port1
                        [1/0] via 172.16.208.2, dmz
                        [1/0] via 172.16.209.2, port15
```

```
                          [1/0] via 172.16.210.2, port16
S       10.1.100.22/32 [10/0] via 172.16.209.2, port15
                               [10/0] via 172.16.210.2, port16
```

Because `tie-break` is set to `fib-best-match`, the first configured member from port15 and port16 is selected to forward traffic to PC_2. For all other traffic, the first configured member from all four of the interfaces is selected to forward traffic.

3. On PC-1, generate traffic to PC-2:

```
ping 10.1.100.22
```

4. On FGT_A, sniff for traffic sent to PC_2:

```
# diagnose sniffer packet any 'host 10.1.100.22' 4
interfaces=[any]
filters=[host 10.1.100.22]
2.831299 port5 in 172.16.205.11 -> 10.1.100.22: icmp: echo request
2.831400 port15 out 172.16.205.11 -> 10.1.100.22: icmp: echo request
```

Traffic is leaving on port15, the first configured member from port15 and port16.

Override quality comparisons in SD-WAN longest match rule matching

In SD-WAN rules, the longest match routes will override the quality comparisons when all of the specific routes are out of SLA.

With this feature in an SD-WAN rule:

- Lowest Cost (`sla`): Even though all of the egress ports on specific routes (longest matched routes) are out of SLA, the SD-WAN rule still selects the first configured or lower-cost port from the egress ports to forward traffic.
- Best Quality (`priority`): Even though the egress ports on specific routes (longest matched routes) have worse quality that all other ports on less specific routes, the SD-WAN rule still selects the best quality port from the ports on specific routes to forward traffic.

This features avoids a situation where, if the members on specific routes (longest matched routes) are out of SLA or have worse quality, the traffic might be forwarded to the wrong members in SLA (higher quality) on the default or aggregate routes.

Example

In this example, four SD-WAN members in two zones are configured. The remote PC (PC_2 - 10.1.100.22) is accessible on port15 and port16, even though there are valid routes for all of the SD-WAN members. A single SD-WAN service rule is configured that allows traffic to balanced between all four of the members, but only chooses between port15 and port16 for the specific 10.1.100.22 address. If neither port15 nor port16 meet the SLAs, traffic will be forwarded on one of these interfaces, instead of on port1 or dmz.

A performance SLA health check is configured to monitor 10.1.100.2. An SD-WAN service rule in Lowest Cost (SLA) mode is configured to select the best interface to steer the traffic. In the rule, the method of selecting a member if more than one meets the SLA (`tie-break`) is configured to select members that meet the SLA and match the longest prefix in the routing table (`fib-best-match`). If there are multiple ECMP routes with the same destination, the FortiGate will take the longest (or best) match in the routing table, and choose from those interface members.

To configure the SD-WAN:

```
config system sdwan
    config zone
        edit "virtual-wan-link"
        next
        edit "z1"
        next
    end
    config members
        edit 1
            set interface "port1"
            set gateway 172.16.200.2
        next
        edit 2
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 3
            set interface "port15"
            set zone "z1"
            set gateway 172.16.209.2
        next
        edit 4
            set interface "port16"
            set zone "z1"
            set gateway 172.16.210.2
        next
    end
    config health-check
        edit "1"
            set server "10.1.100.2"
            set members 0
            config sla
                edit 1
                next
            end
        next
    end
```

```
    config service
        edit 1
            set name "1"
            set mode sla
            set dst "all"
            set src "172.16.205.0"
            config sla
                edit "1"
                    set id 1
                next
            end
            set priority-members 1 2 3 4
            set tie-break fib-best-match
        next
    end
end
```

To check the results:

1. The debug shows the SD-WAN service rule. Both port15 and port16 are up, but out of SLA:

```
FGT_A (root) # diagnose sys sdwan service4
Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
  Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(4):
    1: Seq_num(1 port1), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
    2: Seq_num(2 dmz), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
    3: Seq_num(3 port15), alive, sla(0x0), gid(0), cfg_order(2), cost(0), selected
    4: Seq_num(4 port16), alive, sla(0x0), gid(0), cfg_order(3), cost(0), selected
  Src address(1):
        172.16.205.0-172.16.205.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

2. The routing table shows that there are ECMP default routes on all of the members, and ECMP specific (or best) routes only on port15 and port16:

```
FGT_A (root) # get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 172.16.200.2, port1
                        [1/0] via 172.16.208.2, dmz
                        [1/0] via 172.16.209.2, port15
                        [1/0] via 172.16.210.2, port16
S       10.1.100.22/32 [10/0] via 172.16.209.2, port15
                                  [10/0] via 172.16.210.2, port16
```

   Because `tie-break` is set to `fib-best-match`, even though both port15 and port16 are out of SLA, the first configured member of the two (port15) is selected to forward traffic to PC_2. For all other traffic, the first configured member from all of the interfaces that are in SLA is selected to forward traffic (port1).

3. On PC-1, generate traffic to PC-2:

```
ping 10.1.100.22
```

4. On FGT_A, sniff for traffic sent to PC_2:

```
# diagnose sniffer packet any 'host 10.1.100.22' 4
interfaces=[any]
filters=[host 10.1.100.22]
2.831299 port5 in 172.16.205.11 -> 10.1.100.22: icmp: echo request
2.831400 port15 out 172.16.205.11 -> 10.1.100.22: icmp: echo request
```

Traffic is leaving on port15, the first configured member from port15 and port16, even though both are out of SLA.

Internet service and application control steering

An application, application group, or application category can be selected as an SD-WAN service rule destination criterion for IPv4 and IPv6 address modes.

To configure from the CLI:

```
config system sdwan
    config service
        edit <id>
            set internet-service enable
            set internet-service-app-ctrl <app id> [app id]
            set internet-service-app-ctrl-group <app group> [app group]
            set internet-service-app-ctrl-category <category id> [category id]
        next
    end
end
```

To configure for IPv6 addressing mode from the CLI, enable `addr-mode ipv6`:

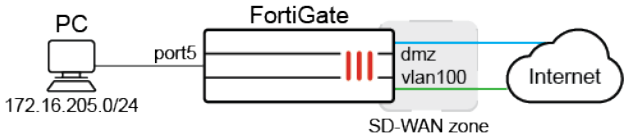
```
config system sdwan
    config service
        edit <id>
            set addr-mode ipv6
        next
    end
end
```

To view the detected application category details based on category ID, use `diagnose sys sdwan internet-service-app-ctrl-list cat-id <cat-id>`.

This topic includes a GUI and CLI Example for application category on page 1080 and a CLI Example for IPv6 on page 1084.

Example for application category

In this example, traffic steering is applied to traffic detected as video/audio (category ID 5) or email (category ID 21) and applies the lowest cost (SLA) strategy to this traffic. When costs are tied, the priority goes to member 1, dmz.



To configure application categories as an SD-WAN rule destination in the GUI:

1. Enable the feature visibility:
   a. Go to *System* > *Feature Visibility*.
   b. In the *Additional Features* section, enable *Application Detection Based SD-WAN*.
   c. Click *Apply*.

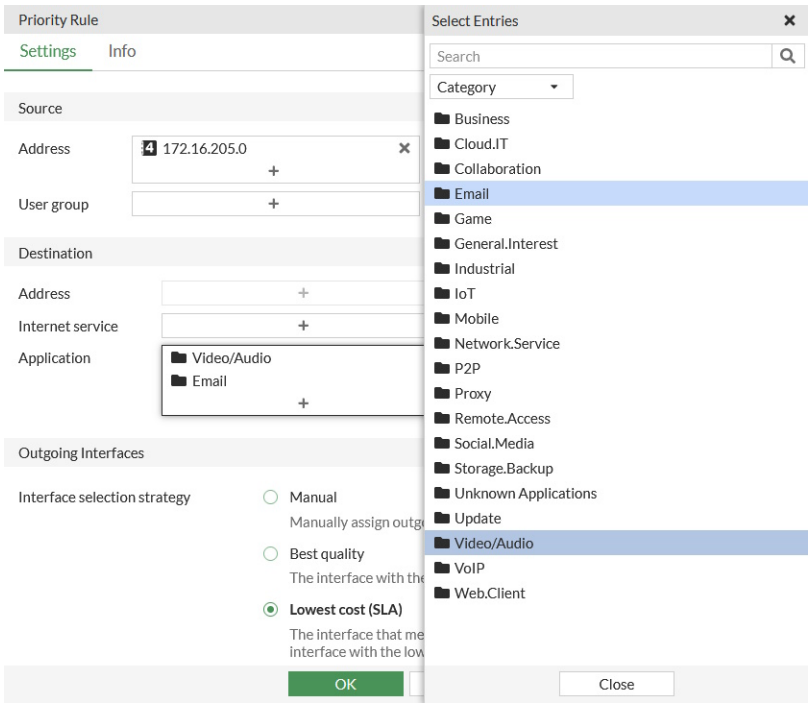
   To enable GUI visibility of application detection based SD-WAN in the CLI:

   ```
   config system global
       set gui-app-detection-sdwan enable
   end
   ```

2. Configure the SD-WAN members:
   a. Go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
   b. Set the *Interface* to *dmz*, and set the *Gateway* to *172.16.208.2*.
   c. Click *OK*.
   d. Repeat these steps to create another member for the *vlan100* interface with gateway *172.16.206.2*.
3. Configure the performance SLA (health check):
   a. Go to *Network* > *SD-WAN*, and select the *Performance SLAs* tab, and click *Create New*.
   b. Configure the following settings:

Name	*1*
Protocol	*DNS*
Server	*8.8.8.8*
SLA Target	Enable

   c. Click *OK*.
4. Configure the SD-WAN rule to use the video/audio and email application categories:
   a. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
   b. In the *Destination* section, click the *+* in the *Application* field.
   c. Click *Category*, and select *Video/Audio* and *Email*.



d. Configure the other settings as needed.

e. Click *OK*.

5. Configure the firewall policy:

a. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.

b. Configure the following settings:

Incoming Interface	*port5*
Outgoing Interface	*virtual-wan-link*
Source	*172.16.205.0*
Destination	*all*
Schedule	*always*
Service	*ALL*
Action	*ACCEPT*
Application Control	*g-default*
SSL Inspection	*certificate-inspection*

c. Click *OK*.

To configure application categories as an SD-WAN rule destination in the CLI:

1. Configure the SD-WAN settings:

```
config system sdwan
    set status enable
```

```
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
        next
        edit 2
            set interface "vlan100"
            set gateway 172.16.206.2
        next
    end
    config health-check
        edit "1"
            set server "8.8.8.8"
            set protocol dns
            set members 0
            config sla
                edit 1
                next
            end
        next
    end
end
```

2. Configure the SD-WAN rule to use application categories 5 and 21:

```
config system sdwan
    config service
        edit 1
            set name "1"
            set mode sla
            set src "172.16.205.0"
            set internet-service enable
            set internet-service-app-ctrl-category 5 21
            config sla
                edit "1"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

3. Configure the firewall policy:

```
config firewall policy
    edit 1
        set srcintf "port5"
```

```
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr 172.16.205.0
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "g-default"
    next
end
```

To test the configuration:

1. Verify that the traffic is sent over dmz:

```
# diagnose firewall proute list
list route policy info(vf=root):
id=2133590017(0x7f2c0001) vwl_service=1(1) vwl_mbr_seq=1 2 dscp_tag=0xff 0xff flags=0x0
tos=0x00 tos_mask=0x00 protocol=0 sport=0-65535 iif=0 dport=1-65535 path(2) oif=5(dmz) oif=95
(vlan100)
source(1): 172.16.205.0-172.16.205.255
destination wildcard(1): 0.0.0.0/0.0.0.0
internet service(2): (null)(0,5,0,0,0) (null)(0,21,0,0,0)
hit_count=469 last_used=2021-12-15 15:06:05
```

2. View some videos and emails on the PC, then verify the detected application details for each category:

```
# diagnose sys sdwan internet-service-app-ctrl-list cat-id 5
List App Ctrl Database Entry(IPv4) in Kernel:

Max_App_Ctrl_Size=32768 Num_App_Ctrl_Entry=4

YouTube(31077 4294838537): IP=142.250.217.110 6 443
YouTube(31077 4294838537): IP= 173.194.152.89 6 443
YouTube(31077 4294838537): IP= 173.194.152.170 6 443
YouTube(31077 4294838537): IP= 209.52.146.205 6 443
```

```
# diagnose sys sdwan internet-service-app-ctrl-list cat-id 21
List App Ctrl Database Entry(IPv4) in Kernel:

Max_App_Ctrl_Size=32768 Num_App_Ctrl_Entry=1

Gmail(15817 4294836957): IP=172.217.14.197 6 443
```

3. Verify that the captured email traffic is sent over dmz:

```
# diagnose sniffer packet any 'host 172.217.14.197' 4
interfaces=[any]
filters=[host 172.217.14.197]
5.079814 dmz out 172.16.205.100.60592 -> 172.217.14.197.443: psh 2961561240 ack 2277134591
```

4. Edit the SD-WAN rule so that dmz has a higher cost and vlan100 is preferred.

5. Verify that the traffic is now sent over vlan100:

```
# diagnose firewall proute list
list route policy info(vf=root):
id=2134048769(0x7f330001) vwl_service=1(1) vwl_mbr_seq=2 1 dscp_tag=0xff 0xff flags=0x0
tos=0x00 tos_mask=0x00 protocol=0 sport=0-65535 iif=0 dport=1-65535 path(2) oif=95(vlan100)
oif=5(dmz)
source(1): 172.16.205.0-172.16.205.255
destination wildcard(1): 0.0.0.0/0.0.0.0
internet service(2): (null)(0,5,0,0,0) (null)(0,21,0,0,0)
hit_count=635 last_used=2021-12-15 15:55:43
```

```
# diagnose sniffer packet any 'host 172.217.14.197' 4
interfaces=[any]
filters=[host 172.217.14.197]
304.625168 vlan100 in 172.16.205.100.60592 -> 172.217.14.197.443: psh 2961572711 ack
2277139565
```

Example for IPv6

In this example, SD-WAN is configured to use an IPv6 service rule to steer traffic from FGT_A to FGT_B based on the following application control options:

- Application Telnet
- An application group for ping
- An application category that includes SSH

When the rule is matched, traffic is steered based on the lowest cost SLA strategy. In this example, vlan100 is the preferred interface, and traffic is routed to vlan100 on FGT_B.

To view the configuration:

1. View the SD-WAN configuration on FGT_A:

   SD-WAN has four members in the default virtual-wan-link zone, each with an IPv4 and IPv6 gateway. The SD-WAN service rule includes `internet-service-app-ctrl 16091` for the Telnet, `internet-service-app-ctrl-group "network-Ping"` for ping , and `internet-service-app-ctrl-category 15` for SSH applications.

```
(sdwan) # show
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "dmz"
            set gateway 172.16.208.2
            set gateway6 2000:172:16:208::2
```

```
        next
        edit 2
            set interface "IPSec-1"
        next
        edit 3
            set interface "agg1"
            set gateway 172.16.203.2
            set gateway6 2000:172:16:203::2
        next
        edit 4
            set interface "vlan100"
            set gateway 172.16.206.2
            set gateway6 2000:172:16:206::2
        next
    end
    config health-check
        edit "1"
            set addr-mode ipv6
            set server "2000::2:2:2:2"
            set members 0
            config sla
                edit 1
                next
            end
        next
    end
    config service
        edit 1
            set name "1"
            set addr-mode ipv6
            set mode sla
            set internet-service enable
            set internet-service-app-ctrl 16091
            set internet-service-app-ctrl-group "network-Ping"
            set internet-service-app-ctrl-category 15
            config sla
                edit "1"
                    set id 1
                next
            end
            set priority-members 4 1 2 3
        next
    end
end
```

2. View the default route for FGT_A:

```
config router static
    edit 5
        set distance 1
        set sdwan-zone "virtual-wan-link"
```

```
    next
end
```

3. View the firewall policy for FGT_A:

   The `utm-status` option is enabled to learn application 3T (3 tuple) information, and the default application profile of `g-default` is selected.

```
config firewall policy
    edit 1
        set uuid f09bddc4-def3-51ed-8517-0d8b6bc18f35
        set srcintf "any"
        set dstintf "any"
        set action accept
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "g-default"
    next
end
```

To verify the configuration:

1. On FGT_A, check the routing table:

   The routing table has ECMP applied to default gateways for each SD-WAN member.

```
# get router info routing-table  static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 172.16.203.2, agg1, [1/0]
                        [1/0] via 172.16.206.2, vlan100, [1/0]
                        [1/0] via 172.16.208.2, dmz, [1/0]
                        [1/0] via IPSec-1 tunnel 172.16.209.2, [1/0]
```

2. Check the SD-WAN service:

   Based on the service rule, member 4 named vlan100 is preferred. Traffic must also match the highlighted internet services.

```
# diagnose system sdwan service

Service(1): Address Mode(IPV6) flags=0x4200 use-shortcut-sla use-shortcut
 Tie break: cfg
  Gen(2), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members(4):
    1: Seq_num(4 vlan100), alive, sla(0x1), gid(0), cfg_order(0), local cost(0), selected
2: Seq_num(1 dmz), alive, sla(0x1), gid(0), cfg_order(1), local cost(0), selected
    3: Seq_num(2 IPSec-1), alive, sla(0x1), gid(0), cfg_order(2), local cost(0), selected
    4: Seq_num(3 agg1), alive, sla(0x1), gid(0), cfg_order(3), local cost(0), selected
  Internet Service(3): Telnet(4294837974,0,0,0,0 16091) IPv6.ICMP(4294837087,0,0,0,0 16321)
Network.Service(0,15,0,0,0)
```

3. Initiate traffic for ping, Telnet, and SSH to FGT_B, then FGT_A will learn 3T information for these applications, and use the SD-WAN rule to route traffic for the applications to the preferred interface of vlan100.
   - Following is the sniffer traffic for ping application. The ping traffic flows out of DMZ before 3T information is recognized, then out from vlan100 after T3 traffic is recognized:

```
# diagnose sniffer packet any 'host 2000::2:0:0:4' 4
interfaces=[any]
filters=[host 2000::2:0:0:4]
16.952138 port5 in 2000:172:16:205::100 -> 2000::2:0:0:4: icmp6: echo request seq 1

4. View the IPv6 application control internet service ID list:

```
# diagnose system sdwan internet-service-app-ctrl6-list

Telnet(16091 4294837974): 2000::2:0:0:4 6 23 Thu Apr 20 17:43:00 2023
IPv6.ICMP(16321 4294837087): 2000::2:0:0:4 58 0 Thu Apr 20 17:43:00 2023
```

5. View the IPv6 application control internet service ID list by category:

```
# diagnose system sdwan internet-service-app-ctrl6-category-list

SSH(16060 4294837772): 2000::2:0:0:4 6 22 Thu Apr 20 17:43:00 2023
```

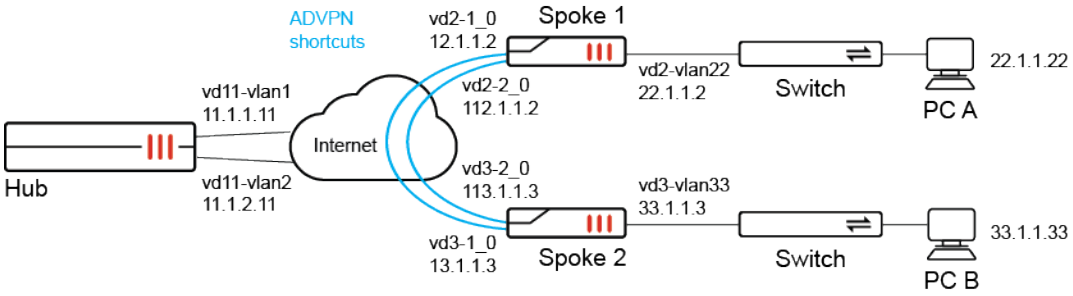
Use maximize bandwidth to load balance traffic between ADVPN shortcuts

When ADVPN is configured on a FortiGate spoke along with an SD-WAN rule set to *Maximize Bandwidth SLA* (GUI) or load balance mode (CLI) as well as `tie-break` set to `fib-best-match`, then spoke-to-spoke traffic is load balanced between multiple ADVPN shortcuts when the shortcuts are within the configured SLA conditions.

Following is an example configuration with `load-balance` enabled and `tie-break` set to `fib-best-match`:

```
config system sdwan
    config service
        edit 3
            set mode sla
            set load-balance enable
            set dst "all"
            config sla
                edit "ping"
                    set id 1
                next
            end
            set priority-members 1 2
            set tie-break fib-best-match
        next
    end
end
```

Example



In this example SD-WAN is configured between one hub and multiple spokes, and the SD-WAN configuration shows SD-WAN rule 3 with the following required settings to enable spoke-to-spoke traffic between multiple ADVPN shortcuts:

- set load-balance enable
- set tie-break fib-best-match

```
show system sdwan
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "zon2"
        next
    end
    config members
        edit 1
            set interface "vd2-1"
            set cost 10
        next
        edit 2
            set interface "vd2-2"
            set cost 20
        next
    end
    config health-check
        edit "ping"
            set server "11.11.11.11"
            set members 1 2
            config sla
                edit 1
                    set latency-threshold 200
                    set jitter-threshold 50
                next
                edit 2
                next
            end
        next
        edit "1"
        next
    end
    config service
        edit 1
            set dst "033"
            set priority-members 1
        next
        edit 2
            set dst "133"
            set priority-members 2
        next
        edit 3
            set mode sla
            set load-balance enable
            set dst "all"
            config sla
                edit "ping"
                    set id 1
                next
```

```
            end
            set priority-members 1 2
            set tie-break fib-best-match
        next
    end
end
```

To trigger spoke-to-spoke communication, run an ICMP ping on PC A with IP address 22.1.1.22 behind spoke 1 that is destined for PC B with IP address 33.1.1.33 behind spoke 2. The spoke-to-spoke traffic will be used to demonstrate load balancing between shortcuts in the CLI output of this topic.

To verify the configuration:

1. Confirm the ADVPN shortcuts are within the SLA conditions:

```
# diagnose system sdwan health-check
Health Check(ping):
Seq(1 vd2-1): state(alive), packet-loss(0.000%) latency(0.029), jitter(0.002), mos(4.404),
bandwidth-up(1999), bandwidth-dw(0), bandwidth-bi(1999) sla_map=0x3
Seq(1 vd2-1_0): state(alive), packet-loss(0.000%) latency(0.026), jitter(0.001), mos(4.404),
bandwidth-up(2000), bandwidth-dw(0), bandwidth-bi(2000) sla_map=0x3
Seq(2 vd2-2): state(alive), packet-loss(0.000%) latency(0.055), jitter(0.064), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x3
Seq(2 vd2-2_0): state(alive), packet-loss(0.000%) latency(0.060), jitter(0.058), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x3
```

2. Confirm the settings for SD-WAN rule 3:

```
# diagnose system sdwan service 3

Service(3): Address Mode(IPV4) flags=0x4200 use-shortcut-sla use-shortcut
 Tie break: fib
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance  hash-mode=round-robin)
  Member sub interface(4):
    1: seq_num(1), interface(vd2-1):
       1: vd2-1_0(125)
    3: seq_num(2), interface(vd2-2):
       1: vd2-2_0(127)
  Members(4):
    1: Seq_num(1 vd2-1), alive, sla(0x1), gid(2), num of pass(1), selected
    2: Seq_num(1 vd2-1_0), alive, sla(0x1), gid(2), num of pass(1), selected
    3: Seq_num(2 vd2-2), alive, sla(0x1), gid(2), num of pass(1), selected
    4: Seq_num(2 vd2-2_0), alive, sla(0x1), gid(2), num of pass(1), selected
  Dst address(1):
        0.0.0.0-255.255.255.255
```

3. Confirm firewall policing routing list:

```
# diagnose firewall proute list 2131230723
list route policy info(vf=vd2):

id=2131230723(0x7f080003) vwl_service=3 vwl_mbr_seq=1 1 2 2 dscp_tag=0xfc 0xfc flags=0x90
```

```
load-balance hash-mode=round-robin  fib-best-match tos=0x00 tos_mask=0x00 protocol=0 sport=0-
65535 iif=0(any) dport=1-65535 path(4) oif=116(vd2-1) num_pass=1 oif=125(vd2-1_0) num_pass=1
oif=117(vd2-2) num_pass=1 oif=127(vd2-2_0) num_pass=1
destination(1): 0.0.0.0-255.255.255.255
source wildcard(1): 0.0.0.0/0.0.0.0
hit_count=117 last_used=2023-04-21 15:49:59
```

4. Confirm the routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B*      0.0.0.0/0 [200/0] via 10.10.100.254 (recursive via vd2-1 tunnel 11.1.1.11), 01:26:14,
[1/0]
                  [200/0] via 10.10.200.254 (recursive via vd2-2 tunnel 11.1.2.11), 01:26:14,
[1/0]
B       1.1.1.1/32 [200/0] via 11.1.1.1 [2] (recursive via 12.1.1.1, vd2-vlan12), 01:26:14,
[1/0]
B       11.11.11.11/32 [200/0] via 10.10.100.254 (recursive via vd2-1 tunnel 11.1.1.11),
01:26:14, [1/0]
                       [200/0] via 10.10.200.254 (recursive via vd2-2 tunnel 11.1.2.11),
01:26:14, [1/0]
B       33.1.1.0/24 [200/0] via 10.10.100.3 [2] (recursive is directly connected, vd2-1_0),
01:19:41, [1/0]
                    [200/0] via 10.10.200.3 [2] (recursive is directly connected, vd2-2_0),
01:19:41, [1/0]
B       100.1.1.0/24 [200/0] via 10.10.100.254 (recursive via vd2-1 tunnel 11.1.1.11),
01:26:14, [1/0]
                     [200/0] via 10.10.200.254 (recursive via vd2-2 tunnel 11.1.2.11),
01:26:14, [1/0]
```

5. Check the packet sniffer output for the default setting.

   This step demonstrates routing for the default setting of `set tie-break zone`. The following packet sniffer output of ICMP pings demonstrates how spoke-to-spoke traffic (ping from 22.1.1.22 to 33.1.1.13) is load balanced between all parent tunnels and shortcuts, and is not limited to shortcuts within SLA.

```
# diagnose sniffer packet any "host 33.1.1.13" 4
interfaces=[any]
filters=[host 33.1.1.13]
14.665232 vd22-vlan22 out 22.1.1.22 -> 33.1.1.13: icmp: echo request
14.665234 npu0_vlink1 out 22.1.1.22 -> 33.1.1.13: icmp: echo request
14.665240 vd2-vlan22 in 22.1.1.22 -> 33.1.1.13: icmp: echo request
14.665262 vd2-1_0 out 22.1.1.22 -> 33.1.1.13: icmp: echo request
14.665274 vd3-1_0 in 22.1.1.22 -> 33.1.1.13: icmp: echo request
14.665284 vd3-vlan33 out 22.1.1.22 -> 33.1.1.13: icmp: echo request
14.665285 npu0_vlink0 out 22.1.1.22 -> 33.1.1.13: icmp: echo request
14.665289 vd33-vlan33 in 22.1.1.22 -> 33.1.1.13: icmp: echo request
14.665299 vd33-vlan33 out 33.1.1.13 -> 22.1.1.22: icmp: echo reply
14.665300 npu0_vlink1 out 33.1.1.13 -> 22.1.1.22: icmp: echo reply
14.665306 vd3-vlan33 in 33.1.1.13 -> 22.1.1.22: icmp: echo reply
14.665314 vd3-1_0 out 33.1.1.13 -> 22.1.1.22: icmp: echo reply
14.665326 vd2-1_0 in 33.1.1.13 -> 22.1.1.22: icmp: echo reply
14.665331 vd2-vlan22 out 33.1.1.13 -> 22.1.1.22: icmp: echo reply
```

7. Check SD-WAN heath.

   When an ADVPN shortcut is out of SLA, traffic does not run on it. Shortcut vd2-1_0 is out of SLA.

```
# diagnose system sdwan health-check
Health Check(ping):
Seq(1 vd2-1): state(alive), packet-loss(6.000%) latency(0.026), jitter(0.001), mos(4.401),
bandwidth-up(1999), bandwidth-dw(0), bandwidth-bi(1999) sla_map=0x0
Seq(1 vd2-1_0): state(alive), packet-loss(18.182%) latency(0.033), jitter(0.003), mos(4.395),
bandwidth-up(2000), bandwidth-dw(0), bandwidth-bi(2000) sla_map=0x0
Seq(2 vd2-2): state(alive), packet-loss(0.000%) latency(0.024), jitter(0.001), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x3
```

```
Seq(2 vd2-2_0): state(alive), packet-loss(0.000%) latency(0.033), jitter(0.005), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x3
```

8. Check the sniffer packet:
   No traffic runs on Shortcut vd2-1_0 because it is out of SLA.

```
# diagnose sniffer packet any "host 33.1.1.13" 4

```

Use SD-WAN rules to steer multicast traffic

SD-WAN rules can steer IPv4 and IPv6 multicast traffic. When an SD-WAN member is out of SLA, multicast traffic can fail over to another SD-WAN member, and switch back when SLA recovers.

The `pim-use-sdwan` option enables or disables the use of SD-WAN for PIM (Protocol Independent Multicast) when checking RP (Rendezvous Point) neighbors and sending packets.

```
config router multicast
    config pim-sm-global
        set pim-use-sdwan {enable | disable}
    end
end
```

or

```
config router multicast6
    config pim-sm-global
        set pim-use-sdwan {enable | disable}
    end
end
```

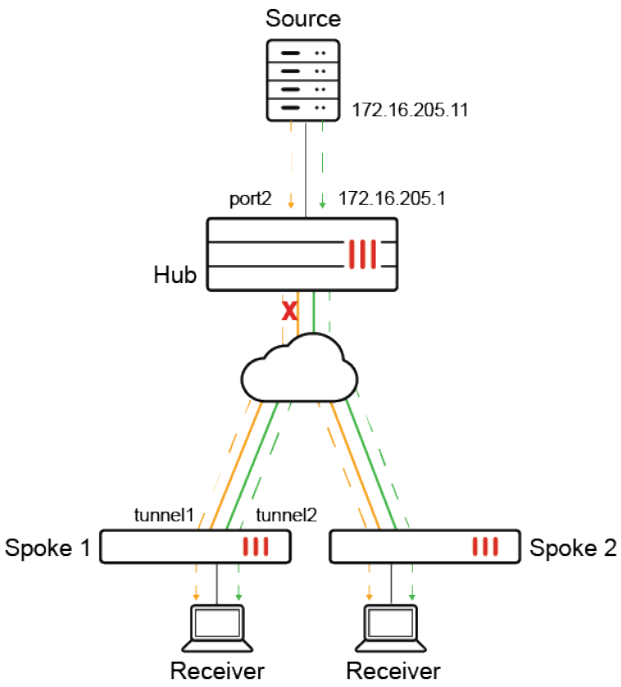
When SD-WAN steers multicast traffic, ADVPN is not supported. Use the `set shortcut` option to disable shortcuts for the service:

```
config system sdwan
    config service
        edit <id>
            set shortcut {enable | disable}
        next
    end
end
```

Example 1

In this hub and spoke example for IPv4 multicast traffic, the PIM source is behind the hub FortiGate, and the RP is set to internal port (port2) of the hub firewall. Each spoke connects to the two WAN interfaces on the hub by using an overlay tunnel. The overlay tunnels are members of SD-WAN.

Receivers behind the spoke FortiGates request a stream from the source to receive traffic on tunnel1 by default. When the overlay tunnel goes out of SLA, the multicast traffic fails over to tunnel2 and continues to flow.



Following is an overview of how to configure the topology:

1. Configure the hub FortiGate in front of the PIM source. The RP is configured on internal port (port2) of the hub FortiGate.
2. Configure the spoke FortiGates.
3. Verify traffic failover.

To configure the hub:

1. On the hub, enable multicast routing, configure the multicast RP, and enable PIM sparse mode on each interface:

```
config router multicast
    set multicast-routing enable
    config pim-sm-global
        config rp-address
            edit 1
                set ip-address 172.16.205.1
            next
        end
    end
    config interface
        edit "tport1"
            set pim-mode sparse-mode
        next
        edit "tagg1"
            set pim-mode sparse-mode
        next
        edit "port2"
            set pim-mode sparse-mode
```

```
        next
    end
end
```

To configure each spoke:

1. Enable SD-WAN with the following settings:
   - Configure the overlay tunnels as member of the SD-WAN zone.
   - Configure a performance SLA health-check using ping.
   - Configure a service rule for the PIM protocol with the following settings:
     - Use the lowest cost (SLA) strategy.
     - Monitor with the ping health-check.
   - Disable ADVPN shortcut.

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "tunnel1"
        next
        edit 2
            set interface "tunnel2"
        next
    end
    config health-check
        edit "ping"
            set server "172.16.205.1"
            set update-static-route disable
            set members 0
            config sla
                edit 1
                next
            end
        next
    end
    config service
        edit 1
            set mode sla
            set protocol 103
            set dst "all"
            config sla
                edit "ping"
                    set id 1
                next
            end
            set priority-members 1 2
```

```
            set use-shortcut-sla disable
            set shortcut disable
        next
        edit 2
            set mode sla
            set dst "all"
            config sla
                edit "ping"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

2. Enable multicast routing and configure the multicast RP. Enable PIM sparse-mode on each interface:

```
config router multicast
    set multicast-routing enable
    config pim-sm-global
        set spt-threshold disable
        set pim-use-sdwan enable
        config rp-address
            edit 1
                set ip-address 172.16.205.1
            next
        end
    end
    config interface
        edit "tunnel1"
            set pim-mode sparse-mode
        next
        edit "tunnel2"
            set pim-mode sparse-mode
        next
        edit "port4"
            set pim-mode sparse-mode
        next
    end
end
```

To verify traffic failover:

With this configuration, multicast traffic starts on tunnel1. When tunnel1 becomes out of SLA, traffic switches to tunnel2. When tunnel1 is in SLA again, the traffic switches back to tunnel1.

The following health-check capture on the spokes shows tunnel1 in SLA with packet-loss (1.000%):

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel1): state(alive), packet-loss(0.000%) latency(0.056), jitter(0.002), mos(4.404),
```

```
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x1
Seq(2 tunnel2): state(alive), packet-loss(0.000%) latency(0.100), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1

# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel1): state(alive), packet-loss(1.000%) latency(0.056), jitter(0.002), mos(4.404),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x1
Seq(2 tunnel2): state(alive), packet-loss(0.000%) latency(0.100), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1
```

The following example shows tunnel1 out of SLA with packet-loss (3.000%):

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel1): state(alive), packet-loss(3.000%) latency(0.057), jitter(0.003), mos(4.403),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x0
Seq(2 tunnel2): state(alive), packet-loss(0.000%) latency(0.101), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1
```

The following example shows tunnel1 back in SLA again:

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel1): state(alive), packet-loss(1.000%) latency(0.061), jitter(0.004), mos(4.404),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x0
Seq(2 tunnel2): state(alive), packet-loss(0.000%) latency(0.102), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1

# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel1): state(alive), packet-loss(0.000%) latency(0.061), jitter(0.004), mos(4.404),
bandwidth-up(999999), bandwidth-dw(1000000), bandwidth-bi(1999999) sla_map=0x0
Seq(2 tunnel2): state(alive), packet-loss(0.000%) latency(0.102), jitter(0.002), mos(4.404),
bandwidth-up(0), bandwidth-dw(0), bandwidth-bi(0) sla_map=0x1
```

The following example how traffic switches to tunnel2 while tunnel1 health-check is out of SLA. Source (172.16.205.11) sends traffic to the multicast group. Later the traffic switches back to tunnel1 once SLA returns to normal:

```
195.060797 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
195.060805 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
196.060744 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
196.060752 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
197.060728 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
197.060740 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
198.060720 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
198.060736 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
199.060647 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
199.060655 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
200.060598 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
200.060604 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
... ...
```

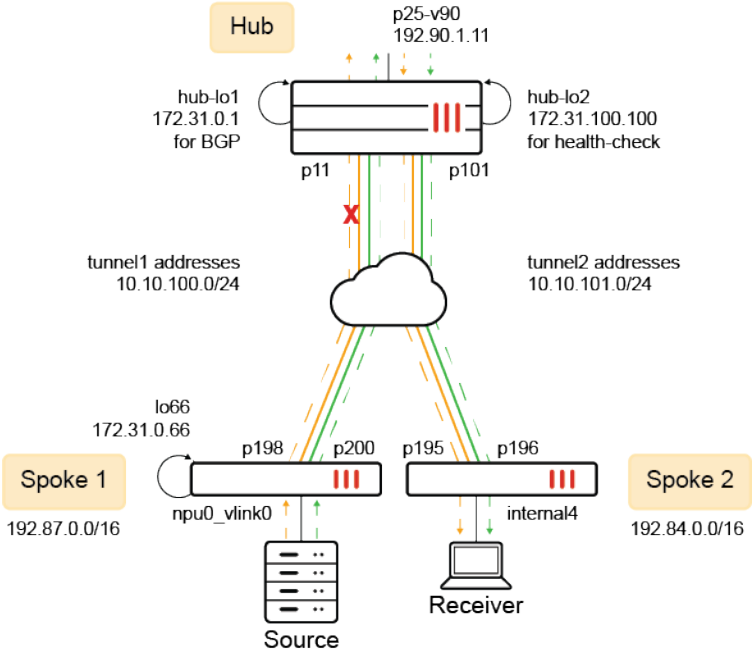
```
... ...
264.060974 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
265.060950 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
265.060958 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
266.060867 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
266.060877 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
267.060828 tunnel2 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
267.060835 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
268.060836 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
268.060854 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
269.060757 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
269.060767 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
270.060645 tunnel1 in 172.16.205.11 -> 225.1.1.1: icmp: echo request
270.060653 port4 out 172.16.205.11 -> 225.1.1.1: icmp: echo request
```

Example 2

In this hub and spoke example for IPv4 multicast traffic, the PIM source is behind spoke 1, and the RP is configured on the hub FortiGate. BGP is used for routing. The hub uses embedded SLA in ICMP probes to determine the health of each tunnel, allowing it to prioritize healthy IKE routes.

The receiver is on another spoke. Upon requesting a stream, source passes the traffic to the RP on the hub FortiGate, and routes the traffic to the receiver over tunnel1. If a tunnel falls out of SLA, the multicast traffic fails over to the other tunnel.

In this configuration, SD-WAN steers multicast traffic by using embedded SLA information in ICMP probes. See also Embedded SD-WAN SLA information in ICMP probes. With this feature, the hub FortiGate can use the SLA information of the spoke's health-check to control BGP and IKE routes over tunnels.



Following is an overview of how to configure the topology:

1. Configure the hub FortiGate. The RP is configured on the hub FortiGate.
2. Configure the spoke FortiGate in front of the traffic receiver.
3. Configure the spoke FortiGate in front of the PIM source.

To configure the hub:

1. Configure loopbacks hub-lo1 172.31.0.1 for BGP and hub-lo100 172.31.100.100 for health-check:

```
config system interface
    edit "hub-lo1"
        set vdom "hub"
        set ip 172.31.0.1 255.255.255.255
        set allowaccess ping
        set type loopback
        set snmp-index 82
    next
    edit "hub-lo100"
        set vdom "hub"
        set ip 172.31.100.100 255.255.255.255
        set allowaccess ping
        set type loopback
        set snmp-index 81
    next
end
```

2. Enable multicast routing with the following settings:
   - Configure internal interface p25-v90 as RP.
   - Enable interfaces for PIM sparse-mode.

```
config router multicast
    set multicast-routing enable
    config pim-sm-global
        config rp-address
            edit 1
                set ip-address 192.90.1.11
            next
        end
    end
    config interface
        edit "p11"
            set pim-mode sparse-mode
        next
        edit "p101"
            set pim-mode sparse-mode
        next
        edit "p25-v90"
            set pim-mode sparse-mode
        next
    end
end
```

3. Enable SD-WAN with the following settings:

- Add interfaces p11 and p101 as members.
- Configure embedded SLA health-checks to detect ICMP probes from each overlay tunnel. Prioritize based on the health of each tunnel.

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "p11"
        next
        edit 2
            set interface "p101"
        next
    end
    config health-check
        edit "1"
            set detect-mode remote
            set probe-timeout 60000
            set recoverytime 1
            set sla-id-redistribute 1
            set members 1
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                    set priority-in-sla 10
                    set priority-out-sla 20
                next
            end
        next
        edit "2"
            set detect-mode remote
            set probe-timeout 60000
            set recoverytime 1
            set sla-id-redistribute 1
            set members 2
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                    set priority-in-sla 15
                    set priority-out-sla 25
                next
            end
        next
    end
end
```

4. Configure BGP to peer with neighbors. Neighbor group is configured for tunnel interface IP addresses:

```
config router bgp
    set as 65505
    set router-id 172.31.0.1
    set ibgp-multipath enable
    set additional-path enable
    set recursive-inherit-priority enable
    config neighbor-group
        edit "gr1"
            set remote-as 65505
            set update-source "hub-lo1"
            set additional-path both
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 10.10.0.0 255.255.0.0
            set neighbor-group "gr1"
        next
        edit 66
            set prefix 172.31.0.66 255.255.255.255
            set neighbor-group "gr1"
        next
    end
    config network
        ....
        edit 90
            set prefix 192.90.0.0 255.255.0.0
        next
    end
end
```

To configure the spoke (in front of the receiver):

1. Enable multicast routing to use SD-WAN. Configure the RP address. Enable interfaces for PIM sparse-mode.

```
config router multicast
    set multicast-routing enable
    config pim-sm-global
        set spt-threshold disable
        set pim-use-sdwan enable
        config rp-address
            edit 1
                set ip-address 192.90.1.11
            next
        end
    end
    config interface
        edit "p195"
            set pim-mode sparse-mode
        next
```

```
        edit "p196"
            set pim-mode sparse-mode
        next
        edit "internal4"
            set pim-mode sparse-mode
            set static-group "225-1-1-122"
        next
    end
end
```

2. Configure SD-WAN with the following settings:
   - Add overlay tunnel interfaces as members.
   - Configure a performance SLA health-check to send ping probes to the hub.
   - Configure a service rule for the PIM protocol. Use the lowest cost (SLA) strategy, and monitor with the ping health-check.
   - Disable ADVPN shortcuts.

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 6
            set interface "p196"
        next
        edit 5
            set interface "p195"
        next
    end
    config health-check
        edit "ping"
            set server "172.31.100.100"
            set update-static-route disable
            set members 0
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
            end
        next
    end
    config service
        edit 1
            set mode sla
            set protocol 103
            set dst "all"
            config sla
                edit "ping"
```

```
                    set id 1
                next
            end
            set priority-members 5 6
            set use-shortcut-sla disable
            set shortcut disable
        next
        edit 2
            set mode sla
            set dst "all"
            config sla
                edit "ping"
                    set id 1
                next
            end
            set priority-members 5 6
        next
    end
end
```

3. Configure BGP and set neighbors to the overlay gateway IP address on the hub:

```
config router bgp
    set as 65505
    set router-id 122.1.1.122
    set ibgp-multipath enable
    set additional-path enable
    config neighbor
        edit "10.10.100.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set connect-timer 10
            set additional-path both
        next
        edit "10.10.101.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set connect-timer 10
            set additional-path both
        next
    end
    config network
        edit 3
            set prefix 192.84.0.0 255.255.0.0
        next
    end
end
```

4. Configure the default gateway to use the SD-WAN zone. Other routes are for the underlay to route traffic to the hub's WAN interfaces:

```
config router static
    edit 10
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
    ....
    next
end
```

To configure the spoke (in front of the source):

1. Enable multicast routing to use SD-WAN. Configure the RP address. Enable interfaces for PIM sparse-mode:

```
config router multicast
    set multicast-routing enable
    config pim-sm-global
        set pim-use-sdwan enable
        config rp-address
            edit 1
                set ip-address 192.90.1.11
            next
        end
    end
    config interface
        edit "p198"
            set pim-mode sparse-mode
        next
        edit "p200"
            set pim-mode sparse-mode
        next
        edit "npu0_vlink0"
            set pim-mode sparse-mode
        next
    end
end
```

2. Configure loopback interface lo66 for BGP and sourcing SD-WAN traffic:

```
config system interface
    edit "lo66"
        set vdom "root"
        set ip 172.31.0.66 255.255.255.255
        set allowaccess ping
        set type loopback
        set snmp-index 21
    next
end
```

3. Configure SD-WAN:
   - Add overlay tunnel interfaces as members.
   - Configure a performance SLA health-check to send ping probes to the hub.

- Configure a service rule for the PIM protocol. Use the lowest cost (SLA) strategy, and monitor with the ping health-check.
- Disable the use of an ADVPN shortcut.

In the following example, 11.11.11.11 is the underlay address for one of the WAN links on the hub, and 172.31.100.100 is the loopback address on the server.

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "overlay"
        next
    end
    config members
        edit 1
            set interface "p198"
            set zone "overlay"
            set source 172.31.0.66
        next
        edit 2
            set interface "p200"
            set zone "overlay"
            set source 172.31.0.66
        next
    end
    config health-check
        edit "ping"
            set server "11.11.11.11"
            set members 0
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
            end
        next
        edit "HUB"
            set server "172.31.100.100"
            set embed-measured-health enable
            set members 0
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
            end
        next
    end
     config service
        edit 1
            set mode sla
```

```
            set protocol 103
            set dst "all"
            config sla
                edit "ping"
                    set id 1
                next
            end
            set priority-members 1 2
            set use-shortcut-sla disable
            set shortcut disable
        next
        edit 2
            set mode sla
            set dst "all"
            config sla
                edit "ping"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

4. Configure BGP:

```
config router bgp
    set as 65505
    set router-id 123.1.1.123
    set ibgp-multipath enable
    set additional-path enable
    config neighbor
        edit "172.31.0.1"
            set next-hop-self enable
            set soft-reconfiguration enable
            set remote-as 65505
            set update-source "lo66"
        next
    end
    config network
        edit 3
            set prefix 192.87.0.0 255.255.0.0
        next
    end
end
```

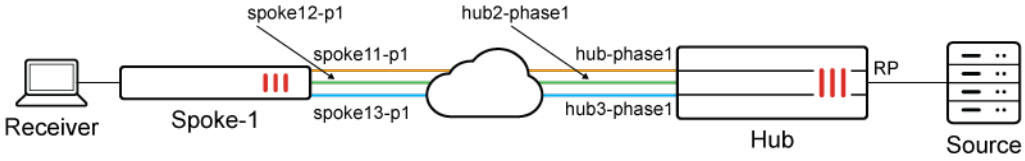
5. Configure the default gateway to use the SD-WAN zone. Other routes are for the underlay to route to the hub's WAN interfaces:

```
config router static
    edit 10
        set distance 1
```

```
        set sdwan-zone "virtual-wan-link" "overlay"
    next
    ...
    next
end
```

Example 3

In the following example for using SD-WAN rules to steer IPv6 multicast traffic, three PIM-SM enabled tunnels are configured between Spoke-1 and the Hub. The multicast source is located at Hub, and the multicast receiver is attached to Spoke-1.



This example focuses on configuration related allowing SD-WAN rules to steer IPv6 multicast traffic. Following is an overview of the configuration steps:

1. On the hub FortiGate, configure multicast routing for the source and the multicast RP.
2. On the spoke FortiGate, configuring multicast routing and enable SD-WAN for steering.
3. Verify traffic failover for the following scenarios:
   - When the cost of an SD-WAN member changes
   - When a link is in SLA
   - When a link is out of SLA

To configure the Hub:

1. On Hub, configure multicast routing for the source and the multicast RP:
   In this example, `port5` is used for the multicast source, and `20000:172:16:205::1` is the IPv6 address for the RP.

```
config router multicast6
    set multicast-routing enable
    config interface
        edit "hub-phase1"
        next
        edit "hub2-phase1"
        next
        edit "port5"
        next
        edit "hub3-phase1"
        next
    end
    config pim-sm-global
        config rp-address
            edit 1
                set ip6-address 2000:172:16:205::1
```

```
            next
        end
    end
end
```

2. Configure the firewall policy:

```
config firewall multicast-policy6
    edit 1
        set srcintf "port5"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
    next
end
```

3. Verify that all PIM-SM neighbors are established:

```
# get router info6 multicast pim sparse-mode neighbor
Neighbor                   Interface          Uptime/Expires    Ver   DR
Address                                                             Prio/Mode
fe80::1                    hub-phase1         06:49:35/00:01:39 v2    1 /
fe80::2                    hub2-phase1        06:49:34/00:01:42 v2    1 /
fe80::1                    hub3-phase1        02:41:17/00:01:31 v2    1 /
```

To configure Spoke-1:

1. On Spoke-1, configure multicast routing and enable SD-WAN for steering:
   In this example, `port5` is used for the multicast receiver, the use of SD-WAN for steering is enabled, and `20000:172:16:205::1` is the IPv6 address for the RP.

```
config router multicast6
    set multicast-routing enable
    config interface
        edit "spoke11-p1"
        next
        edit "spoke12-p1"
        next
        edit "port2"
        next
        edit "spoke13-p1"
        next
    end
    config pim-sm-global
        set pim-use-sdwan enable
        config rp-address
            edit 1
                set ip6-address 2000:172:16:205::1
            next
        end
    end
end
```

2. Configure the firewall policy:

```
config firewall multicast-policy6
    edit 1
        set srcintf "any"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
    next
end
```

3. Configure SD-WAN:
   In this example, the `protocol` is set to `103` to match PIM-SM join/register messages.

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "spoke11-p1"
        next
        edit 2
            set interface "spoke12-p1"
        next
        edit 3
            set interface "spoke13-p1"
        next
    end
    config health-check
        edit "1"
            set addr-mode ipv6
            set server "2000::9:0:0:1"
            set update-static-route disable
            set members 1
            config sla
                edit 1
                next
            end
        next
        edit "2"
            set addr-mode ipv6
            set server "2000::9:0:0:2"
            set update-static-route disable
            set members 2
            config sla
                edit 1
                next
            end
        next
```

```
        edit "3"
            set addr-mode ipv6
            set server "2000::9:0:0:3"
            set update-static-route disable
            set members 3
            config sla
                edit 1
                next
            end
        next
    end
    config service
        edit 1
            set name "1"
            set addr-mode ipv6
            set mode sla
            set protocol 103
            config sla
                edit "1"
                    set id 1
                next
                edit "2"
                    set id 1
                next
                edit "3"
                    set id 1
                next
            end
            set priority-members 1 2 3
            set sla-compare-method number
            set dst6 "all"
        next
    end
end
```

4. Verify that all PIM-SM neighbors are established:

```
# get router info6 multicast pim sparse-mode neighbor
Neighbor                   Interface          Uptime/Expires    Ver   DR
Address                                                             Prio/Mode
fe80:10:10:15::253         spoke11-p1         06:49:50/00:01:16 v2    1 / DR
fe80:10:10:16::253         spoke12-p1         06:49:50/00:01:26 v2    1 / DR
fe80:10:10:17::253         spoke13-p1         02:41:32/00:01:43 v2    1 / DR
```

To verify traffic failover:

1. On Spoke-1, diagnose the SD-WAN service. The preferred route is spoke11-p1 to hub-phase1:

```
# diagnose sys sdwan service6

Service(1): Address Mode(IPV6) flags=0x4200 use-shortcut-sla use-shortcut
 Tie break: cfg
```

```
 Shortcut priority: 2
  Gen(1), TOS(0x0/0x0), Protocol(103): src(1->65535):dst(1->65535), Mode(sla), sla-compare-
number
  Members(3):
    1: Seq_num(1 spoke11-p1 virtual-wan-link), alive, sla(0x1), gid(0), cfg_order(0), local
cost(0), selected           >>>>>>> spoke11-p1 which is connected to hub-phase1 is preferred
    2: Seq_num(2 spoke12-p1 virtual-wan-link), alive, sla(0x2), gid(0), cfg_order(1), local
cost(0), selected
    3: Seq_num(3 spoke13-p1 virtual-wan-link), alive, sla(0x4), gid(0), cfg_order(2), local
cost(0), selected
  Dst6 address(1): ::/0
```

2. When the receiver initiates IGMP to join group `ff15::10`, view `mroute` on Spoke-1 and Hub:
   - On Spoke-1:

     The `RPF idx` is connected to hub-phase1, indicating that PIM-SM join message follows SD-WAN service and is sent to `spoke11-p1`, and `port2` is connected to the receiver.

     ```
     FGT_B (root)# get router info6 multicast pim sparse-mode mroute ff15::10
     IP Multicast Routing Table

     ......

     (*, ff15::10)
     RP: 2000:172:16:205::1
     RPF nbr: fe80:10:10:15::253
     RPF idx: spoke11-p1
     Upstream State: JOINED
      Local:
          port2
      Joined:
      Asserted:
     FCR:
     Source: 2000:172:16:205::100
      Outgoing:
          port2
      KAT timer running, 196 seconds remaining
      Packet count 168
     ...
     ```

   - On the Hub:

     We see that `hub-phase1` is connected to spoke11-p1 on Spoke-1.

     ```
     FGT_A (root) (Interim)# get router info6 multicast pim sparse-mode mroute ff15::10
     IP Multicast Routing Table

     ......

     (*, ff15::10)
     RP: 2000:172:16:205::1
     RPF nbr: ::
     RPF idx: None
     ```

```
Upstream State: JOINED
 Local:
 Joined:
     hub-phase1
 Asserted:
FCR:

...
```

3. The server starts to send multicast traffic to group `ff15::10`, and Hub forwards the traffic to Spoke-1 through hub-phase1.

```
FGT_A (root) (Interim)# diagnose sniffer packet any 'host  ff15::10' 4
interfaces=[any]
filters=[host  ff15::10]
0.637174 port5 in 2000:172:16:205::100.38823 -> ff15::10.12345: udp 46 [flowlabel 0x8ea58]
0.637228 hub-phase1 out 2000:172:16:205::100.38823 -> ff15::10.12345: udp 46 [flowlabel
0x8ea58]
```

4. When the cost of member spoke11-p1 and spoke12-p1 is increased, SD-WAN prefers spoke13-p1.

   The PIM-SM join message from Spoke-1 to RP is sent to member spoke13-p1, and multicast traffic fails over to hub3-phase1 on the Hub accordingly.

   - On Spoke-1:

     In this example, `spoke13-p1`, which is connected to hub-phase3, is preferred.

```
FGT_B (root) (Interim)# diagnose sys sdwan service6

Service(1): Address Mode(IPV6) flags=0x4200 use-shortcut-sla use-shortcut
 Tie break: cfg
 Shortcut priority: 2
  Gen(1), TOS(0x0/0x0), Protocol(103): src(1->65535):dst(1->65535), Mode(sla), sla-
compare-number
  Members(3):
    1: Seq_num(3 spoke13-p1 virtual-wan-link), alive, sla(0x4), gid(0), cfg_order(2),
local cost(0), selected
    2: Seq_num(1 spoke11-p1 virtual-wan-link), alive, sla(0x1), gid(0), cfg_order(0),
local cost(20), selected
    3: Seq_num(2 spoke12-p1 virtual-wan-link), alive, sla(0x2), gid(0), cfg_order(1),
local cost(20), selected
  Dst6 address(1): ::/0
```

   - On the Hub:

     Once the cost of spoke11-p1 is increased, multicast traffic fails over to `hub2-phase1`. Once the cost of spoke12-p1 is increased, multicast traffic fails over to `hub3-phase1`.

```
FGT_A (root) (Interim)# diagnose sniffer packet any 'host  ff15::10' 4
interfaces=[any]
filters=[host  ff15::10]

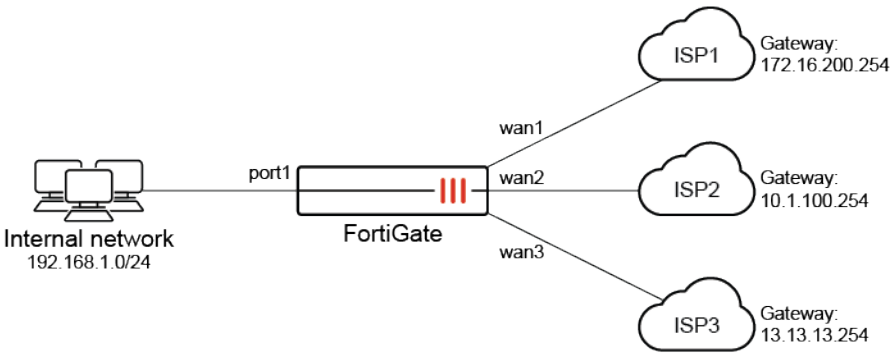
....
385.497887 port5 in 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
```

```
0xa5e3d]
385.497927 hub-phase1 out 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
386.497967 port5 in 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
386.498258 hub2-phase1 out 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
387.498044 port5 in 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
...
400.499075 port5 in 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
400.499120 hub2-phase1 out 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
401.499180 port5 in 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
401.499515 hub3-phase1 out 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
402.499254 port5 in 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
402.499319 hub3-phase1 out 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
403.499330 port5 in 2000:172:16:205::100.41944 -> ff15::10.12345: udp 46 [flowlabel
0xa5e3d]
...
```

5. When spoke13-p1 becomes out of SLA, SD-WAN selects spoke11-p1 as the preferred member.
   This change redirects the PIM-SM join message from Spoke-1 to RP towards spoke11-p1, causing the multicast traffic to failover to hub-phase1 on the Hub.
6. Conversely, when spoke13-p1 is in SLA again, it is prioritized by SD-WAN.
   This adjustment redirects the PIM-SM join message from Spoke-1 to RP towards spoke13-p1, triggering a failover of the multicast traffic to hub3-phase1 on the Hub.

Use SD-WAN rules for WAN link selection with load balancing

This example covers a use case where a user has multiple WAN links and wants to optimize the WAN link selection and performance while limiting the use of more expensive and bandwidth intensive interfaces, such as 5G or LTE.



In this scenario, the user has three WAN links. The goal is to balance the load between wan1 and wan2; however, wan3, which is quite costly to operate, should only be used if both wan1 and wan2 are unavailable.

This configuration involves the following steps:

1. Configuring the SD-WAN members
2. Configuring the manual SD-WAN rule
3. Configuring a static route
4. Configuring a firewall policy for SD-WAN
5. Verifying the configuration

Configuring the SD-WAN members

SD-WAN must be enabled first, and member interfaces must be selected and added to a zone. See Configuring the SD-WAN interface on page 898 for more information.

To configure the SD-WAN members in the GUI:

1. Configure the wan1, wan2, and wan3 interfaces (see Interface settings on page 173 for more details).
   a. Set the wan1 interface *IP/Netmask* to *172.16.200.1 255.255.255.0*.
   b. Set the wan2 interface *IP/Netmask* to *10.1.100.1 255.255.255.0*.
   c. Set the wan3 interface *IP/Netmask* to *13.13.13.1 255.255.255.0*.
2. Go to *Network* > *SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New* > *SD-WAN Member*.
3. Configure the wan1 SD-WAN member:
   a. Set the *Interface* to *wan1*.
   b. Leave the *SD-WAN Zone* as *virtual-wan-link*.
   c. Set the *Gateway* to *172.16.200.254*.
   d. Set the *Status* to *Enable*
   e. Click *OK*.
4. Repeat step 3 for wan2 and wan3.
   a. For wan2, set the *Gateway* to the ISP's gateway, *10.1.100.254*.
   b. For wan3, set the *Gateway* to the ISP's gateway, *13.13.13.254*.

To configure the SD-WAN members in the CLI:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
    end
    config members
        edit 1
            set interface "wan1"
            set gateway 172.16.200.254
        next
        edit 2
            set interface "wan2"
            set gateway 10.1.100.254
        next
        edit 3
            set interface "wan3"
            set gateway 13.13.13.254
        next
    end
end
```

Configuring the manual SD-WAN rule

SD-WAN rules define specific routing options to route traffic to an SD-WAN member. See SD-WAN rules on page 1017 and Manual strategy on page 1031 for more information.

To configure a manual SD-WAN rule in the GUI:

1. Go to *Network* > *SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Configure the following settings:

Name	*test*
Source > Address	*all*
Destination > Address	*all*
Interface selection strategy	*Manual*
Interface preference	*wan1*, *wan2*
Load balancing	Enable this setting.

3. Configure the other settings as needed.
4. Click *OK*.

To configure a manual SD-WAN rule in the CLI:

```
config system sdwan
    config service
        edit 1
            set name "test"
            set load-balance enable
            set dst "all"
            set src "all"
            set priority-members 1 2
        next
    end
end
```

Configuring a static route

A default route for SD-WAN must be configured. See Adding a static route on page 899 for more information.

To configure a static route for SD-WAN in the GUI:

1. Go to *Network* > *Static Routes* and click *Create New*. The *New Static Route* page opens.
2. Set the *Destination* to *Subnet*, and leave the IP address and subnet mask as *0.0.0.0/0.0.0.0*.
3. Set the *Interface* to the SD-WAN zone, *virtual-wan-link*.
4. *Set the Status to Enabled*.
5. Click *OK*.

To configure a static route for SD-WAN in the CLI:

```
config router static
    edit 1
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
end
```

Configuring a firewall policy for SD-WAN

A firewall policy must be configured that allows traffic from the organization's internal network to the SD-WAN zone. See Configuring firewall policies for SD-WAN on page 900 for more information.

To configure the firewall policy for SD-WAN in the GUI:

1. Go to *Policy & Objects* > *Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	*sd-wan*

Incoming interface	*port1*
Outgoing interface	*virtual-wan-link*
Source	*all*
Destination	*all*
Schedule	*always*
Service	*ALL*
Action	*ACCEPT*
NAT	Enable and select *NAT*.
IP Pool Configuration	*Use Outgoing Interface Address*
Enable this policy	Enable this setting.

3. Configure the other settings as needed.
4. Click *OK*.

To configure the firewall policy for SD-WAN in the CLI:

```
config firewall policy
    edit 1
        set name "sd-wan"
        set srcintf "port1"
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Verifying the configuration

To verify the SD-WAN member status:

```
# diagnose sys sdwan member
Member(1): interface: wan1, flags=0x0 , gateway: 172.16.200.254, priority: 1 1024, weight: 0
Member(2): interface: wan2, flags=0x0 , gateway: 10.1.100.254, priority: 1 1024, weight: 0
Member(3): interface: wan3, flags=0x0 , gateway: 13.13.13.254, priority: 1 1024, weight: 0
```

To verify the configuration when both wan1 and wan2 are up:

1. Verify the SD-WAN service rules status:

```
# diagnose sys sdwan service4
Service(1): Address Mode(IPV4) flags=0x24200 use-shortcut-sla use-shortcut
 Tie break: cfg
  Gen(1), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(manual  hash-
mode=round-robin)
  Members(2):
    1: Seq_num(2 wan2 virtual-wan-link), alive, gid(1), selected
    2: Seq_num(1 wan1 virtual-wan-link), alive, gid(1), selected
  Src address(1):
        0.0.0.0-255.255.255.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

   This output indicates that both wan1 and wan2 are operational.

2. Verify the policy route list:

```
# diagnose firewall proute list
list route policy info(vf=root):

id=2130706433(0x7f000001) vwl_service=1(test) vwl_mbr_seq=1 2 dscp_tag=0xfc 0xfc flags=0x10
load-balance hash-mode=round-robin  tos=0x00 tos_mask=0x00 protocol=0 port=src(0->0):dst(0->0)
iif=0(any)
path(2): oif=3(wan1) num_pass=0, oif=6(wan2) num_pass=0
source(1): 0.0.0.0-255.255.255.255
destination(1): 0.0.0.0-255.255.255.255
hit_count=154 last_used=2023-11-09 06:16:
```

   This output indicates that both wan1 and wan2 are used to steer traffic.

To verify the configuration when wan2 is down and wan1 is up:

1. Verify the SD-WAN service rules status:

```
# diagnose sys sdwan service4

Service(1): Address Mode(IPV4) flags=0x24200 use-shortcut-sla use-shortcut
 Tie break: cfg
  Gen(1), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(manual  hash-
mode=round-robin)
  Members(2):
    1: Seq_num(1 wan1 virtual-wan-link), alive, gid(1), selected
    2: Seq_num(2 wan2 virtual-wan-link), dead, gid(1)
  Src address(1):
        0.0.0.0-255.255.255.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

This output indicates that wan1 is operational, and wan2 is not.

2. Verify the policy route list:

```
# diagnose firewall proute list
list route policy info(vf=root):

id=2130706433(0x7f000001) vwl_service=1(test) vwl_mbr_seq=1 dscp_tag=0xfc 0xfc flags=0x10
load-balance hash-mode=round-robin  tos=0x00 tos_mask=0x00 protocol=0 port=src(0->0):dst(0->0)
iif=0(any)
path(1): oif=3(wan1) num_pass=0
source(1): 0.0.0.0-255.255.255.255
destination(1): 0.0.0.0-255.255.255.255
hit_count=482 last_used=2023-11-09 06:27:08
```

This output indicates that wan1 is used to steer traffic.

To verify the configuration when wan1 is down and wan2 is up:

1. Verify the SD-WAN service rules status:

```
# diagnose sys sdwan service4

Service(1): Address Mode(IPV4) flags=0x24200 use-shortcut-sla use-shortcut
 Tie break: cfg
  Gen(1), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(manual  hash-
mode=round-robin)
  Members(2):
    1: Seq_num(2 wan2 virtual-wan-link), alive, gid(1), selected
    2: Seq_num(1 wan1 virtual-wan-link), dead, gid(1)
  Src address(1):
        0.0.0.0-255.255.255.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

This output indicates that wan2 is operational, and wan1 is not.

2. Verify the policy route list:

```
# diagnose firewall  proute list
list route policy info(vf=root):

id=2130706433(0x7f000001) vwl_service=1(test) vwl_mbr_seq=2 dscp_tag=0xfc 0xfc flags=0x10
load-balance has
h-mode=round-robin  tos=0x00 tos_mask=0x00 protocol=0 port=src(0->0):dst(0->0) iif=0(any)
path(1): oif=6(wan2) num_pass=0
source(1): 0.0.0.0-255.255.255.255
destination(1): 0.0.0.0-255.255.255.255
hit_count=903 last_used=2023-11-09 06:41:55
```

This output indicates that wan2 is used to steer traffic.

To verify the configuration when both wan1 and wan2 down, and traffic is steered using wan3:

```
# diagnose sniffer packet wan3
Using Original Sniffing Mode
interfaces=[wan3]
filters=[none]
3.144417 13.13.13.1.52665 -> 204.79.197.239.443: 1610731732 ack 236747780
3.155250 204.79.197.239.443 -> 13.13.13.1.52665: ack 1610731733
5.047264 13.13.13.1.52613 -> 20.185.212.106.443: 1421254032 ack 3784884456
5.126008 20.185.212.106.443 -> 13.13.13.1.52613: ack 1421254033
```

This output indicates that wan3 is used to steer traffic.

To verify the configuration when either wan1 or wan2 is restored, and traffic ceases to be steered through wan3:

1. Verify the SD-WAN service rules status:

```
# diagnose sys sdwan service4

Service(1): Address Mode(IPV4) flags=0x24200 use-shortcut-sla use-shortcut
 Tie break: cfg
  Gen(1), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(manual  hash-
mode=round-robin)
  Members(2):
    1: Seq_num(1 wan1 virtual-wan-link), alive, gid(1), selected
    2: Seq_num(2 wan2 virtual-wan-link), dead, gid(1)
  Src address(1):
        0.0.0.0-255.255.255.255

  Dst address(1):
        0.0.0.0-255.255.255.255
```

   This output indicates that wan1 is operational.

2. Verify the policy route list:

```
# diagnose firewall  proute list
list route policy info(vf=root):

id=2130706433(0x7f000001) vwl_service=1(test) vwl_mbr_seq=1 dscp_tag=0xfc 0xfc flags=0x10
load-balance has
h-mode=round-robin  tos=0x00 tos_mask=0x00 protocol=0 port=src(0->0):dst(0->0) iif=0(any)
path(1): oif=3(wan1) num_pass=0
source(1): 0.0.0.0-255.255.255.255
destination(1): 0.0.0.0-255.255.255.255
hit_count=986 last_used=2023-11-09 06:45:13
```

   This output indicates that wan1 is used to steer traffic.

Advanced routing

The following topics provide instructions on SD-WAN advanced routing:

- Local out traffic on page 1125
- Using BGP tags with SD-WAN rules on page 1132
- BGP multiple path support on page 1135
- Controlling traffic with BGP route mapping and service rules on page 1138
- Applying BGP route-map to multiple BGP neighbors on page 1146
- Using multiple members per SD-WAN neighbor configuration on page 1152

Local out traffic

Local out, or self-originating, traffic is traffic that originates from the FortiGate going to external servers and services. The traffic can be from Syslog, FortiAnalyzer logging, FortiGuard services, remote authentication, and others.

By default, local out traffic relies on routing table lookups to determine the egress interface that is used to initiate the connection. However, many types of local out traffic support selecting the egress interface based on SD-WAN or manually specified interfaces. When manually specifying the egress interface, the source IP address can also be manually configured.

Go to *Network* > *Local Out Routing* to configure the available types of local out traffic. Some types of traffic can only be configured in the CLI.

By default *Local Out Routing* is not visible in the GUI. Go to *System* > *Feature Visibility* to enable it. See Feature visibility on page 3595 for more information.

When VDOMs are enabled, the following entries are available on the local out routing page:

Global view	VDOM view
External Resources	**LDAP Servers**
AWS_IP_Blacklist	ldap
AWS_Malware_Hash	**Log**
Log	Log FortiAnalyzer Override Settings
Log FortiAnalyzer Setting	Log Syslogd Override Settings
Log FortiAnalyzer Cloud Setting	**RADIUS Servers**
FortiGate Cloud Log Settings	fac_radius_server
Log Syslogd Setting	**TACACS+**

Global view	VDOM view
System	TACACS
System DNS	
System FortiGuard	
System FortiSandbox	

If a service is disabled, it is grayed out. To enable it, select the service and click *Enable Service*. If a service is enabled, there is a *Local Out Setting* button in the gutter of that service's edit page to directly configure the local-out settings.

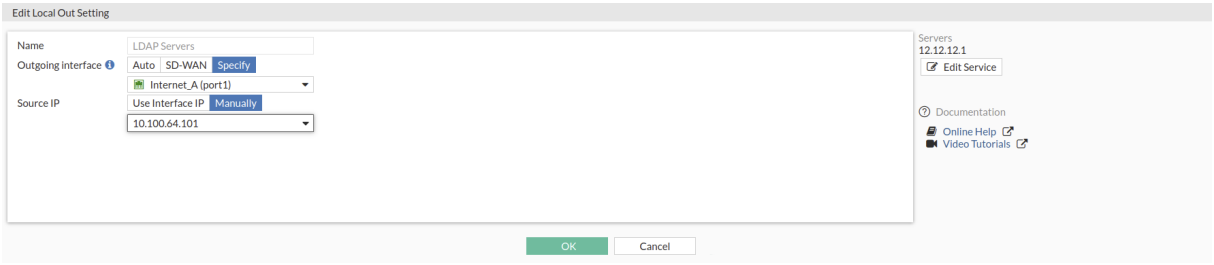
Examples

To configure DNS local-out routing:

1. Go to *Network* > *Local Out Routing* and double-click *System DNS*.
2. For *Outgoing interface*, select one of the following:

Auto	Select the outgoing interface automatically based on the routing table.
SD-WAN	Select the outgoing interface using the configured SD-WAN interfaces and rules.
Specify	Select the outgoing interface from the dropdown.
Use Interface IP	Use the primary IP, which cannot be configured by the user.
Manually	Selected an IP from the list, if the selected interface has multiple IPs configured.

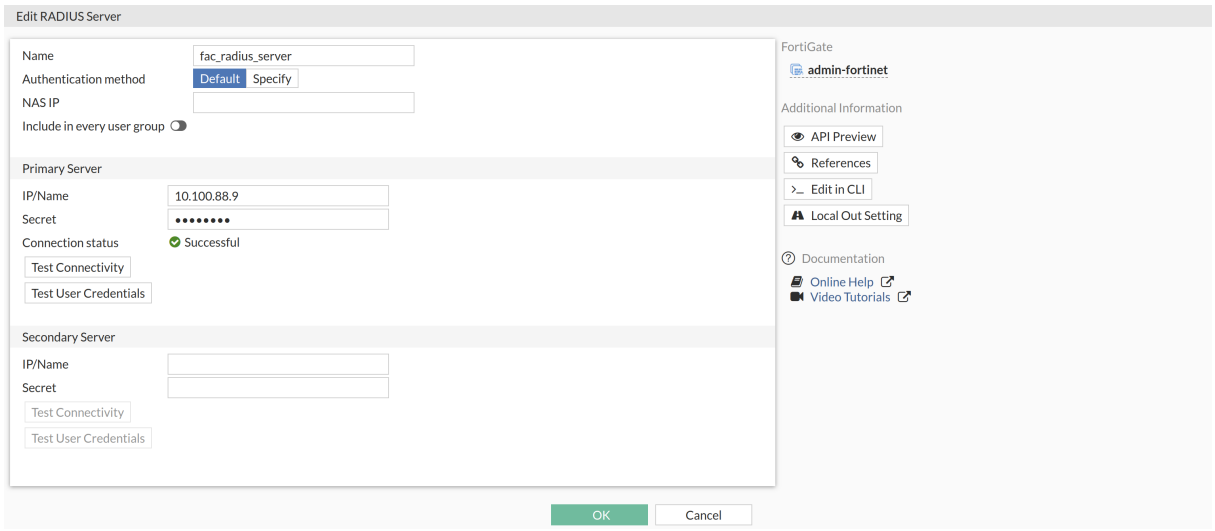
3. If *Specify* is selected, select a setting for *Source IP*:



4. Click *OK*.

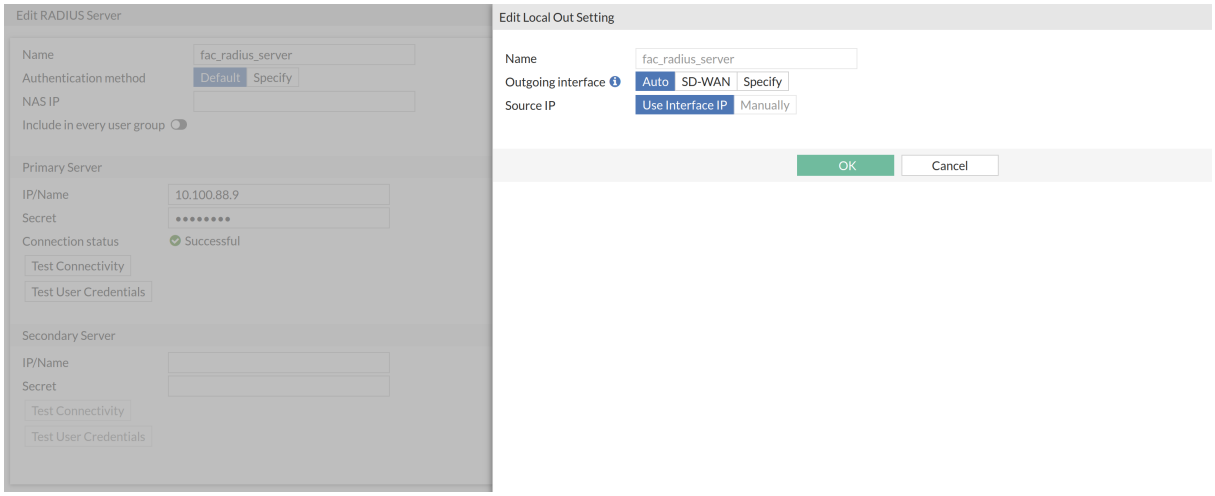
To edit local-out settings from a RADIUS server entry:

1. Go to *User & Authentication* > *RADIUS Servers* and double-click an entry to edit it.
2. Click *Local Out Setting*.



The *Edit Local Out Setting* pane opens.

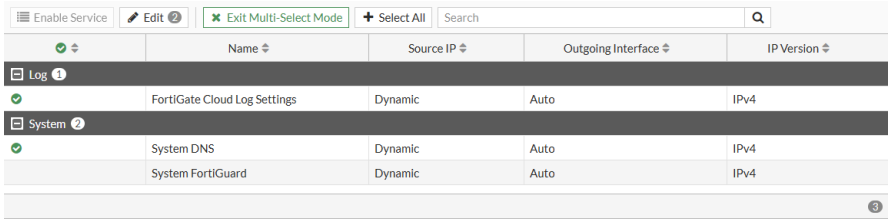
3. Configure the settings for *Outgoing interface* and *Source IP*.



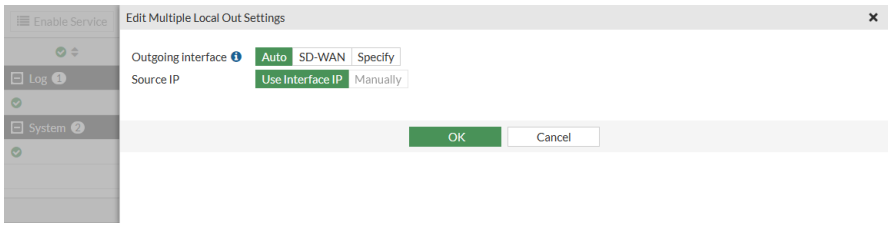
4. Click *OK*.

To edit multiple entries concurrently:

1. Go to *Network* > *Local Out Routing*.
2. If applicable, select *IPv4* or *IPv6*. *IPv4+IPv6* does not support multi-select.
3. Click *Multi-Select Mode*. All of the local out settings that can be edited concurrently are shown.
4. Select the specific entries, or click *Select All* to select all of the entries.



5. Click *Edit* and configure the local out settings as required.



6. Click *OK*.
7. Click *Exit Multi-Select Mode* to return to the normal view.

Configuring local out routing in the CLI

Some local out routing settings can only be configured using the CLI.

PING

IPv4 and IPv6 pings can be configured to use SD-WAN rules:

```
execute ping-options use-sdwan {yes | no}
execute ping6-options use-sd-wan {yes | no}
```

Traceroute

IPv4 traceroute can be configured to use SD-WAN rules:

```
execute traceroute-options use-sdwan {yes | no}
```

Central management

Central management traffic can use SD-WAN rules or a specific interface:

```
config system central-management
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

NTP server

NTP server traffic can use SD-WAN rules or a specific interface:

```
config system ntp
    config ntpserver
        edit <id>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        next
    end
end
```

DHCP proxy

DHCP proxy traffic can use SD-WAN rules or a specific interface:

```
config system settings
    set dhcp-proxy-interface-select-method {auto | sdwan | specify}
    set dhcp-proxy-interface <interface>
end
```

dhcp-proxy-interface-select-method {auto | sdwan | specify}	Select the interface selection method: • `auto`: Set the outgoing interface automatically (default). • `sdwan`: Set the interface by SD-WAN or policy routing rules. • `specify`: Set the interface manually.
dhcp-proxy-interface <interface>	Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.

DHCP relay

DHCP relay traffic can use SD-WAN rules or a specific interface:

```
config system interface
    edit <interface>
        set dhcp-relay-interface-select-method {auto | sdwan | specify}
        set dhcp-relay-interface <interface>
    next
end
```

dhcp-relay-interface-select-method {auto | sdwan | specify}	Select the interface selection method: • `auto`: Set the outgoing interface automatically (default). • `sdwan`: Set the interface by SD-WAN or policy routing rules. • `specify`: Set the interface manually.
dhcp-relay-interface <interface>	Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.

CA and local certificate renewal with SCEP

Certificate renewal with SCEP traffic can use SD-WAN rules or a specific interface:

```
config vpn certificate setting
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

IPS TLS protocol active probing

TLS active probing can use SD-WAN rules or a specific interface:

```
config ips global
    config tls-active-probe
```

```
        set interface-selection-method {auto | sdwan | specify}
        set interface <interface>
        set vdom <VDOM>
        set source-ip <IPv4 address>
        set source-ip6 <IPv6 address>
    end
end
```

interface-select-method {auto | sdwan | specify}	Select the interface selection method: • `auto`: Set the outgoing interface automatically (default). • `sdwan`: Set the interface by SD-WAN or policy routing rules. • `specify`: Set the interface manually.
interface <interface>	Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.
vdom <VDOM>	Specify the VDOM. This option is only available and must be configured when `interface-select-method` is `sdwan` or `specify`.
source-ip <IPv4 address>	Specify the source IPv4 address. This option is only available and must be configured when `interface-select-method` is `sdwan` or `specify`.
source-ip6 <IPv6 address>	Specify the source IPv6 address. This option is only available and must be configured when `interface-select-method` is `sdwan` or `specify`.

NetFlow and sFlow

NetFlow and sFlow can use SD-WAN rules or a specific interface.

The `netflow` command is global, and utilized by the management VDOM. The `vdom-netflow` command is only available for non-management VDOMs.

```
config system {netflow | vdom-netflow}
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

```
config system {sflow | vdom-sflow}
    config collectors
        edit <id>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        next
    end
end
```

interface-select-method {auto | sdwan | specify}	Select the interface selection method: • `auto`: Set the outgoing interface automatically (default). • `sdwan`: Set the interface by SD-WAN or policy routing rules. • `specify`: Set the interface manually.
interface <interface>	Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.

FortiClient EMS

FortiClient EMS endpoint control traffic can use SD-WAN rules or a specific interface:

```
config endpoint-control fctems
    edit 1
        set status enable
        set name fctems1
        set interface-select-method {auto | sdwan | specify}
        set interface <interface>
    next
end
```

TACACS+

System log entries can be sent to external TACACS+ accounting servers. TACACS+ traffic can use SD-WAN rules or a specific IP address:

```
config log tacacs+accounting setting
    set interface-select-method {auto | sdwan | specify}
    set source-ip <IP address>
end
```

SNMP

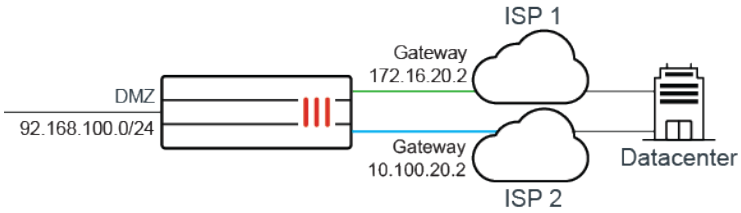
SNMP Trap traffic can use SD-WAN rules or a specific interface:

```
config system snmp community
    edit <id>
        config hosts
            edit <id>
                set interface-select-method {auto | sdwan | specify}
            next
        end

config system snmp user
    edit <user>
        set interface-select-method {auto | sdwan | specify}
    next
end
```

Using BGP tags with SD-WAN rules

SD-WAN rules can use Border Gateway Protocol (BGP) learned routes as dynamic destinations.



In this example, a customer has two ISP connections, wan1 and wan2. wan1 is used primarily for direct access to internet applications, and wan2 is used primarily for traffic to the customer's data center.

The customer could create an SD-WAN rule using the data center's IP address range as the destination to force that traffic to use wan2, but the data center's IP range is not static. Instead, a BGP tag can be used.

For this example, wan2's BGP neighbor advertises the data center's network range with a community number of 30:5.

This example assumes that SD-WAN is enabled on the FortiGate, wan1 and wan2 are added as SD-WAN members in the *virtual-wan-link* SD-WAN zone, and a policy and static route have been created. See SD-WAN quick start on page 897 for details.

FortiOS supports IPv4 and IPv6 route tags.

To configure BGP tags with SD-WAN rules:

1. Configure the community list:

```
config router community-list
    edit "30:5"
        config rule
            edit 1
                set action permit
                set match "30:5"
            next
        end
    next
end
```

2. Configure the route map:

```
config router route-map
    edit "comm1"
        config rule
            edit 1
                set match-community "30:5"
                set set-route-tag 15
```

```
            next
        end
    next
end
```

3. Configure BGP:

```
config router bgp
    set as xxxxx
    set router-id xxxx
    config neighbor
        edit "10.100.20.2"
            set soft-reconfiguration enable
            set remote-as xxxxx
            set route-map-in "comm1"
        next
    end
end
```

4. Configure the route tag address object:

```
config firewall address
    edit "DataCenter_route_tag_15"
        set type route-tag
        set route-tag 15
    next
end
```

5. Configure a firewall policy:

```
config firewall policy
    edit 1
        set name "1"
        set srcintf "dmz"
        set dstintf "virtual-wan-link"
        set srcaddr "all"
        set dstaddr "DataCenter_route_tag_15"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

6. Edit the SD-WAN configuration:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "wan1"
            set gateway 172.16.20.2
```

```
        next
        edit 2
            set interface "wan2"
        next
    end
    config service
        edit 1
            set name "DataCenter"
            set mode manual
            set priority-members 2
            set dst "DataCenter_route_tag_15"
        next
    end
end
```

Troubleshooting BGP tags with SD-WAN rules

Check the network community

Use the `get router info bgp network` command to check the network community:

```
# get router info bgp network
BGP table version is 5, local router ID is 1.1.1.1

Check dynamic BGP addresses used in policy routes

Use the `diagnose firewall proute list` command to check dynamic BGP addresses used in policy routes:

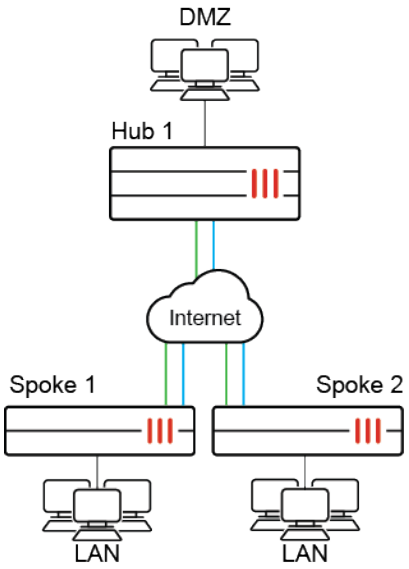
```
# diagnose firewall proute list
list route policy info(vf=root):

id=4278779905 vwl_service=1(DataCenter) flags=0x0 tos=0x00 tos_mask=0x00 protocol=0 sport=0:65535
iif=0 dport=1-65535 oif=16
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 10.100.11.0/255.255.255.0
```

BGP multiple path support

BGP supports multiple paths, allowing an ADVPN to advertise multiple paths. This allows BGP to extend and keep additional network paths according to RFC 7911.

In this example, Spoke1 and Spoke2 each have four VPN tunnels that are connected to the Hub with ADVPN. The Spoke-Hub has established four BGP neighbors on all four tunnels.



Spoke 1 and Spoke 2 can learn four different routes from each other.

To configure the hub:

```
config router bgp
    set as 65505
    set router-id 11.11.11.11
    set ibgp-multipath enable
    set additional-path enable
    set additional-path-select 4
    config neighbor-group
        edit "gr1"
            set capability-default-originate enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 10.10.0.0 255.255.0.0
            set neighbor-group "gr1"
        next
    end
    config network
        edit 12
            set prefix 11.11.11.11 255.255.255.255
        next
    end
end
```

To configure a spoke:

```
config router bgp
    set as 65505
    set router-id 2.2.2.2
    set ibgp-multipath enable
    set additional-path enable
    set additional-path-select 4
    config neighbor
        edit "10.10.100.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
        edit "10.10.200.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
        edit "10.10.203.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
        edit "10.10.204.254"
            set soft-reconfiguration enable
            set remote-as 65505
            set additional-path both
            set adv-additional-path 4
        next
    end
    config network
        edit 3
            set prefix 22.1.1.0 255.255.255.0
        next
    end
end
```

To view the BGP routing table on a spoke:

```
Spoke1 # get router info routing-table bgp
    Routing table for VRF=0
    B*      0.0.0.0/0 [200/0] via 10.10.200.254, vd2-2, 03:57:26
        [200/0] via 10.10.203.254, vd2-3, 03:57:26

        [200/0] via 10.10.100.3, vd2-1, 03:57:26
```

Controlling traffic with BGP route mapping and service rules

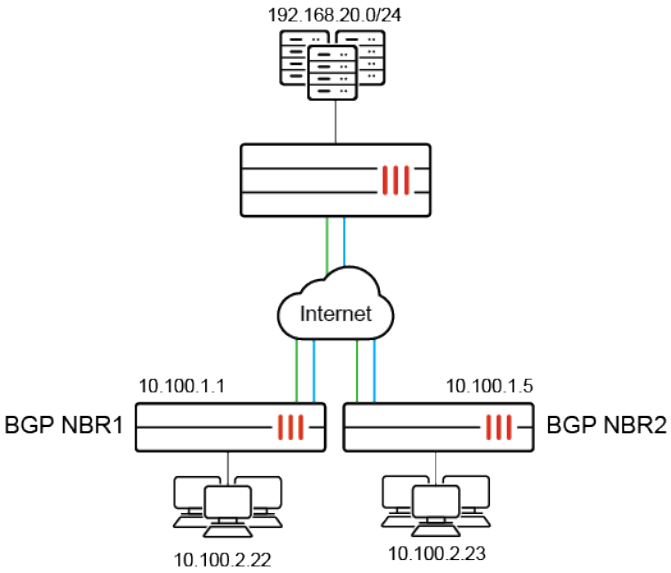
SD-WAN allows you to select different outbound WAN links based on performance SLAs. It is important that BGP neighbors are aware of these settings, and changes to them.

BGP can adapt to changes in SD-WAN link SLAs in the following ways:

- Applying different route-maps based on the SD-WAN's health checks. For example, different BGP community strings can be advertised to BGP neighbors when SLAs are not met.
- Traffic can be selectively forwarded based on the active BGP neighbor. If the SD-WAN service's role matches the active SD-WAN neighbor, the service is enabled. If there is no match, then the service is disabled.

Example

In this topology, a branch FortiGate has two SD-WAN gateways serving as the primary and secondary gateways. The gateways reside in different datacenters, but have a full mesh network between them.



This example shows how route-maps and service rules are selected based on performance SLAs and the member that is currently active. Traffic flows through the primary gateway unless the neighbor's health check is outside of its SLA. If that happens, traffic routes to the secondary gateway.

BGP NBR1 is the primary neighbor and BGP NBR2 is the secondary neighbor.

The branch FortiGate's wan1 and wan2 interfaces are members of the SD-WAN. When the SD-WAN neighbor status is primary, it will advertise community *20:1* to BGP NBR1 and *20:5* to BGP NBR2. When the SD-WAN neighbor status is secondary, it will advertise *20:5* to BGP NBR1 and *20:2* to BGP NBR2.

Only one of the primary or secondary neighbors can be active at one time. The SD-WAN neighbor status is used to decide which neighbor is selected:

- **Primary**: The primary neighbor takes precedence if its SLAs are met.
- **Secondary**: If the primary neighbor's SLAs are not met, the secondary neighbor becomes active if its SLAs are met.
- **Standalone**: If neither the primary or secondary neighbor's SLAs are met, the SD-WAN neighbor status becomes standalone.

Route map

SD-WAN is configured to let BGP advertise different communities when the SLA status changes. When the SLA is missed, it triggers BGP to advertise a different community to its BGP neighbor based on its route-map. The BGP neighbors can use the received community string to select the best path to reach the branch.

To configure BGP route-maps and neighbors:

1. Configure an access for the routes to be matched:

```
config router access-list
    edit "net192"
        config rule
            edit 1
                set prefix 192.168.20.0 255.255.255.0
```

```
            next
        end
    next
end
```

2. Configure the primary neighbor's preferred route-map:

```
config router route-map
    edit "comm1"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "20:1"
            next
        end
    next
end
```

3. Configure the secondary neighbor's preferred route-map:

```
config router route-map
    edit "comm2"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "20:2"
            next
        end
    next
end
```

4. Configure the failed route-map:

```
config router route-map
    edit "comm5"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "20:5"
            next
        end
    next
end
```

5. Configure BGP neighbors:

```
config router bgp
    set as 65412
    set router-id 1.1.1.1
    set ibgp-multipath enable
    config neighbor
        edit "10.100.1.1"
```

```
            set soft-reconfiguration enable
            set remote-as 20
            set route-map-out "comm5"
            set route-map-out-preferable "comm1"
        next
        edit "10.100.1.5"
            set soft-reconfiguration enable
            set remote-as 20
            set route-map-out "comm5"
            set route-map-out-preferable "comm2"
        next
    end
end
```

When SLAs are met, `route-map-out-preferable` is used. When SLAs are missed, `route-map-out` is used.

To configure SD-WAN:

1. Configure the SD-WAN members:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "port1"
        next
        edit 2
            set interface "port2"
        next
    end
end
```

2. Configure health checks for each member:

```
config system sdwan
    config health-check
        edit "ping"
            set server "10.100.2.22"
            set members 1
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 1
                next
            end
        next
        edit "ping2"
            set server "10.100.2.23"
            set members 2
            config sla
                edit 1
                    set link-cost-factor packet-loss
```

```
                    set packetloss-threshold 1
                next
            end
        next
    end
end
```

3. Configure the SD-WAN neighbors and assign them a role and the health checks used to determine if the neighbor meets the SLA:
   SD-WAN neighbors can only be configured in the CLI.

```
config system sdwan
    config neighbor
        edit "10.100.1.1"
            set member 1
            set role primary
            set health-check "ping"
            set sla-id 1
        next
        edit "10.100.1.5"
            set member 2
            set role secondary
            set health-check "ping2"
            set sla-id 1
        next
    end
end
```

Service rules

Create SD-WAN service rules to direct traffic to the primary neighbor when its SLAs are met, and to the secondary neighbor when the primary neighbor's SLAs are missed.

To configure the SD-WAN service rules:

```
config system sdwan
    config service
        edit 1
            set name "Primary-Out"
            set role primary
            set dst "all"
            set src "all"
            set priority-members 1
        next
        edit 2
            set name "Secondary-Out"
            set role secondary
            set dst "all"
            set src "all"
            set priority-members 2
        next
```

```
    end
end
```

If neither the primary nor secondary neighbors are active, the SD-WAN neighbor status becomes standalone. Only service rules with `standalone-action` enabled will continue to pass traffic. This option is disabled by default.

Verification

To verify when the primary neighbor is passing traffic:

1. Verify the health check status:

```
FortiGate-Branch # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(0.569), jitter(0.061) sla_map=0x1
Health Check(ping2):
Seq(2 port2): state(alive), packet-loss(0.000%) latency(3.916), jitter(2.373) sla_map=0x1
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
        Selected role(primary) last_secondary_select_time/current_time in seconds 0/572
Neighbor(10.100.1.1): member(1) role(primary)
        Health-check(ping:1)  sla-pass selected alive
Neighbor(10.100.1.5): member(2) role(secondary)
        Health-check(ping2:1)  sla-pass alive
```

3. Verify service rules status:

```
FortiGate-Branch # diagnose sys sdwan service4

Service(1): Address Mode(IPV4) flags=0x0
  Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Service role: primary
  Members:
    1: Seq_num(1 port1), alive, selected
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255

Service(2): Address Mode(IPV4) flags=0x0
  Gen(6), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Service role: secondary, disabled by unselected.
  Members:
    1: Seq_num(2 port2), alive, selected
  Src address:
        0.0.0.0-255.255.255.255
```

```
Dst address:
      0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:
   a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    10.100.1.2 from 10.100.1.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:1
      Last update: Thu Apr 30 13:41:40 2020
```

   b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    10.100.1.6 from 10.100.1.6 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:5
      Last update: Thu Apr 30 13:41:39 2020
```

To verify when the secondary neighbor is passing traffic:

1. Verify the health check status:

```
FortiGate-Branch # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 port1): state(dead), packet-loss(54.000%) sla_map=0x0
Health Check(ping2):
Seq(2 port2): state(alive), packet-loss(0.000%) latency(4.339), jitter(3.701) sla_map=0x1
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
       Selected role(secondary) last_secondary_select_time/current_time in seconds 936/936
Neighbor(10.100.1.1): member(1) role(primary)
       Health-check(ping:1)  sla-fail dead
Neighbor(10.100.1.5): member(2) role(secondary)
       Health-check(ping2:1)  sla-pass selected alive
```

3. Verify service rules status:

```
FortiGate-Branch # diagnose sys sdwan service4

Service(1): Address Mode(IPV4) flags=0x0
  Gen(4), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Service role: primary, disabled by unselected.
  Members:
    1: Seq_num(1 port1), alive, selected
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255

Service(2): Address Mode(IPV4) flags=0x0
  Gen(7), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Service role: secondary
  Members:
    1: Seq_num(2 port2), alive, selected
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:
   a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    10.100.1.2 from 10.100.1.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:5
      Last update: Thu Apr 30 15:41:58 2020
```

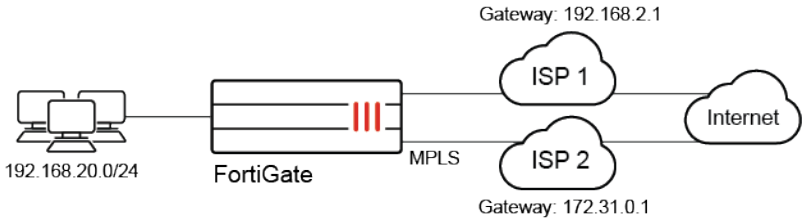
   b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    10.100.1.6 from 10.100.1.6 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:2
      Last update: Thu Apr 30 15:42:07 2020
```

Applying BGP route-map to multiple BGP neighbors

Controlling traffic with BGP route mapping and service rules explained how BGP can apply different route-maps to the primary and secondary SD-WAN neighbors based on SLA health checks.

In this example, SD-WAN neighbors that are not bound to primary and secondary roles are configured.



The FortiGate has multiple SD-WAN links and has formed BGP neighbors with both ISPs.

ISP1 is used primarily for outbound traffic, and has an SD-WAN service rule using the lowest cost algorithm applied to it. When SLAs for ISP1 are not met, it will fail over to the MPLS line.

Inbound traffic is allowed by both WAN links, with each WAN advertising a community string when SLAs are met. When SLAs are not met, the WAN links advertise a different community string.

This example uses two SD-WAN links. The topology can be expanded to include more links as needed.

To configure BGP route-maps and neighbors:

1. Configure an access list for routes to be matched:

```
config router access-list
    edit "net192"
        config rule
            edit 1
                set prefix 192.168.20.0 255.255.255.0
            next
        end
    next
end
```

2. Configure route-maps for neighbor ISP1:

```
config router route-map
    edit "comm1"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "64511:1"
            next
        end
    next
    edit "comm-fail1"
        config rule
            edit 1
                set match-ip-address "net192"
```

```
                set set-community "64511:5"
            next
        end
    next
end
```

3. Configure route-maps for neighbor ISP2:

```
config router route-map
    edit "comm2"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "64522:1"
            next
        end
    next
    edit "comm-fail2"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "64522:5"
            next
        end
    next
end
```

4. Configure the BGP neighbors:

```
config router bgp
    set as 64512
    set keepalive-timer 1
    set holdtime-timer 3
    config neighbor
        edit "192.168.2.1"
            set soft-reconfiguration enable
            set remote-as 64511
            set route-map-out "comm-fail1"
            set route-map-out-preferable "comm1"
        next
        edit "172.31.0.1"
            set soft-reconfiguration enable
            set remote-as 64522
            set route-map-out "comm-fail2"
            set route-map-out-preferable "comm2"
        next
    end
    config network
        edit 1
            set prefix 192.168.20.0 255.255.255.0
        next
```

```
    end
end
```

When SLAs are met, `route-map-out-preferable` is used. When SLAs are missed, `route-map-out` is used.

To configure SD-WAN:

1. Configure the SD-WAN members:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "port1"
            set gateway 192.168.2.1
        next
        edit 2
            set interface "MPLS"
            set cost 20
        next
    end
end
```

2. Configure the health checks that must be met:

```
config system sdwan
    config health-check
        edit "pingserver"
            set server "8.8.8.8"
            set members 2 1
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 2
                next
            end
        next
    end
end
```

3. Configure the SD-WAN neighbors and assign them a role and the health checks used to determine if the neighbor meets the SLA:
When no role is defined, the default role, `standalone`, is used.

```
config system sdwan
    config neighbor
        edit "192.168.2.1"
            set member 1
            set health-check "pingserver"
            set sla-id 1
        next
        edit "172.31.0.1"
```

```
            set member 2
            set health-check "pingserver"
            set sla-id 1
        next
    end
end
```

Service rules

Create SD-WAN service rules to direct traffic to the SD-WAN links based on the lowest cost algorithm The same SLA health check and criteria that are used for the SD-WAN neighbor are used for this SD-WAN service rule.

When no roles are defined in the service rule, the default role, `standalone`, is used.

To configure the SD-WAN service rule:

```
config system sdwan
    config service
        edit 1
            set name "OutboundAll"
            set mode sla
            set dst "all"
            set src "all"
            config sla
                edit "pingserver"
                    set id 1
                next
            end
            set priority-members 1 2
        next
    end
end
```

Verification

To verify that when both SLAs are met, port1 is selected due to its lower cost:

1. Verify the health check status:

```
FortiGate-Branch # diagnose sys sdwan health-check
Health Check(pingserver):
Seq(2 MPLS): state(alive), packet-loss(0.000%) latency(24.709), jitter(14.996) sla_map=0x1
Seq(1 port1): state(alive), packet-loss(0.000%) latency(28.771), jitter(14.840) sla_map=0x1
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
Neighbor(192.168.2.1): member(1) role(standalone)
        Health-check(pingserver:1)  sla-pass selected alive
```

```
Neighbor(172.31.0.1): member(2) role(standalone)
       Health-check(pingserver:1)  sla-pass selected alive
```

3. Verify service rules status:
   Because the service role is `standalone`, it matches both neighbors. The mode (SLA) determines that port1 is lower cost.

```
FortiGate-Branch # diagnose sys sdwan service4

Service(1): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Service role: standalone
  Members:
    1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
    2: Seq_num(2 MPLS), alive, sla(0x1), cfg_order(1), cost(20), selected
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:
   a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    192.168.2.5 from 192.168.2.5 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 64511:1
      Last update: Thu Apr 30 23:59:05 2020
```

   b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    172.31.0.2 from 172.31.0.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 64522:1
      Last update: Fri May  1 00:11:28 2020
```

To verify that when neighbor ISP1 misses SLAs, MPLS is selected and BGP advertises a different community string for ISP1:

1. Verify the health check status:

```
FortiGate-Branch # diagnose sys sdwan health-check
Health Check(pingserver):
Seq(2 MPLS): state(alive), packet-loss(0.000%) latency(25.637), jitter(17.820) sla_map=0x1
Seq(1 port1): state(dead), packet-loss(16.000%) sla_map=0x0
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
Neighbor(192.168.2.1): member(1) role(standalone)
        Health-check(pingserver:1)  sla-fail dead
Neighbor(172.31.0.1): member(2) role(standalone)
        Health-check(pingserver:1)  sla-pass selected alive
```

3. Verify service rules status:
   As SLA failed for neighbor ISP1, MPLS is preferred.

```
FortiGate-Branch # diagnose sys sdwan service4

Service(1): Address Mode(IPV4) flags=0x0
  Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Service role: standalone
  Members:
    1: Seq_num(2 MPLS), alive, sla(0x1), cfg_order(1), cost(20), selected
    2: Seq_num(1 port1), dead, sla(0x0), cfg_order(0), cost(0)
  Src address:
        0.0.0.0-255.255.255.255

  Dst address:
        0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:
   The community received on ISP1 is updated.
   a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    192.168.2.5 from 192.168.2.5 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 64511:5
      Last update: Fri May  1 00:33:26 2020
```

b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    172.31.0.2 from 172.31.0.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 64522:1
      Last update: Fri May  1 00:22:42 2020
```

Using multiple members per SD-WAN neighbor configuration

SD-WAN BGP neighbor configurations are used to define the SLA health check in which an SD-WAN member must meet to qualify as being up. When the SD-WAN member meets the SLA threshold, the FortiGate will apply the route map defined in the BGP neighbor's `route-map-out-preferable` option. If the SD-WAN member fails to meet the SLA, the FortiGate will apply the route map defined in the BGP neighbor's `route-map-out` option instead. This allows the FortiGate to advertise the health of the SD-WAN member to its BGP neighbor by advertising different community strings based on its SLA status.

For more information, refer to the following BGP examples: Controlling traffic with BGP route mapping and service rules on page 1138 and Applying BGP route-map to multiple BGP neighbors on page 1146.

Selecting multiple SD-WAN members allows the SD-WAN neighbor feature to support topologies where there are multiple SD-WAN overlays and/or underlays to a neighbor. The `minimum-sla-meet-members` option is used to configure the minimum number of members that must be in an SLA per neighbor for the preferable route map to be used.

```
config system sdwan
    config neighbor
        edit <ip>
            set member {<seq-num_1>} [<seq-num_2>] ... [<seq-num_n>]
            set minimum-sla-meet-members <integer>
        next
    end
end
```

`member {<seq-num_1>} [<seq-num_2>] ... [<seq-num_n>]`	Enter the member sequence number list. Multiple members can be defined.
`minimum-sla-meet-members <integer>`	Set the minimum number of members that meet SLA when the neighbor is preferred (1 - 255, default = 1). • If the number of in SLA members is less than the `minimum-sla-meet-`

`members` value, the default route map will be used.
- If the number of in SLA members is equal or larger than the `minimum-sla-meet-members` value, the preferable route map will be used.

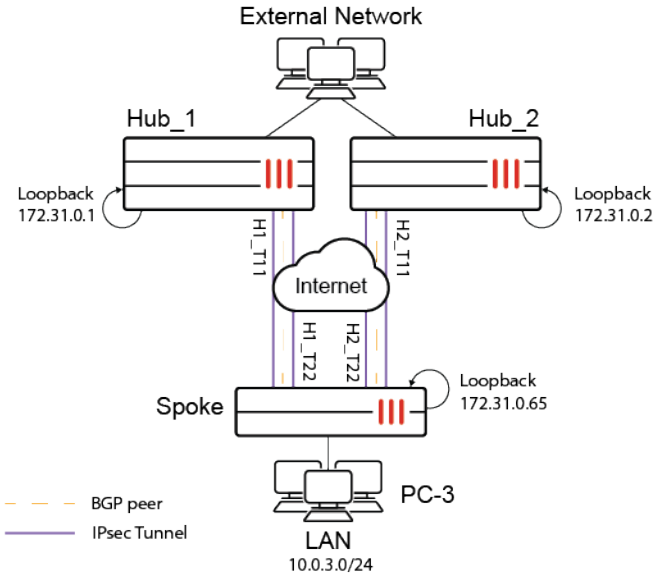
Example

In the following example, the spoke FortiGate has four tunnels: two tunnels to Hub_1 and two tunnels to Hub_2. The spoke has two BGP neighbors: one to Hub_1 and one to Hub-2. BGP neighbors are established on loopback IPs.

The SD-WAN neighbor plus `route-map-out-preferable`configuration is deployed on the spoke to achieve the following:

- If any tunnel to Hub_1 or Hub_2 is in SLA, the preferable route map will be applied on the BGP neighbor to Hub_1 or Hub_2.
- If both tunnels to Hub_1 or Hub_2 are out of SLA, the default route map will be applied on the BGP neighbor to Hub_1 or Hub_2.

The preferable route map and default route map are used to set different custom BGP communities as the spoke advertises its LAN routes to the hub. Each hub can translate communities into different BGP MED or AS prepends and signal them to the external peers to manipulate inbound traffic, thereby routing traffic to the spoke only when the SLAs are met on at least one of two VPN overlays. In this example, community string 10:1 signals to the neighbor that SLAs are met, and 10:2 signals that SLAs are not met.



To configure the BGP route maps and neighbors:

1. Configure an access list of prefixes to be matched:

```
config router access-list
    edit "net10"
        config rule
            edit 1
```

```
                set prefix 10.0.3.0 255.255.255.0
            next
        end
    next
end
```

2. Configure route maps for neighbors in SLA (preferable) and out of SLA (default):

```
config router route-map
    edit "in_sla"
        config rule
            edit 1
                set match-ip-address "net10"
                set set-community "10:1"
            next
        end
    next
    edit "out_sla"
        config rule
            edit 1
                set match-ip-address "net10"
                set set-community "10:2"
            next
        end
    next
end
```

3. Configure the BGP neighbors:

```
config router bgp
    set router-id 172.31.0.65
    config neighbor
        edit "172.31.0.1"
            set route-map-out "out_sla"
            set route-map-out-preferable "in_sla"
            set update-source "Loopback0"
        next
        edit "172.31.0.2"
            set route-map-out "out_sla"
            set route-map-out-preferable "in_sla"
            set update-source "Loopback0"
        next
    end
    config network
        edit 1
            set prefix 10.0.3.0 255.255.255.0
        next
    end
end
```

To configure SD-WAN:

1. Configure the SD-WAN members:

```
config system sdwan
    set status enable
    config members
        edit 1
            set interface "H1_T11"
            set source 172.31.0.65
        next
        edit 4
            set interface "H1_T22"
            set source 172.31.0.65
        next
        edit 6
            set interface "H2_T11"
            set source 172.31.0.65
        next
        edit 9
            set interface "H2_T22"
            set source 172.31.0.65
        next
    end
end
```

2. Configure the health check that must be met:

```
config system sdwan
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set members 0
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
            end
        next
    end
end
```

3. Configure the SD-WAN neighbors:

```
config system sdwan
    config neighbor
        edit "172.31.0.1"
            set member 1 4
            set health-check "HUB"
            set sla-id 1
            set minimum-sla-meet-members 1
        next
```

```
        edit "172.31.0.2"
            set member 6 9
            set health-check "HUB"
            set sla-id 1
            set minimum-sla-meet-members 1
        next
    end
end
```

To verify that when two members to Hub_1/Hub_2 are in SLA, the preferable route map is be applied on BGP neighbors to Hub_1/Hub_2:

```
Branch1_A_FGT (root) # diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(0.209), jitter(0.017), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999999), bandwidth-bi(1999998) sla_map=0x1
Seq(4 H1_T22): state(alive), packet-loss(0.000%) latency(0.171), jitter(0.004), mos(4.404),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1

```

```
# diagnose sys sdwan neighbor
Neighbor(172.31.0.1): member(1 4 )role(standalone)
        Health-check(HUB:1)  sla-pass selected alive
Neighbor(172.31.0.2): member(6 9 )role(standalone)
        Health-check(HUB:1)  sla-pass selected alive
```

On Hub_1 and Hub_2, the expected communities have been attached into the spoke's LAN route:

```
Hub_1_FGT (root) # get router info bgp network 10.0.3.0/24
VRF 0 BGP routing table entry for 10.0.3.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  Local, (Received from a RR-client)
    172.31.0.65 from 172.31.0.65 (172.31.0.65)
      Origin IGP metric 0, localpref 100, valid, internal, best
      Community: 10:1

VPN overlay

The following topics provide instructions on SD-WAN VPN overlays:

- ADVPN 2.0 edge discovery and path management on page 1159
- ADVPN and shortcut paths on page 1189
- Active dynamic BGP neighbor triggered by ADVPN shortcut on page 1203
- SD-WAN monitor on ADVPN shortcuts on page 1214
- Hold down time to support SD-WAN service strategies on page 1215
- Adaptive Forward Error Correction on page 1217
- Dual VPN tunnel wizard on page 1221
- Duplicate packets on other zone members on page 1222
- Duplicate packets based on SD-WAN rules on page 1225
- Interface based QoS on individual child tunnels based on speed test results on page 1227

- SD-WAN in large scale deployments on page 1230
- Keeping sessions in established ADVPN shortcuts while they remain in SLA on page 1242
- SD-WAN multi-PoP multi-hub large scale design and failover on page 1249
- Using a single IKE elector in ADVPN to match all SD-WAN control plane traffic on page 1268
- SD-WAN Overlay-as-a-Service on page 1276

ADVPN 2.0 edge discovery and path management

The SD-WAN with ADVPN solution has evolved to version 2.0 with major changes to ADVPN design and operation, including the introduction of edge discovery and path management for ADVPN spokes.

ADVPN 2.0 incorporates intelligence into the spokes to ensure shortcut tunnels (also known as shortcuts) are established using underlays available on both spokes and chosen based on matching certain link health criteria. In unique circumstances where spokes use different transports than the hub, ADVPN 2.0 can use overlay placeholders to trigger shortcuts between spokes over transports to which hubs are not connected.

ADVPN 2.0 provides a more flexible SD-WAN solution than the original ADVPN to achieve resiliency against underlay outages or degraded underlay performance because it no longer depends on specific BGP routing designs or mechanisms, including route reflection, BGP next hop recursive resolution, BGP per overlay, and BGP on loopback.

Currently, ADVPN 2.0 only supports IPv4.

The following topics describe further details about ADVPN 2.0:

- SD-WAN with ADVPN 2.0 versus previous ADVPN on page 1159
- SD-WAN CLI configuration on page 1160
- Example SD-WAN configurations using ADVPN 2.0 on page 1162
- Example SD-WAN overlay placeholders using ADVPN 2.0 on page 1180

SD-WAN with ADVPN 2.0 versus previous ADVPN

With the previous version of ADVPN and SD-WAN, shortcut path selection relied entirely on the overlays between the spokes. The hub and overlays were used to exchange IKE shortcut messages, and policy routes were configured on the hub to ensure shortcuts were established on the same overlay. In addition, user traffic was needed to trigger the process of establishing shortcuts.

With the latest version of ADVPN and SD-WAN, shortcut path selection is achieved through edge discovery and path management functionality on the ADVPN spokes.

1. Edge discovery:
   - Expand IKE Shortcut-Reply message to allow the local spoke (spoke where user traffic is initiated) to obtain the remote spoke (destination spoke for user traffic) WAN link information, which includes IP address, transport group, link quality, link cost, and member configuration order.

- After shortcut establishment, WAN link information can be exchanged on the shortcut regularly every 5 seconds through UDP traffic. The path management function on the local spoke is regularly updated to pick up changes to remote or local overlays and select the best shortcut path accordingly.

2. Path management:

   The local spoke handles the remote spoke WAN link information, calculates the best shortcut path per SD-WAN service or rule, and then advises IKE to establish a shortcut using the selected path.

   - The local spoke directly sends a shortcut-query to a remote spoke to trigger a shortcut after path management chooses a path.
   - Path management can trigger multiple shortcuts for load balancing SD-WAN rules. Traffic can be load balanced over these multiple shortcuts to use as much of the available WAN bandwidth as possible without wasting idle links if they are healthy. The algorithm to calculate multiple shortcuts for the load balancing service will consider transport group and in-SLA status for both local and remote parent overlays.
   - Spokes can automatically deactivate all shortcuts connecting to the same spoke when user traffic is not observed for a specified time interval. This is achieved by enabling a shared idle timeout setting in the IPsec VPN Phase 1 interface settings for associated overlays.
   - When overlay placeholders are enabled, spokes can use overlay placeholders to trigger shortcuts between spokes over transports to which hubs are not connected.

Currently, ADVPN 2.0 only supports IPv4.

SD-WAN CLI configuration

The `config system sdwan` command is used to configure ADVPN 2.0 on the spokes:

```
config system sdwan
    config zone
        edit <zone-name>
            set advpn-select {enable | disable}
            set advpn-health-check <health-check name>
        next
    end
    config members
        edit <integer>
            set transport-group <integer>
        next
    end
    config service
        edit <integer>
            set shortcut-priority {enable | disable | auto}
        next
    end
end
```

`set advpn-select {enable | disable}`	Enable or disable SDWAN/ADVPN-2.0 (default=disabled).
`set advpn-health-check <health-check name>`	Specify the health check for the spoke whose info will be sent to the peer spoke.
`set transport-group <integer>`	Specify different group ID between (1 -255) to differentiate link-type, such as Internet, MPLS, LTE, Satellite.
`set shortcut-priority {enable | disable | auto}`	Enable or disable making ADVPN shortcut a high priority over overlay parent interfaces, if SLA mode or link cost factor mode conditions are met: • `enable`: enable a high priority of ADVPN shortcut for this service. • `disable`: disable a high priority of ADVPN shortcut for this service. • `auto`: automatically enable a high priority of ADVPN shortcut for this service if ADVPN2.0 is enabled.
`diagnose sys sdwan advpn-session`	Diagnostic command run on local spoke to view remote spoke WAN link information and path manager shortcut path selection.

As with the previous version of ADVPN, on the hub, you must enable ADVPN and configure firewall policies between spokes.

The `config vpn ipsec phase1-interface` command is used to configure the shared idle timeout for overlays used by ADVPN.

```
config vpn ipsec phase1-interface
   edit <phase1-interface name>
      set idle-timeout {enable | disable}
      set shared-idle-timeout {enable | disable}
      set idle-timeoutinterval <integer>
   next
end
```

`set idle-timeout {enable | disable}`	Enable/disable IPsec tunnel idle timeout (default = `disable`). Must be set to `enable` when `shared-idle-timeout` is enabled.
`set shared-idle-timeout {enable | disable}`	Enable/disable `shared-idle-timeout` on involved overlays (default = `disable`).
`set idle-timeoutinterval <integer>`	IPsec tunnel idle timeout, in minutes (5 - 43200, default = 5).

The `config vpn ipsec phase1-interface` command is used to configure overlay placeholders, and shortcut tunnels require each spoke to be configured with these settings:

```
config vpn ipsec phase1-interface
    edit <placeholder_phase1_interface_name>
        set type dynamic
        ...
        set net-device enable
        ...
        set auto-discovery-dialup-placeholder {enable | disable}
    next
end
```

`set auto-discovery-dialup-placeholder {enable | disable}`	Enable/disable overlay placeholder tunnels (default = disable).

Currently, ADVPN 2.0 only supports IPv4.

Example SD-WAN configurations using ADVPN 2.0

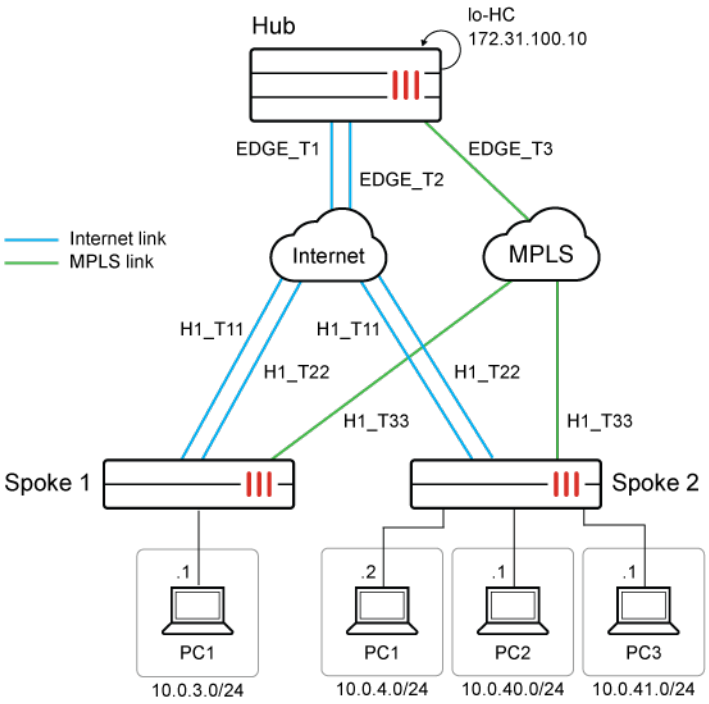
The configuration example illustrates the edge discovery and path management processes for a typical hub and spoke topology. This example focuses on SD-WAN configuration for steering traffic and establishing shortcuts in the direction from Spoke 1 to Spoke 2.

- Network Topology on page 1162
- SD-WAN configuration and health check status on page 1163
- Scenario 1: Traffic matching SD-WAN rule 1 on page 1166
- Scenario 2: Traffic matching SD-WAN rule 2 on page 1168
- Scenario 3: Traffic matching SD-WAN rule 3 on page 1170
- Scenario 4: Spoke 2 H1_T22 overlay link out-of-SLA on page 1171
- Scenario 5: Traffic matching SD-WAN rule configured for load balancing on page 1174

Currently, ADVPN 2.0 only supports IPv4.

Network Topology

In this example, BGP per overlay was used for dynamic routing to distribute the LAN routes behind each spoke to the other spoke. However, this was a design choice. You can also use BGP on loopback for this example.



Spokes 1 and 2 have the following VPN overlays between themselves and the hub:

VPN Overlays	IP address on Spoke 1	IP address on Spoke 2
H1_T11	172.31.80.1/32	172.31.80.2/32
H1_T22	172.31.81.1/32	172.31.81.2/32
H1_T33	172.31.82.1/32	172.31.82.2/32

SD-WAN Rules/Services defined on Spoke 1:

	SD-WAN Rule/Service 1	SD-WAN Rule/Service 2	SD-WAN Rule/Service 3
	H1_T11	H1_T22	H1_T33
	H1_T22	H1_T11	H1_T11
	H1_T33	H1_T33	H1_T22
Strategy for choosing outgoing interfaces	Lowest cost (SLA)	Lowest cost (SLA)	Best quality, link cost factor: packet loss

Throughout this example, transport group 1 is used for VPN overlays over Internet links while transport group 2 is used for the VPN overlay over an MPLS link.

In this example, user traffic is initiated behind Spoke 1 and destined to Spoke 2. Because of this, Spoke 1 is considered the local spoke, and Spoke 2 is considered the remote spoke.

SD-WAN configuration and health check status

This section includes:

- SD-WAN configuration and health check status on Spoke 1: on page 1164
- SD-WAN configuration and health check status on Spoke 2: on page 1165

SD-WAN configuration and health check status on Spoke 1:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "overlay"
            set advpn-select enable
            set advpn-health-check "HUB"
        next
    end
    config members
        edit 1
            set interface "H1_T11"
            set zone "overlay"
            set transport-group 1
        next
        edit 2
            set interface "H1_T22"
            set zone "overlay"
            set transport-group 1
        next
        edit 3
            set interface "H1_T33"
            set zone "overlay"
            set transport-group 2
        next
    end
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set members 1 2 3
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
            end
        next
    end
    config service
        edit 1
            set name "1"
            set mode sla
            set shortcut-priority enable
            set dst "spoke-2_LAN-1" "Tunnel_IPs"
            set src "spoke-1_LAN-1" "Tunnel_IPs"
            config sla
```

```
                edit "HUB"
                    set id 1
                next
            end
            set priority-members 1 2 3
        next
        edit 2
            set name "2"
            set mode sla
            set shortcut-priority enable
            set dst "spoke-2_LAN-2" "Tunnel_IPs"
            set src "spoke-1_LAN-1" "Tunnel_IPs"
            config sla
                edit "HUB"
                    set id 1
                next
            end
            set priority-members 2 1 3
        next
        edit 3
            set name "3"
            set mode priority
            set dst "spoke-2_LAN-3" "Tunnel_IPs"
            set src "spoke-1_LAN-1" "Tunnel_IPs"
            set health-check "HUB"
            set link-cost-factor packet-loss
            set priority-members 3 1 2
        next
    end
end
```

```
# diagnose sys sdwan health-check
Health Check(HUB):
Seq(1 H1_T11): state(alive), packet-loss(0.000%) latency(0.231), jitter(0.029), mos(4.404),

```

SD-WAN configuration and health check status on Spoke 2:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "overlay"
            set advpn-select enable
            set advpn-health-check "HUB"
        next
```

```
    end
    config members
        edit 1
            set interface "H1_T11"
            set zone "overlay"
            set cost 100
            set transport-group 1
        next
        edit 2
            set interface "H1_T22"
            set zone "overlay"
            set transport-group 1
        next
        edit 3
            set interface "H1_T33"
            set zone "overlay"
            set transport-group 2
        next
    end
    config health-check
        edit "HUB"
            set server "172.31.100.100"
            set members 3 1 2
            config sla
                edit 1
                    set link-cost-factor latency
                    set latency-threshold 100
                next
            end
        next
    end
end
```

```
# diagnose sys sdwan health-check
Health Check(HUB):
Seq(3 H1_T33): state(alive), packet-loss(0.000%) latency(0.124), jitter(0.009), mos(4.404),

bandwidth-up(999994), bandwidth-dw(999998), bandwidth-bi(1999992) sla_map=0x1
```

Scenario 1: Traffic matching SD-WAN rule 1

In this scenario, PC1 connected to Spoke 1 initiates an ICMP ping destined for PC1 connected to Spoke 2. Therefore, this user traffic matches SD-WAN rule 1 and triggers shortcut path selection and establishment.

The Path Manager of Spoke 1 calculates the best shortcut path by comparing transport group, link quality (for SLA mode), link cost, and member configuration order between Spoke 1 and Spoke 2.

For an SLA mode service, the following algorithm is used to consider endpoints of the best shortcut path:

1. Overlays with the same transport group
2. In-SLA overlays
3. Lowest link-cost overlays
4. Member configuration order as a final tiebreaker

Based on this algorithm, the Path Manager on Spoke 1 selects Spoke 1 H1_T11 because it is first in the priority-members order for SD-WAN rule 1, it has the lowest link cost, and it is within SLA. Likewise, the Path Manager on Spoke 1 selects Spoke 2 H1_T22 since it has the lowest link cost compared to Spoke 2 H1_T11 (which has a cost of 100), it is within SLA, and has the same transport group as Spoke 1 H1_T11. Therefore, the Path Manager of Spoke 1 calculates the best shortcut path as Spoke 1 H1_T11 to Spoke 2 H1_T22.

The Path Manager will advise IKE to establish the best shortcut and add it to SD-WAN rule 1 as follows:

```
Branch1_FGT# diagnose sys sdwan service4
 Service(1): Address Mode(IPV4) flags=0x4200 use-shortcut-sla use-shortcut
  Tie break: cfg
  Shortcut priority: 1
   Gen(11), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(sla), sla-compare-order
   Member sub interface(4):
     2: seq_num(1), interface(H1_T11):
        1: H1_T11_0(71)
   Members(4):
     1: Seq_num(1 H1_T11_0 overlay), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected     2: Seq_num(1 H1_T11 overlay), alive, sla(0x1), gid(0), cfg_order(0), local cost(0),
selected
     3: Seq_num(2 H1_T22 overlay), alive, sla(0x1), gid(0), cfg_order(1), local cost(0), selected
     4: Seq_num(3 H1_T33 overlay), alive, sla(0x1), gid(0), cfg_order(2), local cost(0), selected
   Src address(2):
         172.31.0.0-172.31.255.255
         10.0.3.0-10.0.3.255
   Dst address(2):
         172.31.0.0-172.31.255.255
         10.0.4.0-10.0.4.255 …
```

Since shortcut-priority is enabled, we observe that the shortcut is formed over the selected overlay path and prioritized over the parent overlay.

From the diagnostic command on Spoke 1, we observe the selected shortcut path in **bold**. (Note that the remote IP matches Spoke 2 H1_T22 in the corresponding table above.)

```
Branch1_FGT# diagnose sys sdwan advpn-session
 Session head(Branch2_FGT-0-overlay:1)

```

Scenario 2: Traffic matching SD-WAN rule 2

In this scenario, PC1 connected to Spoke 1 initiates an ICMP ping destined for PC2 connected to Spoke 2. Therefore, this user traffic matches SD-WAN rule 2, and traffic will go through shortcut H1_T11_0 of Spoke 1 previously established in Scenario 1 above.

The local spoke sends a shortcut-query to the remote spoke to trigger a shortcut after ADVPN 2.0 path management makes a path decision with updated remote spoke WAN link information, which is received periodically (5 seconds) on the established shortcuts.

For an SLA mode service, the following algorithm is followed for considering endpoints of the best shortcut path:

1. Overlays with the same transport group
2. In-SLA overlays
3. Lowest link-cost overlays
4. Member configuration order as a final tiebreaker

Based on this algorithm, the Path Manager on Spoke 1 selects Spoke 1 H1_T22 because it is the first in the priority-members order for SD-WAN rule 2, it has the lowest link cost, and it is within SLA. Likewise, the Path Manager on Spoke 1 selects Spoke 2 H1_T22 since it has the lowest link cost compared to Spoke 2 H1_T11 (which has a cost of 100), it is within SLA, and has the same transport group as Spoke 1 H1_T11. Therefore, the Path Manager of Spoke 1 calculates the best shortcut path as Spoke 1 H1_T22 to Spoke 2 H1_T22.

The Path Manager will advise IKE to establish the best shortcut and add it to SD-WAN rule 2 as follows:

```
Branch1_FGT# diagnose sys sdwan service4
…
Service(2): Address Mode(IPV4) flags=0x4200 use-shortcut-sla use-shortcut
 Tie break: cfg
 Shortcut priority: 1
  Gen(12), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(sla), sla-compare-order
  Member sub interface(5):
    3: seq_num(2), interface(H1_T22):
       1: H1_T22_0(72)
    4: seq_num(1), interface(H1_T11):
       1: H1_T11_0(71)
```

```
  Members(5):
    1: Seq_num(2 H1_T22_0 overlay), alive, sla(0x1), gid(0), cfg_order(0), local cost(0), selected
    2: Seq_num(1 H1_T11_0 overlay), alive, sla(0x1), gid(0), cfg_order(1), local cost(0),
selected, last_used=2023-12-05 14:34:07
    3: Seq_num(2 H1_T22 overlay), alive, sla(0x1), gid(0), cfg_order(0), local cost(0), selected
    4: Seq_num(1 H1_T11 overlay), alive, sla(0x1), gid(0), cfg_order(1), local cost(0), selected
    5: Seq_num(3 H1_T33 overlay), alive, sla(0x1), gid(0), cfg_order(2), local cost(0), selected
  Src address(2):

Scenario 3: Traffic matching SD-WAN rule 3

In this scenario, PC1 connected to Spoke 1 initiates an ICMP ping destined for PC3 connected to Spoke 2. Therefore, this user traffic matches SD-WAN rule 3, and traffic will go through shortcut H1_T11_0 of Spoke 1 previously established in Scenario 1 above.

The local spoke sends a shortcut-query to the remote spoke to trigger a shortcut after ADVPN 2.0 path management makes a path decision with updated remote spoke WAN link information, which is received periodically (5 seconds) on the established shortcuts.

For a best quality mode service, the following algorithm is followed for considering endpoints of the best shortcut path:

1. Overlays with the same transport group
2. Best quality overlays (link cost factor of packet loss, in this scenario)
3. Member configuration order as a final tiebreaker

Based on this algorithm, the Path Manager on Spoke 1 selects Spoke 1 H1_T33 because it is the first in the priority-members order for SD-WAN rule 3, and it has the best quality link. Likewise, the Path Manager on Spoke 1 selects Spoke 2 H1_T33 since it has the same transport group as Spoke 1 H1_T33. Therefore, the Path Manager of Spoke 1 calculates the best shortcut path as Spoke 1 H1_T33 to Spoke 2 H1_T33.

The Path Manager will advise IKE to establish the best shortcut and add it to SD-WAN rule 3 as follows:

```
Branch1_FGT# diagnose sys sdwan service4
…
Service(3): Address Mode(IPV4) flags=0x4200 use-shortcut-sla use-shortcut
 Tie break: cfg
 Shortcut priority: 3
  Gen(13), TOS(0x0/0x0), Protocol(0): src(1->65535):dst(1->65535), Mode(priority), link-cost-
factor(packet-loss), link-cost-threshold(10), heath-check(HUB)

```

Scenario 4: Spoke 2 H1_T22 overlay link out-of-SLA

In this scenario, we place remote Spoke 2 H1_T22 out-of-SLA and observe that this link quality change is sensed by the local spoke through regular WAN link information updates on shortcuts. Because service 1 and 2 are the only rules that have new best shortcut paths when Spoke 2 H1_T22 is out-of-SLA, the local Spoke 1 will directly

send shortcut-queries to the remote Spoke 2 to trigger shortcuts for service 1 and 2 after ADVPN 2.0 path management makes path decisions with updated remote spoke WAN link information.

For an SLA mode service, the following algorithm is followed for considering endpoints of the best shortcut path:

1. Overlays with the same transport group
2. In-SLA overlays
3. Lowest link-cost overlays
4. Member configuration order as a final tiebreaker

Based on this algorithm, the Path Manager on Spoke 1 still selects these Spoke 1 interfaces:

- SD-WAN Rule 1: H1_T11
- SD-WAN Rule 2: H1_T22

These are the first in the priority-members order for SD-WAN rules 1 and 2, respectively.

Based on the updated WAN link information, the Path Manager on Spoke 1 selects these Spoke 2 interfaces because they are the only remaining in-SLA VPN overlays over Internet links (transport group 1):

- SD-WAN Rule 1: H1_T11
- SD-WAN Rule 2: H1_T11

Therefore, the Path Manager of Spoke 1 calculates the best shortcut paths as follows:

- SD-WAN Rule 1: Spoke 1 H1_T11 to Spoke 2 H1_T11
- SD-WAN Rule 2: Spoke 1 H1_T22 to Spoke 2 H1_T11

The Path Manager will advise IKE to establish the best shortcuts and add them to SD-WAN rules 1 and 2 as follows:

- For SD-WAN Rule 1, H1_T11_1 is the new best shortcut.
- For SD-WAN Rule 2, H1_T22_1 is the new best shortcut.

```
# diagnose sys sdwan service4

```

Scenario 5: Traffic matching SD-WAN rule configured for load balancing

This example relies on the same Network Topology on page 1162 used above, except Spoke 1 has a single SD-WAN rule/service that uses the load balancing strategy with SLA targets. For details, see Load balancing strategy with SLA targets on page 1041.

This section shows the SD-WAN configuration, selected IPsec configuration, and health check status on Spoke 1: on page 1175 and Spoke 2: on page 1176:

Spoke 1:

```
config system sdwan
    set status enable
    config zone
        edit "virtual-wan-link"
        next
        edit "overlay"
            set advpn-select enable
