NP7 hyperscale firewall packet sniffer	71
Packet sniffer examples	72

Change log

Date	Change description
June 28, 2023	Added information about hardware logging sending multiple session start log messages if <code>log-processor</code> is set to <code>hardware</code> and <code>log-mode</code> is set to <code>per-session</code> to Hyperscale firewall 6.4.12 incompatibilities and limitations on page 11 .
March 20, 2023	Added a note about ACL policy changes made to a hyperscale firewall VDOM that is processing traffic may take longer than expected to become effective, see Hyperscale firewall 6.4.12 incompatibilities and limitations on page 11 . Added more information about the NP7 <code>hash-config</code> option to Configuring how the internal switch fabric distributes sessions to NP7 processors on page 49 .
March 7, 2023	NP7 hardware logging must use interfaces connected to NP7 processors to communicate with the remove log servers. This information was added to Configuring hardware logging on page 38 .
February 23, 2023	FortiOS 6.4.12 document release.
February 8, 2023	Improvements to Displaying IP pool usage information on page 65 .
January 11, 2023	Added more information about <code>arp-reply</code> support limitations for IPv4 and IPv6 firewall VIPs to Hyperscale firewall 6.4.12 incompatibilities and limitations on page 11 .
November 22, 2022	Corrections to Creating hyperscale firewall VDOMs on page 13 .
October 31, 2022	FortiOS 6.4.11 document release.
October 5, 2022	More information and explanation added to Hyperscale firewall policy engine mechanics on page 36 .
August 25, 2022	FortiOS 6.4.10 document release.
August 9, 2022	Changes to Configuring FGCP HA hardware session synchronization on page 47 . New sections: <ul style="list-style-type: none">• How the NP7 hash-config affects CGNAT on page 49.• How the NP7 hash-config affects sessions that require session helpers or ALGs on page 50. Revised information about using the FortiGate-4200F/4201F and 4400F/4400F HA1, HA2, AUX1 and AUX2 interfaces. Using the following command is no longer recommended. Instead see the new section Recommended interface use for an FGCP HA hyperscale firewall cluster on page 47 . <pre>config system npu config port-path-option set ports-using-npu {ha1 ha2 aux1 aux2} end</pre>
July 20, 2022	Improvements to Hyperscale firewall VDOM session timeouts on page 59 . New section Session timeouts for individual hyperscale policies on page 59 .

Date	Change description
April 26, 2022	FortiOS 6.4.9 document release. Added more information to the following sections: <ul style="list-style-type: none">Hyperscale firewall 6.4.12 incompatibilities and limitations on page 11.Displaying IP pool usage information on page 65.
December 17, 2021	Removed information about the <code>vlan-lookup-cache</code> option of the <code>config system npu</code> command because this command is available on FortiGates with NP7 processors, whether or not they are licensed for hyperscale firewall features. For information about the <code>vlan-lookup-cache</code> option, see vlan-lookup-cache {disable enable} .
December 2, 2021	Added two new FGCP HA-related limitations to Hyperscale firewall 6.4.12 incompatibilities and limitations on page 11. Improved the information in Enabling hyperscale firewall features on page 14.
November 29, 2021	Corrected some of the information in Upgrading hyperscale firewall features to FortiOS 6.4.12 on page 8.
November 25, 2021	FortiOS 6.4.8 document release.
October 18, 2021	Removed the incorrect statement "NP7 fragment reassembly is not supported" from Hyperscale firewall 6.4.12 incompatibilities and limitations on page 11. New section: Reassembling fragmented packets on page 61. Corrected the section Setting the hyperscale firewall VDOM default policy action on page 60.
August 17, 2021	Misc. fixes. Added more information to .
July 12, 2021	Added diagnose commands to Hash table message queue mode on page 61. Corrected information about multicast logging in Configuring hardware logging on page 38 and Multicast logging example on page 43.
July 9, 2021	FortiOS 6.4.6 document release.

What's new

This section describes new Hyperscale firewall features for FortiOS 6.4 releases.

What's new for hyperscale firewall for FortiOS 6.4.12

This section lists the new NP7 hyperscale firewall features added to FortiOS 6.4.12.

- New SNMP PBA statistics fields for polling total PBAs, in use PBAs, expiring PBAs, and free PBAs, see [IP pool MIB and trap fields on page 52](#).

For more information about FortiOS 6.4.12 hyperscale firewall, see the [FortiOS 6.4.12 Hyperscale Firewall Release Notes](#).

Upgrading hyperscale firewall features to FortiOS 6.4.12

If your FortiGate is currently running FortiOS 6.2.6, 6.2.7, 6.2.9, 6.4.6, 6.4.8, 6.4.9, 6.4.10, or 6.4.11 firmware and is licensed for hyperscale firewall features, you can follow a normal firmware upgrade process to upgrade to FortiOS 6.4.12.

If you are currently operating a FortiGate-4200F, 4201F, 4400F, or 4401F without a hyperscale firewall license, you can use the upgrade path to upgrade to FortiOS 6.4.12. Once you have upgraded to 6.4.12 you can activate your hyperscale firewall license and set up your hyperscale firewall configuration.

What's new for hyperscale firewall for FortiOS 6.4.11

This section lists the new NP7 hyperscale firewall features added to FortiOS 6.4.11.

- Hardware logging for hyperscale firewall polices that block sessions, see [Hardware logging for hyperscale firewall polices that block sessions on page 44](#).
- Firewall virtual IP (VIP) features that are not supported by hyperscale firewall policies are no longer visible from the CLI or GUI when configuring firewall VIPs in a hyperscale firewall VDOM, see [Hyperscale firewall 6.4.12 incompatibilities and limitations on page 11](#).

For more information about FortiOS 6.4.11 hyperscale firewall, see the [FortiOS 6.4.11 Hyperscale Firewall Release Notes](#).

What's new for hyperscale firewall for FortiOS 6.4.10

This section lists the new NP7 hyperscale firewall features added to FortiOS 6.4.10. For new FortiOS 6.4.10 NP7 features, see [What's new for FortiGates with NP7 processors for FortiOS 6.4.10](#).

- Upgrades to the hyperscale firewall policy engine, see [Hyperscale firewall policy engine mechanics on page 36](#).

For more information about FortiOS 6.4.10 hyperscale firewall, see the [FortiOS 6.4.10 Hyperscale Firewall Release Notes](#).

What's new for hyperscale firewall for FortiOS 6.4.9

This section lists the new NP7 hyperscale firewall features added to FortiOS 6.4.9. For new FortiOS 6.4.9 NP7 features, see [What's new for FortiGates with NP7 processors for FortiOS 6.4.9](#).

- FortiOS 6.4.9 includes main branch support for FortiGates with NP7 processors and hyperscale firewall features (FortiGate-1800F, FortiGate-1801F, FortiGate-2600F, FortiGate-2601F, FortiGate-4200F, FortiGate-4201F, FortiGate-4400F, and FortiGate-4201F). Previous versions of FortiOS supported FortiGates with NP7 processors through special branch firmware builds.

For more information about FortiOS 6.4.9 hyperscale firewall, see the [FortiOS 6.4.9 Hyperscale Firewall Release Notes](#).

What's new for hyperscale firewall for FortiOS 6.4.8

This section lists the new NP7 hyperscale firewall features added to FortiOS 6.4.8. For new FortiOS 6.4.8 NP7 features, see [What's new for FortiGates with NP7 processors for FortiOS 6.4.8](#).

- The `policy-offload-level` options of the `config system npu` command have been simplified. For FortiOS 6.4.8 you can only select `disable`, `dos-offload`, or `full-offload`. See [Enabling hyperscale firewall features on page 14](#).
- You can configure NP7 processors to override the DF setting and fragment and forward packet that a NAT46 hyperscale firewall policy has converted to an IPv6 packet that exceeds the outgoing interface MTU instead of dropping it. See [Allowing packet fragments for NP7 NAT46 policies when the DF bit is set to 1 on page 64](#).
- You can use the new `log-processing hardware` logging option to change how the FortiGate queues CPU or host logging packets to allow or prevent dropped packets. See [Configuring hardware logging on page 38](#).
- New option to enable or disable background NP7 SSE scanning and configure some SSE scanning options. See [Configuring background SSE scanning on page 63](#).
- Hyperscale firewall VDOMs have improved support for asymmetric routing and ECMP. See [Hyperscale firewall VDOM asymmetric routing with ECMP support on page 58](#).
- You can configure how the NP7 hyperscale firewall policy engine handles traffic in a hyperscale firewall VDOM that matches a blackhole route or a loopback route. See [Adjusting NP7 hyperscale firewall blackhole and loopback route behavior on page 70](#) and [Viewing the NP7 hyperscale policy engine routing configuration on page 70](#).
- You can enable or disable hyperscale firewall per-policy accounting for all hyperscale traffic. See [Enabling or disabling per-policy accounting for hyperscale firewall traffic on page 51](#).

- You can display the current NP7 hyperscale firewall hardware session list by sending a query to the NP7 Session Search Engine (SSE). See [Displaying information about NP7 hyperscale firewall hardware sessions on page 65](#).

For more information about FortiOS 6.4.8 hyperscale firewall, see the [FortiOS 6.4.8 Hyperscale Firewall Release Notes](#).

What's new for hyperscale firewall for FortiOS 6.4.6

This section lists the new NP7 hyperscale firewall features added to FortiOS 6.4.6. For new FortiOS 6.4.6 NP7 features, see [What's new for FortiGates with NP7 processors for FortiOS 6.4.6](#).

- Multicast logging to simultaneously send session setup log messages for CPU or software sessions to multiple remote syslog or NetFlow servers. Multicast logging is not supported for NP7 sessions. See [Multicast logging example on page 43](#).
- Change the hyperscale firewall VDOM default policy action, see [Setting the hyperscale firewall VDOM default policy action on page 60](#).
- Change the hyperscale firewall NP7 hash table message queue mode, see [Hash table message queue mode on page 61](#).
- Hardware logging server IP address recommendations and restrictions, see [Adding hardware logging to a hyperscale firewall policy on page 42](#).
- Adjusting the NP7 TCP reset timer, see [Setting the NP7 TCP reset timeout on page 63](#).

For more information about FortiOS 6.4.6 hyperscale firewall, see the [FortiOS 6.4.6 Hyperscale Firewall Release Notes](#).

Getting started with NP7 hyperscale firewall features

This section provides an overview of FortiOS NP7 hyperscale firewall support. Hyperscale firewall features include:

- NP7 hardware session setup takes place entirely on the NP7 policy and NAT engine (called the Session Search Engine or SSE) without any involvement of the system bus or CPU. Hardware session setup is also called hardware policy offload.
- IPv4 and NAT64 firewall policies includes support for carrier-grade NAT (CGNAT) features.
- Hardware logging (syslog and IPFIX) offloads syslog or NetFlow messages for all offloaded sessions.
- Hardware session synchronization supports HA session sync for hyperscale firewall HA clusters.
- Hyperscale firewall features are enabled per VDOM.
 - Hyperscale firewall VDOMs only support hyperscale firewall policies.
 - Hyperscale firewall VDOMs do not support UTM or NGFW firewall features.
 - Hyperscale firewall VDOMs do not support Central NAT.
 - You must use a special naming convention when creating a hyperscale firewall VDOM, see [Creating hyperscale firewall VDOMs on page 13](#) for details.

Hyperscale firewall 6.4.12 incompatibilities and limitations

Hyperscale firewall for FortiOS 6.4.12 has the following limitations and incompatibilities with FortiOS features:

- Proxy or flow based inspection is not supported. You cannot include security profiles in hyperscale firewall policies.
- Single-sign-on authentication including FSSO and RSSO is not supported. Other types of authentication are supported.
- IPsec VPN is not supported. You cannot create hyperscale firewall policies where one of the interfaces is an IPsec VPN interface.
- Hyperscale firewall VDOMs do not support Central NAT.
- Hyperscale firewall VDOMs do not support Policy-based NGFW Mode.
- Hyperscale firewall VDOMs do not support consolidated firewall policies.
- Hyperscale firewall VDOMs must be NAT mode VDOMs. Hyperscale firewall features are not supported for transparent mode VDOMs.
- Hyperscale firewall VDOMs do not support traffic shaping policies or profiles. Only outbandwidth traffic shaping is supported for hyperscale firewall VDOMs.
- Traffic shaping with queuing using the NP7 QTM module is not compatible with carrier-grade NAT and hyperscale firewall features. See [NP7 traffic shaping](#).
- Hyperscale firewall VDOMs do not support traffic that requires session helpers or ALGs (for example, FTP, TFTP, SIP, MGCP, H.323, PPTP, L2TP, ICMP Error/IP-options, PMAP, TNS, DCE-RPC, RAS, and RSH).
- Active-Active FGCP HA and FGSP HA do not support HA hardware session synchronization. Active-passive HA and virtual clustering do support FGCP HA hardware session synchronization.
- Asymmetric sessions are not supported.
- ECMP usage-based load balancing is not supported. Traffic is not directed to routes with lower spillover-thresholds.
- The Sessions dashboard widget does not display hyperscale firewall sessions.
- Interface device identification should not be enabled on interfaces that send or receive hyperscale firewall traffic.

- The `proxy` action is not supported for DoS policy anomalies when your FortiGate is licensed for hyperscale firewall features. When you activate a hyperscale firewall license, the `proxy` option is removed from the CLI of both hyperscale VDOMs and normal VDOMs.
- Access control list (ACL) policies added to a hyperscale firewall VDOM that is processing traffic may take longer than expected to become effective. During a transition period, traffic that should be blocked by the new ACL policy will be allowed.
- During normal operation, UDP sessions from protocols that use FortiOS session helpers are processed by the CPU. After an FGCP HA failover, when the UDP session helper sessions are re-established, they will not be identified as session helper sessions and instead will be offloaded to the NP7 processors.
- When operating an FGCP HA cluster with session synchronization enabled, some of the sessions accepted by an IPv4 or a NAT64 hyperscale firewall policy with an overload IP pool may not be synchronized to the secondary FortiGate. Some sessions are not synchronized because of resource conflicts and retries. The session loss rate depends on the percentage of resource retries during session setup. You can reduce the session loss by making sure the IP pool has as many IP addresses and ports as possible.
- The following options are not supported for IPv4 firewall VIPs (configured with the `config firewall vip` command) in hyperscale firewall VDOMs: `src-filter`, `service`, `nat44`, `nat46`, `nat-source-vip`, `arp-reply`, `portforward`, and `srcintf-filter`.
- If hardware logging is configured to send log messages directly from NP7 processors (`log-processor` is set to `hardware`) (also called log2hw) and the log server group is configured to send log messages at the start and end of each session (`log-mode` is set to `per-session`), hardware logging may send multiple session start log messages, each with a different start time. Creating multiple session start log messages is a limitation of NP7 processor hardware logging, caused by the NP7 processor creating extra session start messages if session updates occur. You can work around this issue by:
 - Setting `log-mode` to `per-session-ending`. This setting creates a single log message when the session ends. This log message records the time the session ended as well as the duration of the session. This information can be used to calculate the session start time.
 - Setting `log-processor` to `host` (also called log2host). Host hardware logging removes duplicate log start messages created by the NP7 processor. Host logging may reduce performance.
- The following options are not supported for port forwarding IPv6 firewall VIPs (configured with the `config firewall vip6` command) in hyperscale firewall VDOMs: `src-filter`, `nat-source-vip`, `arp-reply`, `portforward`, `nat66`, and `nat64`.

Even though the `arp-reply` CLI option is not supported for IPv4 and IPv6 firewall VIPs, responding to ARP requests for IP addresses in a virtual IP is supported. What is not supported is using the `arp-reply` option to disable responding to an ARP request.

Applying the hyperscale firewall activation code or license key

To activate hyperscale firewall features for your FortiGate, you must purchase a hyperscale firewall license and obtain an activation code or license key from the [Fortinet Support](#) website. You can use the following command to apply your hyperscale firewall activation code or license key to activate hyperscale firewall features for your FortiGate:

```
execute hscalefw-license {<activation-code> | <license-key>}
```

After you enter this command, the FortiGate restarts with hyperscale firewall features available. Check the Licenses dashboard widget to verify that the FortiGate has been successfully licensed for hyperscale firewall features.

If you are operating an HA cluster, all FortiGates in the cluster must have a hyperscale firewall license.

You can also use the `get system status` command to verify that your hyperscale firewall license is enabled:

```
get system status
...
Hyperscale firewall license status: Enabled
...
end
```

You can now create hyperscale firewall configurations for your FortiGate. To apply hyperscale firewall features, your FortiGate must be operating in multi VDOM mode. You cannot use the root VDOM for hyperscale firewall features. Instead you must create new hyperscale firewall VDOMs for the traffic that you want to apply hyperscale firewall features to. You can also use the root VDOM for other traffic or create other VDOMs for other traffic.

Creating hyperscale firewall VDOMs

VDOMs in which you will be enabling hyperscale firewall features must be created with a special VDOM name that also includes a VDOM ID. The VDOM ID is used by FortiOS to create a kernel VDOM_ID for the VDOM that NP7 processors use to track hyperscale firewall sessions for that VDOM.

The number of hyperscale firewall VDOMs that you can create depends on your hyperscale firewall license and is controlled by the following configuration option:

```
config system global
    set hyper-scale-vdom-num <vdom-id-num>
end
```

By default `<vdom-id-num>` is set to the maximum number of hyperscale VDOMs that the FortiGate is licensed for. You can manually change the `<vdom-id-num>` if you want to limit the number of hyperscale VDOMs that can be created. The `<vdom-id-num>` range is 1 to 250.

Use the following syntax to create a hyperscale firewall VDOM:

```
config vdom
    edit <name>-hw<vdom-id>
end
```

Where:

`<name>` is a string that can contain any alphanumeric upper or lower case characters and the `-` and `_` characters. The name cannot contain spaces and you should not use `-hw` in the name.

`<vdom-id>` a VDOM ID number in the range from 1 to `<vdom-id-num>`. For example, if your FortiGate is licensed for 250 hyperscale firewall VDOMs, if you haven't used the `hyper-scale-vdom-num` option to change the number of hyperscale firewall VDOMs, `<vdom-id>` can be from 1 to 250. Each hyperscale firewall VDOM must have a different `<vdom-id>`.

When you add a new hyperscale firewall VDOM with a `<vdom-id>`, FortiOS calculates the kernel VDOM_ID using the following formula:

```
kernel VDOM_ID = 501 - <vdom-id>
```

If you include leading zeros in the <vdom-id>, the kernel removes them when creating the ID. So avoid using leading zeros in the <vdom-id> to keep from accidentally creating duplicate IDs.

The VDOM name, including the <string>, -hw, and <vdom-id> can include up to 11 characters. For example, the VDOM name CGN-1-hw23 is valid but CGN-1234-hw23 is too long.

When you create a new hyperscale firewall VDOM, the CLI displays an output line that includes the VDOM name followed by the kernel VDOM_ID. For example:

```
config vdom
  edit Test-hw150
  current vf=Test-hw150:351
```

In this example, the kernel VDOM_ID is 351.

Another example:

```
config vdom
  edit Test02-hw2
  current vf=Test02-hw2:499
```

In this example, the kernel VDOM_ID is 499.

When you create a VDOM from the CLI, the new hyperscale VDOM becomes the current VDOM. The new hyperscale firewall VDOM may not appear in the VDOM list on the GUI until you log out of the GUI and then log back in.

Enabling hyperscale firewall features

Use the following global command to enable hyperscale firewall features for your FortiGate:

```
config global
  config system npu
    set policy-offload-level full-offload
  end
```

Once you have enabled global hyperscale firewall features, you must edit each hyperscale firewall VDOM and use the following command to enable hyperscale firewall features for that VDOM.

```
config system settings
  set policy-offload-level full-offload
end
```

The following options are available for this command:

disable disable hyperscale firewall features and disable offloading DoS policy sessions to NP7 processors for this VDOM. All sessions are initiated by the CPU. Sessions that can be offloaded are sent to NP7 processors. This is the default setting.

dos-offload offload DoS policy sessions to NP7 processors for this VDOM. All other sessions are initiated by the CPU. Sessions that can be offloaded are sent to NP7 processors.

full-offload enable hyperscale firewall features for the current hyperscale firewall VDOM. This option is only available if the FortiGate is licensed for hyperscale firewall features. DoS policy sessions are also offloaded to NP7 processors. All other sessions are initiated by the CPU. Sessions that can be offloaded are sent to NP7 processors.

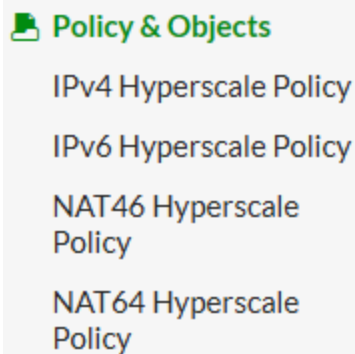

For more information about DoS policy hardware acceleration and how it varies depending on the policy offload level, see [DoS policy hardware acceleration](#).

Hyperscale firewall GUI changes

When hyperscale firewall features are enabled for your FortiGate or for a VDOM, the GUI has the following changes:

Hyperscale firewall policies

Only hyperscale firewall policies are available.

Hyperscale firewall policy options

Hyperscale firewall policies have similar options to normal firewall policies for selecting traffic for which to offload session setup. Hyperscale firewall policies do not support UTM or NGFW features.

ID	<input type="text" value="10"/>
Name 	<input type="text" value="My-policy"/>
Incoming Interface	<input type="text" value="port1"/>  +
Outgoing Interface	<input type="text" value="port2"/>  +
Source Address	<input type="text" value="all"/>  +
Negate Source Address	<input type="checkbox"/>
Destination Address	<input type="text" value="all"/>  +
Negate Destination Address	<input type="checkbox"/>
Service	<input type="text" value="ALL"/>  +
Negate Service	<input type="checkbox"/>
Action	<input checked="" type="checkbox"/> ACCEPT <input type="checkbox"/> DENY

CGNAT features in IPv4 and NAT64 firewall policies

IPv4 and NAT64 Hyperscale firewall policies allow you to configure carrier grade NAT (CGNAT) options.

Firewall / Network Options	
NAT	<input checked="" type="checkbox"/>
IP Pool Configuration	<input type="text" value="CGN_SPA_210.2.2.2.0"/>  +
CGN Session Quota 	<input type="text" value="16777215"/>
CGN Resource Quota 	<input type="text" value="16"/>
Endpoint Independent Filtering	<input checked="" type="checkbox"/>
Endpoint Independent Mapping	<input checked="" type="checkbox"/>

Hardware logging in a firewall policy

You can also add hardware logging to a Hyperscale firewall policy.

Log Hyperscale SPU Offload Traffic

Log Server Group

CGN resource allocation IP pools

CGN resource allocation IP pools are available for adding carrier grade NAT features to an IPv4 or NAT64 hyperscale firewall policy. Go to **Policy & Objects > IP Pools**, Select **Create New > IP Pool**, and set **Type** to **CGN Resource Allocation**. You can also create CGN IP pool groups by going to **Create New > CGN IP Pool Group**.

Type	<input type="text" value="CGN Resource Allocation"/>
Mode	<input checked="" type="text" value="Port Block Allocation"/> <input type="text" value="Overload (Port Block Allocation)"/> <input type="text" value="Single Port Allocation"/> <input type="text" value="Overload (Single Port Allocation)"/> <input type="text" value="Fixed-allocation"/>
External IP address/range 	<input type="text" value="1.1.1.1-1.1.1.10"/>
Start Port	<input type="text" value="5117"/>
End Port	<input type="text" value="65530"/>
Block Size	<input type="text" value="128"/>
ARP Reply	<input checked="" type="checkbox"/>

Hyperscale hardware logging servers

You can set up multiple hyperscale hardware logging servers and add them to server groups. This is a global feature. If multiple VDOMs are enabled, all VDOMs can use these globally configured servers. To configure hardware logging, go to **Log & Report > Hyperscale SPU Offload Log Settings**.

NetFlow version V9 V10

Log Servers

ID	IP address
1	192.168.1.100
2	192.168.2.100

Log Server Groups

Group name	Logging mode	Log format	Servers	Ref.
1	Per-Mapping	Syslog	192.168.1.100 (ID: 1) 192.168.2.100 (ID: 2)	8

Hyperscale firewall CLI changes

The following hyperscale firewall CLI commands are available:

Enable hyperscale firewall features

Use the following global command to enable hyperscale firewall features:

```
config system npu
  set policy-offload-level full-offload
end
```

Use the following command to enable hyperscale firewall features for a VDOM:

```
config system settings
  set policy-offload-level full-offload
end
```

Special hyperscale firewall VDOM naming convention

VDOMs in which you will be enabling hyperscale firewall features must be created with a special VDOM name that also includes a VDOM ID number.

The following option can be used to set the VDOM ID range:

```
config system global
    set hyper-scale-vdom-num
end
```

By default this option is set to 250, allowing you to configure up to 250 hyperscale firewall VDOMs by setting the VDOM in the range of 1 to 250.

Use the following syntax to create a hyperscale firewall VDOM from the global CLI:

```
config vdom
    edit <string>-hw<vdom-id>
```

For information about how to name hyperscale firewall VDOMs, see [Creating hyperscale firewall VDOMs on page 13](#).

Hyperscale firewall policy

The following hyperscale firewall policy commands are available in a hyperscale firewall VDOM:

```
config firewall hyperscale-policy
config firewall hyperscale-policy46
config firewall hyperscale-policy6
config firewall hyperscale-policy64
```

The `policy`, `policy6`, `policy46`, and `policy64` commands appear in the CLI but they cannot be configured.

If you are upgrading your hyperscale firewall configuration from FortiOS 6.2.5 to 6.2.6 you must re-configure all of your hyperscale firewall policies using the new 6.2.6 hyperscale firewall policies.

Here is the CLI syntax for the `config firewall hyperscale-policy` command:

```
config firewall hyperscale-policy
    edit 1
        set name <name>
        set srcintf <interface>
        set dstintf <interface>
        set scraddr <address>
        set dstaddr <address>
        set action {accept | deny}
        set status {enable | disable}
        set service <service>
        set auto-asic-offload {enable | disable}
        set cgn-session-quota <quota>
        set cgn-resource-quota <quots>
        set cgn-eif {disable | enable}
        set cgn-eim {disable | enable}
        set cgn-log-server-grp <group-name>
        set tcp-timeout-pid <profile>
        set udp-timeout-pid <profile>
        set ippool {disable | enable}
```

```
set poolname <cg-ippool-name>
set comments <comment>
set srcaddr-negate {disable | enable}
set dstaddr-negate {disable | enable}
set service-negate {disable | enable}
set traffic-shaper <shaper>
set traffic-shaper-reverse <shaper>
set nat {disable | enable}
end
```

CGN Resource allocation IP pools

You can use the following command to configure CGN Resource allocation IP pools:

```
config firewall ippool
edit <name>
set type cg-resource-allocation
set startip <ip>
set endip <ip>
set arp-reply {disable | enable}
set arp-intf <interface-name>
set cg-spa {disable | enable}
set cg-overload {disable | enable}
set cg-fixedalloc {disable | enable}
set cg-block-size <number-of-ports>
set cg-client-startip <ip>
set cg-client-endip <ip>
set cg-port-start <port>
set cg-port-end <port>
set utilization-alarm-raise <usage-threshold>
set utilization-alarm-clear <usage-threshold>
end
```

CGN Resource allocation IP pool groups

You can use the following command to create CGN Resource Allocation IP pool groups:

```
config firewall ippool_grp
edit <name>
set member <cg-ippool> ...
end
```

Hardware logging

The following hardware logging commands are available:

```
config log npu-server
set log-processor {hardware | host}
set netflow-ver {v9 | v10}
config server-info
edit <index>
set vdom <name>
set ip-family {v4 | v6}
set ipv4-server <ipv4-address>
set ipv6-server <ipv6-address>
```

```

    set source-port <port-number>
    set dest-port <port-number>
    set template-tx-timeout <timeout>
end
config server-group
edit <group-name>
    set log-mode {per-session | per-nat-mapping | per-session-ending}
    set log-format {netflow | syslog}
    set server-number <number>
    set server-start-id <number>
end

```

Hyperscale firewall inter-VDOM link acceleration

You apply NP7 acceleration to inter-VDOM link traffic by creating inter-VDOM links with the `type` set to `npupair`. For example:

```

config system vdom-link
edit <name>
    set type npupair
end

```

Hyperscale sessions dashboard widget

On a FortiGate with a hyperscale firewall license, the Sessions dashboard widget shows Hyperscale sessions as well as CPU, offloaded SPU and nTurbo sessions. **Current sessions** shows the total number of sessions, **CPU** shows the percent of sessions handled by the CPU, **SPU** shows the percentage of these sessions that are SPU sessions, and **nTurbo** shows the percentage that are nTurbo sessions. **Hyperscale SPU** shows the percentage of the total sessions that are hyperscale firewall sessions.

Hardware accelerated Carrier Grade NAT

Hyperscale firewall Carrier Grade NAT (CGN) features can be used to accelerate dynamic SNAT resource management for IPv4 and NAT64 traffic. Using carrier grade NAT features, FortiOS is capable of managing SNAT resources for complex networks containing large numbers of devices with private IPv4 addresses. Hyperscale CGN uses an enhanced implementation of FortiOS IP Pools to apply these CGN resource management features to traffic as it passes through the FortiGate.

For information about FortiOS IP pools, see [Dynamic SNAT](#).

Start a hyperscale firewall carrier grade NAT configuration by creating one or more CGN resource allocation IP pools. These IP pools are variations on an overload IP pool that define how the firewall manages source addresses and source ports. Then you create a hyperscale firewall policy and add the CGN resource allocation IP pools to the firewall policy.

If you add multiple CGN resource allocation IP pools to a hyperscale firewall policy, the IP pools must all have the same CGN mode (none, overload, single port allocation, or fixed-allocation) and their IP ranges must not overlap.

Instead of adding multiple IP pools to a hyperscale firewall policy, you can create a CGN IP pool group and add multiple CGN IP pools to the group. Then add the CGN IP pool group to the firewall policy. All of the CGN IP pools in a CGN IP pool group must have the same CGN mode and their IP ranges must not overlap.

CGN resource allocation IP pools

CGN resource allocation IP pools are variations on overload IP pools that take advantage of NP7 hardware acceleration to apply Carrier Grade NAT (CGN) features to IPv4 or NAT64 hyperscale firewall policies. CGN resource allocation IP pools manage the allocation of IPv4 source ports, addresses, and system resources used for logging.

You create CGN resource allocation IP pools from the GUI by going to **Policy & Objects > IP Pools > Create New > IP Pool**. Set **Type** to **CGN Resource Allocation**, select a **Mode** (or type), and edit settings for the selected mode.

From the CLI, you create CGN resource allocation IP pools by creating an IP pool and setting the `type` to `cg-resource-allocation`. You can then enable or disable `cg-spas`, `cg-overload`, and `cg-fixedalloc` to select a CGN IP pool type and then edit settings for the selected type.

```
config firewall ippool
  edit <name>
    set type cg-resource-allocation
    set startip <ip>
    set endip <ip>
    set arp-reply {disable | enable}
    set arp-intf <interface-name>
    set cg-spas {disable | enable}
    set cg-overload {disable | enable}
    set cg-fixedalloc {disable | enable}
    set cg-block-size <number-of-ports>
    set cg-client-startip <ip>
    set cg-client-endip <ip>
```

```

set cgn-port-start <port>
set cgn-port-end <port>
set utilization-alarm-raise <usage-threshold>
set utilization-alarm-clear <usage-threshold>
end

```

Five different types or modes of CGN resource allocation IP pool modes are available. The following table summarizes each type and the following sections describe the GUI and CLI configuration for each type.

IP pool type (mode)	GUI option	CLI options	Supported CGNAT Features
Port Block Allocation (PBA)	Port Block Allocation	<pre> set cgn-spa disable set cgn-overload disable set cgn-fixedalloc disable </pre>	<ul style="list-style-type: none"> • Dynamic IP consistency • Port block allocation • No port reuse • Deterministic NAT
Overload with port block allocation (PBA, overload)	Overload (Port Block Allocation)	<pre> set cgn-spa disable set cgn-overload enable </pre>	<ul style="list-style-type: none"> • Dynamic IP consistency • Port block allocation • Port reuse within block • Deterministic NAT
Single port allocation (SPA)	Single Port Allocation	<pre> set cgn-spa enable set cgn-overload disable </pre>	<ul style="list-style-type: none"> • Dynamic IP consistency • No port reuse • Deterministic NAT
Overload with single port allocation (SPA, overload)	Overload (Single Port Allocation)	<pre> set cgn-spa enable set cgn-overload enable </pre>	<ul style="list-style-type: none"> • Dynamic IP consistency • Port reuse within the entire port range • Deterministic NAT
Fixed allocation, (also called Port block allocation with fixed NAT or Deterministic NAT) (PBA, fixed NAT)	Fixed-allocation	<pre> set cgn-spa disable set cgn-fixedalloc enable </pre>	<ul style="list-style-type: none"> • Static IP consistency • Static port block allocation • No port reuse • Deterministic NAT

Displaying IP pool data

From the GUI you can hover the mouse pointer over a CGN resource allocation IP pool name to display information about the IP pool including its name and CGN mode as well as the settings of the IP pool including the external IP address and port ranges, whether ARP reply is enabled, the block size, and the number of blocks available for each IP address.

The display also shows real time data calculated for the IP pool including the number of external IP addresses currently in use, the number of client sessions currently using the IP pool, as well as a calculation of the percentage of the TCP and UDP blocks available.

Example FortiGate-4200F IP pool data

Firewall IP Pool	📄 CGN PBA Internet Pool
Type	CGN Resource Allocation
Mode	Port Block Allocation
External IP Range	209.203.50.97 - 209.203.50.98
Port Range	5117 - 65530
ARP Reply	✅ Enabled
Block Size	128
Blocks Per IP	471
External IPs in Use	2/2
Clients Online	11
Blocks Available (TCP)	99.15 % (8/936 blocks used)
Blocks Available (UDP)	98.82 % (11/936 blocks used)
References	1
 Edit	

The TCP and UDP blocks available is calculated as a percentage of the total number of blocks available. The following explains how the total number of blocks available is determined.

The Blocks per IP is the number of ports in the Port Range divided by the Block Size. In this example:

$$(65530 - 5117) / 128 = 471$$

The 471 blocks per IP address are distributed evenly among the available NP7 processors. For a FortiGate-4200F with four NP7 processors, each NP7 processor would have $474 / 4 = 117.75$, rounded down to 117 blocks per IP address.

The total number of blocks available = blocks per IP address x number of IP addresses x number of NP7 processors. In this example:

$$117 \times 2 \times 4 = 936$$

Static IP consistency

If more than one public IP address is available, static IP consistency makes sure that sessions from a given client are always assigned the same public source IP address.

Dynamic IP consistency

The first time a client starts a new session, the session gets any one of the available public IP addresses. New sessions started by the same client use the same public IP address, so all currently active sessions from a client will have the same public IP address. If all sessions from a client time out, the next time the client starts a new session, the session can again get any one of the available public IP addresses.

Port reuse within block

Sessions from the same client may be assigned duplicate public source ports.

Port reuse within whole port range

Sessions from different clients may be assigned the same public source ports.

Port block allocation

A block of source ports is dynamically allocated to each client. Sessions started by a client can use any one of the ports in their allocated block. Whether ports can be re-used and how they are re-used depends on what other features are active.

Static port block allocation

Blocks of ports are assigned to clients exclusively and deterministically. When a block of ports is assigned to a client, all sessions started by that client use the assigned ports and sessions started by other clients cannot use those ports.

Deterministic NAT

Creates a one to one mapping between external and internal IP addresses. You add matching external and internal address ranges to the configuration, and a given internal address is always translated to the same external address. The number of clients that can use a deterministic NAT pool is limited by the number of IP addresses in the pool.

Port block allocation CGN IP pool

This is the default CGNAT IP pool configuration.

On the GUI go to **Policy & Objects > IP Pools > Create New > IP Pool**. Set **Type** to **CGN Resource Allocation** and set **Mode** to **Port Block Allocation**.

Type	<input type="text" value="CGN Resource Allocation"/>
Mode	<input type="text" value="Port Block Allocation"/> <input type="text" value="Overload (Port Block Allocation)"/> <input type="text" value="Single Port Allocation"/> <input type="text" value="Overload (Single Port Allocation)"/> <input type="text" value="Fixed-allocation"/>
External IP address/range 	<input type="text" value="1.1.1.1-1.1.1.10"/>
Start Port	<input type="text" value="5117"/>
End Port	<input type="text" value="65530"/>
Block Size	<input type="text" value="128"/>
ARP Reply	<input checked="" type="checkbox"/>

On the CLI:

```
config firewall ippool
  edit <name>
    set type cgn-resource-allocation
    set startip <ip>
    set endip <ip>
    set arp-reply {disable | enable}
    set arp-intf <interface-name>
    set cgn-spa disable
    set cgn-overload disable
    set cgn-fixedalloc disable
    set cgn-block-size <number-of-ports>
    set cgn-port-start <port>
    set cgn-port-end <port>
    set utilization-alarm-raise <usage-threshold>
    set utilization-alarm-clear <usage-threshold>
  end
```

Port block allocation (PBA) reduces CGNAT logging overhead by creating a log entry only when a client first establishes a network connection and is assigned a port block. The number of log entries are reduced because a log entry is created when the port block is assigned, and not for each client connection.

When all of the client sessions have ended, FortiOS releases the port block and writes another log message. You can also configure logging to only write a log message when the port block is released. See [Configuring hardware logging on page 38](#).

In general, because each customer environment is different, different configurations may be required to achieve optimal performance.

PBA allocates a contiguous set of source translation endpoints called port blocks. These port blocks are associated to a client by one IP address and a block of ports. Port blocks are allocated on-demand and have a fixed size.

Choose these settings carefully to adequately and efficiently service clients that may require a different number of simultaneous connections. Careful analysis and testing is required to find optimal values for the traffic conditions on your network.

You can define a port-block allocation IP pool by configuring the following:

- External IP address range (*start-ip* and *end-ip*). Specifies the set of translation IP addresses available in the pool as a collection of IP prefixes with their prefix lengths. These are typically public-side addresses.
- Start port (*cgN-port-start*). The lowest port number in the port range. The default value is 5117.
- End port (*cgN-port-end*). The highest possible port number in the port range. The default value is 65530.
- Port block size (*cgN-block-size*). The number of ports allocated in a block. The default value is 128. Use a smaller port block size to conserve available ports.
- Enable or disable ARP reply (*arp-reply*) to reply to ARP requests for addresses in the external address range.
- Optionally specify the interface (*arp-intf*) that replies to ARP requests.
- Generate an SNMP trap when the usage of the resources defined by an IP pool exceeds a threshold (*utilization-alarm-raise*). The range is 50 to 100 per cent.
- Generate an SNMP trap when the usage of the resources defined by an IP pool falls below a threshold (*utilization-alarm-clear*). The range is 40 to 100 per cent.

You can also configure PBA with overload. Overload causes FortiOS to re-use ports within a block, allowing for more possible connections before running out of ports. To configure PBA with overload, see [Overload with port-block-allocation CGN IP pool on page 27](#).

Overload with port-block-allocation CGN IP pool

On the GUI go to **Policy & Objects > IP Pools > Create New > IP Pool**. Set **Type** to **CGN Resource Allocation** and set **Mode** to **Overload (Port Block Allocation)**.

Type	CGN Resource Allocation
Mode	<ul style="list-style-type: none"> Port Block Allocation <li style="background-color: #008000; color: white;">Overload (Port Block Allocation) Single Port Allocation Overload (Single Port Allocation) Fixed-allocation
External IP address/range 	1.1.1.1-1.1.1.10
Start Port	5117
End Port	65530
Block Size	128
ARP Reply	<input checked="" type="checkbox"/>

On the CLI:

```
config firewall ippool
  edit <name>
```

```

set type cgn-resource-allocation
set startip <ip>
set endip <ip>
set arp-reply {disable | enable}
set arp-intf <interface-name>
set cgn-spa disable
set cgn-overload enable
set cgn-block-size <number-of-ports>
set cgn-port-start <port>
set cgn-port-end <port>
set utilization-alarm-raise <usage-threshold>
set utilization-alarm-clear <usage-threshold>
end

```

Overload with Port block allocation (PBA) reduces CGNAT logging overhead by creating a log entry only when a client first establishes a network connection and is assigned a port block. The number of log entries are reduced because a log entry is created when the port block is assigned, and not for each client connection. Overload causes FortiOS to re-use ports within a block, allowing for more possible connections before running out of ports.

When all of the client sessions have ended, FortiOS releases the port block and writes another log message. You can also configure logging to only write a log message when the port block is released. See [Configuring hardware logging on page 38](#).

In general, because each customer environment is different, different configurations may be required to achieve optimal performance.

PBA allocates a contiguous set of source translation endpoints called port blocks. These port blocks are associated to a client by one IP address and a block of ports. Port blocks are allocated on-demand and have a fixed size.

Choose these settings carefully to adequately and efficiently service clients that may require a different number of simultaneous connections. Careful analysis and testing is required to find optimal values for the traffic conditions on your network.

You can define an overload port-block allocation IP pool by configuring the following:

- External IP address range (`start-ip` and `end-ip`). Specifies the set of translation IP addresses available in the pool as a collection of IP prefixes with their prefix lengths. These are typically public-side addresses.
- Start port (`cgn-port-start`). The lowest port number in the port range. The default value is 5117.
- End port (`cgn-port-end`). The highest possible port number in the port range. The default value is 65530.
- Port block size (`cgn-block-size`). The number of ports allocated in a block. The default value is 128. Use a smaller port block size to conserve available ports.
- Enable or disable ARP reply (`arp-reply`) to reply to ARP requests for addresses in the external address range.
- Optionally specify the interface (`arp-intf`) that replies to ARP requests.
- Generate an SNMP trap when the usage of the resources defined by an IP pool exceeds a threshold (`utilization-alarm-raise`). The range is 50 to 100 per cent.
- Generate an SNMP trap when the usage of the resources defined by an IP pool falls below a threshold (`utilization-alarm-clear`). The range is 40 to 100 per cent.

Single port allocation CGN IP pool

On the GUI go to **Policy & Objects > IP Pools > Create New > IP Pool**. Set **Type** to **CGN Resource Allocation** and set **Mode** to **Single Port Allocation**.

Type	CGN Resource Allocation ▼
Mode	Port Block Allocation Overload (Port Block Allocation) Single Port Allocation Overload (Single Port Allocation) Fixed-allocation
External IP address/range ⓘ	1.1.1.1-1.1.1.10
Start Port	5117
End Port	65530
ARP Reply	<input checked="" type="checkbox"/>

On the CLI:

```
config firewall ippool
  edit <name>
    set type cgn-resource-allocation
    set startip <ip>
    set endip <ip>
    set arp-reply {disable | enable}
    set arp-intf <interface-name>
    set cgn-spa enable
    set cgn-overload disable
    set cgn-port-start <port>
    set cgn-port-end <port>
    set utilization-alarm-raise <usage-threshold>
    set utilization-alarm-clear <usage-threshold>
  end
```

A single port allocation CGN resource allocation IP pool assigns single ports instead of ranges of ports. This type of CGN IP pool conserves ports by effectively reducing the port block size to 1. Since blocks of ports are not assigned to each client, this CGN IP Pool type works better for networks with large numbers of clients that start fewer individual sessions.

Since this is not an overload IP pool, ports are not re-used. Each client session gets a new port from the range of ports added to the IP pool that are available.

You can define a single port allocation IP pool by configuring the following:

- External IP address range (`start-ip` and `end-ip`). Specifies the set of translation IP addresses available in the pool as a collection of IP prefixes with their prefix lengths. These are typically public-side addresses.
- Start port (`cgn-port-start`). The lowest port number in the port range. The default value is 5117.
- End port (`cgn-port-end`). The highest possible port number in the port range. The default value is 65530.
- Enable or disable ARP reply (`arp-reply`) to reply to ARP requests for addresses in the external address range.
- Optionally specify the interface (`arp-intf`) that replies to ARP requests.
- Generate an SNMP trap when the usage of the resources defined by an IP pool exceeds a threshold (`utilization-alarm-raise`). The range is 50 to 100 per cent.
- Generate an SNMP trap when the usage of the resources defined by an IP pool falls below a threshold (`utilization-alarm-clear`). The range is 40 to 100 per cent.

Overload with single port allocation CGN IP pool

On the GUI go to **Policy & Objects > IP Pools > Create New > IP Pool**. Set **Type** to **CGN Resource Allocation** and set **Mode** to **Overload (Single Port Allocation)**.

Type	CGN Resource Allocation
Mode	Port Block Allocation Overload (Port Block Allocation) Single Port Allocation Overload (Single Port Allocation) Fixed-allocation
External IP address/range 	1.1.1.1-1.1.1.10
Start Port	5117
End Port	65530
ARP Reply	<input checked="" type="checkbox"/>

On the CLI:

```
config firewall ippool
  edit <name>
    set type cgn-resource-allocation
    set startip <ip>
    set endip <ip>
    set arp-reply {disable | enable}
    set arp-intf <interface-name>
    set cgn-spa enable
    set cgn-overload enable
    set cgn-port-start <port>
    set cgn-port-end <port>
    set utilization-alarm-raise <usage-threshold>
    set utilization-alarm-clear <usage-threshold>
  end
```

An overload single port allocation CGN resource allocation IP pool assigns single ports instead of ranges of ports. This type of CGN IP pool conserves ports by effectively reducing the port block size to 1. Since this is an overload IP pool, ports are re-used. A client session can get any port from the range of ports added to the IP pool that are available.

Since blocks of ports are not assigned to each client and ports are re-used, there are no limits on the number of ports that a client IP address can use. Port re-use is determined by how much the pool is utilized. This IP pool type works for networks with large numbers of clients where those clients may start many individual sessions.

You can define an overload single port allocation IP pool by configuring the following:

- External IP address range (`start-ip` and `end-ip`). Specifies the set of translation IP addresses available in the pool as a collection of IP prefixes with their prefix lengths. These are typically public-side addresses.
- Start port (`cgn-port-start`). The lowest port number in the port range. The default value is 5117.
- End port (`cgn-port-end`). The highest possible port number in the port range. The default value is 65530
- Enable or disable ARP reply (`arp-reply`) to reply to ARP requests for addresses in the external address range.

- Optionally specify the interface (`arp-intf`) that replies to ARP requests.
- Generate an SNMP trap when the usage of the resources defined by an IP pool exceeds a threshold (`utilization-alarm-raise`). The range is 50 to 100 per cent.
- Generate an SNMP trap when the usage of the resources defined by an IP pool falls below this threshold (`utilization-alarm-clear`). The range is 40 to 100 per cent.

Fixed allocation CGN IP pool

On the GUI go to **Policy & Objects > IP Pools > Create New > IP Pool**. Set **Type** to **CGN Resource Allocation** and set **Mode** to **Fixed-allocation**.

Type	CGN Resource Allocation ▼
Mode	Port Block Allocation Overload (Port Block Allocation) Single Port Allocation Overload (Single Port Allocation) Fixed-allocation
External IP address/range ⓘ	1.1.1.1-1.1.1.10
Internal IP Range ⓘ	2.2.2.1-2.2.2.10
Start Port	5117
End Port	65530
Block Size	128
ARP Reply	<input checked="" type="checkbox"/>

On the CLI:

```
config firewall ippool
edit <name>
set type cgn-resource-allocation
set startip <ip>
set endip <ip>
set arp-reply {disable | enable}
set arp-intf <interface-name>
set cgn-spa disable
set cgn-fixedalloc enable
set cgn-block-size <number-of-ports>
set cgn-client-startip <ip>
set cgn-client-endip <ip>
set cgn-port-start <port>
set cgn-port-end <port>
set utilization-alarm-raise <usage-threshold>
set utilization-alarm-clear <usage-threshold>
end
```

Also called deterministic NAT, a fixed allocation CGN resource allocation IP pool causes FortiOS to find the maximum possible block size, given the configured NAT resources and gives one block to each client.

The number of clients that can use a fixed allocation CGN resource allocation IP pool is limited by the number of IP addresses in the pool. Since this is not an overload IP pool, ports are not re-used.

You can define a fixed allocation IP pool by configuring the following:

- External IP address range (`start-ip` and `end-ip`). Specifies the set of translation IP addresses available in the pool as a collection of IP prefixes with their prefix lengths. These are typically public-side addresses.
- Internal or client IP address range (`cg-client-startip` and `cg-client-endip`). The range of internal addresses. This range must match or be a subset of the available source IP addresses.
- Start port (`cg-port-start`). The lowest port number in the port range. The default value is 5117.
- End port (`cg-port-end`). The highest possible port number in the port range. The default value is 65530
- Port block size (`cg-block-size`). When `cg-fixedallc` is enabled, the `cg-block-size` configuration is ignored because FortiOS calculates a block-size to find the maximum possible block size and gives one block to each client.
- Enable or disable ARP reply (`arp-reply`) to reply to ARP requests for addresses in the external address range.
- Optionally specify the interface (`arp-intf`) that replies to ARP requests.
- Generate an SNMP trap when the usage of the resources defined by an IP pool exceeds a threshold (`utilization-alarm-raise`). The range is 50 to 100 per cent.
- Generate an SNMP trap when the usage of the resources defined by an IP pool falls below this threshold (`utilization-alarm-clear`). The range is 40 to 100 per cent.

CGN resource allocation IP pool groups

You can configure CGN resource allocation IP pool groups to group together related CGN resource allocation IP pools to be able to add multiple IP pools to the same firewall policy. All of the CGN IP pools in a CGN IP pool group must have the same CGN mode and their IP ranges must not overlap.

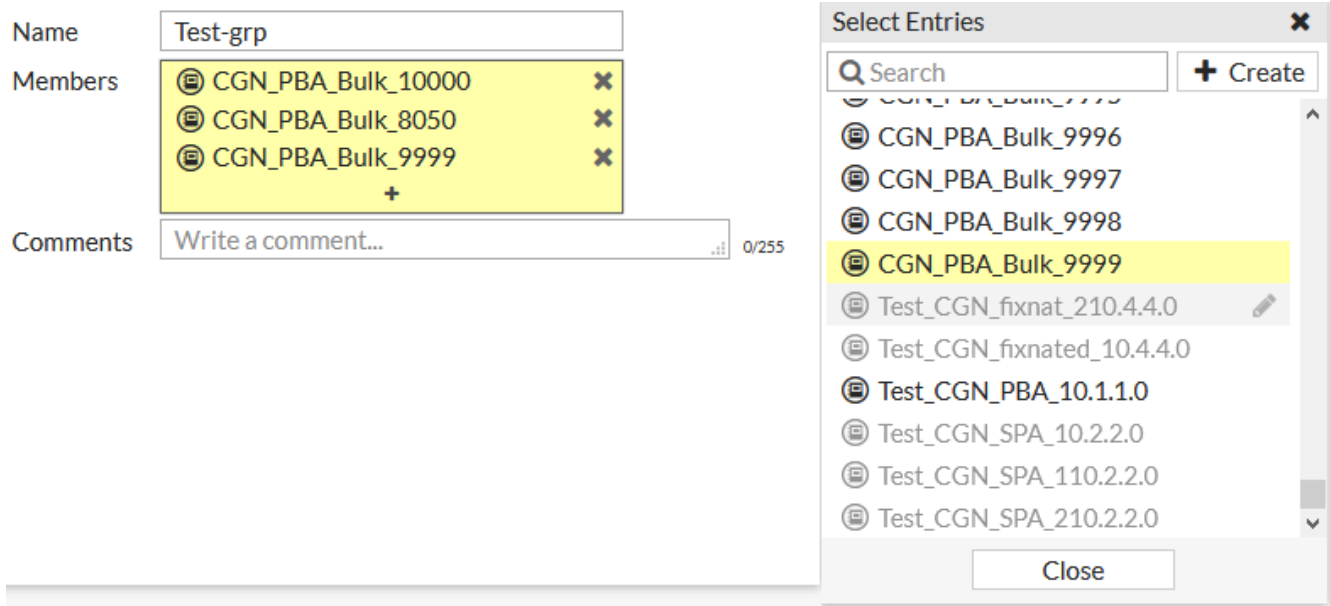

Use the following command to create a CGN resource allocation IP pool group:

```
config firewall ippool_grp
  edit <name>
    set member <cg-ippool> ...
  end
```

`member` select the names of the CGN IP pools to add to the CGN IP pool group.

Use the following steps to configure CGNAT IP pool groups from the GUI:

1. Go to **Policy & Objects > IP Pools**.
2. Select **Create New > CGN IP Pool Group**.
3. Select CGN IP pools to add to the **Members** list.

CGN resource allocation hyperscale firewall policies

Use the following options to configure an IPv4 or NAT64 CGN resource allocation hyperscale firewall policy:

```
config firewall {hyperscale-policy | hyperscale-policy64}
  edit <id>
    set action accept
    set nat enable
    set ippool enable
    set poolname {<cgN-ippool> | <cgN-ippool-group>}...
    set cgn-session-quota <quota>
    set cgn-resource-quota <quota>
    set cgn-eif {enable| disable}
    set cgn-eim {enable| disable}
    set cgn-log-server-grp <group-name>
  end
```

poolname select one or more CGN IP pools or IP pool groups to apply CGN resource allocation IP pools to the firewall policy. To be able to add IP pools, **nat** and **ippool** must be enabled.

cgn-session-quota limit the number of concurrent sessions available for a client IP address (effectively the number of sessions per user). The range is 0 to 16777215 (the default). The default setting effectively means there is no quota.

cgn-resource-quota set a quota for the number port blocks available for a client IP address (effectively the number of port blocks per client IP address). Only applies if the firewall policy includes CGN IP pools with port block sizes. The range is 1 to 16 and the default is 16. If your FortiGate has multiple NP7 processors, the resource quota should be set differently depending on the **hash-config** used by the internal switch fabric (ISF). See [How the NP7 hash-config affects CGNAT on page 49](#) for details.

cgn-eif enable or disable Endpoint Independent Filtering (EIF). Disabled by default. If another server attempts to connect to a public IP and port which is used by an existing session, when EIF is enabled, the NP7 will create the session

and reuse the mapping for the existing session. When EIF is not enabled, the server attempts to connect to the public IP and port will fail. This practice is recommended in [RFC 4787](#) for client applications that require this behavior.

For example, Client-A has an existing session, {A.a, B.b, S.s}. When another server S1.s1 attempts to connect to public address and port B.b, when EIF is enabled, the NP7 creates a new session as {A.a, B.b, S1.s1}. When EIF is disabled, such connection will be checked in full-policy and probably dropped.

`cgn-eim` enable or disable Endpoint Independent Mapping (EIM). If a client uses an existing source port to connect to a different server, the NP7 reuses the existing mapping to create new sessions. This practice is more compatible for some applications to work with NAT devices, also it is more efficient. A new resource allocation counts towards the resource quota. If EIM is triggered, the new session does not cause new resource allocation and the new session only counts towards the session quota.

For example, Client-A has an existing session, represented as {A.a, B.b, S.s}, where A.a is the client IP and port, B.b is the mapped IP and port, and S.s is the server IP and port. When EIM is enabled, if the client uses A.a to connect to another server S1.s1, the NP7 reuses the public IP and port at B.b to create session that can be represented as {A.a, B.b, S1.s1}.

About hairpinning

You can use EIF to support hairpinning. A hairpinning configuration allows a client to communicate with a server that is on the same network as the client, but the communication takes place through the FortiGate because the client only knows the external address of the server.

To set up a hyperscale firewall hairpinning configuration, you need to enable EIF in the firewall policy. As well, the IP pool added to the policy should include addresses that overlap with the firewall policy destination address. In many cases you can do this by setting the firewall policy destination address to all.

If the policy uses a specific address or address range for the destination address, then this destination address and the IP pool address range should have some overlap.

`cgn-log-server-grp` the name of the hardware logging server group. See [Hardware logging on page 38](#).

From the GUI

Use the following steps to configure CGNAT firewall policies from the GUI:

1. Go to **Policy & Objects** and select **IPv4 Hyperscale Policy** or **NAT46 Hyperscale Policy**.
2. Configure source and destination interfaces and addresses and other standard firewall options as required.
3. If you are configuring an IPv4 or NAT64 hyperscale firewall policy you can also configure the following CGN resource allocation options:
 - **IP Pool Configuration** select one or more CGN resource allocation IP pools or CGN resource allocation IP pool groups. All of the IP pools or IP pool groups must have the same mode and their source IP addresses must not overlap.
 - **CGN Session Quota** to limit the concurrent sessions available for a source IP address.
 - **CGN Resource Quota** to limit the number of port blocks assigned to a source IP address.
 - Enable or disable **Endpoint Independent Filtering**.
 - Enable or disable **Endpoint Independent Mapping**.

CGN resource allocation firewall policy source and destination address limits

CGN resource allocation hyperscale firewall policies have the following limitations for the number of source and destination addresses that can be added to a single policy. These limitations result from compiling firewall policies by the FortiOS kernel.

An IPv4 hyperscale firewall policy can have the following number of source or destination addresses. Addresses can be added as any combination of individual firewall addresses or firewall address groups.

- An IPv4 hyperscale firewall policy can have up to 150 unique IP addresses distributed between the source and destination address fields.
- An IPv4 hyperscale firewall policy can have up to 150 unique IP addresses and 10 overlapping subnets distributed between the source and destination address fields. Example subnet: 5.2.226.0/24
- An IPv4 hyperscale firewall policy can have up to 150 unique IP addresses and 9 single IP duplicate range addresses distributed between the source and destination address fields. Example duplicate range IP address: start-ip/end-ip 118.1.1.152.

An IPv6 hyperscale firewall policy can have up to 20 IPv6 IP addresses distributed between the source and destination address fields.

Hyperscale firewall policy engine mechanics

The NP7 hyperscale firewall policy engine is also called the Policy Lookup Engine (PLE). The PLE handles processing of all hyperscale firewall policies in all hyperscale firewall VDOMs. When the hyperscale firewall policy configuration changes, the PLE compiler creates a new policy database (also called a policy set) that is used by NP7 processors to apply hyperscale firewall and carrier grade NAT (CGN) features to offloaded traffic.

Hyperscale firewall policy maximum values

The following maximum values are global limits for all hyperscale VDOMs and are not per individual VDOMs. These maximum values have been tested for FortiOS 6.4.12 and may be changed in the future as the result of ongoing and future optimizations.

- The maximum number of hyperscale firewall policies allowed in the policy database: 20,000.
- The maximum number of IP-ranges specified by firewall addresses that can be added to a single hyperscale firewall policy: 2000.
- The maximum number of IP-ranges that can be added to the firewall policy database: 32,000.
- The maximum number of port-ranges specified by firewall addresses that can be added to a single hyperscale firewall policy: 1,000.
- The maximum number of port-ranges that can be added to the firewall policy database: 4,000.

The maximum number of hyperscale firewall policies allowed in a VDOM is controlled by the maximum value for the number of firewall policies allowed per VDOM for your FortiGate.

Additional considerations

The factors that affect whether a hyperscale policy database can be supported or not includes but are not limited to:

- The total number of hyperscale firewall policies.
- The total number of IP-ranges and port-ranges as defined by firewall addresses added to hyperscale firewall policies in the firewall policy database
- The relationship between policies, such as how IP-ranges are distributed among hyperscale firewall policies.

It is possible to create a hyperscale policy database that is within the maximum values but cannot be supported. If this happens, FortiOS will create an error message when the policy database is compiled. If you receive an error message during policy compilation, contact Fortinet Support for assistance diagnosing and correcting the problem.

You can also create a policy database that exceeds some or all of the maximum values but can be successfully compiled. If you plan to create a configuration with one or more parameters close to or above their maximum values, you should contact Fortinet Support to review your configuration before deploying it.

It is a best practice to restart your FortiGate after making significant changes to a hyperscale policy database, especially if one or more parameters are close to or above their maximum values.

Hyperscale policy database complexity and performance

The complexity of your hyperscale firewall policy set affects how long it takes for your FortiGate to start up. In general, more complex policy databases result in longer start up times.

The complexity of your hyperscale firewall policy database also affects your FortiGate's hyperscale connections per second (CPS) performance. In general, more complex policy databases result in lower CPS performance.

How policy database changes are implemented while the FortiGate is processing traffic

The complexity of your hyperscale firewall policy database affects how long it takes after inputting a policy change before the updated policy database can be applied to new and established sessions. This period of time is called the preparation time.

During the preparation time, new sessions are evaluated with the current policy database.

Access control list (ACL) policies added to a hyperscale firewall VDOM that is processing traffic may take longer than expected to become effective. During a transition period, traffic that should be blocked by the new ACL policy will be allowed.

After the preparation time, new sessions are evaluated with the new policy database. Established sessions are also re-evaluated with the new policy database. The time required to re-evaluate established sessions is called the transition time. CPS performance can be reduced during the transition time.

The transition time is affected by hyperscale policy database complexity, the total number of established sessions to be re-evaluated, and by the rate that the system is receiving new sessions.

During the transition time, FortiOS terminates an established session if:

- The session is matched with a policy that has a different policy search key (for example, a different source IP range) or policy action.
- The session is matched with the same policy but the policy includes a resource, such as an IP pool, that dynamically assigns a value (for example, an IP address) to the session and now it has to be returned because of the policy change.

Hardware logging

You can configure NP7 processors to create traffic or NAT mapping log messages for hyperscale firewall sessions and send them to remote NetFlow or Syslog servers. Hardware logging is supported for IPv4, IPv6, NAT64, and NAT46 hyperscale firewall policies. Full NetFlow is supported through the information maintained in the firewall session.

Hardware logging features include:

- On some FortiGate models with NP7 processors you can configure hardware logging to either use the NP7 processors to create and send log messages or you can configure hardware logging to use FortiGate CPU resources to create and send hardware log messages. Using the NP7 processors to create and send log messages improves performance. Using the FortiGate CPU for hardware logging is called host logging. Each option has some limitations, see [Configuring hardware logging on page 38](#).
- Per session logging creates two log messages per session; one when the session is established and one when the session ends.
- Per session ending logging creates one log message when the session ends. This log message includes the session duration, allowing you to calculate the session start time. Per session ending logging may be preferable to per session logging because fewer log messages are created, but the same information is available.
- Per NAT mapping logging, creates two log messages per session, one when the session allocates NAT mapping resources and one when NAT mapping resources are freed when the session ends.
- By default, log messages are sent in NetFlow v10 format over UDP. NetFlow v10 is compatible with IP Flow Information Export (IPFIX).
- NetFlow v9 logging over UDP is also supported. NetFlow v9 uses a binary format and reduces logging traffic.
- Syslog logging over UDP is also supported.
- You can create multiple log server groups to support different log message formats and different log servers.
- Round-robin load balancing distributes log messages among the log servers in a log server group to reduce the load on individual log servers. A log server group can contain up to 16 log servers. All messages generated by a given session are sent to the same log server.
- Hardware logging log messages are similar to most FortiGate log messages but there are differences that are specific to hardware logging messages. For example, the `dur` (duration) field in hardware logging messages is in milliseconds (ms) and not in seconds.
- Hardware logging is supported for protocols that use session helpers or application layer gateways (ALGs). If hyperscale firewall policies accept session helper or ALG traffic, for example, ICMP traffic, hardware log messages for these sessions are created and sent according to the hardware logging configuration for the policy.

Configuring hardware logging

Use the following command to add log servers and create log server groups. This configuration is shared by all of the NP7s in your FortiGate. If your FortiGate is configured with multiple VDOMs, this is a global configuration and the log server groups are available to all VDOMs with hyperscale firewall features enabled.

```
config log npu-server
  set log-processor {hardware | host}
  set log-processing {may-drop | no-drop}
  set netflow-ver {v9 | v10}
  set syslog-facility <facility>
  set syslog-severity <severity>
```

```

config server-info
  edit <index>
    set vdom <name>
    set ip-family {v4 | v6}
    set ipv4-server <ipv4-address>
    set ipv6-server <ipv6-address>
    set source-port <port-number>
    set dest-port <port-number>
    set template-tx-timeout <timeout>
  end
config server-group
  edit <group-name>
    set log-mode {per-session | per-nat-mapping | per-session-ending}
    set log-format {netflow | syslog}
    set log-tx-mode {roundrobin | multicast}
    set server-number <number>
    set server-start-id <number>
  end

```

`log-processor` select whether to use NP7 processors (`hardware`, the default) or the FortiGate CPUs (`host`) to generate traffic log messages for hyperscale firewall sessions. This option is not available for all FortiGate models that support hyperscale firewall features. If the option is not available, then NP7 processors are used to generate traffic log messages for hyperscale firewall sessions.

If you set this option to `hardware`, (and for FortiGate models that don't support selecting `host`) the following limitations apply:

- The interface through which your FortiGate communicates with the remote log server must be connected to your FortiGate's NP7 processors. Depending on the FortiGate model, this usually means you can't use a management or HA interface to connect to the remote log server. See [FortiGate NP7 architectures](#) for information about the interfaces that are connected to NP7 processors and the interfaces are not for your FortiGate model.
- The interface through which your FortiGate communicates with the remote log server can be in any VDOM and does not have to be in the hyperscale VDOM that is processing the traffic being logged.
- The `vdom=` field in generated traffic log messages includes the VDOM name followed by trailing null characters. If possible, you can configure your syslog server or NetFlow server to remove these trailing null characters.
- Normally the `PID=` field in traffic log messages contains the policy ID of the firewall policy that generated the log message. But, if the policy that generated the traffic log message has recently changed, the `PID=` field can contain extra information used by the NP7 policy engine to track policy changes. You can extract the actual policy ID by converting the decimal number in the `PID=` field to hexadecimal format and removing all but the last 26 bits. These 26 bits contain the policy ID in hexadecimal format. You can convert this hex number back to decimal format to generate the actual policy ID.
- If `log-mode` is set to `per-session`, NP7 hardware logging may send multiple session start log messages, each with a different start time. Creating multiple session start log messages is a limitation of NP7 processor hardware logging, caused by the NP7 processor creating extra session start messages if session updates occur. You can work around this issue by using `host` logging or by setting `log-mode` to `per-session-ending`. This setting creates a single log message when the session ends. This log message records the time the session ended as well as the duration of the session. This information can be used to calculate the session start time.

If you set this option to `host`, all hardware logging functions are supported and the hardware logging configuration is the same with the following limitations:

- There are no restrictions on the interface through which your FortiGate communicates with the remote log server.
- Setting `log-processor` to `host` can reduce overall FortiGate performance because the FortiGate CPUs handle hardware logging instead of offloading logging to the NP7 processors.

- Host logging may not provide the NHI, stats, OID, gateway, expiration, and duration information for short-lived sessions.
- Host logging does not support Netflow v9.

`log-processing {may-drop | no-drop}` change how the FortiGate queues CPU or host logging packets to allow or prevent dropped packets. This option is only available if `log-processor` is set to `host`. In some cases, hyperscale firewall CPU or host logging packets can be dropped, resulting in lost log messages and incorrect traffic statistics.

- `may-drop` the default CPU or host log queuing method is used. Log message packet loss can occur if the FortiGate is very busy.
- `no-drop` use an alternate queuing method that prevents packet loss.

`netflow-ver` select the version of NetFlow that this log server is compatible with. `v10`, which is compatible with IP Flow Information Export (IPFIX), is the default.

`syslog-facility` set the syslog facility number added to hardware log messages. The range is 0 to 255. The default is 23 which corresponds to the local7 syslog facility.

`syslog-severity` set the syslog severity level added to hardware log messages. The range is 0 to 255. The default is 5, which corresponds to the notice syslog severity.

`config server-info` use this command to add up to sixteen log servers. Once you have added log servers using this command, you can add the servers to one or more log server groups.

`edit <index>` create a log server. `<index>` is the number of the log server. You use this number when you add the log server to a server group. `<index>` can be 1 to 16. You must specify the number, setting `<index>` to 0 to select the next available number is not supported.

`vdom` the virtual domain that contains a FortiGate interface that you want to use to communicate with the log server.

`ip-family` the IP version of the remote log server. `v4` is the default.

`ipv4-server` the IPv4 address of the remote log server.

`ipv6-server` the IPv6 address of the remote log server.

`source-port` the source UDP port number added to the log packets in the range 0 to 65535. The default is 514.

`dest-port` the destination UDP port number added to the log packets in the range 0 to 65535. The default is 514.

`template-tx-timeout` the time interval between sending NetFlow template packets. NetFlow template packets communicate the format of the NetFlow messages sent by the FortiGate to the NetFlow server. Since the message format can change if the NetFlow configuration changes, the FortiGate sends template updates at regular intervals to make sure the server can correctly interpret NetFlow messages. The timeout range is from 60 to 86,400 seconds. The default timeout is 600 seconds.

`server-group` create log server groups. Collect multiple log servers into a group to load balance log messages to the servers in the group. You add log server groups to hyperscale firewall policies.

`log-mode` select one of the following log modes:

- `per-session` (the default) create two log messages per session, one when the session is established and one when the session ends. If `log-processor` is set to `hardware`, NP7 processors may incorrectly create multiple session start messages due to a hardware limitation.
- `per-nat-mapping` create two log messages per session, one when the session allocates NAT mapping resources and one when NAT mapping resources are freed when the session ends.
- `per-session-ending` create one log message when a session ends. This log message includes the session duration, allowing you to calculate the session start time. `per-session-ending` logging may be preferable to `per-session` logging because fewer log message are created, but the same information is available.

`log-format` select the log message format. You can select `netflow` or `syslog`. If you select `netflow`, the NetFlow version (v9 or v10) is set for each log server.

`log-tx-mode` select `roundrobin` (the default) to load balance log messages to the log servers in the server group. Select `multicast` to simultaneously send session setup log messages for CPU or software sessions to multiple remote syslog or NetFlow servers. Multicast logging is not supported for NP7 sessions.

`server-number` the number of log servers, created using `config server-info`, in this log server group. The range is 1 to 16 and the default is 0 and must be changed.

`server-start-id` the ID of one of the log servers in the `config server-info` list. The range is 1 to 16 and the default is 0 and must be changed.

Use `server-number` and `server-start-id` to select the log servers to add to a log server group. For example, if you have used the `config server-info` command to create five log servers with IDs 1 to 5, you can add the first three of them (IDs 1 to 3) to a log server group by setting `server-number` to 3 and `server-start-id` to 1. This adds the log servers with ID 1, 2, and 3 to this log server group. To add the other two servers to a second log server group, set `server-number` to 2 and `server-start-id` to 4. This adds log servers 4 and 5 to the second log server group.

You can add a log server to multiple server groups.

From the GUI

1. Go to **Log & Report > Hyperscale SPU Offload Log Settings**.
This is a global setting.
2. Select the **Netflow version**.
3. Under **Log Servers**, select **Create New** to create a log server.
4. Select the **Virtual Domain** containing the interface that can communicate with the log server.
5. Select the **IP version** supported by the log server and enter the log server **IP address** or **IPv6 address**.
6. Enter the **Source port** and **Destination port** to be added to the log message packets.
7. Set the Template transmission timeout, or the time interval between sending NetFlow template packets.
8. Select **OK** to save the log server.
9. Repeat to add more log servers.
10. Under **Log Server Groups** select **Create New** to add a log server group.
11. Enter a **Name** for the log server group.
12. Select the **Logging Mode** and **Log format**.
13. Add one or more **Log servers**.
14. Select **OK** to save the log server group.
15. Select **Apply** to apply your hardware logging changes.

NetFlow version V9 V10

Log Servers

ID	IP address
1	192.168.1.100
2	192.168.2.100

Log Server Groups

Group name	Logging mode	Log format	Servers	Ref.
1	Per-Mapping	Syslog	192.168.1.100 (ID: 1) 192.168.2.100 (ID: 2)	8

Adding hardware logging to a hyperscale firewall policy

Use the following command to enable hardware logging in a hyperscale firewall policy and assign a hardware logging server group to the firewall policy.

```
config firewall {hyperscale-policy | hyperscale-policy46 | hyperscale-policy6 | hyperscale-policy64}
edit <id>
  set policy-offload {enable | disable}
  set cgn-log-server-grp <group-name>
end
```

From the GUI:

1. Go to **Policy & Objects** and select **IPv4 Hyperscale Policy, IPv6 Hyperscale policy, NAT46 Hyperscale Policy, or NAT46 Hyperscale Policy**.
2. While configuring the policy, select **Log Hyperscale SPU Offload Traffic**.
3. Select a **Log Server Group**.

Log Hyperscale SPU Offload Traffic

Log Server Group

Lab_67_34.0.2.12

When configuring hardware logging, the recommended or required IP addresses of the hardware logging servers that you can use with hyperscale firewall policies are the following:

- You should only use logging servers that have IPv4 addresses with IPv4 hyperscale firewall policies. Logging servers with IPv6 IP addresses can be used but are not recommended.
- You should only use logging servers that have IPv6 addresses with IPv6 hyperscale firewall policies. Logging servers with IPv4 IP addresses can be used but are not recommended.
- You can only use logging servers that have IPv6 addresses with NAT64 hyperscale firewall policies.
- You can only use logging servers that have IPv4 addresses with NAT46 hyperscale firewall policies.

Multicast logging example

You can use multicast logging to simultaneously send session setup log messages for CPU or software sessions to multiple remote syslog or NetFlow servers. Multicast logging is not supported for NP7 sessions.

Enable multicast logging by creating a log server group that contains two or more remote log servers and then set `log-tx-mode` to `multicast`:

```
config log npu-server
  set log-processor {hardware | host}
  config server-group
    edit "log_ipv4_server1"
      set log-format {netflow | syslog}
      set log-tx-mode multicast
    end
```

The following example shows how to set up two remote syslog servers and then add them to a log server group with multicast logging enabled.

```
config log npu-server
  set log-processor {hardware | host}
  config server-info
    edit 1
      set vdom "root"
      set ipv4-server <server-ip>
      set source-port 8055
      set dest-port 2055
      set template-tx-timeout 60
    next
    edit 2
      set vdom "root"
```

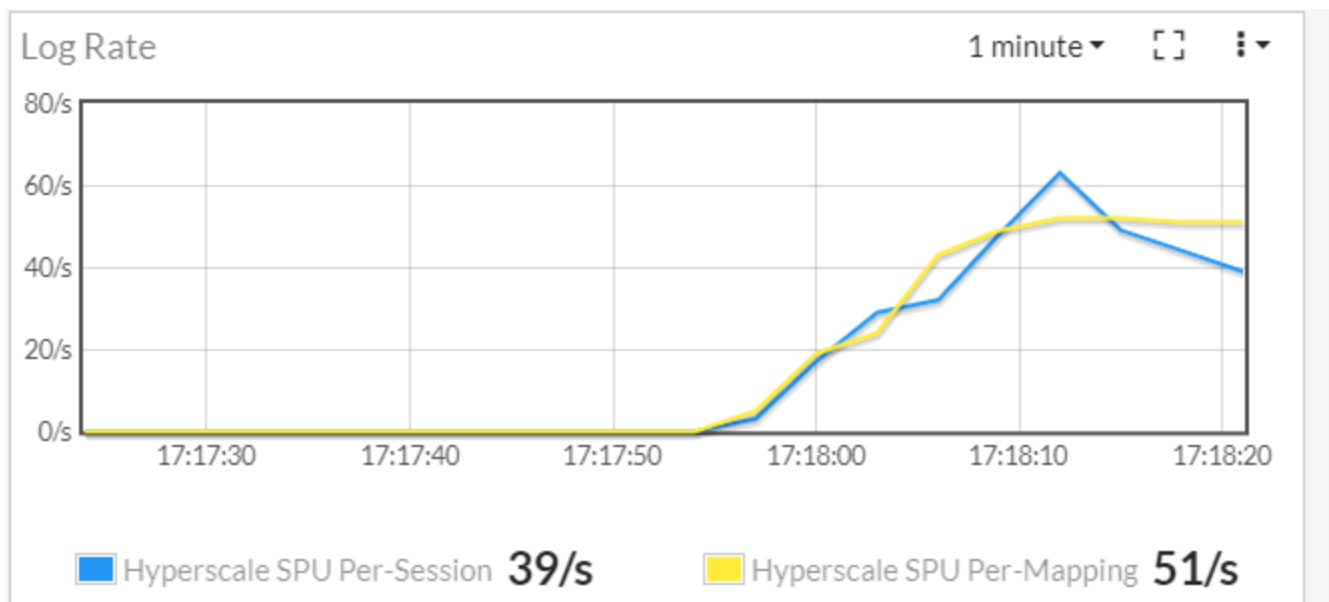

```

    set ipv4-server <server-ip>
    set source-port 8055
    set dest-port 2055
    set template-tx-timeout 60
  end
end
config server-group
  edit "Example-Multicast"
    set log-format syslog
    set log-tx-mode multicast
    set server-number 2
    set server-start-id 1
  end
end

```

Hardware logging log rate dashboard widget

You can enable the Log Rate dashboard widget to see hardware logging log message creation rates. The widget shows the average hyperscale per-session and per mapping log message creation rates for the NP7 processors (SPUs) in the FortiGate. You can also click on the widget to access hardware logging settings.

Hardware logging for hyperscale firewall policies that block sessions

Hardware logging supports the following features related to hyperscale firewall policies that block sessions, that is hyperscale firewall policies with action set to deny:

- You can enable hardware logging for hyperscale firewall policies with action set to deny. Hardware logging creates a log message for each session that is blocked.

- Hardware session information includes information about whether the session blocked traffic. For example, when displaying session information from the CLI, a field similar to the following appears to indicate that the session blocked traffic: `Session action (DROP/TO-HOST): DROP.`

Hardware log messages indicate if the session accepted or denied traffic. For example:

- Example log messages for a policy that accepts traffic:

```
Oct 5 23:29:33 172.16.200.26 date=2022-10-06 time=02:29:32 sn=F2K61FTK21900840
vd=cgn-hw1 pid=805306369 type=sess act=start tran=snat proto=6 ipold=v4 ipnew=v4
sip=10.1.100.11 dip=172.16.200.155 sport=40836 dport=80 nsip=172.16.201.182
ndip=172.16.200.155 nsport=8117 ndport=80 sentp=0 sentb=0 rcvdp=0 rcvdb=0
```

```
Oct 5 23:29:36 172.16.200.26 date=2022-10-06 time=02:29:35 sn=F2K61FTK21900840
vd=cgn-hw1 pid=805306369 type=sess act=end tran=snat proto=6 ipold=v4 ipnew=v4
sip=10.1.100.11 dip=172.16.200.155 sport=40836 dport=80 nsip=172.16.201.182
ndip=172.16.200.155 nsport=8117 ndport=80 dur=2936 sentp=6 sentb=398 rcvdp=4
rcvdb=1307
```

Decimal version of the pid = 805306369

Binary version of the pid = 0011 0000 0000 0000 0000 0000 0000 0001

pid[30] is '0' for accept action (count from bit0 to bit31 and right to left)

- Example log messages for a policy that blocks or denies traffic:

```
Oct 5 23:31:49 172.16.200.26 date=2022-10-06 time=02:31:49 sn=F2K61FTK21900840
vd=cgn-hw1 pid=1946157057 type=sess act=start tran=none proto=6 ipold=v4 ipnew=v4
sip=10.1.100.11 dip=172.16.200.155 sport=40837 dport=80 nsip=10.1.100.11

pid[30] is '1' for deny action (count from bit0 to bit31 and right to left)

FGCP HA hardware session synchronization

When configuring active-passive FGCP HA or active-passive virtual clustering for two FortiGates with hyperscale firewall support, you can use FGCP HA hardware session synchronization to synchronize NP7 sessions between the FortiGates in the cluster.

HA hardware session synchronization is currently only supported between two FortiGates using a direct connection between the HA hardware session synchronization interfaces. You can't use a switch for this connection and you can't synchronize sessions between more than two FortiGates.

In an active-passive FGCP cluster, HA hardware session synchronization copies sessions from the primary FortiGate to the secondary FortiGate. Both FortiGates maintain their own session tables with their own session timeouts. FGCP HA hardware session synchronization does not compare FortiGate session tables to keep them synchronized. In some cases you may notice that the secondary FortiGate in the HA cluster may have a lower session count than the primary FortiGate. This is a known limitation of FGCP HA hardware session synchronization. Normally the difference in session count is relatively minor and in practice could result in very few lost sessions after a failover.

In an active-passive FGCP virtual clustering configuration, FGCP HA hardware session synchronization copies sessions from VDOMs processing traffic to VDOMs on the other FortiGate in the virtual cluster that are not processing traffic. All VDOM instances maintain their own session tables with their own session timeouts. FGCP HA hardware session synchronization does not compare VDOM session tables between FortiGates to keep them synchronized.

FGCP HA hardware session synchronization packets are the same as standard session synchronization packets. For FGCP HA they are layer 2 TCP and UDP packets that use destination port 703. FGCP HA does not require you to add IP addresses to the interfaces that you use for FGCP HA hardware session synchronization.

HA hardware session synchronization is not supported for active-active FGCP HA or FGSP HA or for inter-cluster session synchronization (FGSP between FGCP clusters).

The HA Status dashboard widget shows hardware session synchronization status.

HA Status

Mode	Active-Passive
Group	4201
Master	✔ FortiGate-191
Uptime	00:00:06:14
State Changed	00:00:06:06
Hardware Session Synchronization	⚠ Not Synchronized

Configuring FGCP HA hardware session synchronization

Use the following command to configure HA hardware session synchronization.

```
config system ha
  set session-pickup enable
  set hw-session-sync-dev <interface>
end
```

`session-pickup` must be enabled for FGCP HA hardware session synchronization.

`hw-session-sync-dev` select an interface to use to synchronize hardware sessions between the FortiGates in an FGCP cluster. Fortinet recommends using a data interface as the FGCP HA hardware session synchronization interface. The interface can only be used for FGCP HA hardware session synchronization. See [Recommended interface use for an FGCP HA hyperscale firewall cluster on page 47](#).

For some FortiGates there is a limitation on the interfaces that can be used for hardware session synchronization. For example, for the FortiGate-1800F and 1801F you can only use the port25 to port40 interfaces as hardware session synchronization interfaces.

Hardware session synchronization can use a lot of bandwidth so you should use a dedicated data interface. Both FortiGates in the HA cluster must use the same data interface for FGCP HA hardware session synchronization and these interfaces must be directly connected.

Recommended interface use for an FGCP HA hyperscale firewall cluster

When setting up an FGCP HA cluster of two FortiGates operating as hyperscale firewalls, you need to select interfaces to use for some or all of the following features:

- Management.
- HA heartbeat (also called HA CPU heartbeat).
- HA session synchronization (also called HA CPU session synchronization).
- HA hardware session synchronization.
- Hardware logging.
- CPU logging.
- Logging to FortiAnalyzer

The following table contains Fortinet's recommendations for the FortiGate interfaces to use to support these features.

Interfaces	Recommended for
MGMT1 and MGMT2	Normal management communication with the FortiGates in the cluster.
HA1 and HA2	HA heartbeat (also called HA CPU heartbeat) between the FortiGates in the cluster.
AUX1 and AUX2	HA session synchronization (also called HA CPU session synchronization) or session pickup.

Interfaces	Recommended for
	<p>The AUX1 and AUX2 interfaces are available only on the FortiGate 4200F/4201F and 4400F/4401F. For other FortiGate models, you can use any available interface or LAG for HA CPU session synchronization. For example, you may be able to use the HA interfaces for both HA CPU heartbeat and HA CPU session synchronization. If you need to separate HA CPU heartbeat and HA CPU session synchronization, you can use a data interface or a data interface LAG for HA CPU session synchronization.</p>
Data interface	FGCP HA hardware session synchronization.
Data interface or data interface LAG	<p>Hardware logging, CPU logging, and logging to a FortiAnalyzer. Depending on bandwidth use, you can use the same data interface or data interface LAG for all of these features.</p>

Operating a hyperscale firewall

This chapter is a collection of information that you can use when operating a FortiGate with hyperscale firewall features enabled.

Configuring how the internal switch fabric distributes sessions to NP7 processors

On FortiGates with multiple NP7 processors, you can use the following command to configure how the internal switch fabric (ISF) distributes sessions to the NP7 processors.

```
config system global
  config system npu
    set hash-config {src-dst-ip | 5-tuple | src-ip}
  end
```

Changing the `hash-config` causes the FortiGate to restart.

`src-dist-ip`, use 2-tuple source and destination IP address hashing. This option is only available on FortiGates with an odd number of NP7 processors. For example, the FortiGate-3500F and 3501F have three NP7 processors, so this is the default `hash-config` for these models. On FortiGates with an odd number of NP7 processors, `src-dist-ip` is the default value.

`5-tuple`, the default value on FortiGates with an even number of NP7 processors. To distribute sessions, a hash is created for each session based on the session's source and destination IP address, IP protocol, and source and destination TCP/UDP port. In most cases `5-tuple` distribution provides the best performance. However, CGNAT resource quotas are distributed differently depending on the `hash-config`.

`src-ip`, sessions are distributed by source IP address. All sessions from a source IP address are processed by the same NP7 processor.

How the NP7 hash-config affects CGNAT

In most cases Setting `hash-config` to `5-tuple` distribution provides the best performance. However, CGNAT resource quotas are distributed differently depending on the `hash-config`.

For example, you could use the following command to configure an IPv4 CGN resource allocation hyperscale firewall policy:

```
config firewall policy
  edit <id>
    set action accept
    set dstaddr <address>
    set nat enable
    set ippool enable
    set poolname {<cg-n-ippool> | <cg-n-ippool-group>}...
    set cgn-session-quota <quota>
    set cgn-resource-quota <quota>
    set cgn-eif {enable| disable}
```

```

set cgn-eim {enable| disable}
set cgn-log-server-grp <group-name>
end

```

The `cgn-resource-quota` option sets a quota for the number port blocks available for a client IP address (effectively the number of port blocks per client IP address). When `hash-config` is set to `src-ip`, each NP7 processor has the same `cgn-resource-quota` and the quota is applied to all traffic from a given source address.

When `hash-config` is set to `5-tuple`, the number of blocks in the resource quota are divided evenly among each NP7 processor and only a portion of the resource quota is available on each NP7 processor. So to make sure each NP7 has access to the intended number of port blocks, you should adjust the `cgn-session-quota` to limit the number of sessions available for each client IP address. The intended resource quota should be multiplied by the number of NP7 processors that the FortiGate has to find the value to set as the session quota.

For example, the FortiGate-4200F has four NP7 processors. If you want each client IP address to have a resource quota of 2 port blocks, you should set `cgn-session-quota` using the following calculation:

$$\langle \text{number of NP7 processors} \rangle \times \langle \text{intended cgn-resource-quota} \rangle = \langle \text{cgn-session-quota} \rangle$$

For the FortiGate-4200F the calculation would be:

$$4 \times 2 = 8$$

For a FortiGate-4200F to impose a resource quota of 2 port blocks, set `cgn-session-quota` to 8.

The FortiGate-4400F has six NP7 processors. If you want each client IP address to have a resource quota of 3 port blocks, you should set `cgn-session-quota` using the following calculation:

$$6 \times 3 = 18$$

For a FortiGate-4200F to impose a resource quota of 3 port blocks, set `cgn-session-quota` to 18.

On FortiGates with an odd number of NP7 processors, for example the FortiGate-3500F and 3501F, when `hash-config` is set to `src-dst-ip`, the number of blocks in the resource quota are divided evenly among each NP7 processor and only a portion of the resource quota is available on each NP7 processor. So to make sure each NP7 has access to the intended number of port blocks, you should adjust the `cgn-session-quota` to limit the number of sessions available for each client IP address. The intended resource quota should be multiplied by the number of NP7 processors that the FortiGate has to find the value to set as the session quota.

For example, the FortiGate-3500F has three NP7 processors. If you want each client IP address to have a resource quota of 2 port blocks, you should set `cgn-session-quota` using the following calculation:

$$\langle \text{number of NP7 processors} \rangle \times \langle \text{intended cgn-resource-quota} \rangle = \langle \text{cgn-session-quota} \rangle$$

For the FortiGate-3500F the calculation would be:

$$3 \times 2 = 6$$

How the NP7 hash-config affects sessions that require session helpers or ALGs

Setting `hash-config` to `src-ip` is required to offload traffic that requires session helpers or application layer gateways (ALGs) (for example, FTP, TFTP, SIP, MGCP, H.323, PPTP, L2TP, ICMP Error/IP-options, PMAP, TNS, DCE-RPC, RAS, and RSH).

On a FortiGae with hyperscale firewall features enabled, session helper and ALG traffic should be processed by normal VDOMs and not by hyperscale firewall VDOMs. Traffic that requires session helpers or ALGs is not compatible with hyperscale firewall functionality since the initial packets of a new session must be processed by the CPU. As well, some traffic that requires ALGs, for example SIP traffic, also requires a security profile and security profiles are not compatible with hyperscale firewall functionality.

Session helper and ALG traffic can be partially offloaded by NP7 processors. For example, SIP setup sessions are processed by the CPU, but the RTP and RTCP sessions that result from SIP setup sessions can be accelerated by NP7 processors.

Enabling or disabling per-policy accounting for hyperscale firewall traffic

Per-policy accounting records hit counts for packets accepted or denied by hyperscale firewall policies and makes this information available from the firewall policy GUI and from the CLI.

Per-policy accounting for hyperscale firewall policies can reduce hyperscale firewall performance. You can use the following command to enable or disable hyperscale firewall per-policy accounting for all hyperscale traffic:

```
config system npu
  set per-policy-accounting {disable | enable}
end
```

Per-policy accounting is disabled by default. When per-policy accounting is enabled, you can see hyperscale firewall policy hit counts on the GUI and CLI. If you disable per-policy-accounting for hyperscale firewall traffic, FortiOS will not collect hit count information for traffic accepted or denied by hyperscale firewall policies.

Enabling or disabling per-policy accounting deletes all current sessions, disrupting traffic. Changing the per-policy accounting configuration should only be done during a quiet period.

Hyperscale firewall inter-VDOM link acceleration

If hyperscale firewall support is enabled, you apply NP7 acceleration to inter-VDOM link traffic by creating inter-VDOM links with the `type` set to `npupair`. For example:

```
config system vdom-link
  edit <name>
    set type npupair
  end
```

The command creates a pair of interfaces that are connected logically. For example, the following command:

```
config system vdom-link
  edit vdom-link0
    set type npupair
  end
```

Creates two interfaces, named `vdom-link00` and `vdom-link01`.

The default NPU VDOM inter-VDOM links (for example `npu0_vlink0`, `npu0_vlink1`, `npu1_vlink0`, and so on) are not supported for links to or from VDOMs with hyperscale firewall acceleration enabled.

Hyperscale firewall SNMP MIB and trap fields

This section describes hyperscale firewall SNMP MIB and trap fields.

IP pool MIB and trap fields

You can use the following MIB fields to get hyperscale firewall IP pool information:

```
FgFwIppStatsEntry ::= SEQUENCE {
    fgFwIppStatsName          DisplayString,
    fgFwIppStatsType          DisplayString,
    fgFwIppStatsStartIp      IPAddress,
    fgFwIppStatsEndIp        IPAddress,
    fgFwIppStatsTotalSessions Gauge32,
    fgFwIppStatsTcpSessions  Gauge32,
    fgFwIppStatsUdpSessions  Gauge32,
    fgFwIppStatsOtherSessions Gauge32,
    fgFwIppStatsTotalPBAs    Gauge32,
    fgFwIppStatsInusePBAs    Gauge32,
    fgFwIppStatsExpiringPBAs Gauge32,
    fgFwIppStatsFreePBAs     Gauge32,
    fgFwIppStatsFlags        DisplayString,
    fgFwIppStatsGroupName    DisplayString,
    fgFwIppStatsBlockSize    Gauge32,
    fgFwIppStatsPortStart    InetPortNumber,
    fgFwIppStatsPortEnd      InetPortNumber,
    fgFwIppStatsStartClientIP IPAddress,
    fgFwIppStatsEndClientIP  IPAddress,
    fgFwIppStatsRscTCP       Gauge32,
    fgFwIppStatsRscUDP       Gauge32,
    fgFwIppStatsUsedRscTCP   Gauge32,
    fgFwIppStatsUsedRscUDP   Gauge32,
    fgFwIppStatsPercentageTCP Gauge32,
    fgFwIppStatsPercentageUDP Gauge32
}
```

The following SNMP trap is also available for IP pool utilization:

```
fgTrapPoolUsage NOTIFICATION-TYPE
    OBJECTS      { fnSysSerial, sysName, fgFwIppTrapType, fgFwIppStatsName,
fgFwIppStatsGroupName, fgFwTrapPoolUtilization, fgFwIppTrapPoolProto }
    STATUS       current
    DESCRIPTION
        "A trap for ippool."
    ::= { fgTrapPrefix 1401 }
```

Hyperscale firewall policy MIB fields

You can use the following MIB fields to send SNMP queries for hyperscale firewall policy information. These MIB fields support IPv4 and IPv6 hyperscale firewall policies and are available from the latest FORTINET-FORTIGATE-MIB.mib.

Path: FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgFirewall.fgFwPolicies.fgFwPolTables

OID: 1.3.6.1.4.1.12356.101.5.1.2

Index	MIB field	Description
.3	fgFwHsPolStatsTable	IPv4 hyperscale firewall policy statistics table.
.3.1	fgFwHsPolStatsEntry	IPv4 hyperscale firewall policy statistics entry.
.3.1.1	fgFwHsPolID	IPv4 hyperscale firewall policy ID.
.3.1.2	fgFwHsPolPktCount	IPv4 hyperscale firewall policy packet count.
.3.1.3	fgFwHsPolByteCount	IPv4 hyperscale firewall policy byte count.
.3.1.4	fgFwHsPolLastUsed	The last date and time the ipv4 hyperscale firewall policy was used to start a session.
.4	fgFwHsPol6StatsTable	IPv6 hyperscale firewall policy stats table.
.4.1	fgFwHsPol6StatsEntry	IPv6 hyperscale firewall policy statistics entry.
.4.1.1	fgFwHsPol6ID	IPv6 hyperscale firewall statisticsID.
.4.1.2	fgFwHsPol6PktCount	IPv6 hyperscale firewall policy packet count.
.4.1.3	fgFwHsPol6ByteCount	IPv6 hyperscale firewall policy byte count.
.4.1.4	fgFwHsPol6LastUsed	The last date and time the IPv6 hyperscale firewall policy was used to start a session.

Queries of these fields follow the convention `.oid.<vdom-id>.<policy-id>`

Example SNMP query for IPv4 hyperscale firewall policy statistics:

```
$ snmpwalk -v2c -c public <ip-address> 1.3.6.1.4.1.12356.101.5.1.2.3.1
```

Example SNMP query for IPv6 hyperscale firewall policy statistics:

```
$ snmpwalk -v2c -c public <ip-address> 1.3.6.1.4.1.12356.101.5.1.2.4.1
```

SNMP queries for hardware session counts

You can use the following MIB fields to send SNMP queries for NP7 IPv4 and IPv6 hardware session counts and session setup rates.

The fgSysNpuSesCount MIB field returns the total session count for both IPv4 and IPv6 sessions. The fgSysNpuSes6Count MIB field always returns 0.

Path: FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgSystem.fgSystemInfo

OID: 1.3.6.1.4.1.12356.101.4.1

Index	MIB field	Description
.24	fgSysNpuSesCount	NP7 IPv4 and IPv6 session count.
.25	fgSysNpuSesRate1	NP7 IPv4 session setup rate in the last 1 minute.
.26	fgSysNpuSesRate10	NP7 IPv4 session setup rate in the last 10 minutes.
.27	fgSysNpuSesRate30	NP7 IPv4 session setup rate in the last 30 minutes.
.28	fgSysNpuSesRate60	NP7 IPv4 session setup rate in the last 60 minutes.
.29	fgSysNpuSes6Count	0
.30	fgSysNpuSes6Rate1	NP7 IPv6 session setup rate in the last 1 minute.
.31	fgSysNpuSes6Rate10	NP7 IPv6 session setup rate in the last 10 minutes.
.32	fgSysNpuSes6Rate30	NP7 IPv6 session setup rate in the last 30 minutes.
.33	fgSysNpuSes6Rate60	NP7 IPv6 session setup rate in the last 60 minutes.

SNMP queries for NAT46 and NAT64 policy statistics

You can use the following MIB fields to send SNMP queries for hyperscale firewall NAT46 and NAT64 policy statistics. These MIB fields are available from the latest FORTINET-FORTIGATE-MIB.mib.

Path: FORTINET-FORTIGATE-MIB:fortinet.fnFortiGateMib.fgFirewall.fgFwPolicies.fgFwPolTables

OID: 1.3.6.1.4.1.12356.101.5.1.2

Index	MIB field	Description
.5	fgFwHsPol46StatsTable	NAT46 hyperscale firewall policy statistics table.
.5.1	fgFwHsPol46StatsEntry	NAT46 hyperscale firewall policy statistics entry.
.5.1.1	fgFwHsPol46ID	NAT46 hyperscale firewall policy ID.
.5.1.2	fgFwHsPol46PktCount	NAT46 hyperscale firewall policy packet count.
.5.1.3	fgFwHsPol46ByteCount	NAT46 hyperscale firewall policy byte count.
.5.1.4	fgFwHsPol46LastUsed	The last date and time the NAT46 hyperscale firewall policy was used to start a session.
.6	fgFwHsPol64StatsTable	NAT64 hyperscale firewall policy statistics table.
.6.1	fgFwHsPol64StatsEntry	NAT64 hyperscale firewall policy statistics entry.
.6.1.1	fgFwHsPol64ID	NAT64 hyperscale firewall policy ID.
.6.1.2	fgFwHsPol64PktCount	NAT64 hyperscale firewall policy packet count.
.6.1.3	fgFwHsPol64ByteCount	NAT64 hyperscale firewall policy byte count.
.6.1.4	fgFwHsPol64LastUsed	The last date and time the NAT64 hyperscale firewall policy was used to start a session.

Queries of these fields follow the convention `.oid.<vdom-id>.<policy-id>`

Example SNMP query for NAT46 hyperscale firewall policy statistics:

```
$ snmpwalk -v2c -c public <ip-address> 1.3.6.1.4.1.12356.101.5.1.2.5.1
```

Example SNMP query for NAT64 hyperscale firewall policy statistics:

```
$ snmpwalk -v2c -c public <ip-address> 1.3.6.1.4.1.12356.101.5.1.2.6.1
```

SNMP queries of NP7 fgProcessor MIB fields

FortiGates with NP7 processors can now respond to SNMP queries for the following paths and OIDs:

- Path: FORTINET-FORTIGATE-MIB:fgProcessorCount
OID: 1.3.6.1.4.1.12356.101.4.4.1
- Path: FORTINET-FORTIGATE-MIB:fgProcessorModuleCount
OID: 1.3.6.1.4.1.12356.101.4.5

For example, for a FortiGate-4200F:

```
root@pc1:~# snmpwalk -v2c -c REGR-SYS 10.1.100.1 1.3.6.1.4.1.12356.101.4.4.1
FORTINET-FORTIGATE-MIB::fgProcessorCount.0 = INTEGER: 84
root@pc1:~# snmpwalk -v2c -c REGR-SYS 10.1.100.1 1.3.6.1.4.1.12356.101.4.5
FORTINET-FORTIGATE-MIB::fgProcessorModuleCount.0 = INTEGER: 5
FORTINET-FORTIGATE-MIB::fgProcModIndex.1 = INTEGER: 1
FORTINET-FORTIGATE-MIB::fgProcModIndex.2 = INTEGER: 2
FORTINET-FORTIGATE-MIB::fgProcModIndex.3 = INTEGER: 3
FORTINET-FORTIGATE-MIB::fgProcModIndex.4 = INTEGER: 4

FORTINET-FORTIGATE-MIB::fgProcModSACount.2 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgProcModSACount.3 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgProcModSACount.4 = Gauge32: 0
FORTINET-FORTIGATE-MIB::fgProcModSACount.5 = Gauge32: 0

```

BGP IPv6 conditional route advertisement

IPv6 BGP conditional route advertisement supports traffic failover for a FortiGate with hyperscale firewall features operating as a CGNAT translator connected to two ISPs over IPv6.

When the FortiGate can connect to the primary ISP, IPv6 BGP routes to the primary ISP are shared with the networks (LANs) behind the FortiGate. With BGP IPv6 conditional route advertisement enabled, if the FortiGate connection to the primary ISP fails, the FortiGate acquires IPv6 BGP routes to the secondary ISP and advertises these routes to the networks (LANs) behind the FortiGate.

Use the following configuration to enable IPv6 conditional route advertisement:

```

config router bgp
  config neighbor
    edit <name>
      config conditional-advertise6
        edit <name>
          set condition-routemap <name>
          set condition-type {exist | non-exist}
        end
      end

```

`exist` true if condition route map is matched.

`non-exist` true if condition route map is not matched.

BGP IPv6 conditional route advertisement configuration example

The following configuration shows how to use the `condition-type` option to control how a FortiGate advertises routes when it is connected to two external routers.

When `condition-type` is set to `non-exist` the FortiGate advertises route2 (2003:172:22:1::/64) to Router2 when it learns route1 (2003:172:28:1::/64). When `condition-type` is set to `exist`, the FortiGate will not advertise route2 (2003:172:22:1::/64) to Router2 when it knows route1 (2003:172:28:1::/64).

```

config router prefix-list6
  edit adv-222
    config rule
      edit 1
        set prefix6 2003:172:22:1::/64
      end
    end

config router prefix-list6
  edit list6-1
    config rule

```

```

    edit 1
      set prefix6 2003:172:28:1::/64
    end

config router route-map
  edit map-222
    config rule
      edit 1
        set match-ip6-address adv-222
      end
    end
config router route-map
  edit "map-281"
    config rule
      edit 1
        set match-ip6-address list6-1
      end
    end
config router bgp
  set as 65412
  set router-id 1.1.1.1
  set ibgp-multipath enable
  set network-import-check disable
  set graceful-restart enable
  config neighbor
    edit 2003::2:2:2:2
      set soft-reconfiguration6 enable
      set remote-as 65412
      set update-source loopback1
      config conditional-advertise6
        edit map-222
          set condition-routemap map-281
          set condition-type {exist | non-exist}
        end
      end
    edit 2003::3:3:3:3
      set soft-reconfiguration6 enable
      set remote-as 65412
      set update-source loopback1
    end
  end
end

```

Hyperscale firewall VDOM asymmetric routing with ECMP support

In most cases asymmetric routing with ECMP support works the same way in a hyperscale firewall VDOM as in a normal VDOM, with the following notes and exceptions:

- The `auxiliary-session` and `asymroute-icmp` options of the `config system settings` command do not have to be enabled for the hyperscale firewall VDOM for asymmetric routing to work.
- Make sure that original routes (O-routes) do not overlap with reverse routes (R-routes). If you have created overlapping O- and R-routes, all reply traffic uses the same O-route.
- If possible, create an even number of ECMP paths. Traffic distribution is uneven if you have an odd number of ECMP paths. For example, if your configuration includes one O-route and three R-routes, the reply traffic distribution will be approximately 2:1:1 among the three R-routes.

Hyperscale firewall VDOM session timeouts

Using the following command you can define session timeouts for a specific protocols and port ranges for a hyperscale firewall VDOM. These session timeouts apply to sessions processed by the current hyperscale firewall VDOM. You can set up different session timeouts for each hyperscale firewall VDOM.

```
config vdom
  edit <hyperscale-firewall-vdom-name>
    config system session-ttl
      config port
        edit 1
          set protocol <protocol-number>
          set timeout <timeout>
          set refresh-direction {outgoing | incoming | both}
        end
      end
    end
  end
```

`protocol <protocol-number>` a protocol number in the range 0 to 255. Default 0.

`timeout <timeout>` the time in seconds after which a matching idle session is terminated. Range 1 to 2764800. Default 300.

`refresh-direction {outgoing | incoming | both}` control whether idle outgoing or incoming or both outgoing and incoming sessions are terminated when the timeout is reached.

Global session timeouts apply to sessions in hyperscale firewall VDOMs that do not match `config system session-ttl` settings in individual hyperscale firewall VDOMs.

You can also override global and per-VDOM session timeouts by setting the `tcp-timeout-pid` and `udp-timeout-pid` options in individual hyperscale firewall policies. See [Session timeouts for individual hyperscale policies on page 59](#).

Session timeouts for individual hyperscale policies

You can use the following commands to create TCP and UDP session timeout profiles and then apply these profiles to individual hyperscale firewall policies.

Use the following command to create a TCP timeout profile:

```
config global
  config system npu
    config tcp-timeout-profile
      edit <tcp-profile-id>
        set tcp-idle <seconds>
        set fin-wait <seconds>
        set close-wait <seconds>
        set time-wait <seconds>
        set syn-sent <seconds>
        set syn-wait <seconds>
      end
    end
  end
```

Use the following command to create a UDP timeout profile:

```
config global
  config system npu
```

```
config udp-timeout-profile
  edit <udp-profile-id>
    set udp-idle <seconds>
  end
```

Use the following command to apply a TCP and a UDP timeout profile to a hyperscale firewall policy:

```
config vdom
  edit <hyperscale-firewall-vdom-name>
    config firewall policy
      edit 1
        set action accept
        set policy-offload enable
        ...
        set tcp-timout-pid <tcp-profile-id>
        set udp-timout-pid <udp-profile-id>
        ...
      end
    end
```

For more information about creating TCP timeout profiles, see [Configuring hyperscale TCP timeout profiles](#).

For more information about creating UDP timeout profiles, see [Configuring hyperscale UDP timeout profiles](#).

Modifying trap session behavior in hyperscale firewall VDOMs

Hyperscale VDOMs create trap sessions for all sessions that need to be handled by the CPU. Trap sessions make sure CPU sessions are successfully sent to the CPU. If CPU sessions are not trapped, they may be incorrectly converted to hardware sessions and dropped.

You can use the following command to modify trap session behavior in a hyperscale firewall VDOM

```
config system settings
  set trap-session-flag {udp-both | udp-reply | tcpudp-both | tcpudp-reply | trap-none}
end
```

`udp-both` trap UDP send and reply sessions.

`udp-reply` trap UDP reply sessions only.

`tcpudp-both` trap TCP and UDP send and reply sessions. This is the default setting.

`tcpudp-reply` trap TCP and UDP reply sessions only.

`trap-none` disable trapping sessions.

The default setting creates trap sessions for all TCP and UDP sessions to be handled by the CPU. You can change the trap session behavior depending on CPU sessions processed by the VDOM.

Setting the hyperscale firewall VDOM default policy action

You can use the following system settings option for each hyperscale firewall VDOM to set the hyperscale firewall default policy action for that VDOM. The hyperscale policy default action determines what NP7 processors do with TCP and UDP packets that are not accepted by any hyperscale firewall policies.

```
config system settings
```

```
set hyperscale-default-policy-action {drop-on-hardware | forward-to-host}
end
```

`drop-on-hardware` the default setting, NP7 processors drop TCP and UDP packets that don't match a hyperscale firewall policy. In most cases you would not want to change this default setting since it means the CPU does not have to process TCP and UDP packets that don't match hyperscale firewall policies. In most cases, this option should reduce the number of packets sent to the CPU. With this option enabled, all other packet types (for example, ICMP packets) that don't match a hyperscale firewall policy are sent to the CPU. Packets accepted by session helpers are also sent to the CPU.

`forward-to-host` NP7 processors forward packets that don't match a hyperscale firewall policy to the CPU. If the packet is forwarded to the CPU, the packet will be matched with the policy list and eventually be subject to the implicit deny policy and dropped by the CPU. This setting can affect performance because the CPU would be handling these packets.

Reassembling fragmented packets

FortiGates with NP7 processors that are licensed for hyperscale firewall features support reassembling fragmented packets in sessions offloaded to the NP7 processors.

To support reassembling fragmented packets, the NP7 processor `hash-config` can be set to `src-dst-ip` or `src-ip`. As well, NP7 `ip-reassembly` must be enabled. You can also adjust the `ip-reassembly` minimum and maximum timeouts. The currently recommended configuration includes the following minimum and maximum timeouts. You can adjust these timeouts for your network configuration and traffic profile.

```
config system npu
  set hash-config {src-dst-ip | src-ip}
  config ip-reassembly
    set status enable
    set min_timeout 64
    set max_timeout 200000
  end
```

For more information about the `hash-config` option, see [hash-config {src-dst-ip | src-ip}](#).

For more information on the `ip-reassembly` option, see [Reassembling and offloading fragmented packets](#).

Hash table message queue mode

You can use the following commands to change the hyperscale firewall NP7 hash table message queue mode.

```
config system npu
  set htab-msg-queue {data | idle | dedicated}
  set htab-dedi-queue-nr <number-of-queues>
end
```

You can use the `htab-msg-queue` option to alleviate performance bottlenecks that may occur when hash table messages use up all of the available hyperscale NP7 data queues.

You can use the following commands to get the hash table message count and rate.

```
diagnose npu np7 msg htab-stats {all| chip-id}
diagnose npu np7 msg htab-rate {all| chip-id}
```

You can use the following command to show MSWM information:

```
diagnose npu np7 mswm
```

You can use the following command to show NP7 Session Search Engine (SSE) drop counters:

```
diagnose npu np7 dce-sse-drop 0 v
```

You can use the following command to show command counters:

```
diagnose npu np7 cmd
```

The following `htab-msg-queue` options are available:

- `data` (the default) use all available data queues.
- `idle` if you notice the data queues are all in use, you can select this option to use idle queues for hash table messages.
- `dedicated` use between 1 to 8 of the highest number data queues. Use the option `htab-dedi-queue-nr` to set the number of data queues to use.

If you are using dedicated queues for hash table messages for hyperscale firewall sessions, you can use the `htab-dedi-queue-nr` option to set the number of queues to use. The range is 1 to 8 queues. The default is 4 queues.

Message-related diagnose commands:

```
diagnose npu np7 msg
summary          Show summary of message counters. [Take 0-1 arg(s)]
msg-by-mod       Show/clear message counters by source module. [Take 0-2 arg(s)]
msg-by-code     Show/clear message counters by message code. [Take 0-2 arg(s)]
msg-by-que     Show/clear message counters by RX queue. [Take 0-2 arg(s)]
msg-by-cpu     Show/clear message counters by CPU. [Take 0-2 arg(s)]
htab-stats     Show/clear hash table message counters. [Take 0-2 arg(s)]
htab-rate      Show/clear hash table message rate. [Take 0-2 arg(s)]
ipsec-stats    Show/clear IPsec message counters. [Take 0-2 arg(s)]
ipsec-rate     Show/clear IPsec message rate. [Take 0-2 arg(s)]
ipt-stats     Show/clear IP tunnel message counters. [Take 0-2 arg(s)]
ipt-rate      Show/clear IP tunnel message rate. [Take 0-2 arg(s)]
mse-stats     Show/clear MSE message counters. [Take 0-2 arg(s)]
mse-rate      Show/clear MSE message rate. [Take 0-2 arg(s)]
spath-stats   Show/clear hyperscale message counters. [Take 0-2 arg(s)]
spath-rate    Show/clear hyperscale message rate. [Take 0-2 arg(s)]
tpe-tce-stats Show/clear TPC/TCE message counters. [Take 0-2 arg(s)]
tpe-tce-rate  Show/clear TPE/TCE message rate. [Take 0-2 arg(s)]
```

MSWM diag commands.

```
diagnose npu np7 mswm
mswm-all       Show/clear all MSWM counters. [Take 0-2 arg(s)]
module-to-mswm Show/clear module-to-MSWM counters. [Take 0-2 arg(s)]
mswm-to-module Show/clear MSWM-to-module counters. [Take 0-2 arg(s)]
mswh-all      Show/clear all MSWH counters. [Take 0-2 arg(s)]
module-to-mswh Show/clear module-to-MSWH counters. [Take 0-2 arg(s)]
mswh-to-hrx   Show/clear MSWH-to-HRX counter. [Take 0-2 arg(s)]
```

Diagnose command to show SSE drop counters:

```
diagnose npu np7 dce-sse-drop 0 v
```

Diagnose command to show command counters:

```
diagnose npu np7 cmd
all          Show/clear all command counters. [Take 0-2 arg(s)]
```

```
sse          Show/clear SSE command counters. [Take 0-2 arg(s)]
mse          Show/clear MSE command counters. [Take 0-2 arg(s)]
dse          Show/clear DSE command counters. [Take 0-2 arg(s)]
lpm-rlt     Show/clear LPM/RLT command counters. [Take 0-2 arg(s)]
rate        Show/clear command rate. [Take 0-2 arg(s)]
measure-rate Enable/disable command rate measurement. [Take 0-1 arg(s)]
```

Setting the NP7 TCP reset timeout

The NP7 TCP reset (RST) timeout in seconds. The range is 0-16777215. The default timeout is 5 seconds. This timeout is optimal in most cases, especially when hyperscale firewall is enabled. A timeout of 0 means no time out.

Configuring background SSE scanning

To support reporting accurate UDP session statistics, normal UDP session synchronization is disabled for FortiGates with hyperscale firewall features enabled and background Session Search Engine (SSE) scanning is used to keep UDP sessions synchronized.

Background SSE scanning uses the CPU instead of the NP7 processors and can cause CPU spikes; however, these spikes should not usually affect overall performance. You can use the following command to adjust background SSE scanning behavior:

```
config system npu
  config background-sse-scan
    set scan {disable | enable}
    set stats-update-interval <interval>
    set udp-keepalive-interval <interval>
  end
```

`scan` enable or disable background SSE scanning. This option is enabled by default. If disabled, UDP O-session and R-session synchronization is enabled so UDP sessions will remain synchronized. However, the statistics reported by traffic logging for UDP O-sessions will be incorrect.

`stats-update-interval` statistics update interval in seconds. The range is 300 to 1073741823 seconds and the default update interval is 300 seconds. You can increase the statistics update interval to reduce how often the CPU is used for SSE background scanning.

`udp-keepalive-interval` UDP keepalive interval in seconds. The range is 90 to 1073741823 seconds and the default keepalive interval is 90 seconds. The 90 second keepalive interval is recommended because the default UDP session timeout is 180 seconds. If you increase the keepalive interval, some UDP sessions may be dropped prematurely.

Allowing packet fragments for NP7 NAT46 policies when the DF bit is set to 1

The packet size increase that occurs when a NAT46 hyperscale firewall policy converts an IPv4 packet into an IPv6 packet can cause the packet to be dropped if the larger packet exceeds the outgoing interface MTU and the DF bit is set to 1 (do not fragment). You can use the following command to cause NP7 processors to override the DF setting and fragment and forward the packet instead of dropping it. This is a global setting that affects all NAT64 traffic offloaded by NP7 processors.

```
config system npu
  set nat46-force-ipv4-packet-forwarding enable
end
```

When this option is disabled, packets with DF=1 that exceed the outgoing interface MTU are dropped.

Hyperscale firewall get and diagnose commands

This section describes some `get` and `diagnose` commands that you can use to display hyperscale firewall information.

Displaying information about NP7 hyperscale firewall hardware sessions

You can use the following `diagnose` commands to display the current NP7 hyperscale firewall hardware IPv4 and IPv6 session lists:

```
diagnose sys npu-session list
diagnose sys npu-session list6
```

These commands display the current session list stored in the logging buffer. For sessions accepted by firewall policies that use hardware logging (`log-processor` is set to `hardware`), the logging buffer includes all session details. For sessions accepted by firewall policies using CPU or host logging (`log-processor` is set to `host`), the command displays fewer details about the session list, because CPU or host logging only maintains a subset of all of the information available for each session in the session list.

You can also use the following commands to display the current NP7 hyperscale firewall hardware session list by sending a query to the NP7 Session Search Engine (SSE). The output of these commands does not depend on the hardware logging configuration because they query the SSE. However, because the commands are querying the SSE, the response time will be longer.

```
diagnose sys npu-session list-full
diagnose sys npu-session list-full6
```

Displaying the hyperscale firewall license status

Use the `get system status` command to verify that your hyperscale firewall license is enabled:

```
get system status
...
Hyperscale firewall license status: Enabled
...
end
```

Displaying IP pool usage information

Use the following `diagnose` commands from a hyperscale firewall VDOM to display details about CGN IP pools including client IP addresses, PBA blocks, and public IP addresses currently in use.

```
diagnose firewall ippool {list {pba | nat-ip | user} | stats}
```

```
diagnose firewall ippool {list {pba | nat-ip | user} | stats | get-priv | get-pub | get-
pub6}
diagnose firewall ippool get-priv <public-ipv4> [<public-port>]
diagnose firewall ippool get-pub <private-ipv4>
diagnose firewall ippool get-pub6 <private-ipv6>
diagnose firewall ippool {list {pba | nat-ip | user} | stats}
```

`stats` list the total number of CGN IP pools that have been allocated, the number of currently active client IP addresses, NAT IP addresses, and PBA blocks.

`pba` list currently active source addresses of CGN clients and the PBA blocks assigned to them.

`user` list currently active source addresses of CGN clients and the number of PBA blocks assigned to them.

`nat-ip` list currently active public IP addresses and the number of PBA blocks and user sessions connected to each public IP.

`get-priv <public-ipv4> [<public-port>]` query private information of a public IPv4 address and optionally a port number.

`get-pub <private-ipv4>` query public information of a private IPv4 address.

`get-pub6 <private-ipv6>` query public information of a private IPv6 address.

diagnose firewall ippool list

Use `diagnose firewall ippool list` with no options to display the names, configuration details and current usage information for all of the CGN and non-CGN IP pools in the current VDOM.

For CGN IP pools that have been added to hyperscale firewall policies, IP pool usage information consists of two parts:

- Kernel firewall usage information (basically placeholder information that doesn't represent actual CGN IP pool usage).
- NP7 hyperscale firewall policy engine (or PLE) usage information (actual CGN IP pool usage information).

If a CGN IP pool has not been added to a hyperscale firewall policy, then only the kernel firewall information is shown.

The following example includes a CGN IP pool named `test-cgn-pba-1` that has been added to a hyperscale firewall policy. The first 5 lines of output contain configuration and kernel firewall usage information. The final four lines of output, beginning with `grp=N/A` is NP7 hyperscale firewall policy engine (or PLE) usage information. These final four lines include the correct usage information for the CGN IP pool.

The IP pool in the example named `test-cgn-opba-1` has not been added to a hyperscale firewall policy and only contains configuration and kernel firewall usage information.

```
diagnose firewall ippool list
list ippool info:(vf=cgn-hw1)
ippool test-cgn-pba-1: id=1, block-sz=64, num-block=8, fixed-port=no, use=4
  ip-range=172.16.201.181-172.16.201.182 start-port=5117, num-pba-per-ip=944
  clients=1, inuse-NAT-IPs=1
  total-PBAs=1888, inuse-PBAs=1, expiring-PBAs=0, free-PBAs=99.95%
  allocate-PBA-times=1, reuse-PBA-times=0
  grp=N/A, start-port=8117, end-port=8629
  npu-clients=1, npu-inuse-NAT-IPs=1, total-NAT-IP=2
  npu-total-PBAs=16, npu-inuse-PBAs=4/0, npu-free-PBAs=75.00%/100.00%
  npu-tcp-sess-count=256, npu-udp-sess-count=0
ippool test-cgn-opba-1: id=2, block-sz=256, num-block=8, fixed-port=no, use=2
  ip-range=172.16.201.183-172.16.201.184 start-port=5117, num-pba-per-ip=236
```

```
clients=0, inuse-NAT-IPs=0
total-PBAs=472, inuse-PBAs=0, expiring-PBAs=0, free-PBAs=100.00%
allocate-PBA-times=0, reuse-PBA-times=0
```

The following example shows two CGN IP pools named `cg_n-pool1` and `cg_n-pool2` that have been added to a CGN IP pool group named `cg_n_pool_grp1`. The information displayed for the IP pools in the group is the same as is displayed for individual IP pools, except that the `grp` field includes an IP pool group name.

Also, the information displayed for each IP pool in the group is actually the usage information for the entire IP pool group and not for each individual IP pool in the group. As a result, the usage information displayed for each IP pool is the same, since it is the information for the entire group.

```
F2K61F-TIGER-194-31 (global) # sudo cg_n-hw1 diagnose firewall ippool list
list ippool info:(vf=cg_n-hw1)
ippool cg_n-pool1: id=1, block-sz=64, num-block=8, fixed-port=no, use=2
  ip-range=203.0.113.2-203.0.113.3 start-port=5117, num-pba-per-ip=944
  clients=0, inuse-NAT-IPs=0
  total-PBAs=1888, inuse-PBAs=0, expiring-PBAs=0, free-PBAs=100.00%
  allocate-PBA-times=10, reuse-PBA-times=0
  grp=cg_n_pool_grp1, start-port=5117, end-port=65530
  npu-clients=1, npu-inuse-NAT-IPs=1, total-NAT-IP=0
  npu-total-PBAs=0, npu-inuse-PBAs=16/0, npu-free-PBAs=0.00%/-nan%
  npu-tcp-sess-count=1024, npu-udp-sess-count=0
ippool cg_n-pool2: id=2, block-sz=64, num-block=8, fixed-port=no, use=2
  ip-range=203.0.113.4-203.0.113.5 start-port=5117, num-pba-per-ip=944
  clients=0, inuse-NAT-IPs=0
  total-PBAs=1888, inuse-PBAs=0, expiring-PBAs=0, free-PBAs=100.00%
  allocate-PBA-times=0, reuse-PBA-times=0
  grp=cg_n_pool_grp1, start-port=5117, end-port=65530
  npu-clients=1, npu-inuse-NAT-IPs=1, total-NAT-IP=0
  npu-total-PBAs=0, npu-inuse-PBAs=16/0, npu-free-PBAs=0.00%/-nan%
  npu-tcp-sess-count=1024, npu-udp-sess-count=0
```

diagnose firewall ippool list pba

This command lists the PBAs in the IP pools in the current VDOM. For each IP pool, the command lists the client IP, NAT IP, NAT port range, port block index, and a kernel reference counter. The final line of the command output shows the number of PBAs allocated by NP7 processors for this VDOM

```
diag firewall ippool list pba
user 10.1.100.200: 172.16.201.181 8117-8180, idx=0, use=1
user 10.1.100.200: 172.16.201.181 8181-8244, idx=1, use=1
user 10.1.100.200: 172.16.201.181 8245-8308, idx=2, use=1
user 10.1.100.200: 172.16.201.181 8309-8372, idx=3, use=1
Total pba in NP: 4
```

diagnose firewall ippool list nat-ip

This command lists the NAT IPs in use in the VDOM. For each NAT IP, the command shows the number of PBAs allocated for the NAT IP and the number of PBAs in use:

```
diag firewall ippool list nat-ip
NAT-IP 172.16.201.181: pba=8, use=4
Total nat-ip in NP: 1
```

diagnose firewall ippool list user

This command lists all of the user IP addresses allocated by NP7processors for the current VDOM. For each user IP address, the command lists the number of PBAs assigned to the user IP and the number of PBAs being used. The final line of the command output shows the total number of user IPs in use for the current VDOM.

```
diagnose firewall ippool list user
User-IP 100.64.0.2: pba=1, use=1
User-IP 100.64.0.3: pba=1, use=1
User-IP 100.64.0.4: pba=1, use=1
User-IP 100.64.0.5: pba=1, use=1
User-IP 100.64.0.8: pba=1, use=1
User-IP 100.64.0.9: pba=1, use=1
...
User-IP 100.64.3.229: pba=1, use=1
User-IP 100.64.3.241: pba=1, use=1
User-IP 100.64.3.252: pba=1, use=1
User-IP 100.64.3.253: pba=1, use=1
Total user in NP: 218
```

Session setup information

Use the `get sys performance status` command to show hardware session setup information:

```
get system performance status | grep 'HW-setup'
Average HW-setup sessions: 4 sessions in last 1 minute, 4 sessions in last 10 minutes, 4
sessions in last 30 minutes
```

HA hardware session synchronization status

Use the `get system ha status` command to show the status of the hardware HA session synchronization link.

```
get system ha status
...
HW SessionSync dev stats:
  FG421FTK19900013:
    port24: in-sync
...
```

List hardware session setup sessions

Use the `diagnose sys npu-session` command to view hardware session information. The following commands are available:

- Use the `diagnose sys npu-session list {44 | 46 | host}` command to list IPv4 hardware sessions, NAT46 hardware sessions, or host IPv4 sessions. Host IPv4 sessions are IPv4 sessions that have not been offloaded.

- Use the `diagnose sys npu-session list6 {66 | 64 | host}` command to list IPv6 hardware sessions, NAT64 hardware sessions, or host IPv6 sessions. Host IPv6 sessions are IPv6 sessions that have not been offloaded.
- Use the `diagnose sys npu-session filter {filter-options}` command to filter the sessions that you list or clear. You can use `filter-options` to display or clear sessions from specific VDOMs, display sessions for specific policy IDs, to specific source and destination addresses, and so on. Use the CLI help to list all of the options available.
- Use the `diagnose sys npu-session stat verbose {44 | 66 | 64 | 46}` command to view details about IPv4, IPv6, NAT64, and NAT46 sessions. The information displayed includes session counts, the number of SNAT, DNAT and dual NAT sessions, and so on. If you use `diagnose sys npu-session filter` to create a filter, the filter is also applied to the output of the `diagnose sys npu-session stat verbose` command for IPv4 and IPv6 sessions. Using the `verbose` option scans the SSEs of all available NP7 processors in the FortiGate and sends this data to the CPU. On a busy system processing a large number of hardware sessions, this process can send a very large number of messages that may overrun the messaging driver. As a result, the `verbose` output may show lower than expected session counts. This problem is expected to be addressed in future releases.

You can also use `diagnose sys session list` and `diagnose sys session6 list` to list sessions that have not been offloaded.

For example, to list IPv4 hardware sessions enter:

```
diagnose sys npu-session list 44
session info: proto=6 proto_state=01 duration=64721 expire=0 timeout=3600 flags=00000000
sockflag=00000000 sockport=0 av_idx=0 use=1
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=255/255
state=new f18
statistic(bytes/packets/allow_err): org=3620/40/0 reply=0/0/0 tuples=2
tx speed(Bps/kbps): 0/0 rx speed(Bps/kbps): 0/0
orgin->sink: org pre->post, reply pre->post dev=22->23/0->0 gwy=10.100.200.1/10.160.21.191
hook=post dir=org act=snat 192.168.10.12:49698->52.230.222.68:443(10.3.3.5:5128)
hook=pre dir=reply act=dnat 52.230.222.68:443->10.3.3.5:5128(192.168.10.12:49698)
pos/(before,after) 0/(0,0), 0/(0,0)
misc=0 policy_id=0 auth_info=0 chk_client_info=0 vd=0
serial=000163ff tos=ff/ff app_list=0 app=0 url_cat=0
rpdb_link_id = 00000000 ngfwid=n/a
dd_type=0 dd_mode=0
  setup by offloaded-policy: origin=native
  O: npid=255/0, in: OID=76/VID=0, out: NHI=77/VID=0
  R: npid=0/0, in: OID=0/VID=0, out: NHI=0/VID=0
```

To show stats for IPv4 sessions after adding an IPv4 filter:

```
diagnose sys npu-session stat verbose 44
misc info: session_count=10000 tcp_session_count=10000 udp_session_count=0
           snat_count=10000 dnat_count=0 dual_nat_count=0
           3T_hit_count=0 accounting_enabled_count=0
TCP sessions:
  10000 in ESTABLISHED state
Session filter:
  vd: 2
  sintf: 10
```

```
proto: 6-6
3 filters
```

Adjusting NP7 hyperscale firewall blackhole and loopback route behavior

You can use the following diagnose command to configure how the NP7 hyperscale firewall policy engine handles traffic in a hyperscale firewall VDOM that matches a blackhole route or a loopback route. The NP7 policy engine is implemented by the NP7 `npd` process. By default the NP7 policy engine:

- Drops traffic that matches a blackhole route (drop).
- Sends traffic that matches a loopback route to the CPU (host).

You can use the following diagnose command to change this behavior. Because this is a diagnose command, any changes are reverted to defaults when the FortiGate restarts:

The command syntax is:

```
diagnose npd debug cmd 14 {28 | 29} {0 | 1 | 2}
```

28 configure how the NP7 policy engine handles traffic that matches a blackhole route.

29 configure how the NP7 policy engine handles traffic that matches a loopback route.

0 set blackhole or loopback route handling to ignore.

1 send traffic that matches a blackhole or loopback route to the CPU (host).

2 drop traffic that matches a blackhole or loopback route.

For example, use the following command to send traffic that matches a blackhole route to the CPU:

```
diagnose npd debug cmd 14 28 1
```

Use the following command to set loopback routing to drop:

```
diagnose npd debug cmd 14 29 2
```

Viewing the NP7 hyperscale policy engine routing configuration

You can use the following diagnose command to view the current NP7 hyperscale policy engine routing configuration. You can also use this command to add and remove routes. Because this is a diagnose command, any changes are reverted to defaults when the FortiGate restarts:

```
diagnose npd route {lookup | dump | stats| sync | flush | add | del}
```

`lookup` lookup route links.

`dump` list the NP7 policy engine routing table.

`stats` display route statistics.

`sync` update the NP7 policy engine routing table to match the CPU kernel routing table.

`flush` flush the NP7 policy engine routing table.

`add` add a route to the NP7 policy engine routing table.

`del` delete a route to the NP7 policy engine routing table.

The syntax for the `add` and `del` command is:

```
diagnose npd route {add | del} <destination> <prefix-length> <gateway> <oif> <table> <scope>
    <type> <proto> <priority> <tos> <flags>
```

For blackhole and loopback routes, set `<flags>` to the following `nh_flags` values:

- For blackhole routes the `nh_flags` value is `0x80`.
- For loopback routes, the `nh_flags` value is `0x100`.

For example, use the following command to add a blackhole route to the NP7 policy engine routing table:

```
diagnose npd route add 1.1.1.1 24 0.0.0.0 54 254 0 1 11 3333 0 0x80
```

The following command will delete this route from the NP7 policy engine routing table:

```
diagnose npd route del 1.1.1.1 24 0.0.0.0 54 254 0 1 11 3333 0 0x80
```

NP7 hyperscale firewall packet sniffer

You can use the following command as a hyperscale firewall packet sniffer. This packet sniffer displays information about packets offloaded by NP7 processors. You can also use this command to mirror sniffed packets to a FortiGate interface.

```
diagnose npu sniffer {start | stop | filter}
```

Use `start` and `stop` to start or stop displaying packets on the CLI. Before the sniffer will start you need to use the `filter` to specify the packets to display. Use the command `diagnose sniffer packet npudbg` to display sniffed packets on the CLI.

Use `filter` to create a definition of the types of packets to display. Filter options include:

`selector` you can create up to four filters (numbered 0 to 3). Use this command to create a new filter or select the stored filter to be used when you start the packet sniffer. You can also use this command to have multiple filters active at one time. See below for an example of sniffing using multiple active filters.

`intf <interface-name>` the name of an interface to display packets passing through that interface. You can monitor traffic on any interface except IPv4 or IPv6 IPsec VPN tunnel interfaces.

`dir {0 | 1 | 2}` the direction of the packets passing through the interface. 0 displays ingress packets, 1 displays egress packets, and 2 displays both ingress and egress packets.

`ethtype <type>` the ethertype of the packets to sniff if you want to see non-IP packets.

`protocol <number>` the IP protocol number of the packets to sniff in the range 0 to 255. The packet sniffer can only sniff protocols that can be offloaded by the NP7 processors.

`srcip <ipv4-ip-address>/<ipv4-mask>` an IPv4 IP address and netmask that matches the source address of the packets to be sniffed.

`dstip <ipv4-ip-address>/<ipv4-mask>` an IPv4 IP address and netmask that matches the destination address of the packets to be sniffed.

`ip <ipv4-ip-address>/<ipv4-mask>` an IPv4 IP address and netmask that matches a source or destination address in the packets to be sniffed.

`srcip6 <ipv6-ip-address>/<ipv6-mask>` an IPv6 IP address and netmask that matches the source address of the packets to be sniffed.

`dstip6 <ipv6-ip-address>/<ipv6-mask>` an IPv6 IP address and netmask that matches the destination address of the packets to be sniffed.

`ip6 <ipv6-ip-address>/<ipv6-mask>` an IPv6 IP address and netmask that can match source or destination addresses in the packets to be sniffed.

`sport <port-number>` layer 4 source port of the packets to be sniffed.

`dport <port-number>` layer 4 destination port of the packets to be sniffed.

`port <port-number>` layer 4 source or destination port of the packets to be sniffed.

`outgoing_intf <interface>` the name of the interface out of which to send mirrored traffic matched by the filter.

`outgoing_vlan <vlan-id>` the VLAN ID added to mirrored traffic matched by the filter and sent out the mirror interface.

`clear` clear all filters.

Packet sniffer examples

First, a basic example to sniff offloaded TCP packets received by the port23 interface. In the following example:

- The first line clears the filter.
- The second line sets the sniffer to look for packets on port23.
- The third line looks for packets exiting the interface.
- The fourth line looks for TCP packets.
- The fifth line starts the sniffer.
- The sixth line starts displaying the packets on the CLI.

```
diagnose npu sniffer filter
diagnose npu sniffer filter intf port23
diagnose npu sniffer filter dir 2
diagnose npu sniffer filter protocol 6
diagnose npu sniffer start
```

```
diagnose sniffer packet npudbg
```

Second, an example that uses the following two filters:

- The first filter, selector 0, looks for incoming and outgoing TCP packets on port1.
- The second filter, selector 1, looks for outgoing UDP packets on port2.
- The final line starts displaying packets for both filters on the CLI.

```
diagnose npu sniffer filter selector 0
diagnose npu sniffer filter intf port1
diagnose npu sniffer filter protocol 6
diagnose npu sniffer filter dir 2
diagnose npu sniffer start
```

```
diagnose npu sniffer filter selector 1
diagnose npu sniffer filter intf port2
diagnose npu sniffer filter protocol 17
diagnose npu sniffer filter dir 1
diagnose npu sniffer start
```

```
diagnose sniffer packet npudbg
```
