FortiOS 7.0.15 Administration Guide

01-7015-700620-20240415

TABLE OF CONTENTS

Change Log	21
Getting started	22
Summary of steps	23
Setting up FortiGate for management access	24
Completing the FortiGate Setup wizard	25
Configuring basic settings	25
Registering FortiGate	29
Configuring a firewall policy	32
Backing up the configuration	32
Troubleshooting your installation	33
Using the GUI	34
Connecting using a web browser	35
Menus	35
Tables	36
Entering values	38
GUI-based global search	40
Loading artifacts from a CDN	41
Using the CLI	41
Connecting to the CLI	41
CLI basics	44
Command syntax	50
Subcommands	53
Permissions	55
Configuration and management	55
Using FortiExplorer Go and FortiExplorer	56
Accessing Fortinet Developer Network	63
Terraform: FortiOS as a provider	67
Product registration with FortiCare	71
FortiCare and FortiGate Cloud login	71
Transfer a device to another FortiCloud account	74
FortiGate models	76
Differences between models	77
Low encryption models	77
LEDs	77
Dashboards and Monitors	83
Using dashboards	83
Using widgets	84
Widgets	86
Viewing device dashboards in the Security Fabric	88
Creating a fabric system and license dashboard	89
Example	89
Dashboards	90
Resetting the default dashboard template	91
Status dashboard	91

Security dashboard	93
Network dashboard	95
Users & Devices	103
WiFi dashboard	107
Monitors	113
Non-FortiView monitors	113
FortiView monitors	113
FortiView monitors and widgets	114
Adding FortiView monitors	115
Using the FortiView interface	118
Enabling FortiView from devices	121
FortiView sources	123
FortiView Sessions	124
FortiView Top Source and Top Destination Firewall Objects monitors	126
Viewing top websites and sources by category	128
Cloud application view	131
Network	142
Interfaces	142
Interface settings	143
Aggregation and redundancy	149
VLANs	152
Enhanced MAC VLANs	159
Inter-VDOM routing	162
Software switch	167
Hardware switch	169
Zone	173
Virtual wire pair	175
PRP handling in NAT mode with virtual wire pair	179
Virtual VLAN switch	179
VXLAN	185
QinQ 802.1Q in 802.1ad	209
QinQ 802.1Q in 802.1Q	210
Configure IPAM locally on the FortiGate	212
Interface MTU packet size	218
One-arm sniffer	220
Interface migration wizard	224
Captive portals	227
DNS	230
Important DNS CLI commands	230
DNS domain list	232
FortiGate DNS server	233
DDNS	239
DNS latency information	243
DNS over TLS and HTTPS	245
DNS troubleshooting	249
Explicit and transparent proxies	251
Explicit web proxy	251
FTP proxy	254

Transparent proxy	256
Proxy policy addresses	259
Proxy policy security profiles	265
Explicit proxy authentication	269
Transparent web proxy forwarding	276
Upstream proxy authentication in transparent proxy mode	279
Multiple dynamic header count	281
Restricted SaaS access	283
Explicit proxy and FortiGate Cloud Sandbox	292
Proxy chaining	294
WAN optimization SSL proxy chaining	299
Agentless NTLM authentication for web proxy	307
Multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers	310
Learn client IP addresses	311
Explicit proxy authentication over HTTPS	312
mTLS client certificate authentication	314
CORS protocol in explicit web proxy when using session-based, cookie-enabled, and captive portal-enabled SAML authentication	319
DHCP servers and relays	323
Default DHCP server for entry-level FortiGates	323
Basic configuration	324
DHCP options	327
DHCP addressing mode on an interface	333
Multiple DHCP relay servers	336
FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses	338
Static routing	338
Routing concepts	339
Policy routes	351
Equal cost multi-path	353
Dual internet connections	357
Dynamic routing	362
RIP	364
OSPF	383
BGP	395
BFD	431
Routing objects	440
Multicast	450
Multicast routing and PIM support	450
Configuring multicast forwarding	451
FortiExtender	455
WAN extension mode	455
LAN extension mode	455
Adding a FortiExtender	456
Direct IP support for LTE/4G	457
Sample LTE interface	459
Limitations	459
LLDP reception	460

Virtual routing and forwarding	463
Implementing VRF	463
VRF routing support	464
Route leaking between VRFs with BGP	469
Route leaking between multiple VRFs	472
VRF with IPv6	482
IBGP and EBGP support in VRF	486
Support cross-VRF local-in and local-out traffic for local services	488
NetFlow	491
Verification and troubleshooting	492
NetFlow templates	492
NetFlow on FortiExtender and tunnel interfaces	505
sFlow	508
Configuring sFlow	509
Link monitor	511
Link monitor with route updates	511
Enable or disable updating policy routes when link health monitor fails	513
Add weight setting on each link health monitor server	515
IPv6	518
IPv6 overview	519
IPv6 quick start	520
Neighbor discovery proxy	524
IPv6 address assignment	525
NAT66, NAT46, NAT64, and DNS64	537
DHCPv6 relay	548
IPv6 tunneling	549
IPv6 Simple Network Management Protocol	555
Dynamic routing in IPv6	558
IPv6 configuration examples	560
SD-WAN	604
SD-WAN overview	604
SD-WAN components and design principles	604
SD-WAN designs and architectures	607
SD-WAN quick start	608
Configuring the SD-WAN interface	609
Adding a static route	610
Selecting the implicit SD-WAN algorithm	610
Configuring firewall policies for SD-WAN	611
Link monitoring and failover	611
Results	613
Configuring SD-WAN in the CLI	616
SD-WAN members and zones	618
Topology	619
Configuring SD-WAN member interfaces	619
Configuring SD-WAN zones	621
Using SD-WAN zones	622
Specify an SD-WAN zone in static routes and SD-WAN rules	624
Performance SLA	629

Performance SLA overview	629
Link health monitor	634
Monitoring performance SLA	636
Passive WAN health measurement	640
Passive health-check measurement by internet service and application	646
SD-WAN rules	650
SD-WAN rules overview	651
Implicit rule	658
Automatic strategy	662
Manual strategy	663
Best quality strategy	664
Lowest cost (SLA) strategy	668
Maximize bandwidth (SLA) strategy	671
Manual interface speedtest	674
Scheduled interface speedtest	675
SD-WAN traffic shaping and QoS	677
SDN dynamic connector addresses in SD-WAN rules	682
Application steering using SD-WAN rules	685
DSCP tag-based traffic steering in SD-WAN	697
ECMP support for the longest match in SD-WAN rule matching	704
Override quality comparisons in SD-WAN longest match rule matching	706
Use SD-WAN rules for WAN link selection with load balancing	709
Advanced routing	715
Local out traffic	716
Using BGP tags with SD-WAN rules	721
BGP multiple path support	724
Controlling traffic with BGP route mapping and service rules	727
Applying BGP route-map to multiple BGP neighbors	733
VPN overlay	739
ADVPN and shortcut paths	740
SD-WAN monitor on ADVPN shortcuts	753
Hold down time to support SD-WAN service strategies	754
SD-WAN integration with OCVPN	756
Adaptive Forward Error Correction	763
Dual VPN tunnel wizard	767
Duplicate packets on other zone members	768
Duplicate packets based on SD-WAN rules	771
Speed tests run from the hub to the spokes in dial-up IPsec tunnels	772
Interface based QoS on individual child tunnels based on speed test results	779
Advanced configuration	782
SD-WAN with FGCP HA	782
Configuring SD-WAN in an HA cluster using internal hardware switches	789
SD-WAN configuration portability	793
SD-WAN cloud on-ramp	799
Configuring the VPN overlay between the HQ FortiGate and cloud FortiGate-VM	800
Configuring the VPN overlay between the HQ FortiGate and AWS native VPN gateway	805
Configuring the VIP to access the remote servers	808
Configuring the SD-WAN to steer traffic between the overlays	811

Verifying the traffic	815
Hub and spoke SD-WAN deployment example	822
Datacenter configuration	822
Branch configuration	827
Validation	831
Dynamic definition of SD-WAN routes	832
Adding another datacenter	833
Troubleshooting SD-WAN	834
Tracking SD-WAN sessions	834
Understanding SD-WAN related logs	834
SD-WAN related diagnose commands	837
SD-WAN bandwidth monitoring service	842
Using SNMP to monitor health check	845
Policy and Objects	848
Policies	848
Firewall policy parameters	849
Profile-based NGFW vs policy-based NGFW	850
NGFW policy mode application default service	854
Application logging in NGFW policy mode	856
Policy views and policy lookup	857
Policy with source NAT	859
Policy with destination NAT	875
Local-in policies	896
DoS protection	900
Access control lists	907
Mirroring SSL traffic in policies	908
Inspection mode per policy	911
OSPFv3 neighbor authentication	913
Firewall anti-replay option per policy	915
Enabling advanced policy options in the GUI	915
Recognize anycast addresses in geo-IP blocking	916
Matching GeoIP by registered and physical location	917
Authentication policy extensions	918
HTTP to HTTPS redirect for load balancing	919
Use Active Directory objects directly in policies	921
FortiGate Cloud / FDN communication through an explicit proxy	925
No session timeout	926
MAP-E support	928
Seven-day rolling counter for policy hit counters	931
Cisco Security Group Tag as policy matching criteria	933
NAT46 and NAT64 policy and routing configurations	935
Per-policy disclaimer messages	946
Address objects	948
Address Types	949
Address Group	950
Subnet	950
Dynamic policy — fabric devices	951
IP range	953

FQDN addresses	954
Using wildcard FQDN addresses in firewall policies	955
Geography based addresses	957
IPv6 geography-based addresses	960
Wildcard addressing	962
Interface subnet	963
Address group	964
Address folder	965
Address group exclusions	966
FSSO dynamic address subtype	967
ClearPass integration for dynamic address objects	971
FortiNAC tag dynamic address	974
MAC addressed-based policies	977
ISDB well-known MAC address list	978
IPv6 MAC addresses and usage in firewall policies	980
Protocol options	982
Log oversized files	982
RPC over HTTP	982
Protocol port mapping	982
Common options	982
Web options	983
Email options	984
Traffic shaping	984
Configuration methods	985
Traffic shaping policy	986
Traffic shaping policies	987
Traffic shaping profiles	990
Traffic shapers	1000
Global traffic prioritization	1010
DSCP matching and DSCP marking	1013
Examples	1017
Zero Trust Network Access	1034
Zero Trust Network Access introduction	1035
Basic ZTNA configuration	1037
Establish device identity and trust context with FortiClient EMS	1046
SSL certificate based authentication	1050
ZTNA configuration examples	1052
Migrating from SSL VPN to ZTNA	1134
ZTNA scalability support for up to 50 thousand concurrent endpoints	1141
ZTNA troubleshooting and debugging commands	1143
ZTNA troubleshooting scenarios	1148
Internet Service	1153
Using Internet Service in policy	1153
Using custom Internet Service in policy	1155
Using extension Internet Service in policy	1157
Global IP address information database	1159
IP reputation filtering	1161
Internet service groups in policies	1163
Allow creation of ISDB objects with regional information	1166

Internet service customization	1168
Security Profiles	1170
Inspection modes	1170
Flow mode inspection (default mode)	1171
Proxy mode inspection	1171
Inspection mode feature comparison	1172
Antivirus	1174
Antivirus introduction	1175
Advanced configurations	1197
Configuration examples	1210
Web filter	1217
URL filter	1218
FortiGuard filter	1223
Credential phishing prevention	1231
Additional antiphishing settings	1233
Usage quota	1236
Web content filter	1239
Advanced filters 1	1242
Advanced filters 2	1245
Web filter statistics	1249
URL certificate blocklist	1250
Video filter	1250
Configuring a video filter profile	1251
Filtering based on FortiGuard categories	1251
Filtering based on YouTube channel	1255
DNS filter	1260
DNS filter behavior in proxy mode	1261
FortiGuard DNS rating service	1262
Configuring a DNS filter profile	1262
FortiGuard category-based DNS domain filtering	1266
Botnet C&C domain blocking	1269
DNS safe search	1273
Local domain filter	1275
DNS translation	1279
Applying DNS filter to FortiGate DNS server	1282
DNS inspection with DoT and DoH	1283
Troubleshooting for DNS filter	1286
Application control	1289
Configuring an application sensor	1290
Basic category filters and overrides	1291
Excluding signatures in application control profiles	1295
Port enforcement check	1297
Protocol enforcement	1297
SSL-based application detection over decrypted traffic in a sandwich topology	1299
Matching multiple parameters on application control signatures	1300
Application signature dissector for DNP3	1303
Intrusion prevention	1303
Signature-based defense	1305

Configuring an IPS sensor	1308
IPS configuration options	1311
IPS signature filter options	1316
IPS with botnet C&C IP blocking	1319
IPS signatures for the industrial security service	1323
IPS sensor for IEC 61850 MMS protocol	1324
SCTP filtering capabilities	1326
File filter	1329
Configuring a file filter profile	1330
Supported file types	1335
Email filter	1337
Protocol comparison between email filter inspection modes	1338
Configuring an email filter profile	1338
Local-based filters	1339
FortiGuard-based filters	1346
Third-party-based filters	1348
Filtering order	1348
Protocols and actions	1350
Configuring webmail filtering	1351
Data leak prevention	1352
Protocol comparison between DLP inspection modes	1353
Logging and blocking files by file name	1353
Basic DLP filter types	1353
DLP fingerprinting	1356
VoIP solutions	1360
General use cases	1361
SIP message inspection and filtering	1365
SIP pinholes	1368
SIP over TLS	1370
Voice VLAN auto-assignment	1371
Scanning MSRP traffic	1373
ICAP	1377
ICAP configuration example	1378
ICAP response filtering	1380
Secure ICAP clients	1382
Web application firewall	1383
Protecting a server running web applications	1383
SSL & SSH Inspection	1386
Configuring an SSL/SSH inspection profile	1386
Certificate inspection	1389
Deep inspection	1390
Protecting an SSL server	1393
Handling SSL offloaded traffic from an external decryption device	1394
SSH traffic file scanning	1396
Redirect to WAD after handshake completion	1398
HTTP/2 support in proxy mode SSL inspection	1399
Define multiple certificates in an SSL profile in replace mode	1400
Disabling the FortiGuard IP address rating	1402

Custom signatures	1403
Configuring custom signatures	1404
Blocking applications with custom signatures	1405
Filters for application control groups	1408
Application groups in traffic shaping policies	1410
Overrides	1414
Web rating override	1414
Using local and remote categories	1423
Web profile override	1425
IP ban	1429
IP ban using the CLI	1430
IP ban using security profiles	1431
Profile groups	1433
VPN	1437
IPsec VPNs	1437
General IPsec VPN configuration	1437
Site-to-site VPN	1467
Remote access	1520
Aggregate and redundant VPN	1564
Overlay Controller VPN (OCVPN)	1608
ADVPN	1639
Other VPN topics	1673
VPN IPsec troubleshooting	1710
SSL VPN	1718
SSL VPN best practices	1718
SSL VPN security best practices	1721
SSL VPN quick start	1728
SSL VPN tunnel mode	1735
SSL VPN web mode	1759
SSL VPN authentication	1774
SSL VPN to IPsec VPN	1857
SSL VPN protocols	1864
Configuring OS and host check	1867
FortiGate as SSL VPN Client	1873
Dual stack IPv4 and IPv6 support for SSL VPN	1882
Disable the clipboard in SSL VPN web mode RDP connections	1893
SSL VPN IP address assignments	1898
Using SSL VPN interfaces in zones	1900
SSL VPN troubleshooting	1903
User & Authentication	1907
User definition, groups, and settings	1907
Users	1908
User groups	1910
Authentication settings	1917
Retail environment guest access	1920
LDAP servers	1923
Configuring an LDAP server	1923
Enabling Active Directory recursive search	1926

Configuring LDAP dial-in using a member attribute	1927
Configuring wildcard admin accounts	1928
Configuring least privileges for LDAP admin account authentication in Active Directory	1930
Tracking users in each Active Directory LDAP group	1930
RADIUS servers	1933
Configuring a RADIUS server	1934
Using multiple RADIUS servers	1935
RADIUS AVPs and VSAs	1938
Restricting RADIUS user groups to match selective users on the RADIUS server	1940
Configuring RADIUS SSO authentication	1942
RSA ACE (SecurID) servers	1948
Support for Okta RADIUS attributes filter-Id and class	1952
Sending multiple RADIUS attribute values in a single RADIUS Access-Request	1954
Traffic shaping based on dynamic RADIUS VSAs	1954
SAML	1961
Usage	1962
Identity providers	1962
Configuring SAML SSO	1962
SSL VPN with FortiAuthenticator as a SAML IdP	1967
Using a browser as an external user-agent for SAML authentication in an SSL VPN connection	1972
Outbound firewall authentication with Microsoft Entra ID as a SAML IdP	1976
SAML authentication in a proxy policy	1986
TACACS+ servers	1990
FortiTokens	1992
FortiToken Mobile quick start	1993
FortiToken Cloud	2001
Registering hard tokens	2001
Managing FortiTokens	2004
FortiToken Mobile Push	2006
Synchronizing LDAP Active Directory users to FortiToken Cloud using the group filter	2007
FortiGuard distribution of updated Apple certificates for push notifications	2011
Troubleshooting and diagnosis	2012
PKI	2015
Configuring a PKI user	2015
FSSO	2019
FSSO polling connector agent installation	2021
FSSO using Syslog as source	2024
Configuring the FSSO timeout when the collector agent connection fails	2027
Configuring FSSO firewall authentication	2029
Include usernames in logs	2035
Install and configure FSSO Agent	2036
Configure the FortiGate	2038
Log, monitor, and report examples	2040

Wireless configuration	2044
Switch Controller	2045
System	2046
Basic system settings	2046
Advanced system settings	2046
Operating modes	2047
Administrators	2049
Administrator profiles	2049
Add a local administrator	2052
Remote authentication for administrators	2053
Password policy	2055
Associating a FortiToken to an administrator account	2057
REST API administrator	2058
SSO administrators	2059
FortiGate administrator log in using FortiCloud single sign-on	2060
Firmware	2061
Firmware maturity levels	2061
Firmware upgrade notifications	2063
Downloading a firmware image	2064
Testing a firmware version	2065
Upgrading the firmware	2066
Downgrading to a previous firmware version	2067
Installing firmware from system reboot	2068
Restoring from a USB drive	2070
Controlled upgrade	2070
Settings	2071
Default administrator password	2071
Changing the host name	2073
Setting the system time	2073
Configuring ports	2077
Setting the idle timeout time	2078
Setting the password policy	2078
Changing the view settings	2078
Setting the administrator password retries and lockout time	2079
TLS configuration	2080
Controlling return path with auxiliary session	2080
Email alerts	2084
Using configuration save mode	2089
Trusted platform module support	2090
Virtual Domains	2092
Global and per-VDOM resources	2093
Split-task VDOM mode	2094
Multi VDOM mode	2097
High Availability	2117
FortiGate Clustering Protocol (FGCP)	2117
FortiGate Session Life Support Protocol (FGSP)	2117
VRRP	2117
FGCP	2118

FGSP	2179
Standalone configuration synchronization	2233
VRRP	2238
Session failover	2249
SNMP	2255
Basic configuration	2256
MIB files	2259
Important SNMP traps	2259
SNMP examples	2261
Replacement messages	2265
Modifying replacement messages	2266
Replacement message images	2267
Replacement message groups	2269
FortiGuard	2272
Anycast	2273
Configuring FortiGuard updates	2275
Configuring a proxy server for FortiGuard updates	2275
Manual updates	2276
Automatic updates	2277
Scheduled updates	2278
Sending malware statistics to FortiGuard	2279
Update server location	2280
Filtering	2281
Online security tools	2282
Anycast and unicast services	2282
Using FortiManager as a local FortiGuard server	2283
Cloud service communication statistics	2284
IoT detection service	2286
FortiAP query to FortiGuard IoT service to determine device details	2288
FDS-only ISDB package in firmware images	2289
License expiration	2290
Feature visibility	2292
Certificates	2292
Uploading a certificate using the GUI	2293
Uploading a certificate using the CLI	2296
Uploading a certificate using an API	2297
Generate a new certificate	2302
Procuring and importing a signed SSL certificate	2303
Microsoft CA deep packet inspection	2306
Automatically provision a certificate	2310
ECDSA in SSH administrative access	2314
Creating certificates with XCA	2316
Security	2323
BIOS-level signature and file integrity checking	2323
Real-time file system integrity checking	2327
Running a file system check automatically	2329
FortiGate VM unique certificate	2330
Configuration scripts	2331

Workspace mode	2332
Custom languages	2334
RAID	2335
FortiGate encryption algorithm cipher suites	2338
HTTPS access	2338
SSH access	2339
SSL VPN	2341
Additional features	2344
Other Products	2346
Conserve mode	2348
Proxy inspection in conserve mode	2348
Flow inspection in conserve mode	2349
Diagnostics	2349
Using APIs	2350
Token-based authentication	2350
Best Practices	2351
Making an API call to retrieve information from the FortiGate	2351
Configuration backups and reset	2355
Fortinet Security Fabric	2360
Security Fabric settings and usage	2360
Components	2361
Configuring the root FortiGate and downstream FortiGates	2364
Configuring FortiAnalyzer	2371
Configuring FortiGate Cloud	2373
Configuring FortiAnalyzer Cloud service	2377
Configuring FortiManager	2381
Configuring FortiManager Cloud service	2384
Configuring Sandboxing	2386
Configuring FortiClient EMS	2391
Synchronizing FortiClient ZTNA tags	2405
Configuring FortiNAC	2408
Configuring FortiAP and FortiSwitch	2410
Configuring FortiMail	2411
Configuring FortiNDR	2413
Configuring FortiDeceptor	2417
Configuring FortiWeb	2420
Configuring FortiTester	2422
Configuring FortiMonitor	2425
Configuring FortiVoice	2427
Configuring additional devices	2431
Using the Security Fabric	2432
Deploying the Security Fabric	2448
Deploying the Security Fabric in a multi-VDOM environment	2456
Synchronizing objects across the Security Fabric	2461
Group address objects synchronized from FortiManager	2469
Security Fabric over IPsec VPN	2470
Leveraging LLDP to simplify Security Fabric negotiation	2476
Integrate user information from EMS and Exchange connectors in the user store	2479

Configuring the Security Fabric with SAML	2482
Configuring single-sign-on in the Security Fabric	2482
CLI commands for SAML SSO	2488
SAML SSO with pre-authorized FortiGates	2489
Navigating between Security Fabric members with SSO	2490
Integrating FortiAnalyzer management using SAML SSO	2492
Integrating FortiManager management using SAML SSO	2496
Advanced option - FortiGate SP changes	2498
Security rating	2499
Security Fabric score	2505
Automation stitches	2506
Creating automation stitches	2507
Triggers	2521
Actions	2533
Public and private SDN connectors	2593
Getting started with public and private SDN connectors	2594
AliCloud SDN connector using access key	2598
AWS SDN connector using certificates	2600
Azure SDN connector using service principal	2606
Cisco ACI SDN connector using a standalone connector	2607
ClearPass endpoint connector via FortiManager	2609
GCP SDN connector using service account	2612
IBM Cloud SDN connector using API keys	2614
Kubernetes (K8s) SDN connectors	2618
Nuage SDN connector using server credentials	2634
Nutanix SDN connector using server credentials	2636
OCI SDN connector using certificates	2638
OpenStack SDN connector using node credentials	2640

Change Log

Date	Change Description
2024-04-04	Initial release.
2024-04-11	Updated SSH traffic file scanning on page 1396, Inspection mode feature comparison on page 1172, SSL VPN security best practices on page 1721, and Running ping and traceroute on page 2863.
2024-04-12	Updated Web rating override on page 1414. Added Configuring the category override rule on page 1415, Sub-category actions on page 1417, and Category override examples on page 1418.
2024-04-15	Updated Configuring FortiManager on page 2381.

Getting started

FortiOS is the operating system that runs on Fortinet's FortiGate Next-Generation Firewall (NGFW). It supports different platforms, including:

- Physical appliances
- Hypervisors
- Cloud computing platforms

FortiOS delivers security as a hybrid mesh firewall that spans a meshed topology of on-prem and cloud environments. With FortiGuard's AI-powered security services, FortiOS provides protection across the attack surface with IPS, advanced malware protection, web security, inline malware prevention, data loss prevention, and more.

In addition, FortiOS is central to the SD-WAN solution by providing SD-WAN functionality and intelligence in a single FortiGate, a mesh of FortiGates, or integrated into a SASE environment. It is also central to the Zero Trust Network Access (ZTNA) solution by making policy decisions and applying policy enforcement based on security posture input.

Use the following resources to get started with FortiOS:

Task	Documentation links
Get started with my new FortiGate	See Summary of steps on page 23 . If you are migrating a configuration from another vendor to FortiGate, see the Migration section of the Best Practices guide or use the FortiConverter service .
Learn about best practices for FortiOS	Review Basic configuration in the Best Practices guide.
Learn about new FortiOS features	See FortiOS New Features and FortiOS Release Notes .
Learn about standard practices for deploying a solution or an architecture	Go to Best Practices 4-D Resources and review the document categories.
Review information about FortiOS releases, including resolved and known issues	See FortiOS Release Notes .

For the latest information about FortiOS 7.0, see the latest patch version of the [Administration Guide](#).

Summary of steps

These steps summarize how to get your FortiGate up and running by using the GUI. For information about the Command Line Interface (CLI), see [Using the CLI on page 41](#).

1. Set up your FortiGate for initial management access with the GUI. See [Setting up FortiGate for management access on page 24](#).

For more information	Go to
Physical appliances, such as FortiGate	Go to FortiGate/FortiOS Hardware Guides to view QuickStart Guides for all supported FortiGate models.
Hypervisors, such as FortiGate-VM on ESXi, KVM, Hyper-V, and so on.	Go to FortiGate Public Cloud or FortiGate Private Cloud and follow the deployment section of the administration guide for your hypervisor, for example, Microsoft Hyper-V Administration Guide > Deployment .

Depending on the topology and FortiGate model, internet access may not yet be configured for the FortiGate. If no internet access, you cannot yet register the FortiGate with Fortinet until later in the setup.

2. In the GUI, follow the *FortiGate Setup* wizard to change the hostname, change the password, and specify a default layout for the FortiOS dashboards. See [Completing the FortiGate Setup wizard on page 25](#).
3. Complete the basic configuration steps for FortiOS. After this step, all FortiGate models should have internet access. See [Configuring basic settings on page 25](#).
4. Register FortiGate with Fortinet by using your FortiCare/FortiCloud account with Fortinet Technical Support (<https://support.fortinet.com>). See [Registering FortiGate on page 29](#).
5. Configure a policy for the FortiGate to give clients behind FortiGate access to the internet. See [Configuring a firewall policy on page 32](#).
6. Back up the configuration. See [Backing up the configuration on page 32](#).
7. If necessary, troubleshoot the installation. See [Troubleshooting your installation on page 33](#).

After completing the Getting started section, next steps can include:

- Getting familiar with the FortiOS GUI and CLI:
 - See [Using the GUI on page 34](#).
 - See [Using the CLI on page 41](#).
- Configuring FortiOS features. The following table lists a few of the features available with FortiOS. Many additional features are available:

For	Go to
Security profiles	See antivirus, IPS, web filter, and application control .
VPN	See IPsec VPNs on page 1437 .
Fortinet Security Fabric	See Fortinet Security Fabric on page 2360 .
User & Authentication	See User & Authentication on page 1907 .
Software-defined wide area network (SD-WAN)	See SD-WAN on page 604 .
Zero Trust Network Access (ZTNA)	See Zero Trust Network Access on page 1034 .

Setting up FortiGate for management access

After you receive your FortiGate, open the box, connect the cables for management and internet access, and use a management computer to access the FortiOS GUI.

For information about setting up FortiGate on hypervisors, such as FortiGate-VM on ESXi, KVM, Hyper-V, and so on, go to [FortiGate Public Cloud](#) or [FortiGate Private Cloud](#) and follow the deployment section of the administration guide for your hypervisor and cloud computing platform, for example, [Microsoft Hyper-V Administration Guide > Deployment](#).

To set up FortiGate for initial management access:

1. Unpack the FortiGate box, and locate the following items:

- FortiGate device
- Power cable
- Ethernet cable

You will also need to provide the following items:

- Second Ethernet cable. Only one Ethernet cable is provided to connect the FortiGate to a management computer. Locate a second Ethernet cable to connect the FortiGate to a port for internet access.
- Management computer to access the FortiOS GUI

2. Use the power cable to connect the FortiGate to a power source.

3. Use one Ethernet cable to connect the management port on the FortiGate to a management computer.

The default interface used for management differs from model to model. On most units with a single dedicated management port, the port is named MGMT. On units with multiple management ports, the names MGMT1 and MGMT2 are used. On units without dedicated management ports, port1 is used for initial management access, and the port can be part of a virtual switch group.

The following example is for a FortiGate 80F, which uses port1 for initial management access. For information about your FortiGate hardware model, go to [FortiGate/FortiOS Hardware Guides](#).

4. Use a second Ethernet cable to connect the WAN on the FortiGate to an upstream router, switch, or modem with access to the internet.

On some FortiGate models, dedicated WAN interface(s) labeled WAN1, WAN2, and so on are available. If no dedicated WAN interfaces are present, select an interface of your choice for the WAN connection.

Internet access is available when the FortiGate model has addressing mode set to DHCP by default on the WAN interface, and the WAN interface is connected to a network with a DHCP server assigning the correct IP and gateway for internet access. If these conditions are not met, then internet access is not available after connecting your WAN interface. See .

5. On the management computer, assign an address in the 192.168.1.0/24 network.

6. In a web browser, go to <https://192.168.1.99> and enter the default user name, `admin`, and leave the password field blank.

By default, the management interface or the internal interface is configured to allow HTTPS access with the IP address 192.168.1.99.

The GUI is displayed in your browser.

7. Watch the video and complete the FortiGate Setup wizard. See [Completing the FortiGate Setup wizard on page 25](#).

Completing the FortiGate Setup wizard

After logging in to FortiOS, you can access a FortiOS video as well as a FortiGate Setup wizard to help you get familiar with the product.

To complete the FortiGate Setup wizard:

1. After logging in to the FortiOS GUI, a FortiOS 7.0 What's new video is presented. Watch the video, and then click *OK* to proceed.

The *FortiGate Setup* wizard is displayed to help you set up the FortiGate by completing the following steps:

- Specify a hostname
- Change your password
- Set up the FortiOS dashboard
- Register with FortiCare

2. Click *Begin* to start the wizard.

The *Specify Hostname* page is displayed.

3. Specify a name for the FortiGate, and click *OK*.

The *Change your Password* page is displayed.

4. Change the password for the admin account for the FortiGate, and click *OK*.

The *Dashboard Setup* page is displayed.

5. Choose what dashboards to display by default in FortiOS, and click *OK*.

The *Register with FortiCare* page is displayed.

6. If the FortiGate has internet access, register with FortiCare, and click *OK*.

If internet access is not yet set up for the FortiGate, you cannot complete registration. Click *Later*.

The *FortiGate Setup* is complete, and the FortiOS GUI is displayed.

Configuring basic settings

Complete the following basic settings on the FortiGate to get the device up and running

1. Plan interface usage for MGMT, WAN, and LAN access, and configure the interfaces. See [Planning and configuring the MGMT, WAN, and LAN interfaces on page 26](#).
2. Configure the default route. See [Configuring the default route on page 28](#).
3. Configure the hostname. See [Configuring the hostname on page 28](#).
4. Ensure internet and FortiGuard connectivity. See [Ensuring internet and FortiGuard connectivity on page 29](#).

After configuring the basic settings, the FortiGate can access the internet and communicate with FortiGuard. Next, you can register the FortiGate with Fortinet. See [Registering FortiGate on page 29](#). Firewall policies are also ready to be configured using the WAN and LAN interfaces.

Planning and configuring the MGMT, WAN, and LAN interfaces

On a typical deployment where the FortiGate NGFW is configured as an edge firewall, the administrator typically sets up access control between the LAN and WAN interface, and permanent management access either through in-band management or out-of-band management. The following sections outline steps to plan and configure your management, WAN, and LAN interfaces

Management access

So far the new FortiGate setup has been completed over a management interface, which is either a dedicated MGMT port named MGMT or MGMT1 or a port on the internal switch interface.

What interface to use for FortiGate management can depend on the FortiGate model. Some FortiGate models have a dedicated MGMT interface and some do not:

- Mid-size and high-end FortiGate models typically have a dedicated MGMT interface, and you can use the MGMT interface for FortiGate management. There is also a separate management network for accessing the FortiGate and other devices on the network. This is called out-of-band management.
- Desktop FortiGate models typically do not have a dedicated MGMT interface. In this case, you might be using the Internal or LAN interface for FortiGate management. There is no dedicated management network, and the management traffic is shared with internal traffic. This is called in-band management.

Following is a summary of what FortiGate models typically support in-band and out-of-band management:

FortiGate model	MGMT interface	In-band management	Out-of-band management
Desktop models	No	Recommended	Not supported*
Mid-size models	Yes	Supported	Recommended
High-end models	Yes	Supported	Recommended

*Although natively the FortiGate does not support out-of-band management, you can pick an unused interface and configure it as a dedicated interface for out-of-band management.

WAN interface

Similar to the management interface, some models have an interface labelled WAN, WAN1, or WAN2, and other models do not. On models with dedicated WAN interface(s), the interfaces are also configured as DHCP clients. Therefore, if a DHCP server is present in the WAN network that points to the correct internet gateway, then internet access is available without further configuration.

On models without dedicated WAN interfaces, or in situations where you choose to configure the WAN interface statically, select an interface for WAN access. Connect the interface to your upstream router, L3 switch, or modem. Then use the following steps to configure your WAN interface.

To configure a WAN interface in the GUI:

1. Go to *Network > Interfaces*. Select an interface and click *Edit*.
2. (Optional) Enter an *Alias*, such as WAN.
3. In the *Address* section, enter the *IP/Netmask*.

4. In *Administrative Access* section, select the access options as needed. For a WAN interface, it is recommended to only allow *PING*.
5. Click *OK*.

To configure a WAN interface in the CLI:

```
config system interface
  edit "port2"
    set ip 203.0.113.99 255.255.255.0
    set allowaccess ping
    set alias "WAN"
  next
end
```

LAN interface

On desktop and some mid-range models, a set of ports are grouped together by default in virtual switch mode for LAN access. The virtual switch interface may be called *internal* or *lan*, and it helps facilitate connecting endpoints directly to the FortiGate on the same L2 switching network.

Endpoints connected this way will also share the same access control configured for the *internal* or *lan* interface.

On models that lack a default LAN interface, or when you choose to configure a LAN interface manually, select an interface for LAN access. Connect this interface to an internal switch that connects to your LAN network. Then use the following steps to configure your LAN interface.

To configure a LAN interface in the GUI:

1. Go to *Network > Interfaces*. Select an interface and click *Edit*.
2. (Optional) Enter an *Alias*, such as *LAN*.
3. In the *Address* section, enter the *IP/Netmask*.
4. In *Administrative Access* section, select the access options as needed, such as *PING*. For in-band management, you may also want to allow administrative access for *HTTPS* and *SSH*.
5. Optionally, enable *DHCP Server* and configure as needed.
6. Click *OK*.

To configure a LAN interface in the CLI:

```
config system interface
  edit "port1"
    set ip 192.168.10.99 255.255.255.0
    set allowaccess ping https ssh
    set alias "LAN"
  next
end
config system dhcp server
  edit 1
    set dns-service default
    set default-gateway 192.168.10.99
    set netmask 255.255.255.0
    set interface "port1"
    config ip-range
      edit 1
```

```
        set start-ip 192.168.10.2
        set end-ip 192.168.10.254
    next
end
next
end
```

Configuring the default route

Setting the default route enables the FortiGate to route traffic through this interface and default gateway when no specific routes are found for a particular destination. The gateway address should be your upstream router or L3 switch that the FortiGate is connected to. Set the interface to be the WAN interface that the gateway is connected to.

If the WAN interface uses DHCP for address assignment, the default route may already be learned from the DHCP server, and this step is not needed.

To configure the default route in the GUI:

1. Go to *Network > Static Routes* and click *Create New*.
2. Leave the destination subnet as *0.0.0.0/0.0.0.0*. This is known as a default route, since it would match any IPv4 address.
3. Enter the *Gateway Address*.
4. Select an *Interface*.
5. Click *OK*.

To configure the default route in the CLI:

```
config router static
    edit 0
        set gateway 203.0.113.1
        set device port2
    next
end
```

Configuring the hostname

Setting the FortiGate's hostname assists with identifying the device, and it is especially useful when managing multiple FortiGates. Choose a meaningful hostname as it is used in the CLI console, SNMP system name, device name for FortiGate Cloud, and to identify a member of an HA cluster.

To configure the hostname in the GUI:

1. Go to *System > Settings*.
2. Enter a name in the *Host name* field.
3. Click *Apply*.

To configure the hostname in the CLI:

```
config system global
    set hostname 200F_YVR
end
```

Ensuring internet and FortiGuard connectivity

This step is not necessary for the configuration; however, it is necessary in order to keep your FortiGate up to date against the latest threats. Updates are provided to FortiGates that are registered and make a request to the FortiGuard network to verify if there are any more recent definitions.

Use `execute ping <domain.tld>` to ensure the DNS resolution is able to resolve the following FortiGuard servers:

- `fds1.fortinet.com`
- `service.fortiguard.net`
- `update.fortiguard.net`

You also need to ensure the necessary ports are permitted outbound in the event your FortiGate is behind a filtering device. Refer to the [Ports and Protocols](#) document for more information.

Registering FortiGate

The FortiGate, and then its service contract, must be registered to have full access to [Fortinet Customer Service and Support](#), and [FortiGuard](#) services. The FortiGate can be registered in either the FortiGate GUI or the FortiCloud support portal. The service contract can be registered from the FortiCloud support portal.

The service contract number is needed to complete registrations on the FortiCloud support portal. You can find this 12-digit number in the email that contains your service registration document (sent from `do-not-reply-contract@fortinet.com`) in the service entitlement summary.

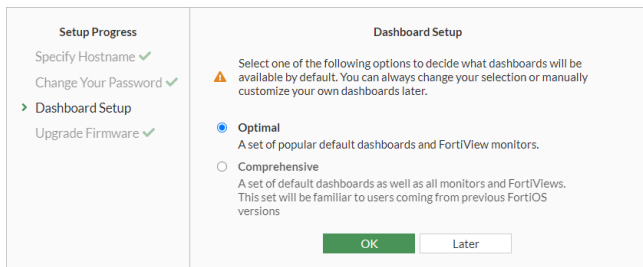

To register your FortiGate in the GUI:

1. Connect to the FortiGate GUI. A dialog box appears, which indicates the steps you should take to complete the setup of your FortiGate. These steps include:

- Specify Hostname*
- Change Your Password*
- Dashboard Setup*
- Upgrade Firmware*

If you completed the [Configuring basic settings on page 25](#), the hostname and password steps are already marked as complete (checkmark). If you chose to deploy the latest firmware, the *Upgrade Firmware* step is marked as complete.

2. Click *Begin* to complete the dashboard setup. Two options appear (*Optimal* and *Comprehensive*).

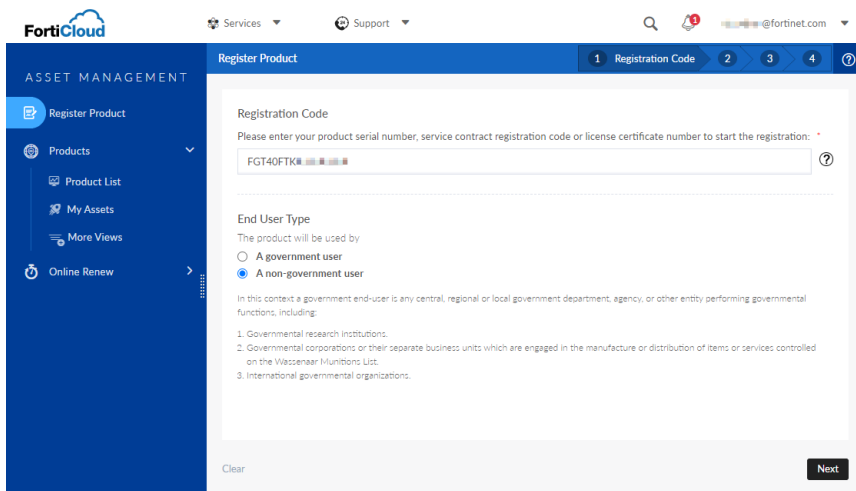

3. Select the desired setting and click *OK*. The *Dashboard > Status* page opens. Note that the licenses are grayed out because the device or virtual machine is not registered.
4. Go to *System > FortiGuard* and click *Enter Registration Code*.

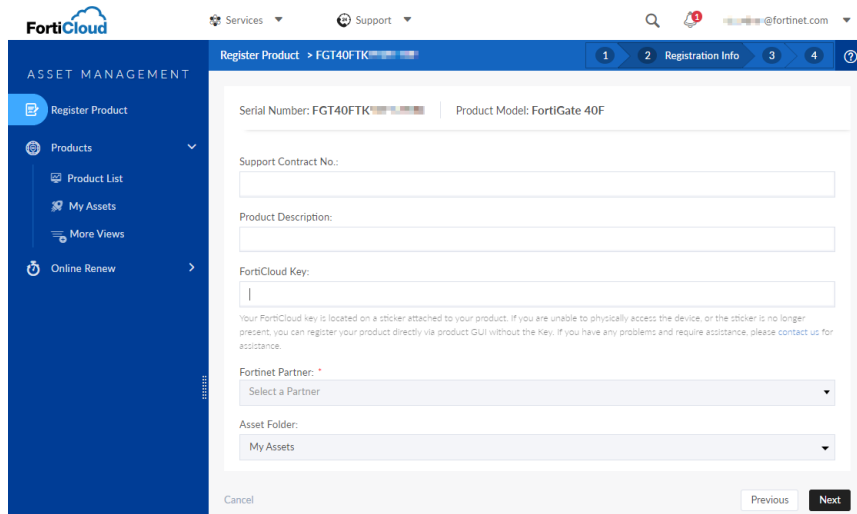

5. Enter the contract registration code from your service registration document.
6. Click *OK*.

To register the FortiGate on the FortiCloud support portal:

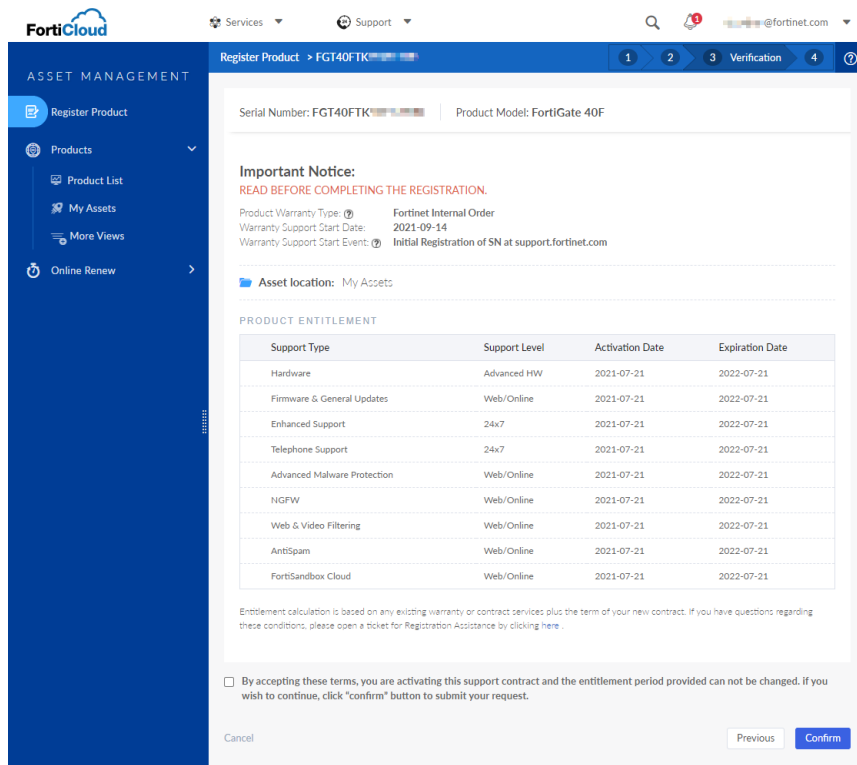

1. Go to support.fortinet.com and log in using your FortiCloud account credentials. If you do not have an account, click *Register* to create one.
2. In the left-side menu, click *Register Product*.
3. Enter the product serial number or license certificate number for a VM, select an end user type, then click *Next*.

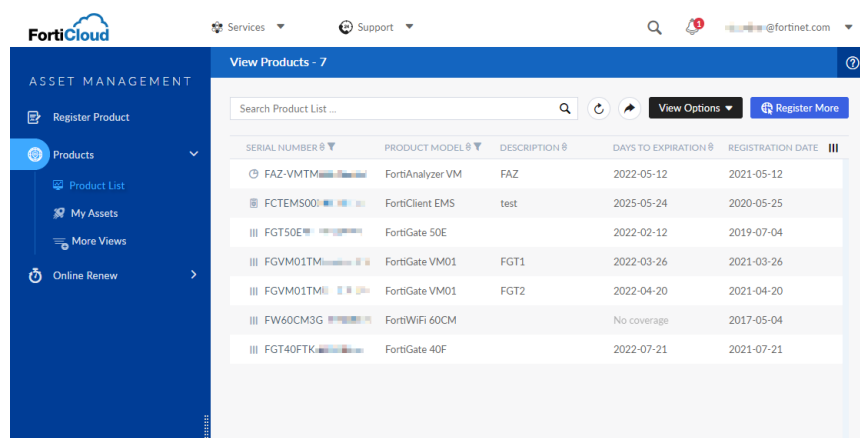

4. Enter the *Support Contract* number and *FortiCloud Key* (optionally, enter a product description), then click *Next*.

5. Review the product entitlement information, select the checkbox to accept the terms, then click *Confirm*.

6. Go to *Products > Product List*. The FortiGate is now visible in the product list.

Configuring a firewall policy

When devices are behind FortiGate, you must configure a firewall policy on FortiGate to grant the devices access to the internet. In other words, a firewall policy must be in place for any traffic that passes through a FortiGate.

To create a firewall policy in the GUI:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New*. The *New Policy* pane is displayed.
3. Enter a Name and configure the following necessary settings:

Incoming Interface	LAN (port1)
Outgoing Interface	WAN (port2)
Source	Source IPv4 address name and address group names
Destination	Destination IPv4 address name and address group names
Schedule	Always
Service	All
Action	Accept

4. Click *Save*.

Backing up the configuration

Once you successfully configure the FortiGate, it is extremely important that you back up the configuration. In some cases, you may need to reset the FortiGate to factory defaults or perform a TFTP upload of the firmware, which will erase the existing configuration. In these instances, the configuration on the device must be recreated, unless a backup can be used to restore it.

You can save the local PC and USB key.

To back up the configuration in FortiOS format using the GUI:

1. Click on the user name in the upper right-hand corner of the screen and select *Configuration > Backup*.
2. Direct the backup to your *Local PC* or to a *USB Disk*.
The *USB Disk* option will not be available if no USB drive is inserted in the USB port. You can also backup to the FortiManager using the CLI.
3. If VDOMs are enabled, indicate whether the scope of the backup is the entire FortiGate configuration (*Global*) or only a specific VDOM configuration (*VDOM*).
If backing up a VDOM configuration, select the VDOM name from the list.
4. Enable *Encryption*.

This is recommended to secure your backup configurations and prevent unauthorized parties from reloading your configuration.

5. Enter a password, and enter it again to confirm it. This password will be required to restore the configuration.
6. Click *OK*.
7. When prompted, select a location on the PC or USB disk to save the configuration file. The configuration file will have a *.conf* extension.

Troubleshooting your installation

If your FortiGate does not function as desired after installation, try the following troubleshooting tips:

1. Check for equipment issues

Verify that all network equipment is powered on and operating as expected. Refer to the QuickStart Guide for information about connecting your FortiGate to the network.

2. Check the physical network connections

Check the cables used for all physical connections to ensure that they are fully connected and do not appear damaged, and make sure that each cable connects to the correct device and the correct Ethernet port on that device.

3. Verify that you can connect to the internal IP address of the FortiGate

Connect to the GUI from the FortiGate's internal interface by browsing to its IP address. From the PC, try to ping the internal interface IP address; for example, `ping 192.168.1.99`. If you cannot connect to the internal interface, verify the IP configuration of the PC. If you can ping the interface but can't connect to the GUI, check the settings for administrative access on that interface. Alternatively, use SSH to connect to the CLI, and then confirm that HTTPS has been enabled for Administrative Access on the interface.

4. Check the FortiGate interface configurations

Check the configuration of the FortiGate interface connected to the internal network (under *Network > Interfaces*) and check that *Addressing mode* is set to the correct mode.

5. Verify the security policy configuration

Go to *Policy & Objects > Firewall Policy* and verify that the internal interface to Internet-facing interface security policy has been added and is located near the top of the policy list. Check the *Active Sessions* column to ensure that traffic has been processed (if this column does not appear, right-click on the table header and select *Active Sessions*). If you are using NAT mode, check the configuration of the policy to make sure that *NAT* is enabled and that *Use Outgoing Interface Address* is selected.

- 6. Verify the static routing configuration**

Go to *Network > Static Routes* and verify that the default route is correct. Go to *Monitor > Routing Monitor* and verify that the default route appears in the list as a static route. Along with the default route, you should see two routes shown as *Connected*, one for each connected FortiGate interface.
- 7. Verify that you can connect to the Internet-facing interface's IP address**

Ping the IP address of the Internet-facing interface of your FortiGate. If you cannot connect to the interface, the FortiGate is not allowing sessions from the internal interface to Internet-facing interface. Verify that PING has been enabled for *Administrative Access* on the interface.
- 8. Verify that you can connect to the gateway provided by your ISP**

Ping the default gateway IP address from a PC on the internal network. If you cannot reach the gateway, contact your ISP to verify that you are using the correct gateway.
- 9. Verify that you can communicate from the FortiGate to the Internet**

Access the FortiGate CLI and use the command `execute ping 8.8.8.8`. You can also use the `execute traceroute 8.8.8.8` command to troubleshoot connectivity to the Internet.
- 10. Verify the DNS configurations of the FortiGate and the PCs**

Check for DNS errors by pinging or using traceroute to connect to a domain name; for example: `ping www.fortinet.com`.

If the name cannot be resolved, the FortiGate or PC cannot connect to a DNS server and you should confirm that the DNS server IP addresses are present and correct.
- 11. Confirm that the FortiGate can connect to the FortiGuard network**

Once the FortiGate is on your network, you should confirm that it can reach the FortiGuard network. First, check the *License Information* widget to make sure that the status of all FortiGuard services matches the services that you have purchased. Go to *System > FortiGuard*, and, in the Filtering section, click *Test Connectivity*. After a minute, the GUI should indicate a successful connection. Verify that your FortiGate can resolve and reach FortiGuard at `service.fortiguard.net` by pinging the domain name. If you can reach this service, you can then verify the connection to FortiGuard servers by running the command `diagnose debug rating`. This displays a list of FortiGuard IP gateways you can connect to, as well as the following information:

 - **Weight:** Based on the difference in time zone between the FortiGate and this server
 - **RTT:** Return trip time
 - **Flags:** D (IP returned from DNS), I (Contract server contacted), T (being timed), F (failed)
 - **TZ:** Server time zone
 - **Curr Lost:** Current number of consecutive lost packets
 - **Total Lost:** Total number of lost packets
- 12. Use FortiExplorer if you cannot connect to the FortiGate over Ethernet**

If you cannot connect to the FortiGate GUI or CLI, you may be able to connect using FortiExplorer. Refer to the QuickStart Guide or see the section on FortiExplorer for more details.
- 13. Contact Fortinet Support for assistance**

If you require further assistance, visit the [Fortinet Support](#) website.

Using the GUI

This section presents an introduction to the graphical user interface (GUI) on your FortiGate.

The following topics are included in this section:

- [Connecting using a web browser](#)
- [Menus](#)
- [Tables](#)
- [Entering values](#)
- [GUI-based global search](#)
- [Loading artifacts from a CDN on page 41](#)

For information about using the dashboards, see [Dashboards and Monitors on page 83](#).

Connecting using a web browser

In order to connect to the GUI using a web browser, an interface must be configured to allow administrative access over HTTPS or over both HTTPS and HTTP. By default, an interface has already been set up that allows HTTPS access with the IP address 192.168.1.99.

Browse to <https://192.168.1.99> and enter your username and password. If you have not changed the admin account's password, use the default user name, `admin`, and leave the password field blank.

The GUI will now display in your browser, and you will be required to provide a password for the administrator account.

To use a different interface to access the GUI:

1. Go to *Network > Interfaces* and edit the interface you wish to use for access. Take note of its assigned IP address.
2. In *Administrative Access*, select *HTTPS*, and any other protocol you require. You can also select *HTTP*, although this is not recommended as the connection will be less secure.
3. Click *OK*.
4. Browse to the IP address using your chosen protocol.
The GUI will now be displayed in your browser.

Menus

If you believe your FortiGate model supports a menu that does not appear in the GUI, go to *System > Feature Visibility* and ensure the feature is enabled. For more information, see [Feature visibility on page 2292](#).

The GUI contains the following main menus, which provide access to configuration options for most FortiOS features:

Dashboard	The dashboard displays various widgets that display important system information and allow you to configure some system options. For more information, see Dashboards and Monitors on page 83 .
Network	Options for networking, including configuring system interfaces and routing options. For more information, see Network on page 142 .
Policy & Objects	Configure firewall policies, protocol options, and supporting content for policies, including schedules, firewall addresses, and traffic shapers. For more information, see Policy and Objects on page 848 .

Security Profiles	Configure your FortiGate's security features, including Antivirus, Web Filter, and Application Control. For more information, see Security Profiles on page 1170 .
VPN	Configure options for IPsec and SSL virtual private networks (VPNs). For more information, see IPsec VPNs on page 1437 and SSL VPN on page 1718 .
User & Authentication	Configure user accounts, groups, and authentication methods, including external authentication and single sign-on (SSO).
WiFi & Switch Controller	Configure the unit to act as a wireless network controller, managing the wireless Access Point (AP) functionality of FortiWiFi and FortiAP units. On certain FortiGate models, this menu has additional features allowing for FortiSwitch units to be managed by the FortiGate. For more information, see Wireless configuration on page 2044 and Switch Controller on page 2045 .
System	Configure system settings, such as administrators, HA, FortiGuard, and certificates. For more information, see System on page 2046 .
Security Fabric	Access the physical topology, logical topology, automation, and settings of the Fortinet Security Fabric. For more information, see Fortinet Security Fabric on page 2360 .
Log & Report	Configure logging and alert email as well as reports. For more information, see Log and Report on page 2716 .

Tables

Many GUI pages contain tables of information that can be filtered and customized to display specific information in a specific way. Some tables allow content to be edited directly on that table, or rows to be copied and pasted.

Navigation

Some tables contain information and lists that span multiple pages. Navigation controls will be available at the bottom of the page.

Filters

Filters are used to locate a specific set of information or content in a table. They can be particularly useful for locating specific log entries. The filtering options vary, depending on the type of information in the log.

Depending on the table content, filters can be applied using the filter bar, using a column filter, or based on a cell's content. Some tables allow filtering based on regular expressions.

Administrators with read and write access can define filters. Multiple filters can be applied at one time.

To manually create a filter:

1. Click *Add Filter* at the top of the table. A list of the fields available for filtering is shown.
2. Select the field to filter by.
3. Enter the value to filter by, adding modifiers as needed.
4. Press *Enter* to apply the filter.

To create a column filter:

1. Click the filter icon on the right side of the column header
2. Choose a filter type from the available options.
3. Enter the filter text, or select from the available values.
4. Click *Apply*.

To create a filter based on a cell's content:

1. Right click on a cell in the table.
2. Select a filtering option from the menu.

Column settings

Columns can be rearranged, resized, and added or removed from tables.

To add or remove columns:

1. Right a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Select columns to add or remove.
3. Click *Apply*.

To rearrange the columns in a table:

1. Click and drag the column header.

To resize a column:

1. Click and drag the right border of the column header.

To resize a column to fit its contents:

1. Click the dots or filter icon on the right side of the column header and select *Resize to Contents*.

To resize all of the columns in a table to fit their content:

1. Right a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Click *Best Fit All Columns*.

To reset a table to its default view:

1. Right a column header, or click the gear icon on the left side of the header row that appears when hovering the cursor over the headers.
2. Click *Reset Table*.
Resetting a table does not remove filters.

Editing objects

In some tables, parts of a configuration can be edited directly in the table. For example, security profiles can be added to an existing firewall policy by clicking the edit icon in a cell in the *Security Profiles* column.

Copying rows

In some tables, rows can be copied and pasted using the right-click menu. For example, a policy can be duplicated by copying and pasting it.

Entering values

Numerous fields in the GUI and CLI require text strings or numbers to be entered when configuring the FortiGate. When entering values in the GUI, you will be prevented from entering invalid characters, and a warning message will be shown explaining what values are not allowed. If invalid values are entered in a CLI command, the setting will be rejected when you apply it.

- [Text strings on page 38](#)
- [Numbers on page 39](#)

Text strings

Text strings are used to name entities in the FortiGate configuration. For example, the name of a firewall address, administrator, or interface are all text strings.

The following characters cannot be used in text strings, as they present cross-site scripting (XSS) vulnerabilities:

- ` - double quotes
- ' - single quote
- > - greater than
- < - less than

Most GUI text fields prevent XSS vulnerable characters from being added.

VDOM names and hostnames can only use numbers (0-9), letters (a-z and A-Z), dashes, and underscores.

The `tree` CLI command can be used to view the number of characters allowed in a name field. For example, entering the following commands show that a firewall address name can contain up to 80 characters, while its FQDN can contain 256 characters:

```

tree firewall address
-- [address] --*name      (80)
  |- uuid
  |- subnet
  |- type
  |- sub-type
  |- clearpass-spt
  |- [macaddr] --*macaddr (128)
  |- start-ip
  |- end-ip
  |- fqdn (256)
  |- country (3)
  |- wildcard-fqdn (256)
  |- cache-ttl (0,86400)
  |- wildcard
  |- sdn (36)
  |- [fssso-group] --*name (512)
  |- interface (36)
  |- tenant (36)
  |- organization (36)
  |- epg-name (256)
  |- subnet-name (256)
  |- sdn-tag (16)
  |- policy-group (16)
  |- obj-tag (256)
  |- obj-type
  |- tag-detection-level (16)
  |- tag-type (64)
  |- dirty
  |- comment
  |- associated-interface (36)
  |- color (0,32)
  |- filter
  |- sdn-addr-type
  |- node-ip-only
  |- obj-id
  |- [list] --*ip (36)
      |- obj-id (128)
      +- net-id (128)
  |- [tagging] --*name (64)
      |- category (64)
      +- [tags] --*name (80)
  |- allow-routing
  +- fabric-object

```

Numbers

Numbers are used to set sizes, rates, addresses, port numbers, priorities, and other such numeric values. They can be entered as a series of digits (without commas or spaces), in a dotted decimal format (such as IP addresses), or separated by colons (such as MAC addresses). Most numeric values use base 10 numbers, while some use hexadecimal values.

Most GUI and CLI fields prevent invalid numbers from being entered. The CLI help text includes information about the range of values allowed for applicable settings.

GUI-based global search

The global search option in the GUI allows users to search for keywords appearing in objects and navigation menus to quickly access the object and configuration page. Click the magnifying glass icon in the top-left corner of the banner to access the global search.

The global search includes the following features:

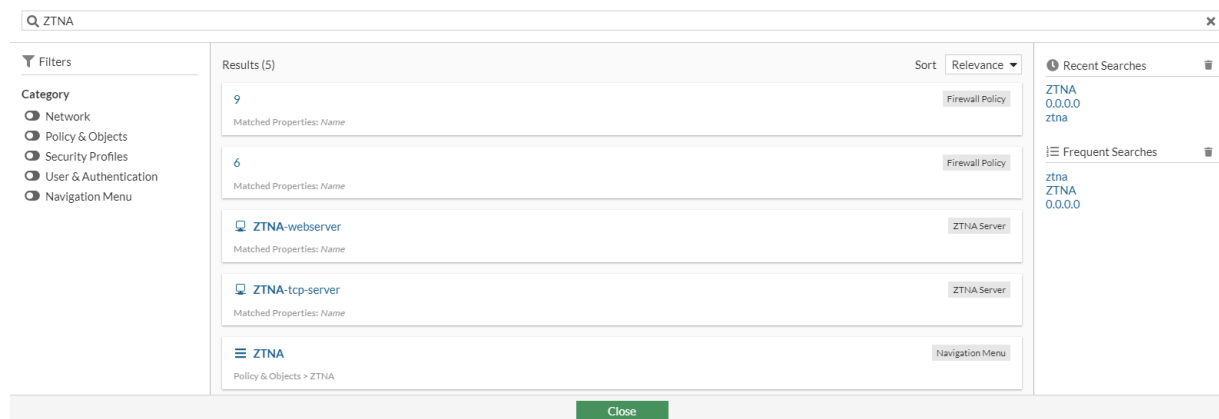

- Keep a history of frequent and recent searches
- Sort results alphabetically by increasing or decreasing order, and relevance by search weight
- Search by category
- Search in Security Fabric members (accessed by the Security Fabric members dropdown menu in the banner)

Examples

In this example, searching for the word *ZTNA* yields the following results:

- Firewall policy object *9*, which contains *ZTNA* in the property value, *Name*. The name of the policy is *ZTNA-TCP*.
- *ZTNA* server object *ZTNA-webserver*, which contains *ZTNA* in the property value, *Name*.
- *ZTNA* navigation menu item under *Policy & Objects > ZTNA*.

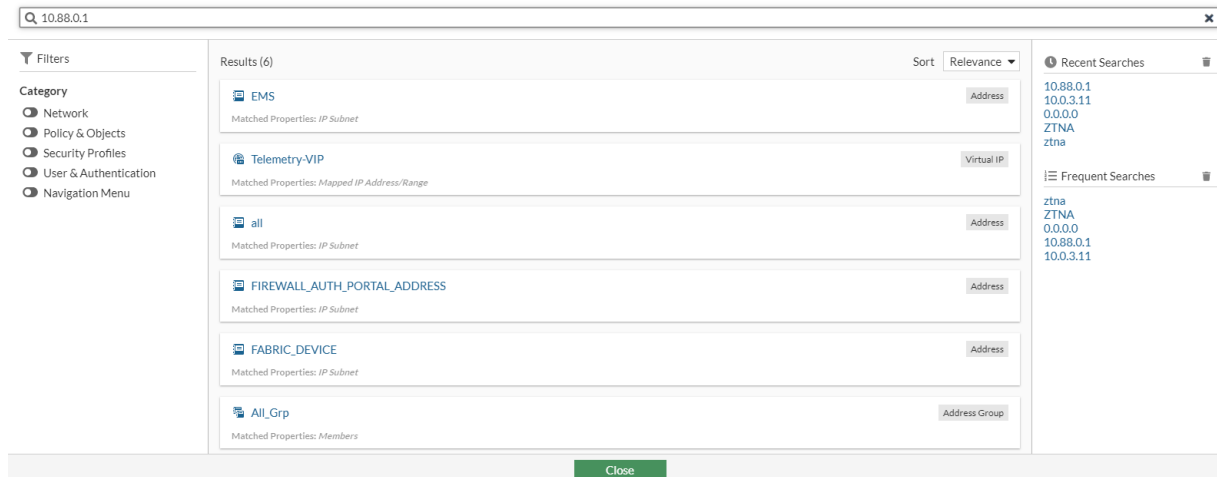

Since CMDB objects have a higher search weight (50) than navigation objects (20), the navigation menu result appears at the bottom.

In this example, searching for the address *10.88.0.1* yields the following results:

- Address object *EMS* that has a subnet of *10.88.0.1/32*, which matches the search term.
- Virtual IP object *Telemetry-VIP* that has a mapped IP range of *10.88.0.1*, which matches the search term.
- Address objects *all*, *FIREWALL_AUTH_PORTAL_ADDRESS*, and *FABRIC_DEVICE* that have IP subnets of *0.0.0.0/0*, which the searched term falls into.
- Address group object *All_Grp* that contains members addresses that have IP subnets of *0.0.0.0/0*, which the searched term falls into.

Sorting by *Relevance* will display address objects that are more closely matched at the top (*10.88.0.1*), and more loosely matched at the bottom (*0.0.0.0*).

Loading artifacts from a CDN

To improve GUI performance, loading static GUI artifacts cached in CDN (content delivery network) servers closer to the user instead of the FortiGate can be enabled. This allows the GUI to load more quickly with less latency for administrators who are accessing the FortiGate remotely. Upon failure, the files fall back to loading from the FortiGate. The CDN is only used after successful administrator logins.

To configure loading static GUI files from a CDN:

```
config system global
    set gui-cdn-usage {enable | disable}
end
```

Using the CLI

The Command Line Interface (CLI) can be used in lieu of the GUI to configure the FortiGate. Some settings are not available in the GUI, and can only be accessed using the CLI.

This section briefly explains basic CLI usage. For more information about the CLI, see the [FortiOS CLI Reference](#).

- [Connecting to the CLI on page 41](#)
- [CLI basics on page 44](#)
- [Command syntax on page 50](#)
- [Subcommands on page 53](#)
- [Permissions on page 55](#)

Connecting to the CLI

You can connect to the CLI using a direct console connection, SSH, the FortiExplorer app on your iOS device, or the CLI console in the GUI.

You can access the CLI outside of the GUI in three ways:

- **Console connection:** Connect your computer directly to the console port of your FortiGate.
- **SSH access:** Connect your computer through any network interface attached to one of the network ports on your FortiGate.
- **FortiExplorer:** Connect your device to the FortiExplorer app on your iOS device to configure, manage, and monitor your FortiGate. See [Using FortiExplorer Go and FortiExplorer on page 56](#) for details.

To open a CLI console, click the `_>` icon in the top right corner of the GUI. The console opens on top of the GUI. It can be minimized and multiple consoles can be opened.

To edit policies and objects directly in the CLI, right-click on the element and select *Edit in CLI*.

Console connection

A direct console connection to the CLI is created by directly connecting your management computer or console to the FortiGate using its DB-9 or RJ-45 console port.

Direct console access to the FortiGate may be required if:

- You are installing the FortiGate for the first time and it is not configured to connect to your network.
- You are restoring the firmware using a boot interrupt. Network access to the CLI will not be available until after the boot process has completed, making direct console access the only option.

To connect to the FortiGate console, you need:

- A console cable to connect the console port on the FortiGate to a communications port on the computer. Depending on your device, this is one of:
 - null modem cable (DB-9 to DB-9)
 - DB-9 to RJ-45 cable (a DB-9-to-USB adapter can be used)
 - USB to RJ-45 cable
- A computer with an available communications port
- Terminal emulation software

To connect to the CLI using a direct console connection:

1. Using the console cable, connect the FortiGate unit's console port to the serial communications (COM) port on your management computer.
2. Start a terminal emulation program on the management computer, select the COM port, and use the following settings:

Bits per second	9600
Data bits	8
Parity	None
Stop bits	1
Flow control	None

3. Press *Enter* on the keyboard to connect to the CLI.
4. Log in to the CLI using your username and password (default: *admin* and no password). You can now enter CLI commands, including configuring access to the CLI through SSH.

SSH access

SSH access to the CLI is accomplished by connecting your computer to the FortiGate using one of its network ports. You can either connect directly, using a peer connection between the two, or through any intermediary network.

If you do not want to use an SSH client and you have access to the GUI, you can access the CLI through the network using the CLI console in the GUI.

SSH must be enabled on the network interface that is associated with the physical network port that is used.

If your computer is not connected either directly or through a switch to the FortiGate, you must also configure the FortiGate with a static route to a router that can forward packets from the FortiGate to the computer. This can be done using a local console connection, or in the GUI.

To connect to the FortiGate CLI using SSH, you need:

- A computer with an available serial communications (COM) port and RJ-45 port
- An appropriate console cable
- Terminal emulation software
- A network cable
- Prior configuration of the operating mode, network interface, and static route.

To enable SSH access to the CLI using a local console connection:

1. Using the network cable, connect the FortiGate unit's port either directly to your computer's network port, or to a network through which your computer can reach the FortiGate.
2. Note the number of the physical network port.
3. Using direct console connection, connect and log into the CLI.
4. Enter the following command:

```
config system interface
  edit <interface_str>
    append allowaccess ssh
  next
end
```

Where `<interface_str>` is the name of the network interface associated with the physical network port, such as `port1`.

5. Confirm the configuration using the following command to show the interface's settings:

```
show system interface <interface_str>
```

For example:

```
show system interface port1
config system interface
  edit "port1"
    set vdom "root"
    set ip 192.168.1.99 255.255.255.0
    set allowaccess ping https ssh
    set type hard-switch
    set stp enable
    set role lan
```

```
        set snmp-index 6
    next
end
```

Connecting using SSH

Once the FortiGate is configured to accept SSH connections, use an SSH client on your management computer to connect to the CLI.

The following instructions use PuTTY. The steps may vary in other terminal emulators.

To connect to the CLI using SSH:

1. On your management computer, start PuTTY.
2. In the *Host Name (or IP address)* field, enter the IP address of the network interface that you are connected to and that has SSH access enabled.
3. Set the port number to 22, if it is not set automatically.
4. Select *SSH* for the *Connection type*.
5. Click *Open*. The SSH client connect to the FortiGate.
The SSH client may display a warning if this is the first time that you are connecting to the FortiGate and its SSH key is not yet recognized by the SSH client, or if you previously connected to the FortiGate using a different IP address or SSH key. This is normal if the management computer is connected directly to the FortiGate with no network hosts in between.
6. Click *Yes* to accept the FortiGate's SSH key.
The CLI displays the log in prompt.
7. Enter a valid administrator account name, such as `admin`, then press *Enter*.
8. Enter the administrator account password, then press *Enter*.
The CLI console shows the command prompt (FortiGate hostname followed by a #). You can now enter CLI commands.

If three incorrect log in or password attempts occur in a row, you will be disconnected. If this occurs, wait for one minute, then reconnect and attempt to log in again.

CLI basics

Basic features and characteristics of the CLI environment provide support and ease of use for many CLI tasks.

Help

Press the question mark (?) key to display command help and complete commands.

- Press the question mark (?) key at the command prompt to display a list of the commands available and a description of each command.
- Enter a command followed by a space and press the question mark (?) key to display a list of the options available for that command and a description of each option.
- Enter a command followed by an option and press the question mark (?) key to display a list of additional options available for that command option combination and a description of each option.

- Enter a question mark after entering a portion of a command to see a list of valid complete commands and their descriptions. If there is only one valid command, it will be automatically filled in.

Shortcuts and key commands

Shortcut key	Action
?	List valid complete or subsequent commands. If multiple commands can complete the command, they are listed with their descriptions.
Tab	Complete the word with the next available match. Press multiple times to cycle through available matches.
Up arrow or Ctrl + P	Recall the previous command. Command memory is limited to the current session.
Down arrow, or Ctrl + N	Recall the next command.
Left or Right arrow	Move the cursor left or right within the command line.
Ctrl + A	Move the cursor to the beginning of the command line.
Ctrl + E	Move the cursor to the end of the command line.
Ctrl + B	Move the cursor backwards one word.
Ctrl + F	Move the cursor forwards one word.
Ctrl + D	Delete the current character.
Ctrl + C	Abort current interactive commands, such as when entering multiple lines. If you are not currently within an interactive command such as <code>config</code> or <code>edit</code> , this closes the CLI connection.
\ then Enter	Continue typing a command on the next line for a multiline command. For each line that you want to continue, terminate it with a backslash (\). To complete the command, enter a space instead of a backslash, and then press <i>Enter</i> .

Command tree

Enter `tree` to display the CLI command tree. To capture the full output, connect to your device using a terminal emulation program and capture the output to a log file. For some commands, use the `tree` command to view all available variables and subcommands.

Command abbreviation

You can abbreviate words in the command line to their smallest number of non-ambiguous characters.

For example, the command `get system status` could be abbreviated to `g sy stat`.

Adding and removing options from lists

When configuring a list, the `set` command will remove the previous configuration.

For example, if a user group currently includes members A, B, and C, the command `set member D` will remove members A, B, and C. To avoid removing the existing members from the group, the command `set members A B C D` must be used.

To avoid this issue, the following commands are available:

append	Add an option to an existing list. For example, <code>append member D</code> adds user D to the user group without removing any of the existing members.
select	Clear all of the options except for those specified. For example, <code>select member B</code> removes all member from the group except for member B.
unselect	Remove an option from an existing list. For example, <code>unselect member C</code> removes only member C from the group, without affecting the other members.

Environment variables

The following environment variables are support by the CLI. Variable names are case-sensitive.

\$USERFROM	The management access type (<code>ssh</code> , <code>jsconsole</code> , and so on) and the IPv4 address of the administrator that configured the item.
\$USERNAME	The account name of the administrator that configured the item.
\$SerialNum	The serial number of the FortiGate.

For example, to set a FortiGate device's host name to its serial number, use the following CLI command:

```
config system global
    set hostname $SerialNum
end
```

Special characters

The following characters cannot be used in most CLI commands: `<`, `>`, `(`, `)`, `#`, `'`, and `"`

If one of those characters, or a space, needs to be entered as part of a string, it can be entered by using a special command, enclosing the entire string in quotes, or preceding it with an escape character (backslash, `\`).

To enter a question mark (`?`) or a tab, `Ctrl + V` or `Ctrl + Shift + -` must be entered first.

Question marks and tabs cannot be copied into the CLI Console or some SSH clients. They must be typed in.

Character	Keys
?	Ctrl + V or Ctrl + Shift + - then ?
Tab	Ctrl + V then Tab
Space (as part of a string value, not to end the string)	Enclose the string in single or double quotation marks: "Security Administrator" or 'Security Administrator'. Precede the space with a backslash: Security\ Administrator.
' (as part of a string value, not to begin or end the string)	\'
" (as part of a string value, not to begin or end the string)	\"
\	\\

Using grep to filter command output

The `get`, `show`, and `diagnose` commands can produce large amounts of output. The `grep` command can be used to filter the output so that it only shows the required information.

The `grep` command is based on the standard UNIX `grep`, used for searching text output based on regular expressions.

For example, the following command displays the MAC address of the internal interface:

```
get hardware nic internal | grep Current_HWaddr
Current_HWaddr          00:09:0f:cb:c2:75
```

The following command will display all TCP sessions that are in the session list, including the session list line number in the output:

```
get system session list | grep -n tcp
```

The following command will display all of the lines in the HTTP replacement message that contain `URL` or `url`:

```
show system replacemsg http | grep -i url
```

The following options can also be used:

```
-A <num> After
-B <num> Before
-C <num> Context
```

The `-f` option is available to support contextual output, in order to show the complete configuration. The following example shows the difference in the output when `-f` is used versus when it is not used:

Without `-f`:

```
show | grep ldap-group1
edit "ldap-group1"
set groups "ldap-group1"
```

With `-f`:

```
show | grep -f ldap-group1
config user group
edit "ldap-group1"
```

```
        set member "pc40-LDAP"
    next
end
config firewall policy
    edit 2
        set srcintf "port31"
        set dstintf "port32"
        set srcaddr "all"
        set action accept
        set identity-based enable
        set nat enable
        config identity-based-policy
            edit 1
                set schedule "always"
                set groups "ldap-group1"
                set dstaddr "all"
                set service "ALL"
            next
        next
    end
next
end
```

Language support and regular expressions

Characters such as ñ and é, symbols, and ideographs are sometimes acceptable input. Support varies depending on the type of item that is being configured. CLI commands, objects, field names, and options must use their exact ASCII characters, but some items with arbitrary names or values can be input using your language of choice. To use other languages in those cases, the correct encoding must be used.

Input is stored using Unicode UTF-8 encoding, but is not normalized from other encodings into UTF-8 before it is stored. If your input method encodes some characters differently than in UTF-8, configured items may not display or operate as expected.

Regular expressions are especially impacted. Matching uses the UTF-8 character values. If you enter a regular expression using a different encoding, or if an HTTP client sends a request in a different encoding, matches may not be what is expected.

For example, with Shift-JIS, backslashes could be inadvertently interpreted as the symbol for the Japanese yen (¥), and vice versa. A regular expression intended to match HTTP requests containing monetary values with a yen symbol may not work if the symbol is entered using the wrong encoding.

For best results:

- use UTF-8 encoding, or
- use only characters whose numerically encoded values are the same in UTF-8, such as the US-ASCII characters that are encoded using the same values in ISO 8859-1, Windows code page 1252, Shift-JIS, and other encoding methods, or
- for regular expressions that must match HTTP requests, use the same encoding as your HTTP clients.

HTTP clients may send requests in encodings other than UTF-8. Encodings usually vary based on the client's operating system or input language. If the client's encoding method cannot be predicted, you might only be able to match the parts of the request that are in English, as the values for English characters tend to be encoded identically, regardless of the encoding method.

If the FortiGate is configured to use an encoding method other than UTF-8, the management computer's language may need to be changed, including the web browser and terminal emulator. If the FortiGate is configured using non-ASCII characters, all the systems that interact with the FortiGate must also support the same encoding method. If possible, the same encoding method should be used throughout the configuration to avoid needing to change the language settings on the management computer.

The GUI and CLI client normally interpret output as encoded using UTF-8. If they do not, configured items may not display correctly. Exceptions include items such as regular expression that may be configured using other encodings to match the encoding of HTTP requests that the FortiGate receives.

To enter non-ASCII characters in a terminal emulator:

1. On the management computer, start the terminal client.
2. Configure the client to send and receive characters using UTF-8 encoding.
Support for sending and receiving international characters varies by terminal client.
3. Log in to the FortiGate.
4. At the command prompt, type your command and press *Enter*.
Words that use encoded characters may need to be enclosed in single quotes (').
Depending on your terminal client's language support, you may need to interpret the characters into character codes before pressing *Enter*. For example, you might need to enter: `edit '\743\601\613\743\601\652'`
5. The CLI displays the command and its output.

Screen paging

By default, the CLI will pause after displaying each page worth of text when a command has multiple pages of output. This can be useful when viewing lengthy outputs that might exceed the buffer of terminal emulator.

When the display pauses and shows `--More--`, you can:

- Press *Enter* to show the next line,
- Press *Q* to stop showing results and return to the command prompt,
- Press an arrow key, *Insert*, *Home*, *Delete*, *End*, *Page Up*, or *Page Down* to show the next few pages,
- Press any other key to show the next page, or
- Wait for about 30 seconds for the console to truncate the output and return to the command prompt.

When pausing the screen is disabled, press *Ctrl + C* to stop the output and log out of the FortiGate.

To disable pausing the CLI output:

```
config system console
    set output standard
end
```

To enable pausing the CLI output:

```
config system console
  set output more
end
```

Changing the baud rate

The baud rate of the local console connection can be changed from its default value of 9600.

To change the baud rate:

```
config system console
  set baudrate {9600 | 19200 | 38400 | 57600 | 115200}
end
```

Editing the configuration file

The FortiGate configuration file can be edited on an external host by backing up the configuration, editing the configuration file, and then restoring the configuration to the FortiGate.

Editing the configuration file can save time if many changes need to be made, particularly if the plain text editor that you are using provides features such as batch changes.

To edit the configuration file:

1. Backup the configuration. See [Configuration backups and reset on page 2355](#) for details.
2. Open the configuration file in a plain text editor that supports UNIX-style line endings.
3. Edit the file as needed.

Do not edit the first line of the configuration file.

This line contains information about the firmware version and FortiGate model. If you change the model number, the FortiGate will reject the configuration when you attempt to restore it.

4. Restore the modified configuration to the FortiGate. See [Configuration backups and reset on page 2355](#) for details. The FortiGate downloads the configuration file and checks that the model information is correct. If it is correct, the configuration file is loaded and each line is checked for errors. If a command is invalid, that command is ignored. If the configuration file is valid, the FortiGate restarts and loads the downloaded configuration.

Command syntax

When entering a command, the CLI console requires that you use valid syntax and conform to expected input constraints. It rejects invalid commands. Indentation is used to indicate the levels of nested commands.

Each command line consists of a command word, usually followed by configuration data or a specific item that the command uses or affects.

Notation

Brackets, vertical bars, and spaces are used to denote valid syntax. Constraint notations, such as `<address_ipv4>`, indicate which data types or string patterns are acceptable value input.

All syntax uses the following conventions:

Angle brackets < >	Indicate a variable of the specified data type.
Curly brackets { }	Indicate that a variable or variables are mandatory.
Square brackets []	Indicate that the variable or variables are optional. For example: <code>show system interface [<name_str>]</code> To show the settings for all interfaces, you can enter <code>show system interface</code> To show the settings for the Port1 interface, you can enter <code>show system interface port1</code> .
Vertical bar 	A vertical bar separates alternative, mutually exclusive options. For example: <code>set protocol {ftp sftp}</code> You can enter either <code>set protocol ftp</code> or <code>set protocol sftp</code> .
Space	A space separates non-mutually exclusive options. For example: <code>set allowaccess {ping https ssh snmp http fgfm radius-acct probe-response capwap ftm}</code> You can enter any of the following: <code>set allowaccess ping</code> <code>set allowaccess https ping ssh</code> <code>set allowaccess http https snmp ssh ping</code> In most cases, to make changes to lists that contain options separated by spaces, you need to retype the entire list, including all the options that you want to apply and excluding all the options that you want to remove.

Optional values and ranges

Any field that is optional will use square-brackets. The overall config command will still be valid whether or not the option is configured.

Square-brackets can be used to show that multiple options can be set, even intermixed with ranges. The following example shows a field that can be set to either a specific value or range, or multiple instances:

```
config firewall service custom
    set iprange <range1> [<range2> <range3> ...]
end
```

next

The `next` command is used to maintain a hierarchy and flow to CLI commands. It is at the same indentation level as the preceding `edit` command, to mark where a table entry finishes.

The following example shows the next command used in the subcommand `entries`:

```
config dlp filepattern
  edit <1>
    set name <name>
    set comment [comment]
    config entries
      edit <2>
        set filter-type {pattern | type}
      next
    ←
```

After configuring table entry <2> then entering `next`, the <2> table entry is saved and the console returns to the `entries` prompt:

```
FGT60E1Q23456789 (entries) #
```

You can now create more table entries as needed, or enter `end` to save the table and return to the `filepattern` table element prompt.

end

The `end` command is used to maintain a hierarchy and flow to CLI commands.

The following example shows the same command and subcommand as the `next` command example, except `end` has been entered instead of `next` after the subcommand:

```
config dlp filepattern
  edit <1>
    set name <name>
    set comment [comment]
    config entries
      edit <2>
        set filter-type {pattern | type}
      end
    ←
```

Entering `end` will save the <2> table entry and the table, and exit the `entries` subcommand entirely. The console returns to the `filepattern` table element prompt:

```
FGT60E1Q23456789 (1) #
```

Subcommands

Subcommands are available from within the scope of some commands. When you enter a subcommand level, the command prompt changes to indicate the name of the current command scope. For example, after entering:

```
config system admin
```

the command prompt becomes:

```
(admin)#
```

Applicable subcommands are available until you exit the command, or descend an additional level into another subcommand. Subcommand scope is indicated by indentation.

For example, the `edit` subcommand is only available in commands that affects tables, and the `next` subcommand is available only in the `edit` subcommand:

```
config system interface
  edit port1
    set status up
  next
end
```

The available subcommands vary by command. From a command prompt under the `config` command, subcommands that affect tables and fields could be available.

Table subcommands

edit <table_row>

Create or edit a table value.

In objects such as security policies, <table_row> is a sequence number. To create a new table entry without accidentally editing an existing entry, enter `edit 0`. The CLI will confirm that creation of entry 0, but will assign the next unused number when the entry is saved after entering `end` or `next`.

For example, to create a new firewall policy, enter the following commands:

```
config firewall policy
  edit 0
  ....
  next
end
```

To edit an existing policy, enter the following commands:

```
config firewall policy
  edit 27
  ....
  next
end
```

The `edit` subcommand changes the command prompt to the name of the table value that is being edited.

delete <table_row>

Delete a table value.

For example, to delete firewall policy 30, enter the following commands:

```
config firewall policy
  delete 30
end
```

purge	<p>Clear all table values.</p> <p>The <code>purge</code> command cannot be undone. To restore purged table values, the configuration must be restored from a backup.</p>
move	<p>Move an ordered table value.</p> <p>In the firewall policy table, this equivalent to dragging a policy into a new position. It does not change the policy's ID number.</p> <p>For example, to move policy 27 to policy 30, enter the following commands:</p> <pre>config firewall policy move 27 to 30 end</pre> <p>The <code>move</code> subcommand is only available in tables where the order of the table entries matters.</p>
clone <table_row> to <table_row>	<p>Make a clone of a table entry.</p> <p>For example, to create firewall policy 30 as a clone of policy 27, enter the following commands:</p> <pre>config firewall policy clone 27 to 30 end</pre> <p>The <code>clone</code> subcommand may not be available for all tables.</p>
rename <table_row> to <table_row>	<p>Rename a table entry.</p> <p>For example to rename an administrator from Flank to Frank, enter the following commands:</p> <pre>config system admin rename Flank to Frank end</pre> <p>The <code>rename</code> subcommand is only available in tables where the entries can be renamed.</p>
get	<p>List the current table entries.</p> <p>For example, to view the existing firewall policy table entries, enter the following commands:</p> <pre>config firewall policy get</pre>
show	<p>Show the configuration. Only table entries that are not set to default values are shown.</p>
end	<p>Save the configuration and exit the current <code>config</code> command.</p>

Purging the `system interface` or `system admin` tables does not reset default table values. This can result in being unable to connect to or log in to the FortiGate, requiring the FortiGate to be formatted and restored.

Field subcommands

set <field> <value>	Modify the value of a field.
--	------------------------------

	For example, the command <code>set fssso enable</code> sets the <code>fssso</code> field to the value <code>enable</code> .
unset	Set the field to its default value.
select	Clear all of the options except for those specified. For example, if a group contains members A, B, C, and D, to remove all members except for B, use the command <code>select member B</code> .
unselect	Remove an option from an existing list. For example, if a group contains members A, B, C, and D, to remove only member B, use the command <code>unselect member B</code> .
append	Add an option to an existing multi-option table value.
clear	Clear all the options from a multi-option table value.
get	List the configuration of the current table entry, including default and customized values.
show	Show the configuration. Only values that are not set to default values are shown.
next	Save changes to the table entry and exit the <code>edit</code> command so that you can configure the next table entry.
abort	Exit the command without saving.
end	Save the configuration and exit the current <code>config</code> command.

Permissions

Administrator (or access) profiles control what CLI commands an administrator can access by assigning read, write, or no access to each area of FortiOS. For information, see [Administrator profiles on page 2049](#).

Read access is required to view configurations. Write access is required to make configuration changes. Depending on your account's profile, you may not have access to all CLI commands. To have access to all CLI commands, an administrator account with the `super_admin` profile must be used, such as the `admin` account.

Accounts assigned the `super_admin` profile are similar to the root administrator account. They have full permission to view and change all FortiGate configuration options, including viewing and changing other administrator accounts.

To increase account security, set strong passwords for all administrator accounts, and change the passwords regularly.

Configuration and management

FortiOS can be managed through the graphical user interface (GUI) or the Command Line Interface (CLI) as well as other tools.

For	Use
Direct or individual configuration	FortiOS GUI and CLI. See Using the GUI on page 34 and Using the CLI on page 41 .

For	Use
	FortiExplorer Go and FortiExplorer. See Using FortiExplorer Go and FortiExplorer on page 56 .
Mass provisioning, management, and orchestration	FortiManager and FortiGate Cloud. See the FortiManager page and the FortiGate Cloud page on the Fortinet Document Library.
Automation	REST API accessible through Fortinet Developer Network (FNDN). See Accessing Fortinet Developer Network on page 63 and REST API administrator . Automation tools, such as Terraform and Ansible. See Terraform: FortiOS as a provider on page 67 .

Using FortiExplorer Go and FortiExplorer

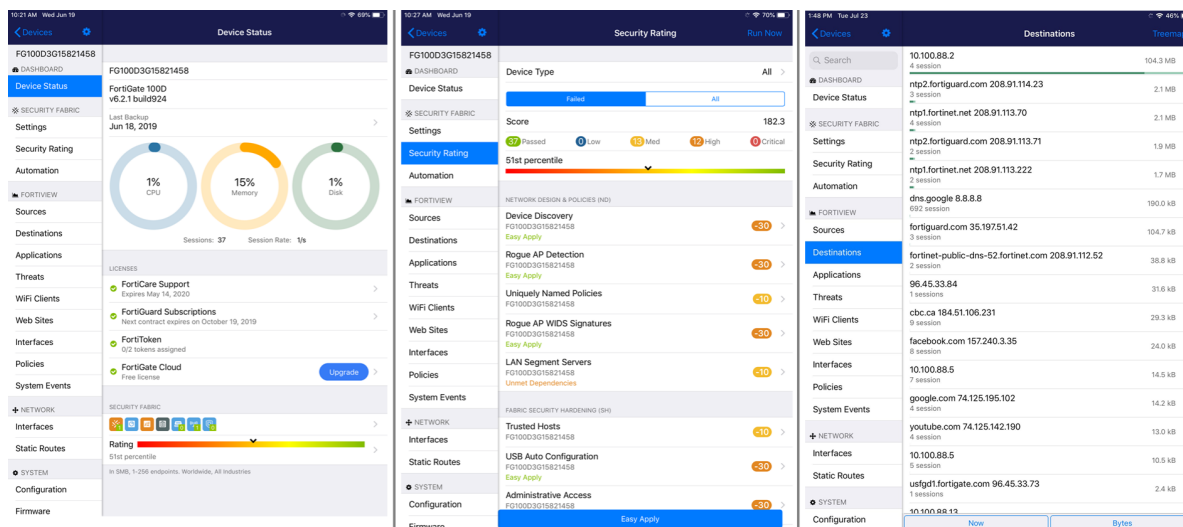

FortiExplorer Go

FortiExplorer Go is a free mobile application that provisions and deploys BLE capable FortiGates with the BLE Autodiscovery feature. You can also use FortiExplorer Go to remotely manage FortiGates registered to your FortiCare account and deployed in FortiGate Cloud.

FortiExplorer Go is available on both iOS and Android devices. For more information, refer to the [FortiExplorer Go User Guide](#) for your respective device OS.

FortiExplorer management

FortiExplorer for iOS is a user-friendly application that helps you to rapidly provision, deploy, and monitor Security Fabric components from your iOS device.

FortiExplorer for iOS requires iOS 10.0 or later and is compatible with iPhone, iPad, and Apple TV. It is supported by FortiOS 5.6 and later, and is available on the [App Store](#) for iOS devices.

Up to six members can use this app with 'Family Sharing' enabled in the App Store.

Firmware upload requires a valid firmware license. Users can download firmware for models with a valid support contract.

Getting started with FortiExplorer

If your FortiGate is accessible on a wireless network, you can connect to it using FortiExplorer provided that your iOS device is on the same network. See [Connecting FortiExplorer to a FortiGate with WiFi](#). If your 200F series or 80F series FortiGate is in close proximity, you can connect to it using FortiExplorer using Bluetooth Low Energy (BLE). See [Configure FortiGate with FortiExplorer using BLE on page 61](#). Otherwise, you will need to physically connect your iOS device to the FortiGate using a USB cable.

To connect and configure a FortiGate with FortiExplorer using a USB connection:

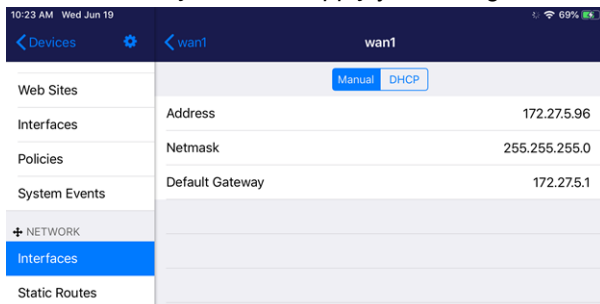

1. Connect your iOS device to your FortiGate USB A port. If prompted on your iOS device, *Trust* this computer.
2. Open FortiExplorer and select your FortiGate from the *FortiGate Devices* list . A blue USB icon will indicate that you are connected over a USB connection.

3. On the *Login* screen, select *USB*.
4. Enter the default *Username* (*admin*) and leave the *Password* field blank.
5. Optionally, select *Remember Password*.
6. Tap *Done* when you are ready.
FortiExplorer opens the FortiGate management interface to the *Device Status* page:

7. Go to *Network > Interfaces* and configure the WAN interface or interfaces.
8. The *wan1* interface *Address mode* is set to *DHCP* by default. Set it to *Manual* and enter its *Address*, *Netmask*, and *Default Gateway*, and then *Apply* your changes.

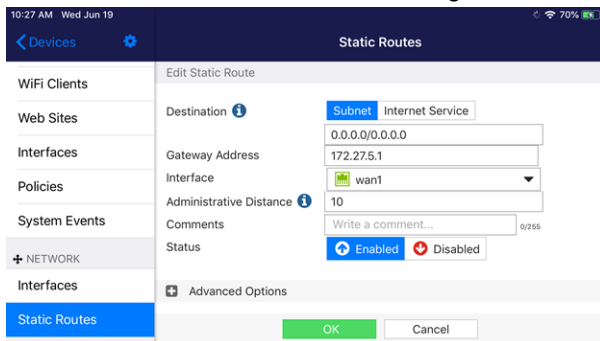

9. Optionally, configure *Administrative Access* to allow *HTTPS* access. This will allow administrators to access the FortiGate GUI using a web browser.

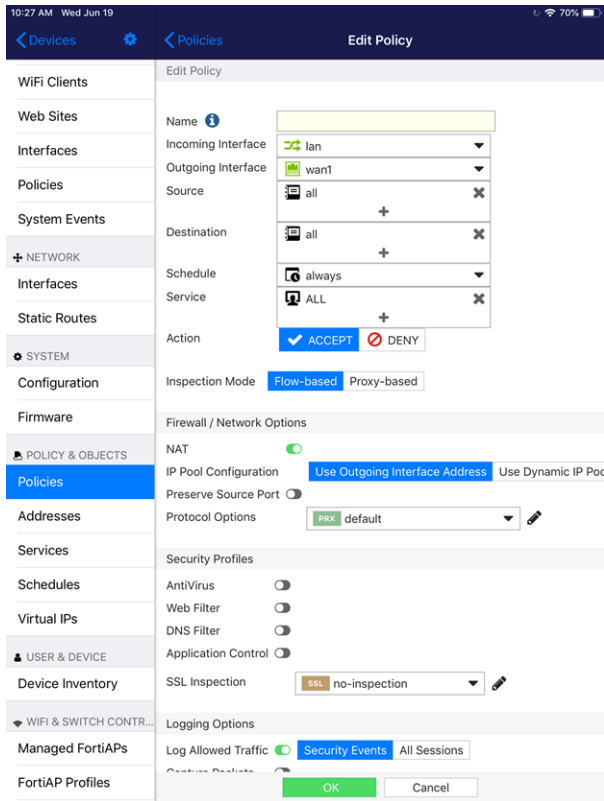

10. Go to *Network > Interfaces* and configure the local network (internal) interface.
11. Set the *Address* mode as before and configure *Administrative Access* if required.
12. Configure a *DHCP Server* for the internal network subnet.

13. Return to the internal interface using the < button at the top of the screen.
14. Go to *Network > Static Routes* and configure the static route to the gateway.

15. Go to *Policy & Objects > Firewall Policy* and edit the Internet access policy. Enter a *Name* for the policy, enable the required *Security Profiles*, configure *Logging Options*, then tap *OK*.

Connecting FortiExplorer to a FortiGate with WiFi

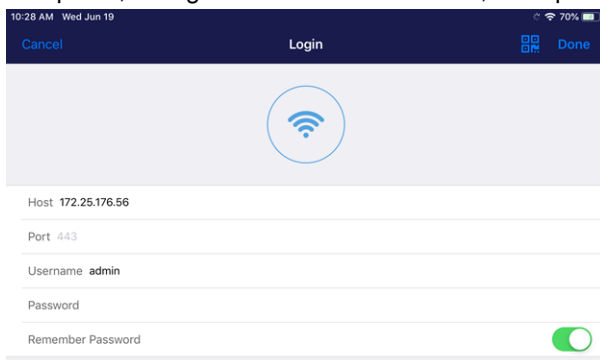

You can wirelessly connect to the FortiGate if your iOS device and the FortiGate are both connected to the same wireless network.

To connect and configure a FortiGate with FortiExplorer wirelessly:

1. Open the FortiExplorer app and tap *Add* on the *Devices* page.
2. On the *Add Device By* page, tap *HTTPS*.

3. Enter the *Host* information, *Username*, and *Password*.
4. If required, change the default *Port* number, and optionally enable *Remember Password*.

5. Tap *Done*.
6. If the FortiGate device identity cannot be verified, tap *Connect* at the prompt. FortiExplorer opens the FortiGate management interface to the *Device Status* page.

Configure FortiGate with FortiExplorer using BLE

FortiGate 200F series and 80F series devices can be initially configured in FortiExplorer using Bluetooth Low Energy (BLE).

The state of the status LED on the device shows if BLE is enabled. See the device QuickStart guides for more information about LED states: [FortiGate 200F Series QuickStart Guide](#) and [FortiGate 80F Series QuickStart Guide](#).

When the status LED is flashing green, pressing and holding the reset button for five seconds or longer will reset the device to factory default settings.

BLE is enabled or disabled in the following scenarios after the FortiGate boots up:

- In factory default settings:
 - After the FortiGate has finished booting up (when the console login prompt is shown), the status LED will be flashing amber or red to indicate that BLE is enabled.
 - If the FortiGate is configured without using BLE, BLE will immediately be disabled and the status LED will turn solid green.
 - If the FortiGate is configured using BLE, the LED will continue flashing until the configuring device disconnects from BLE, after which BLE is disabled and the status LED turns solid green.
- Not in factory default configuration:
 - One minute after the FortiGate has finished booting up (when the console login prompt is shown), the status LED will turn solid green. Press and hold the reset button for one second. The status LED will start flashing to indicate that BLE is enabled.
 - If no BLE connection is made with the FortiGate, BLE will be disabled after one minute and the status LED will turn solid green.
 - If the FortiGate is configured without using BLE, BLE will immediately be disabled and the status LED will turn solid green.
 - If the FortiGate is configured using BLE, the LED will continue flashing until the configuring device disconnects from BLE, after which BLE is disabled and the status LED turns solid green.

To enable BLE for one minute when the FortiGate is running and not in factory default configuration:

```
# diagnose bluetooth enable 1
```

To connect to and configure a FortiGate with FortiExplorer using BLE:

1. Ensure that BLE is enabled on the FortiGate device.
2. Enable Bluetooth on your iOS device and open the FortiExplorer app.
If the app has detected the FortiGate device, the device's serial number will be shown.
3. Log into the FortiGate in the app using the default credentials: *admin* and no password.
4. If this is the first time logging into the device, set a password.
5. Optionally, register with FortiCare.
6. Configure the FortiGate, including the WAN and internal interfaces, static routes, and other required settings.
After configuring the FortiGate and disconnecting, BLE is disabled.

To check the status of BLE on the FortiGate:

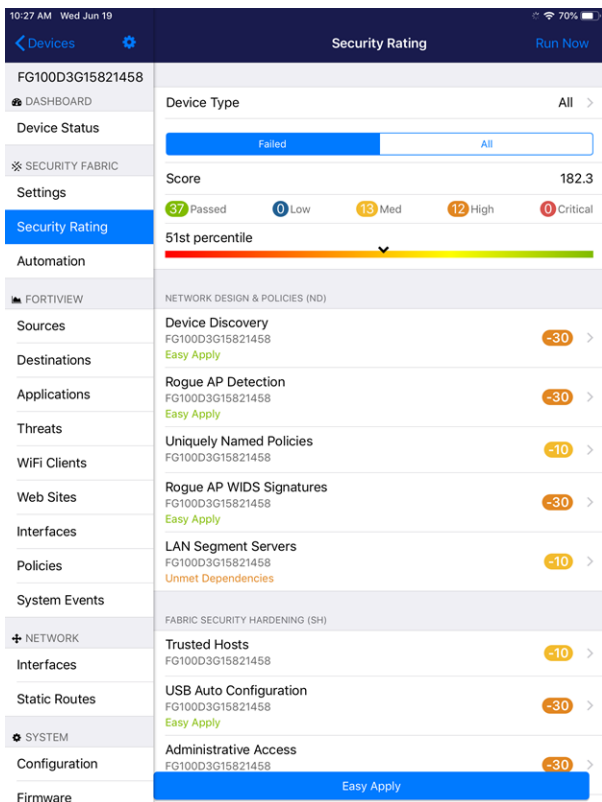

```
diagnose hardware test ble
diagnose bluetooth status
diagnose bluetooth get_bt_version
```

diagnose bluetooth clean_bt_mode

Running a security rating

After configuring your network, run a security rating check to identify vulnerabilities and highlight best practices that could improve your network's security and performance.

Go to *Security Fabric > Security Rating* and follow the steps to determine the score. See [Security rating on page 2499](#) for more information.

Accessing Fortinet Developer Network

The [Fortinet Developer Network \(FNDN\)](#) is a subscription-based community that helps administrators enhance and increase the effectiveness of Fortinet products. Administrators can access the FortiAPI forum in FNDN to help create applications that interact with Fortinet products, such as custom web portals, automated deployment and provisioning systems, and scripted tasks. FNDN makes it easy for administrators and Fortinet professionals to interact, share sample code, and upload their own tools. The [FortiOS REST API](#) documentation is available within the FortiAPI forum.

All FNDN users must be sponsored by two Fortinet employees. The sponsors must be able to confirm the user's identity and need for access. Approvals from both sponsors are required before access is granted to new users. The sponsors' email addresses are required to create a new FNDN account.

Basic and licensed access options are available. Refer to the [Fortinet Developer Network](#) data sheet for more information.

To create an FNDN account:

1. Obtain sponsorship from two Fortinet employees.
2. Go to the FNDN website, <https://fndn.fortinet.net/>. The log in page appears.

Fortinet Developer Network

Email Address

Password

Remember me

Sign In

[I forgot my password](#) [Create a new account](#)

3. Click *Create a new account*. The *Sign Up* page appears.

4. Enter the information in the form fields and agree to the *Terms of Use*.

Sign Up

Existing user? [Sign In](#)

Email Address *

Please enter a valid business email address. Public email accounts and aliases are not permitted.

Password *

Confirm Password *

All new accounts require two Fortinet Sponsors. Sponsors are Fortinet employees that can confirm your identity and validate your need for an FNDN account. Please enter emails of your Sponsors in the fields below and assure that they are correct.

Main Sponsor *

Supporting Sponsor *

Optional: If you have an FNDN contract, you can enter the associated activation code now or anytime after your account has been created. The activation code can be found in your Fortinet Support Center account.

Activation Code

Full name *

Personal social profiles

LinkedIn, Facebook or anything else.

Shipping address *

Beta hardware will be provided to FNDN users selected to participate in our hardware beta program. Your shipping address is where you wish to receive these hardware units.

Company name *

Company website *

Create my Account

5. Click *Create my Account*.

New accounts are reviewed and approved by an FNDN administrator. After both sponsors approve the request, an FNDN administrator reviews the request and approves account access in around one business day if all requirements are met.

Terraform: FortiOS as a provider

Fortinet's Terraform support provides customers with more ways to efficiently deploy, manage, and automate security across physical FortiGate appliances and virtual environments. You can use Terraform to automate various IT infrastructure needs, thereby diminishing mistakes from repetitive manual configurations.

For example, if Fortinet is releasing a new FortiOS version, your organization may require you to test a new functionality to determine how it may impact the environment before globally deploying the new version. In this case, the ability to rapidly stand up environments and test these functions prior to production environment integration provides a resource-efficient and fault-tolerant approach.

The following example demonstrates how to use the Terraform FortiOS provider to perform simple configuration changes on a FortiGate unit. It requires the following:

- FortiOS 6.0 or later
- [FortiOS Provider](#): This example uses terraform-provider-fortios 1.0.0.
- [Terraform](#): This example uses Terraform 0.11.14.
- REST API administrator created on the FortiGate with the API key

For more information, see the Terraform FortiOS Provider at <https://www.terraform.io/docs/providers/fortios/index.html>.

To create a REST API administrator:

1. On the FortiGate, go to *System > Administrators* and click *Create New > REST API Admin*.
2. Enter the *Username* and, optionally, enter *Comments*.
3. Select an *Administrator Profile*.
4. We recommend that you create a new profile with minimal privileges for this terraform script:
 - a. In the *Administrator Profile* drop down click *Create New*.
 - b. Enter a name for the profile.
 - c. Configure the *Access Permissions*:
 - *None*: The REST API is not permitted access to the resource.
 - *Read*: The REST API can send read requests (HTTP GET) to the resource.
 - *Read/Write*: The REST API can send read and write requests (HTTP GET/POST/PUT/DELETE) to the resource.
 - d. Click *OK*.
5. Enter *Trusted Hosts* to specify the devices that are allowed to access this FortiGate.
6. Click *OK*.

An API key is displayed. This key is only shown once, so you must copy and store it securely.

To configure FortiGate with Terraform Provider module support:

1. Download the terraform-provider-fortios file to a directory on the management computer.
2. Create a new file with the .tf extension for configuring your FortiGate:

```
root@mail:/home/terraform# ls
terraform-provider-fortios_v1.0.0_x4 test.tf
```

3. Edit the test.tf Terraform configuration file:

In this example, the FortiGate's IP address is 10.6.30.5, and the API user token is 17b*****63ck. Your provider information must also be changed.

```
# Configure the FortiOS Provider
provider "fortios" {
  hostname = "10.6.30.5"
  token = "17b*****63ck"
}
```

4. Create the resources for configuring your DNS object and adding a static route:

```
resource "fortios_system_setting_dns" "test1" {
  primary = "172.16.95.16"
  secondary = "8.8.8.8"
}

resource "fortios_networking_route_static" "test1" {
  dst = "110.2.2.122/32"
  gateway = "2.2.2.2"
  blackhole = "disable"
  distance = "22"
  weight = "3"
  priority = "3"
  device = "port2"
  comment = "Terraform test"
}
```

5. Save your Terraform configuration file.**6. In the terminal, enter `terraform init` to initialize the working directory.**

It reads the provider if the name follows the convention `terraform-provider-[name]`:

```
root@mail:/home/terraform# terraform init
Initializing the backend...
Terraform has been successfully initialized!
You may now begin working with Terraform. Try running "terraform plan" to see
any changes that are required for your infrastructure. All Terraform commands
should now work.
If you ever set or change modules or backend configuration for Terraform,
rerun this command to reinitialize your working directory. If you forget, other
commands will detect it and remind you to do so if necessary.
```

7. Run `terraform -v` to verify the version of loaded provider module:

```
root@mail:/home/terraform# terraform -v
Terraform v0.11.14
+ provider.fortios v1.0.0
```

8. Enter `terraform plan` to parse the configuration file and read from the FortiGate configuration to see what Terraform changes:

This example create a static route and updates the DNS address. You can see that Terraform reads the DNS addresses from the FortiGate and then lists them.

```
root@mail:/home/terraform# terraform plan
Refreshing Terraform state in-memory prior to plan...
The refreshed state will be used to calculate this plan, but will not be
persisted to local or remote state storage.
fortios_networking_route_static.test1: Refreshing state... (ID: 2)
fortios_system_setting_dns.test1: Refreshing state... (ID: 96.45.45.45)
```

```
-----  
An execution plan has been generated and is shown below.  
Resource actions are indicated with the following symbols:
```

```
+ create  
~ update in-place  
Terraform will perform the following actions:  
+ fortios_networking_route_static.test1  
id: <computed>  
blackhole: "disable"  
comment: "Terraform test"  
device: "port2"  
distance: "22"  
dst: "110.2.2.122/32"  
gateway: "2.2.2.2"  
priority: "3"  
weight: "3"  
~ fortios_system_setting_dns.test1  
primary: "96.45.45.45" => "172.16.95.16"  
secondary: "208.91.112.22" => "8.8.8.8"  
Plan: 1 to add, 1 to change, 0 to destroy.  
-----
```

Note: You didn't specify an "-out" parameter to save this plan, so Terraform can't guarantee that exactly these actions will be performed if "terraform apply" is subsequently run.

If you are running terraform-provider-fortios 1.1.0, you may see the following error:

```
Error: Error getting CA Bundle, CA Bundle should be set when  
insecure is false.
```

In this case, add the following line to the FortiOS provider configuration in the test.tf file:

```
insecure = "true"
```

9. Enter terraform apply to continue the configuration:

```
root@mail:/home/terraform# terraform apply  
fortios_system_setting_dns.test1: Refreshing state... (ID: 96.45.45.45)  
fortios_networking_route_static.test1: Refreshing state... (ID: 2)  
An execution plan has been generated and is shown below.  
Resource actions are indicated with the following symbols:  
+ create  
~ update in-place  
Terraform will perform the following actions:  
+ fortios_networking_route_static.test1  
id: <computed>  
blackhole: "disable"  
comment: "Terraform test"  
device: "port2"  
distance: "22"  
dst: "110.2.2.122/32"  
gateway: "2.2.2.2"  
priority: "3"  
weight: "3"  
~ fortios_system_setting_dns.test1  
primary: "96.45.45.45" => "172.16.95.16"  
secondary: "208.91.112.22" => "8.8.8.8"  
Plan: 1 to add, 1 to change, 0 to destroy.
```

```

Do you want to perform these actions?
Terraform will perform the actions described above.
Only 'yes' will be accepted to approve.
Enter a value: yes
fortios_networking_route_static.test1: Creating...
blackhole: "" => "disable"
comment: "" => "Terraform test"
device: "" => "port2"
distance: "" => "22"
dst: "" => "110.2.2.122/32"
gateway: "" => "2.2.2.2"
priority: "" => "3"
weight: "" => "3"
fortios_system_setting_dns.test1: Modifying... (ID: 96.45.45.45)
primary: "96.45.45.45" => "172.16.95.16"
secondary: "208.91.112.22" => "8.8.8.8"
fortios_networking_route_static.test1: Creation complete after 0s (ID: 2)
fortios_system_setting_dns.test1: Modifications complete after 0s (ID: 172.16.95.16)
Apply complete! Resources: 1 added, 1 changed, 0 destroyed.

```

The FortiGate is now configured according to the configuration file.

10. To change or delete something in the future, edit the configuration file and then apply it again. In supported cases, it deletes, adds, or updates new entries as configured. For instance, in this example you can remove the static route and revert the DNS address to its original configuration by changing the .tf file:

- a. Edit the configuration file:

```

# Configure the FortiOS Provider
provider "fortios" {
  hostname = "10.6.30.5"
  token = "17b*****63ck"
}
resource "fortios_system_setting_dns" "test1" {
  primary = "96.45.45.45"
  secondary = "208.91.112.22"
}
#resource "fortios_networking_route_static" "test1" {
# dst = "110.2.2.122/32"
# gateway = "2.2.2.2"
# blackhole = "disable"
# distance = "22"
# weight = "3"
# priority = "3"
# device = "port2"
# comment = "Terraform test"
#}

```

- b. Entering `terraform apply` deletes the static route that is commented out of the configuration file, and reverts the DNS address to the old address:

```

root@mail:/home/terraform# terraform apply
fortios_system_setting_dns.test1: Refreshing state... (ID: 172.16.95.16)
fortios_networking_route_static.test1: Refreshing state... (ID: 2)
An execution plan has been generated and is shown below.
Resource actions are indicated with the following symbols:
~ update in-place
- destroy
Terraform will perform the following actions:

```

```
- fortios_networking_route_static.test1
~ fortios_system_setting_dns.test1
primary: "172.16.95.16" => "96.45.45.45"
secondary: "8.8.8.8" => "208.91.112.22"
Plan: 0 to add, 1 to change, 1 to destroy.
Do you want to perform these actions?
Terraform will perform the actions described above.
Only 'yes' will be accepted to approve.
Enter a value: yes
fortios_networking_route_static.test1: Destroying... (ID: 2)
fortios_system_setting_dns.test1: Modifying... (ID: 172.16.95.16)
primary: "172.16.95.16" => "96.45.45.45"
secondary: "8.8.8.8" => "208.91.112.22"
fortios_networking_route_static.test1: Destruction complete after 0s
fortios_system_setting_dns.test1: Modifications complete after 0s (ID: 96.45.45.45)
Apply complete! Resources: 0 added, 1 changed, 1 destroyed.
```

Troubleshooting

Use the HTTPS daemon debug to begin troubleshooting why a configuration was not accepted:

```
# diagnose debug enable
# diagnose debug application httpsd -1
```

The REST API 403 error means that your administrator profile does not have sufficient permissions.

The REST API 401 error means that you do not have the correct token or trusted host.

Product registration with FortiCare

It is recommended to register your product with Fortinet. A FortiCare/FortiCloud account with Fortinet Technical Support (<https://support.fortinet.com>) is required to register products. This section describes how to register the product and includes information about other tasks performed with a FortiCare/FortiCloud account.

- [FortiCare and FortiGate Cloud login on page 71](#)
- [Transfer a device to another FortiCloud account on page 74](#)

FortiCare and FortiGate Cloud login

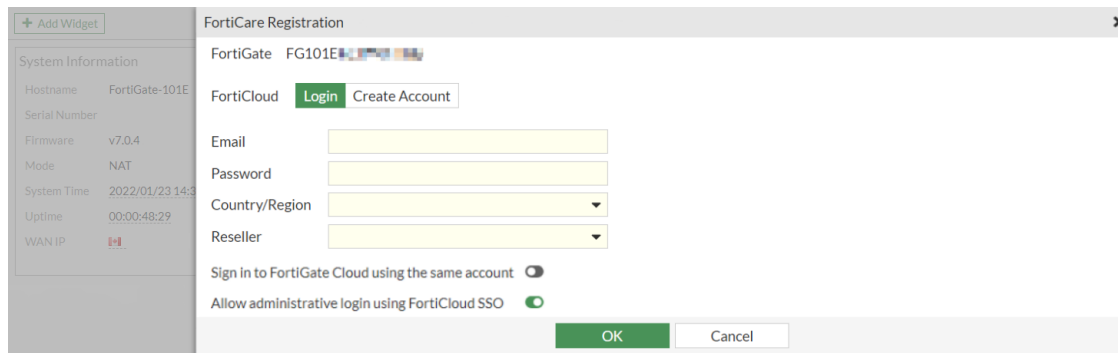

With FortiCloud, FortiOS supports a unified login to FortiCare and FortiGate Cloud. The FortiGate Cloud setup is a subset of the FortiCare setup.

- If the FortiGate is not registered, activating FortiGate Cloud will force you to register with FortiCare.
- If a FortiGate is registered in FortiCare using a FortiCloud account, then only that FortiCloud account can be used to activate FortiGate Cloud.
- If a different FortiCloud account was already used to activate FortiGate Cloud, then a notification asking you to migrate to FortiCloud is shown in the GUI after upgrading FortiOS.

The CLI can be used to activate FortiGate Cloud without registration, or with a different FortiCloud account.

To activate FortiGate Cloud and register with FortiCare at the same time:

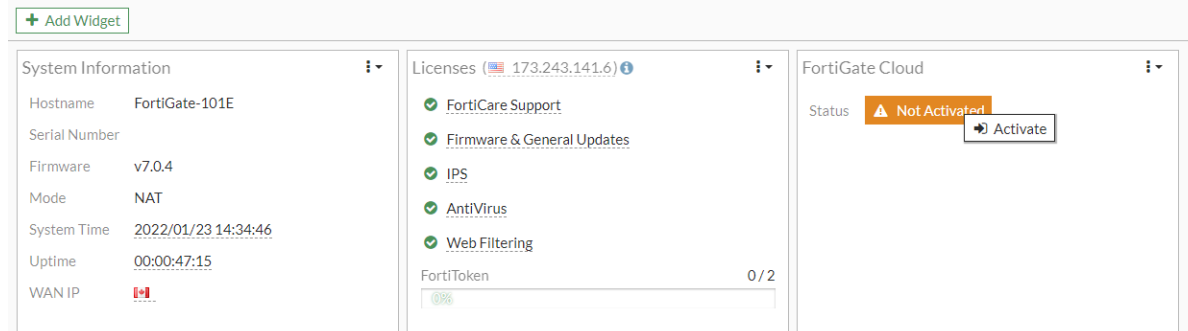

1. Go to *Dashboard > Status*.
2. In the FortiGate Cloud widget, click *Not Activated > Activate*.
You must register with FortiCare before activating FortiGate Cloud.

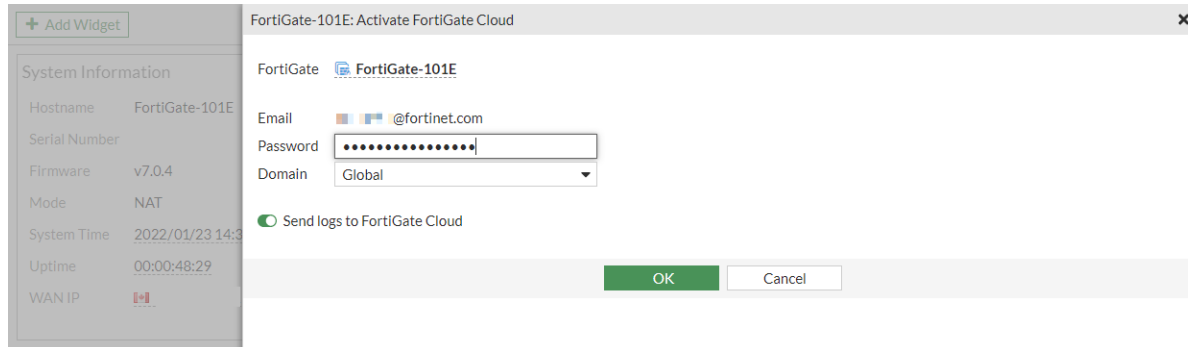

3. Enter your FortiCare *Email* address and *Password*.
4. Select your *Country/Region* and *Reseller*.
5. Enable *Sign in to FortiGate Cloud using the same account*.
6. Click *OK*.

To activate FortiGate Cloud on an already registered FortiGate:

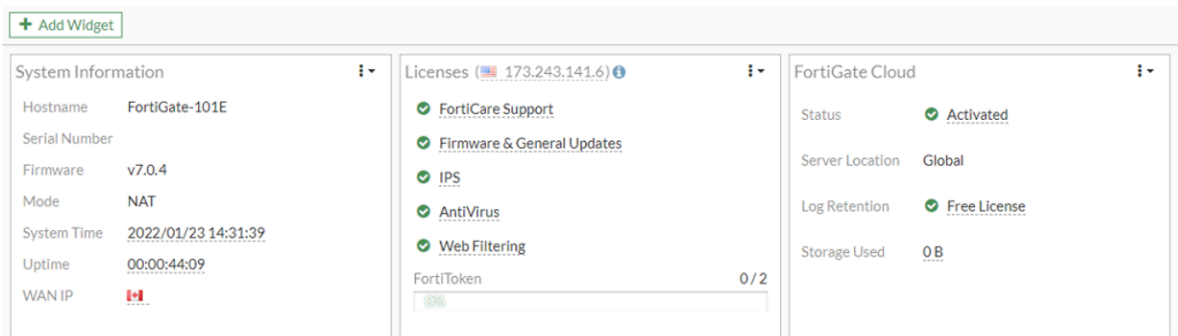

1. Go to *Dashboard > Status*.
2. In the *FortiGate Cloud* widget, click *Not Activated > Activate*.

3. Enter the password for the account that was used to register the FortiGate.

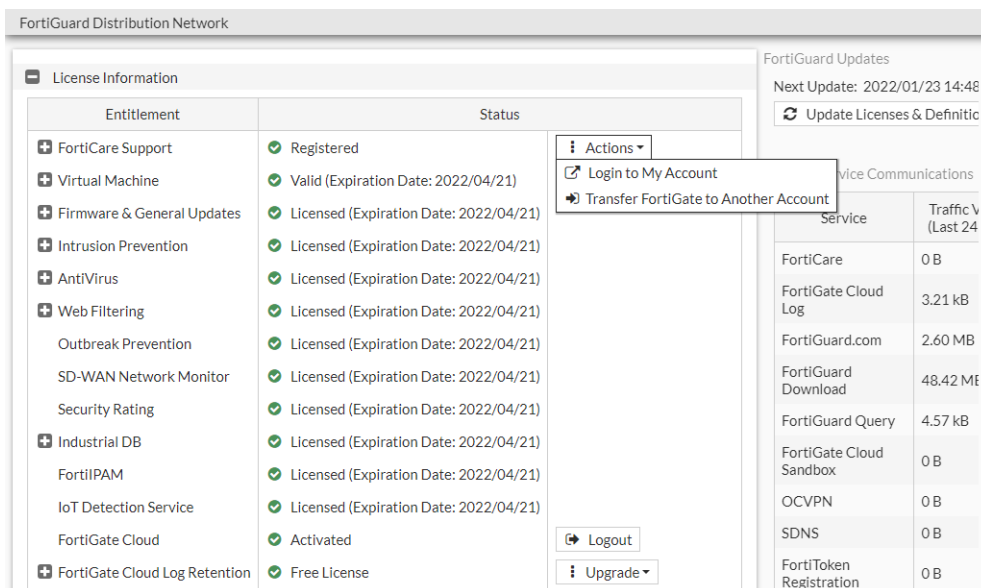

4. Click *OK*.
The *FortiGate Cloud* widget now shows the activated FortiCloud account.

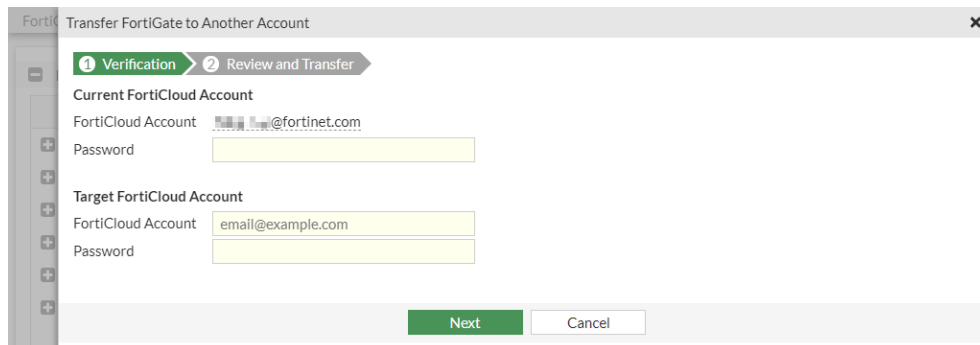

To migrate from the activated FortiGate Cloud account to the registered FortiCloud account:

1. Go to *System > FortiGuard*.
2. In the *FortiCare Support* row, click *Actions > Transfer FortiGate to Another Account*.

3. Enter the *Password* of the current FortiCloud account.

4. Enter the target *FortiCloud Account* name and *Password*, then click *Next*.
5. Review the information in the *From* and *To* fields, then click *Transfer*.

To activate FortiGate Cloud using an account that is not used for registration:

1. Enter the following with the credentials for the account being used to activate FortiGate Cloud:

```
# execute fortiguard-log login <account_id> <password>
```

2. Check the account type:

```
# diagnose fdsm contract-controller-update
Protocol=2.0|Response=202|Firmware=FAZ-4K-FW-2.50-
100|SerialNumber=FAMS000000000000|Persistent=false|ResponseItem=HomeServer:172.16.95.151
:443*AlterServer:172.16.95.151:443*Contract:20200408*NextRequest:86400*UploadConfig:False*
ManagementMode:Local*ManagementID:737941253*AccountType:multitenancy

Result=Success
```

A FortiCloud account that is not used for the support portal account cannot be used to register FortiGate. Attempting to activate FortiGate Cloud with this type of account will fail.

Transfer a device to another FortiCloud account

Master account users can transfer a device from one FortiCloud/FortiCare account to another. Users can transfer a device up to three times within a twelve-month time period. If more transfers are required within the twelve-month time period, contact [Technical Support](#) to request the transfer.

Requirements:

To transfer an account, you must:

- Have access to the FortiGate, as well as both the FortiCloud and FortiCare accounts.
- Be a master account user.

To verify if you are the master account user, log in to support.fortinet.com. Click the username, then select *My Account*.

The *Account Profile* page opens.

FortiCloud Services Support Account Name/ID: [redacted]

[For more information about Email Interaction, please Click Here](#)

Edit

To transfer an account in the GUI:

1. Go to *Dashboard > Status*.
2. In the *Licenses* widget, click the *FortiCare Support* link, then click *Transfer FortiGate to Another Account*.

You can also transfer an account from *System > FortiGuard*.

+ Add Widget

System Information

Hostname: FGDocs
 Serial Number: FGVM [redacted]
 Firmware: v7.0.3
 Mode: NAT

3. In the *Current FortiCloud Account* fields, enter the username and password for the current account. In the *Target FortiCloud Account* fields, enter the new username and password.

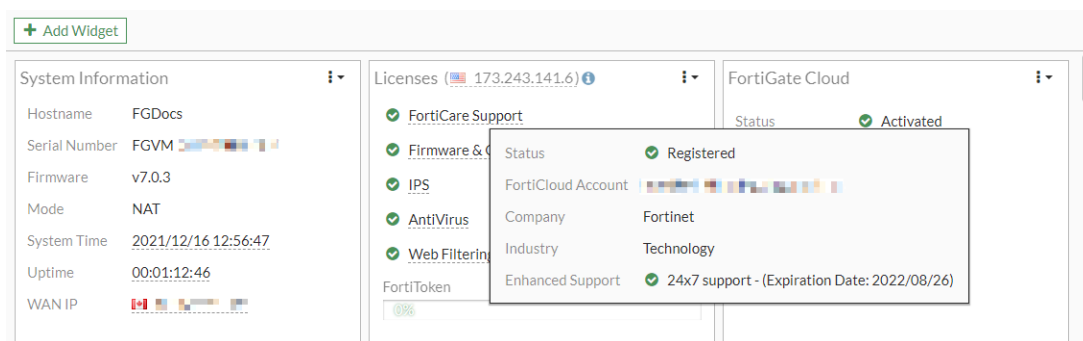

4. Click *Next*.

5. Review the information, then click *Transfer*.

After the transfer is complete, the new the FortiCloud account is displayed in the *Licenses* widget.

FortiGate models

Not all FortiGates have the same features, and some models support low encryption. This section also describes typical LEDs found on FortiGate models.

- [Differences between models on page 77](#)
- [Low encryption models on page 77](#)
- [LEDs on page 77](#)

Differences between models

Not all FortiGates have the same features, particularly entry-level models (models 30 to 90). A number of features on these models are only available in the CLI.

Consult your model's QuickStart Guide, [hardware manual](#), or the [Feature / Platform Matrix](#) for further information about features that vary by model.

FortiGate models differ principally by the names used and the features available:

- Naming conventions may vary between FortiGate models. For example, on some models the hardware switch interface used for the local area network is called *lan*, while on other units it is called *internal*.
- Certain features are not available on all models. Additionally, a particular feature may be available only through the CLI on some models, while that same feature may be viewed in the GUI on other models.

If you believe your FortiGate model supports a feature that does not appear in the GUI, go to *System > Feature Visibility* and confirm that the feature is enabled. For more information, see [Feature visibility on page 2292](#).

Low encryption models

Some FortiGate models support a low encryption (LENC) license. With an LENC license, FortiGate devices are considered low encryption models and are identified by *LENC*, for example FG-100E-LENC.

LENC models cannot use or inspect high encryption protocols, such as 3DES and AES. LENC models only use 56-bit DES encryption to work with SSL VPN and IPsec VPN, and they are unable to perform SSL inspection.

For a list of FortiGate models that support an LENC license, see [FortiGate LENC Models](#).

LEDs

Check your device's QuickStart guide for specific LED information: [FortiGate QuickStart Guides](#).

The following faceplates show where the LEDs are typically found on FortiGate models:

LED	State	Description
Logo	Green	The unit is on
	Blue	The FortiWiFi unit is on
	Off	The unit is off
Power (PWR)	Green	The unit is on and/or both power supplies are functioning
	Amber	One power supply is functioning
	Flashing Amber	Power supply failure
	Red	The unit is on, but only one power supply is functional
	Flashing Red	Power failure
	Off	The unit is off
Status (STA)	Green	Normal
	Flashing Green	Booting up
	Amber	Major or minor alarm
	Flashing Amber	BLE is on
	Red	Major alarm
	Flashing Red	BLE is on
	Off	The unit is off
Bypass (BYP)	Amber	Bypass Port Pair is active
	Off	Bypass Port Pair is off

LED	State	Description
Alarm	Red	Major alarm
	Amber	Minor alarm
	Off	No alarms
HA	Green	Operating in an HA cluster
	Amber or Red	HA failover
	Off	HA disabled
Max PoE	Green, Amber, or Red	Maximum PoE power allocated
	Off	PoE power available or normal
PoE	Green	Power delivered
	Flashing Green	Error or PoE device requesting power
	Off	No PoE device connected or no power delivered
SVC	Green	SVC is on
	Flashing Green	SVC activity
	Off	SVC is off
3G / 4G	Green	3G / 4G service is on
	Flashing Green	3G / 4G activity
	Off	3G / 4G service is off
WiFi	Green	WiFi connected
	Flashing Green	WiFi activity
	Off	WiFi is off
Power Supply	Green	Power supply operating normally
	Flashing Green	Power detected, but power supply not providing power or is in standby mode
	Amber	Power output is off, there is a power supply error, or there is no input power but the redundant supply is on
	Flashing Amber	Power supply error or warning events, or the power supply should be replaced
	Red	Cord unplugged or power lost
	Flashing Red	Power supply warning events
	Off	Power not detected

LED	State	Description
Power Supply OK	Green	Standby rail and main output on
	Flashing Green	Standby rail and main output off
	Off	Error or no AC power input
Power Supply Fail	Amber	Main output or fan error detected
	Flashing Amber	Power supply warning event detected
	Off	No errors or no power
Power Supply Input	Green	Input voltage within normal range
	Flashing Green	Over or under voltage warning
	Off	No input power
Power Supply Output	Green	Output voltage normal
	Flashing Green	Standby mode
	Amber	Critical error
	Flashing Amber	Warning
	Off	No output
Fan	Green	Fan(s) operating normally
	Flashing Green	Fan switching/initialization in progress
	Amber	Fan failure
	Red	Fan error, RPM too low or too high, or both fan sets have at least one alert
	Flashing Red	One fan set has at least one alert
	Off	Fan error or fan is off

Port LEDs

LED	State	Description
Ethernet	Green	Connected at 1 Gbps
	Flashing Green	Transmitting and receiving data at 1 Gbps
	Amber	Connected at 10/100 Mbps
	Flashing Amber	Transmitting and receiving data at 10/100 Mbps
	Off	No link established

LED	State	Description
Ethernet Link/Activity	Green	Connected
	Flashing Green	Transmitting data
	Off	No link established
Ethernet Speed	Green	Connected at 1 Gbps
	Amber	Connected at 100 Mbps
	Off	Not connected or connected at 10 Mbps
Ethernet 10G Link/Activity	Green	Connected
	Flashing Green	Transmitting data
	Off	No link established
Ethernet 10G Speed	Green	Connected at 10 Gbps
	Amber	Connected at 5 Gbps, 2.5 Gbps, or 1 Gbps
	Off	Not connected or connected at 100 Mbps
PoE	Green	PoE power on or PoE device receiving power
	Amber	Providing power
	Red	Connected but not powered
	Off	PoE power off or no device receiving power
SFP	Green	Connected at 1 Gbps
	Flashing Green	Data activity
	Off	No link established
SFP+	Green	Connected at 10 Gbps or 1 Gbps
	Flashing Green	Data activity
	Off	No link established
SFP28	Green	Connected at 25 Gbps, 10 Gbps, or 1 Gbps
	Flashing Green	Data activity
	Off	No link established
QSFP28	Green	Connected at 100 Gbps or 40 Gbps
	Flashing Green	Data activity
	Off	No link established

Alarm levels

Minor alarm

Also called an IPMI non-critical (NC) alarm, it indicates a temperature or power level outside of the normal operating range that is not considered a problem. For a minor temperature alarm, the system could respond by increasing the fan speed. A non-critical threshold can be an upper non-critical (UNC) threshold (for example, a high temperature or a high power level) or a lower non-critical (LNC) threshold (for example, a low power level).

Major alarm

Also called an IPMI critical or critical recoverable (CR) alarm, it indicates that the system is unable to correct the cause of the alarm, and that intervention is required. For example, the cooling system cannot provide enough cooling to reduce the temperature. It can also mean that the conditions are approaching the outside limit of the allowed operating range. A critical threshold can also be an upper critical (UC) threshold (such as a high temperature or high power level) or a lower critical (LC) threshold (such as a low power level).

Critical alarm

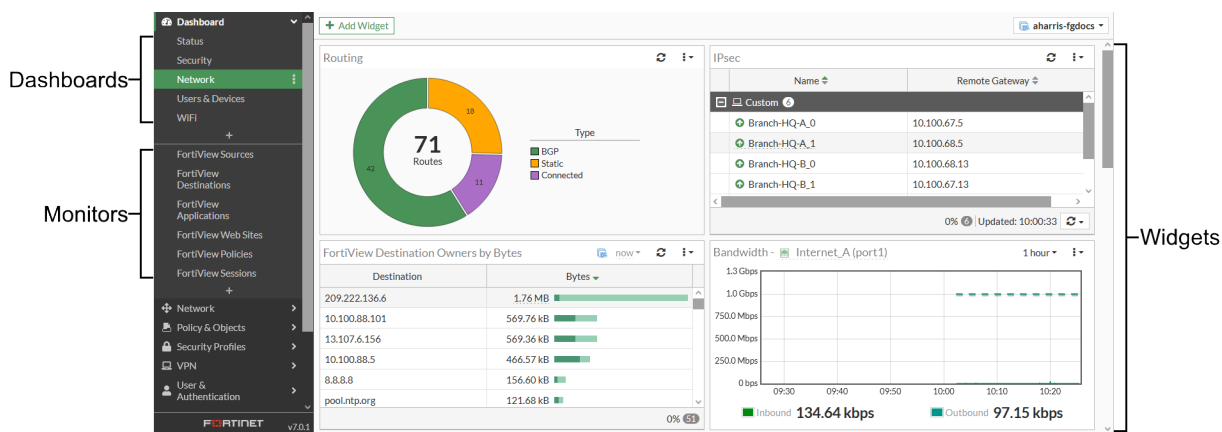

Also called an IPMI non-recoverable (NR) alarm, it indicates that the system has detected a temperature or power level that is outside of the allowed operating range and physical damage is possible.

Dashboards and Monitors

FortiOS includes predefined dashboards so administrators can easily monitor device inventory, security threats, traffic, and network health. You can customize the appearance of a default dashboard to display data pertinent to your Security Fabric or combine widgets to create custom dashboards. Many dashboards also allow you to switch views between fabric devices.

Each dashboard contains a set of widgets that allow you to view drilldown data and take actions to prevent threats. Use widgets to perform tasks such as viewing device inventory, creating and deleting DHCP reservations, and disconnecting dial-up users. You can add or remove widgets in a dashboard or save a widget as a standalone monitor.

Monitors display information in both text and visual format. Use monitors to change views, search for items, view drilldown information, or perform actions such as quarantining an IP address. FortiView monitors for the top categories are located below the dashboards. All of the available widgets can be added to the tree menu as a monitor.

Using dashboards

You can combine widgets to create custom dashboards. You can also use the dropdown in the tree menu to switch to another device in the Security Fabric.

To create a new dashboard:

1. Under *Dashboard*, click the *Add Dashboard* button. The *Add Dashboard* window opens.

2. Enter a name in the *Name* field and click *OK*. The new dashboard opens.

To add a widget to a dashboard:

1. In the tree menu, select a dashboard.
2. In the banner, click *Add Widget*. The *Add Dashboard Widget* pane opens.
3. Click the *Add* button next to the widget. You can use the *Search* field to search for a widget. Enable *Show More* to view more widgets in a category.
4. Configure the widget settings, then click *Add Widget*.
5. Click *Close*.
6. (Optional) Click and drag the widget to the desired location in the dashboard.

To edit a dashboard:

1. Click the *Actions* menu next to the dashboard and select *Edit Dashboard*.

2. Edit the dashboard and click *OK*.

To delete a dashboard:

1. Click the *Actions* menu next to the dashboard and select *Delete Dashboard*.

2. Click *Delete Dashboard*. The *Confirm* dialog opens.
3. Click *OK*.

You cannot delete the *Status* dashboard.

To switch to another device in the Security Fabric:

1. In the tree menu, click the device name and select a fabric device from dropdown.

Using widgets

You can convert a widget to a standalone monitor, change the view type, configure tables, and filter data.

To save a dashboard widget as a monitor:

1. Hover over the widget and click *Expand to full screen*.

Full screen mode is not supported in all widgets.

2. In the widget, click *Save as Monitor*. The *Add Monitor* window opens.

3. (Optional) Enter a new name for the monitor in the *Name* field.
4. Click *OK*.

To view the widget settings:

1. Click the menu dropdown at the right side of the widget and select *Settings*.

2. Configure the widget settings and click *OK*.

The settings will vary depending on the widget.

To configure a table in the widget:

1. Hover over the left side of the table header and click *Configure Table*.

- Configure the table options:

Option	Description
Best Fit All Columns	Resizes all of the columns in a table to fit their content.
Reset Table	Resets the table to the default view.
Select Columns	Adds or removes columns from the view.

- Click *Apply*.

To filter or configure a column in a table:

- Hover over a column heading, and click *Filter/Configure Column*.

- Configure the column options.

Option	Description
Resize to Contents	Resizes the column to fit the content.
Group by this Column	Groups the table rows by the contents in the selected column.

- Click *Apply*.
- To filter a column, enter a value in the *Filter* field, and click *Apply*.

Filtering is not supported in all widgets.

Widgets

Dashboards are created per VDOM when VDOM mode is enabled. For information about VDOM mode, see [Virtual Domains on page 2092](#).

Some dashboards and widgets are not available in Multi-VDOM mode.

The following table lists the available widgets in VDOM mode:

Category	Widgets
FortiView	<ul style="list-style-type: none"> FortiView Application Bandwidth FortiView

Category	Widgets
	<ul style="list-style-type: none"> • Applications FortiView Cloud Applications • FortiView Destination Interfaces FortiView • Destination Owners FortiView Destinations • FortiView Policies FortiView Sessions • FortiView Source Interfaces FortiView • Sources FortiView VPN FortiView Web • Categories FortiView Countries/Regions • FortiView Destination Firewall Objects • FortiView Interface Pairs FortiView Search • Phrases FortiView Servers FortiView Source • Firewall Objects FortiView Sources - WAN • FortiView Traffic Shaping
Security Fabric	<ul style="list-style-type: none"> • Fabric Device • FortiGate Cloud • Security Fabric Status
Network	<ul style="list-style-type: none"> • DHCP • Interface Bandwidth • IP Pool Utilization • IPsec • Routing • SD-WAN • SSL-VPN • Top IP Pools by Assigned IPs <hr/> <div style="display: flex; align-items: center;">  <p>The <i>Interface Bandwidth</i> widget can monitor a maximum of 25 interfaces.</p> </div> <hr/>
System	<ul style="list-style-type: none"> • Administrators • Botnet Activity • HA Status • License Status • System Information • Top System Events • Virtual Machine
Resource Usage	<ul style="list-style-type: none"> • CPU Usage • Disk Usage • Log Rate Memory Usage • Session Rate • Sessions
Security	<ul style="list-style-type: none"> • Advanced Threat Protection Statistics • Compromised Hosts

Category	Widgets
	<ul style="list-style-type: none"> FortiClient Detected Vulnerabilities GTP Tunnel Rate GTP Tunnels Host Scan Summary Quarantine Top Endpoint Vulnerabilities Top Failed Authentication Top FortiSandbox Files Top Threats Top Threats - WAN
User & Authentication	<ul style="list-style-type: none"> Device Inventory Firewall Users FortiClient FortiGuard Quota FortiSwitch NAC VLANs Top Admin Logins Top Vulnerable Endpoint Devices Top Cloud Users
WiFi	<ul style="list-style-type: none"> Channel Utilization Clients By FortiAP FortiAP Status Historical Clients Interfering SSIDs Login Failures Rogue APs Signal Strength Top WiFi Clients

Viewing device dashboards in the Security Fabric

Use the device dropdown to view the dashboards in downstream fabric devices. You can also create dedicated device dashboards or log in and configure fabric devices.

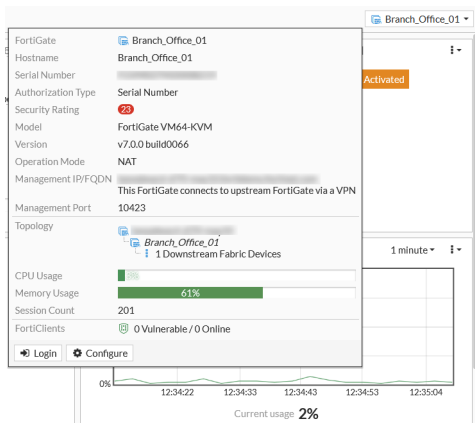

To view the dashboards in fabric devices, click the device dropdown at the left side of the page, and select a device from the list.

The device dropdown is available in the *Status*, *Security*, *Network*, *Users & Devices*, and *WiFi* dashboards. You can also enable the dropdown when you create a dashboard.

To log in to or configure a fabric device, hover over the device name until the device dialog opens and then select *Login* or *Configure*.

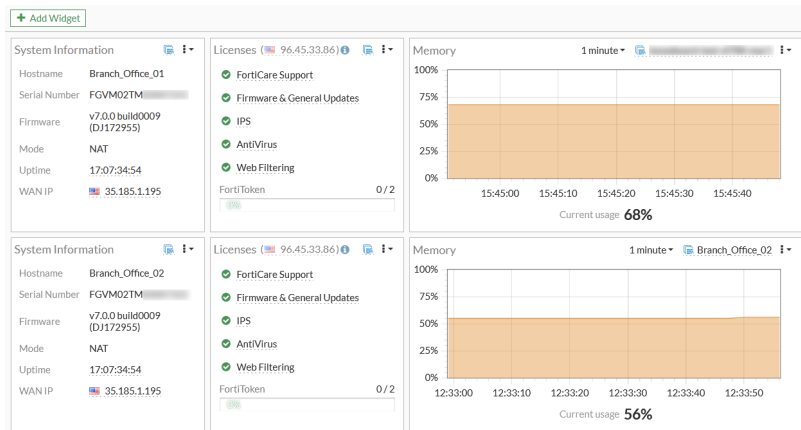

Creating a fabric system and license dashboard

Create a dashboard summary page to monitor all the fabric devices in a single view. You can use this dashboard to monitor aspects of the devices such as system information, VPN and routing.

Example

The following image is an example of a *Fabric System & License* dashboard to monitor the *System Information*, *Licenses*, and *Memory* usage for *Branch_Office_01* and *Branch_Office_02*.

To create a system dashboard:

1. Click the *Add Dashboard* button. The *Add Dashboard* window opens.

2. In the *Name* field, enter a name such as *Fabric System & Licences*, and click *OK*. The new dashboard appears.
3. In the banner, click *Add Widget*. The *Add Dashboard Widget* window opens. You can use the *Search* field to search for a specific widget (for example, *License Status*, *System Information*, and *Memory Usage*).
4. Click the *Add* button next to widget. The *Add Dashboard Widget* window opens.
5. In the *Fabric member* area, select *Specify* and select a device in the Security Fabric.

6. Click *Add Widget*. The widget is added to the dashboard.
Repeat this step for all the devices you want to view in the dashboard.
7. (Optional) Arrange the widgets in the dashboard by fabric device.

Dashboards

A dashboard is a collection of widgets that show the status of your devices, network, and Security Fabric at a glance. Widgets are condensed monitors that display a summary of the key details about your FortiGate pertaining to routing, VPN, DHCP, devices, users, quarantine, and wireless connections.

The following dashboards are included in the dashboard templates:

Dashboard	Default Template	Use these widgets to:
Status	<ul style="list-style-type: none"> • Comprehensive • Optimal 	<ul style="list-style-type: none"> • View the device serial number, licenses, and administrators • View the status of devices in the security fabric • Monitor CPU and Memory usage • Monitor IPv4 and IPv6 sessions • View VMs and Cloud devices
Security	<ul style="list-style-type: none"> • Optimal 	<ul style="list-style-type: none"> • View compromised hosts and host scan summary • View top threats and vulnerabilities
Network	<ul style="list-style-type: none"> • Optimal 	<ul style="list-style-type: none"> • Monitor DHCP clients • Monitor IPsec VPN connections • Monitor current routing table • Monitor SD-WAN status • Monitor SSL-VPN connections

Dashboard	Default Template	Use these widgets to:
Users & Devices	<ul style="list-style-type: none"> Optimal 	<ul style="list-style-type: none"> View users and devices connected to the network Identify threats from individual users and devices View FortiGuard and FortiClient data Monitor traffic bandwidth over time
WiFi	<ul style="list-style-type: none"> Comprehensive Optimal 	<ul style="list-style-type: none"> View FortiAP status, channel utilization, and clients View login failures and signal strength View the number of WiFi clients

Resetting the default dashboard template

You can use the GUI to change the default dashboard template. The *Optimal* template contains a set of popular default dashboards and FortiView monitors. The *Comprehensive* template contains a set of default dashboards as well as all of the FortiView monitors.

Resetting the default template will delete any custom dashboards and monitors, and reset the widget settings.

To reset all dashboards:

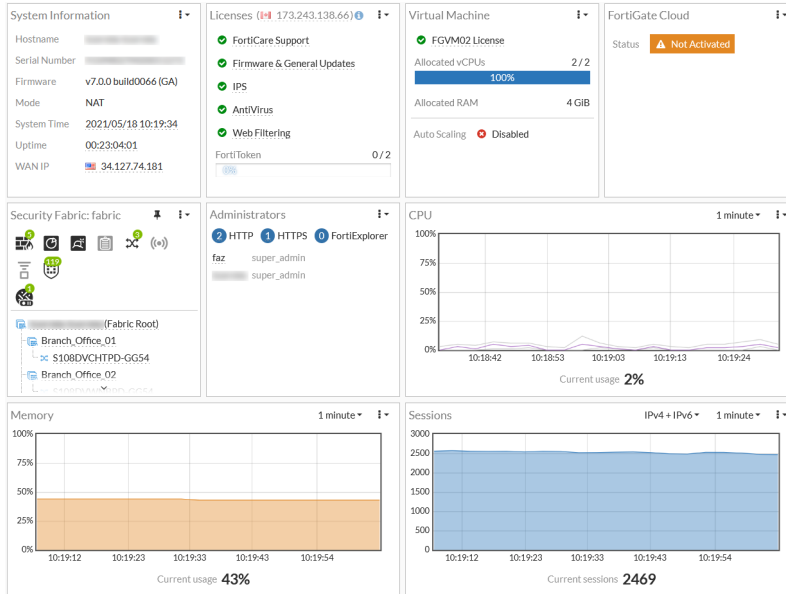

1. Click the *Actions* menu next to *Add Dashboard* or *Add Monitor* and click *Reset All Dashboards*. The *Dashboard Setup* window opens.

2. Select *Optimal* or *Comprehensive* and click *OK*.

Status dashboard

The *Status* dashboard provides an overview of your FortiGate device and the devices in your Security Fabric. If your FortiGate is a Virtual Machine, information about the Virtual Machine is also displayed in the dashboard.

Updating system information

The *System Information* widget contains links to the *Settings* module where you can update the *System Time*, *Uptime*, and *WAN IP*.

A notification will appear in the *Firmware* field when a new version of FortiOS is released. Click *Update firmware in System > Firmware* to view the available versions and update FortiOS.

Viewing fabric devices

The *Security Fabric* widget provides a visual overview of the devices connected to the fabric and their connection status. Hover of a device icon to view more information about the device.

Click a device in the fabric to:

- View the device in the physical or logical topology
- Register, configure, deauthorize, or log in to the device
- Open *Diagnostics and Tools*
- View the *FortiClient Monitor*

These options will vary depending on the device.

Click *Expand & Pin hidden content* to view all the devices in the fabric at once.

Viewing administrators

The *Administrators* widget displays the active administrators and their access interface. Click the username to view the *Active Administrator Sessions* monitor. You can use the monitor to end an administrator's session.

Resource widgets

The resource widgets show the current usage statistics for *CPU*, *Memory*, and *Sessions*.

Click the *CPU* monitor to show the per core CPU usage.

You can switch between *IPv4*, *IPv6*, or *IPv4+IPv6* in the *Sessions* monitor.

Security dashboard

The widgets in the *Security* dashboard provide a snapshot of the current threats and vulnerabilities targeting your Security Fabric.

The *Security* dashboard contains the following widgets:

Widget	Description
Compromised Hosts by Verdict	Shows the session information for a compromised host. See Viewing session information for a compromised host on page 94 .
Top Threats by Threat Level	Shows the top traffic sessions aggregated by threat. You can expand the widget to view drilldown information about the <i>Threat</i> , <i>Threat Category</i> , <i>Threat Level</i> , <i>Threat Score</i> and <i>Sessions</i> .
FortiClient Detected Vulnerabilities	Shows a summary of vulnerabilities detected by FortiClient. FortiClient must be enabled.
Host Scan Summary	Shows a summary of hosts scanned. Hover over a color in the chart to view the number of hosts by category. Click the chart to view the <i>FortiClient Monitor</i> or <i>Device Inventory</i> monitor.
Top Vulnerable Endpoint Devices by Detected Vulnerabilities	Shows a summary devices aggregated by vulnerabilities. Expand the widget to view drilldown information about the <i>Device</i> , <i>Source</i> and <i>Detected Vulnerabilities</i> .

Viewing session information for a compromised host

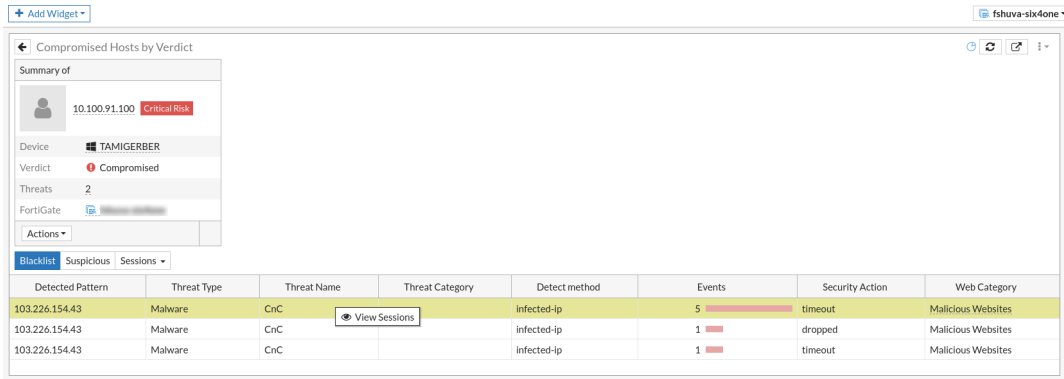

You can use the *Compromised Hosts by Verdict* widget to view the session information for a compromised host.

To view session information for a compromised host in the GUI:

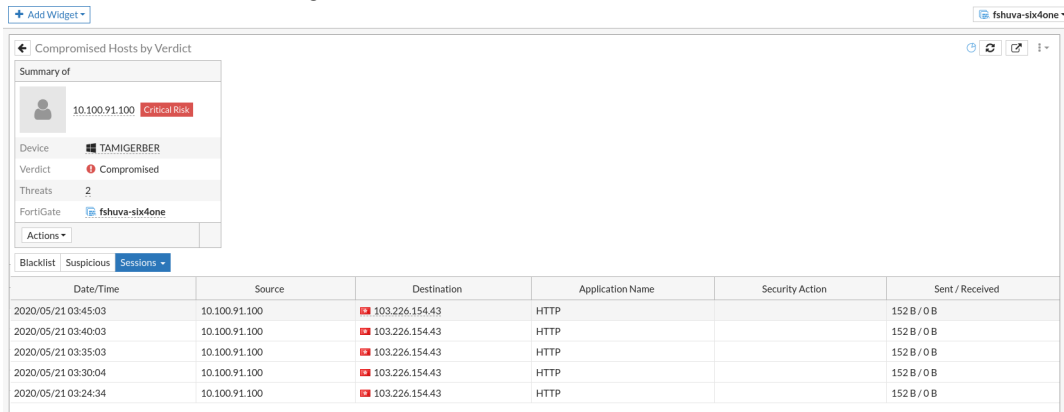

1. Go to *Dashboard > Security* and expand the *Compromised Hosts by Verdict* widget.

Source	Device	Verdict	Threats
10.200.1.21	LAN-FSW-GUEST	Compromised	1
10.100.92.5	00:09:0F:00:03:02	Compromised	1
10.200.1.19	LAN-FSW-GUEST	Compromised	1
10.100.92.5	LAN-FINANCE	Compromised	1
10.200.1.20	LAN-FSW-GUEST	Compromised	1
10.100.92.15	LAN-FINANCE	Compromised	1

2. Double-click a compromised host to view the session information. You can also right-click a compromised host, and select *View Sessions*.

3. Double-click a session, or right-click the session and select *View Sessions* to view the information.

Network dashboard

The widgets in the Network dashboard show information related to networking for this FortiGate and other devices connected to your Security Fabric. Use this dashboard to monitor the status of Routing, DHCP, SD-WAN, IPsec and SSL VPN tunnels. All of the widgets in the *Network* dashboard can be expanded to full screen and saved as a monitor.

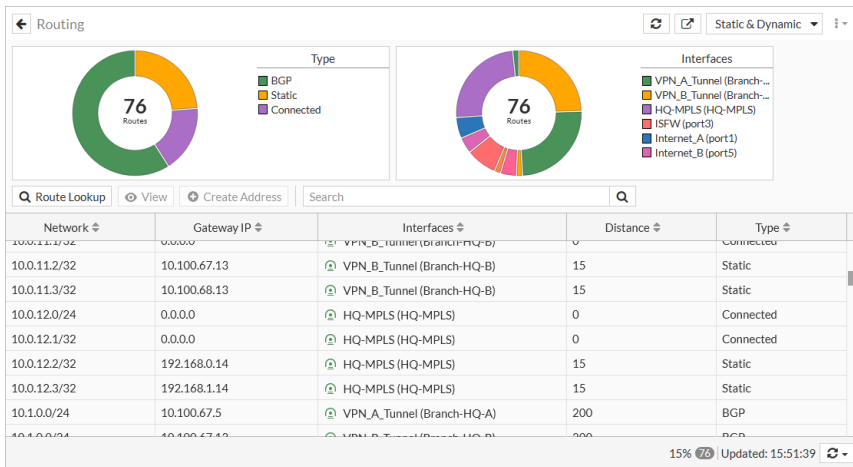

The *Network* dashboard contains the following widgets:

Widget	Description
Static & Dynamic Routing	Shows the static and dynamic routes currently active in your routing table. The widget also includes policy routes, BGP neighbors and paths, and OSPF neighbors. See Static & Dynamic Routing monitor on page 96 .
DHCP	Shows the addresses leased out by FortiGate's DHCP servers. See DHCP monitor on page 99 .
SD-WAN	Shows a summary of the SD-WAN status, including ADVPN shortcut information.
IPsec	Shows the connection statuses of your IPsec VPN site to site and dial-up tunnels. See IPsec monitor on page 100 .
SSL-VPN	Shows a summary of remote active users and the connection mode. See SSL-VPN monitor on page 102 .

Widget	Description
IP Pool Utilization	Shows IP pool utilization.

Static & Dynamic Routing monitor

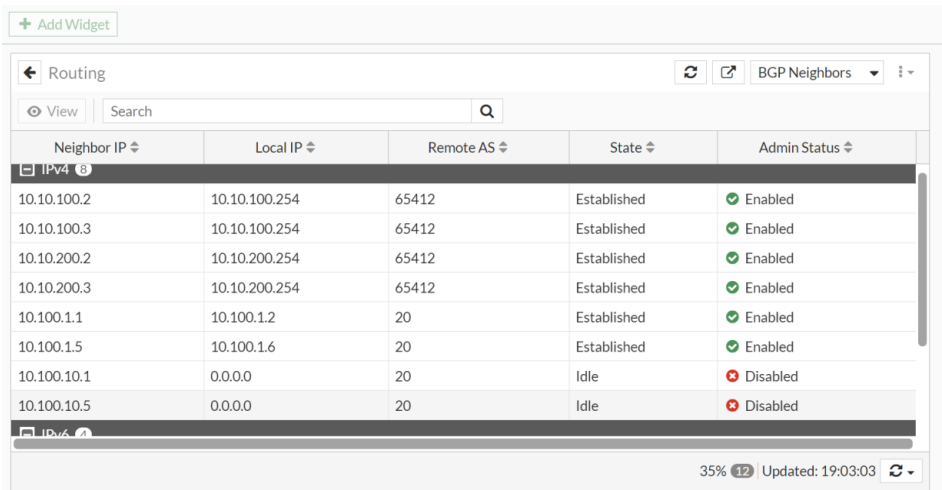

The *Static & Dynamic Routing Monitor* displays the routing table on the FortiGate, including all static and dynamic routing protocols in IPv4 and IPv6. You can also use this monitor to view policy routes, BGP neighbors and paths, and OSPF neighbors.

To view the routing monitor in the GUI:

1. Go to *Dashboard > Network*.
2. Hover over the *Routing* widget, and click *Expand to Full Screen*. The *Routing* monitor is displayed.
3. To view neighbors and paths, click the monitors dropdown at the top of the page.

4. To filter the *Interfaces* and *Type* columns:
 - a. Click the *Static & Dynamic* tab.
 - b. Hover over the column heading, and click the *Filter/Configure Column* icon.

- c. Click *Group By This Column*, then click *Apply*.

5. (Optional) Click *Save as Monitor* to save the widget as monitor.

To look up a route in the GUI:

1. Click *Route Lookup*.
2. Enter an IP address in the *Destination* field, then click *Search*. The matching route is highlighted on the *Routing* monitor.

To view the routing table in the CLI:

```
# get route info routing-table all
```

Sample output:

```
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default
```

```

To view neighbors and paths

DHCP monitor

The DHCP monitor shows all the addresses leased out by FortiGate's DHCP servers. You can use the monitor to revoke an address for a device, or create, edit, and delete address reservations.

To view the DHCP monitor:

1. Go to *Dashboard > Network*.
2. Hover over the *DHCP* widget, and click *Expand to Full Screen*.

To filter or configure a column in the table, hover over the column heading and click *Filter/Configure Column*.

To revoke a lease:

1. Select a device in the table.
2. In the toolbar, click *Revoke*, or right-click the device, and click *Revoke Lease(s)*. The *Confirm* page is displayed.
3. Click *OK*.

A confirmation window opens only if there is an associated address reservation. If there is no address, the lease will be removed immediately upon clicking *Revoke*.

To create a DHCP reservation:

1. Select a server in the table.
2. In the toolbar, click *Reservation*, or right-click the device and click *Create DHCP Reservation*. The *Create New DHCP Reservation* page is displayed.
3. Configure the DHCP reservation settings.

4. Click *OK*.

To view top sources by bytes:

1. Right-click a device in the table and click *Show in FortiView*. The *FortiView Sources by Bytes* widget is displayed.

To view the DHCP lease list in the CLI:

```
# execute dhcp lease-list
```

IPsec monitor

The IPsec monitor displays all connected Site to Site VPN, Dial-up VPNs, and ADVPN shortcut tunnel information. You can use the monitor to bring a phase 2 tunnel up or down or disconnect dial-up users. A notification appears in the monitor when users have not enabled two-factor authentication.

Name	Remote Gateway	Peer ID	Incoming Data	Outgoing Data	Phase 1	Phase 2 Selectors
Branch-HQ-A_0	10.100.68.5		1.27 GB	1.75 GB	Branch-HQ-A_0	Branch-HQ-A
Branch-HQ-A_1	10.100.67.5		2.30 GB	1.09 GB	Branch-HQ-A_1	Branch-HQ-A
Branch-HQ-B_0	10.100.68.13		1.20 GB	1.64 GB	Branch-HQ-B_0	Branch-HQ-B
Branch-HQ-B_1	10.100.67.13		2.36 GB	3.27 GB	Branch-HQ-B_1	Branch-HQ-B
HQ-MPLS_0	192.168.0.14		682.10 MB	869.48 MB	HQ-MPLS_0	HQ-MPLS
HQ-MPLS_1	192.168.1.14		1.62 GB	1.82 GB	HQ-MPLS_1	HQ-MPLS

To view the IPsec monitor in the GUI:

1. Go to *Dashboard > Network*.
2. Hover over the *IPsec* widget, and click *Expand to Full Screen*. A warning appears when an unauthenticated user is detected.

To filter or configure a column in the table, hover over the column heading and click *Filter/Configure Column*.

3. Hover over a record in the table. A tooltip displays the *Phase 1* and *Phase 2* interfaces. A warning appears next to a user who has not enabled two-factor authentication.

To reset statistics:

1. Select a tunnel in the table.
2. In the toolbar, click *Reset Statistics* or right-click the tunnel, and click *Reset Statistics*. The *Confirm* dialog is displayed.
3. Click *OK*.

To bring a tunnel up:

1. Select a tunnel in the table.
2. Click *Bring Up*, or right-click the tunnel, and click *Bring Up*. The *Confirm* dialog is displayed.
3. Click *OK*.

To bring a tunnel down:

1. Select a tunnel in the table.
2. Click *Bring Down*, or right-click the tunnel, and click *Bring Down*. The *Confirm* dialog is displayed.
3. Click *OK*.

To locate a tunnel on the VPN Map:

1. Select a tunnel in the table.
2. Click *Locate on VPN Map*, or right-click the tunnel, and click *Locate on VPN Map*. The *VPN Location Map* is displayed.

To view the IPsec monitor in the CLI:

```
# diagnose vpn tunnel list
```

Sample output:

```
list all ipsec tunnel in vd 0
```

```

SSL-VPN monitor

The SSL-VPN monitor displays remote user logins and active connections. You can use the monitor to disconnect a specific connection. The monitor will notify you when VPN users have not enabled two-factor authentication.

To view the SSL-VPN monitor in the GUI:

1. Go *Dashboard > Network*.
2. Hover over the *SSL-VPN* widget, and click *Expand to Full Screen*. The *Duration* and *Connection Summary* charts are displayed at the top of the monitor.

To filter or configure a column in the table, hover over the column heading and click *Filter/Configure Column*.

To disconnect a user:

1. Select a user in the table.
2. In the table, right-click the user, and click *End Session*. The Confirm window opens.
3. Click *OK*.

To monitor SSL-VPN users in the CLI:

```
# get vpn ssl monitor
```

Sample output

```
SSL VPN Login Users:
Index User Group Auth Type Timeout From HTTP in/out HTTPS in/out
0 amitchell TAC 1(1) 296 10.100.64.101 3838502/11077721 0/0

```

```
SSL VPN sessions:
Index User Group Source IP Duration I/O Bytes Tunnel/Dest IP
```

Users & Devices

The *Users & Devices* dashboard shows the current status of users and devices connected to your network. All of the widgets can be expanded to view as monitor. In monitor view, you can create firewall addresses, deauthenticate a user, or remove a device from the network.

The *User & Devices* dashboard contains the following widgets:

Widget	Description
Device Inventory	Shows a summary of the hardware and software that is connected to the network. See Device inventory on page 103 .
FortiClient	Shows a summary of the FortiClient endpoints.
Firewall Users	Shows a summary of the users logged into the network.
Quarantine	Shows a summary of quarantined devices.
FortiSwitch NAC VLANs	Shows a summary of VLANs assigned to devices by FortiSwitch NAC policies.

Device inventory

You can enable device detection to allow FortiOS to monitor your networks and gather information about devices operating on those networks, including:

- MAC address
- IP address
- Operating system
- Hostname
- Username
- Endpoint tags
- When FortiOS detected the device and on which interface

You can enable device detection separately on each interface in *Network > Interfaces*.

Device detection is intended for devices directly connected to your LAN and DMZ ports. The widget is only available when your *Interface Role* is *LAN*, *DMZ* or *Undefined*. It is not available when the role is *WAN*.

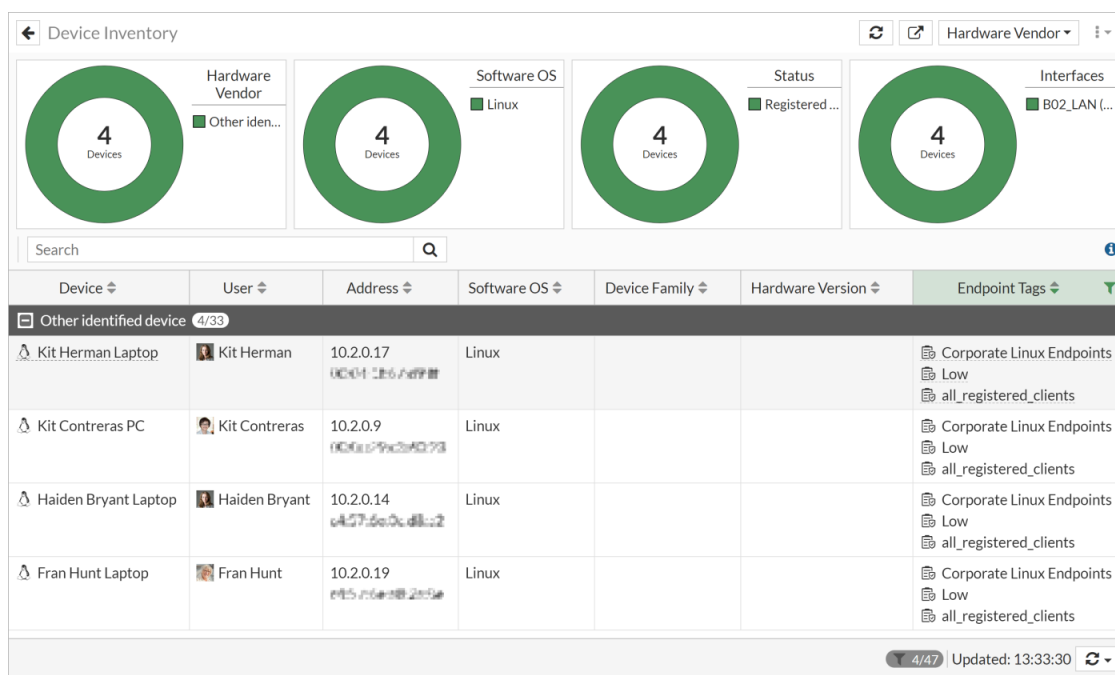

You can also manually add devices to Device Inventory to ensure that a device with multiple interfaces displays as a single device.

To view the device inventory monitor:

1. Go to *Dashboard > Users & Devices*.
If you are using the Comprehensive dashboard template, go to *Dashboard > Device Inventory Monitor*.
2. Hover over the *Device Inventory* widget, and click *Expand to Full Screen*. The *Device Inventory* monitor is displayed.

To filter or configure a column in the table, hover over the column heading, and click *Filter/Configure Column*. See [Device inventory and filtering on page 104](#).

Device inventory and filtering

The *Device Inventory* widget contains a series of summary charts that provide an overview of the hardware, operating system, status, and interfaces. You can use these clickable charts to simplify filtering among your devices.

To view the device inventory and apply a filter:

1. Go to *Dashboard > Users & Devices*.
If you are using the Comprehensive dashboard template, go to *Dashboard > Device Inventory Monitor*. See .
2. Hover over the *Device Inventory* widget, and click *Expand to Full Screen*. The *Device Inventory* monitor is displayed.
3. To filter the order of the charts by operating system, click the dropdown in the top menu bar and select *Software OS*.
4. To filter a chart, click an item in the legend or chart area. The table displays the filter results.

- To combine filters, hover over a column heading and click *Filter/Configure Column*.

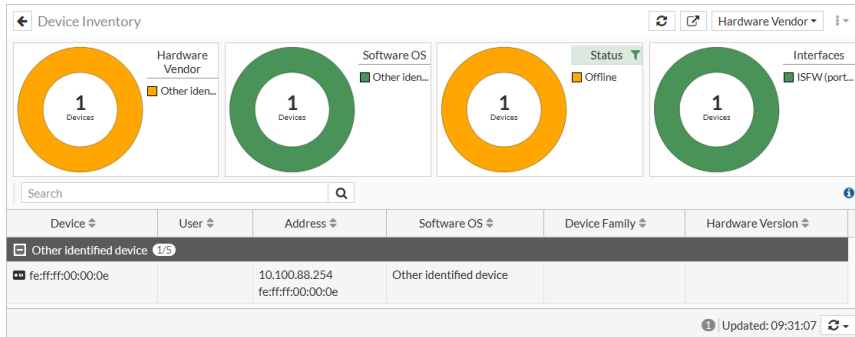

- Click the filter icon in the top-right corner of the chart to remove the filter.

Filter examples

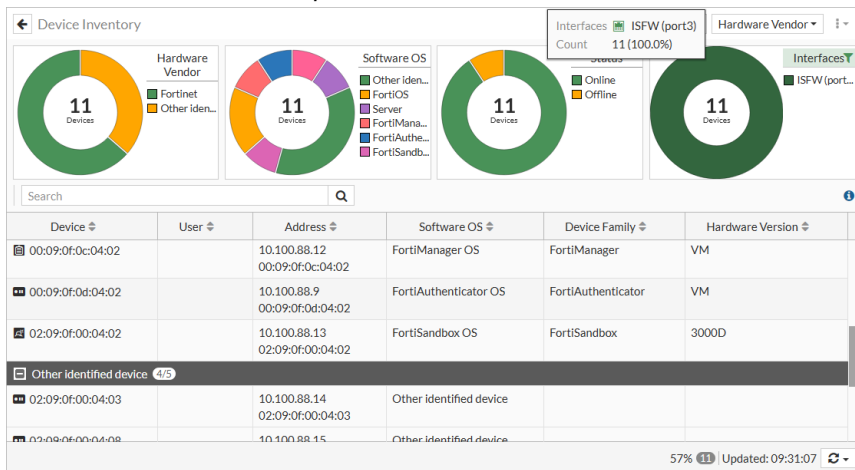

To filter all offline devices:

- In the *Status* chart, click *Offline* in the legend or on the chart itself.

To filter all devices discovered on port3:

- In the *Interfaces* chart, click *port3*.

Adding MAC-based addresses to devices

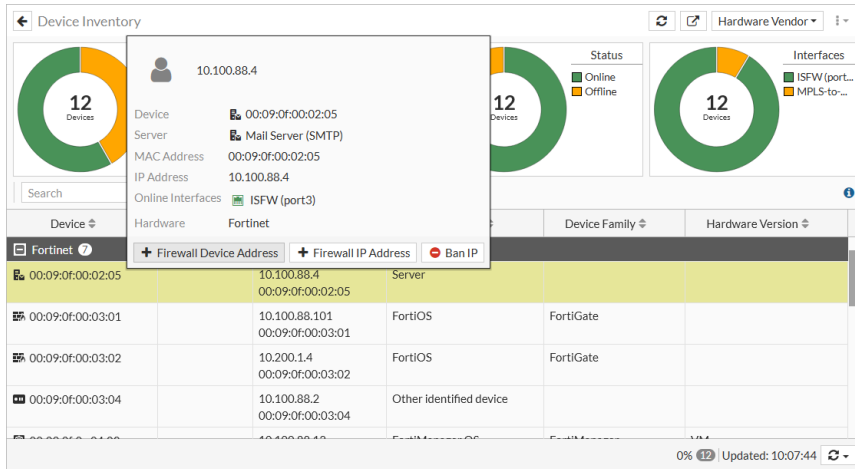

Assets detected by device detection appear in the *Device Inventory* widget. You can manage policies around devices by adding a new device object (MAC-based address) to a device. Once you add the MAC-based address, the device can be used in address groups or directly in policies.

To add a MAC-based address to a device:

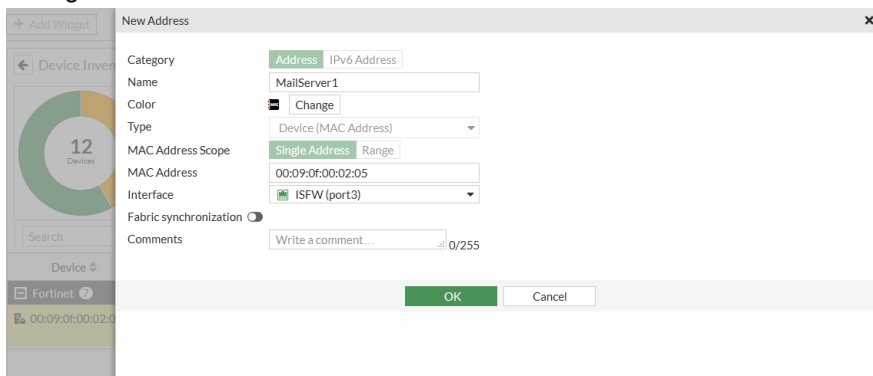

- Go to *Dashboard > Users & Devices*.

If you are using the Comprehensive dashboard template, go to *Dashboard > Device Inventory Monitor*. See .

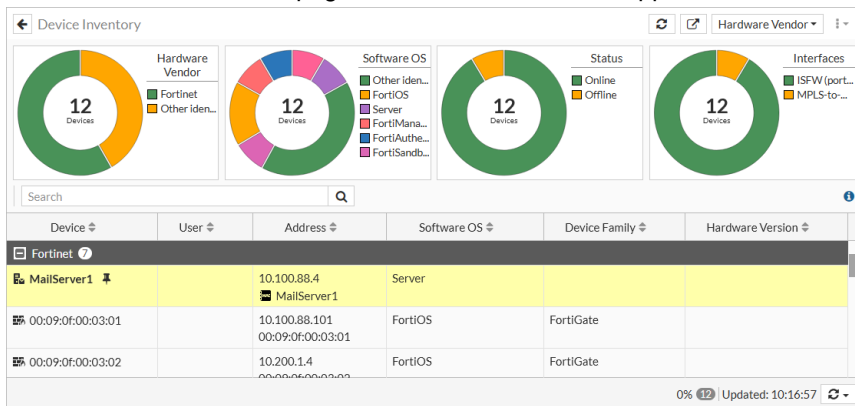

2. Hover over the *Device Inventory* widget, and click *Expand to Full Screen*. The *Device Inventory* monitor is displayed.
3. Click a device, then click *Firewall Device Address*. The *New Address* dialog is displayed.

4. In the *Name* field, give the device a descriptive name so that it is easy to in the *Device* column.
5. Configure the *MAC Address*.

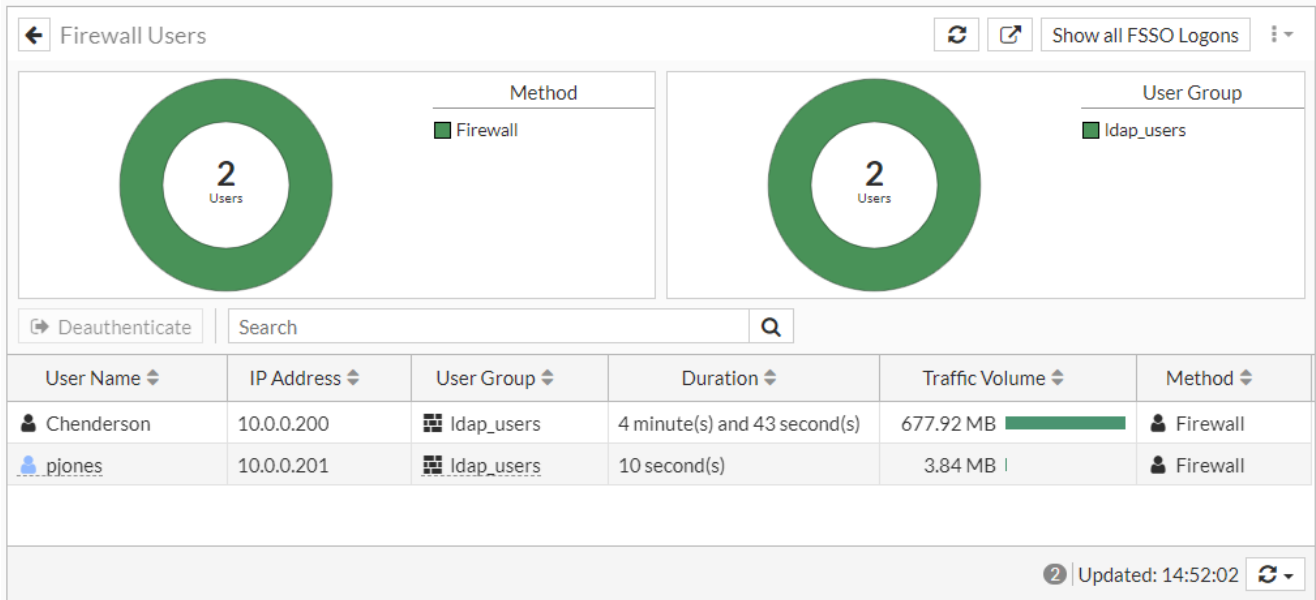

6. Click *OK*, then refresh the page. The *MAC* address icon appears in the *Address* column next to the device name.

Firewall Users monitor

The Firewall Users monitor displays all firewall users currently logged in. You can use the monitor to diagnose user-related logons or to highlight and deauthenticate a user.

To view the firewall monitor:

1. Go to *Dashboard > Users & Devices*.
If you are using the Comprehensive dashboard template, go to *Dashboard > Firewall User Monitor*. See .
2. Hover over the *Firewall Users* widget, and click *Expand to Full Screen*.
3. To show FSSO logons, click *Show all FSSO Logons* at the top right of the page.

To filter or configure a column in the table, hover over the column heading and click *Filter/Configure Column*.

To deauthenticate a user:

1. Go to *Dashboard > Users & Devices*.
2. Hover over the *Firewall Users* widget, and click *Expand to Full Screen*.
3. (Optional) Use the *Search* field to search for a specific user.
4. In the toolbar, click *Deauthenticate*, or right-click the user, and click *Deauthenticate*. The *Confirm* dialog is displayed.
5. Click *OK*.

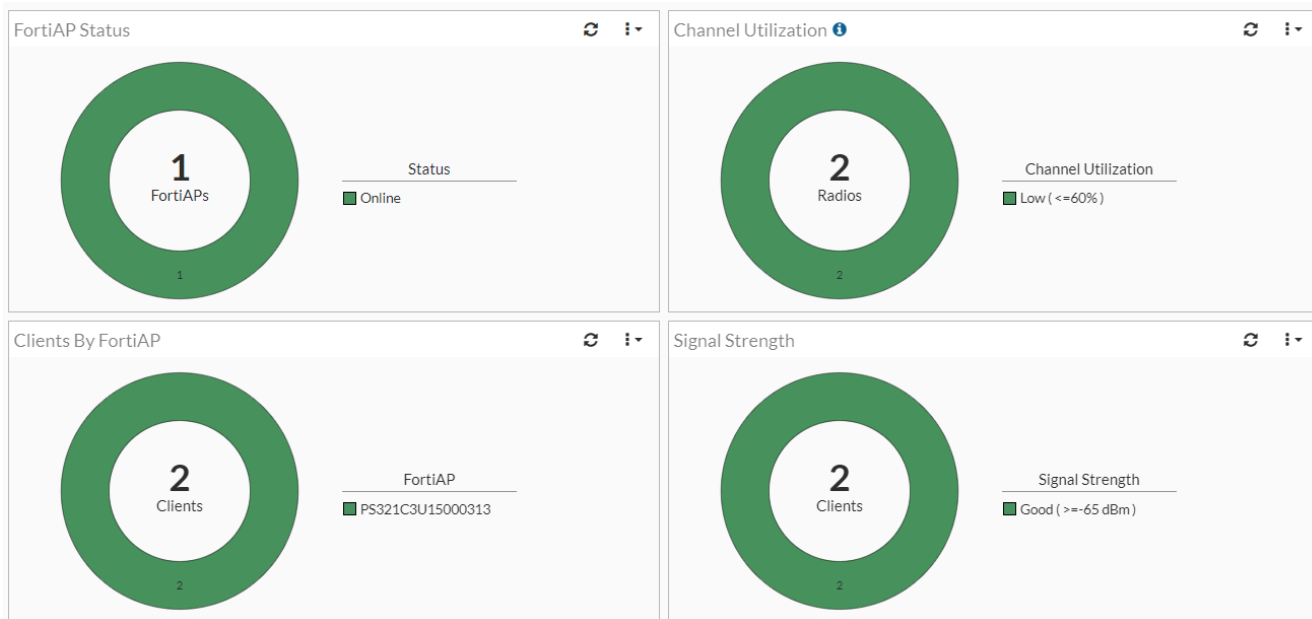

To view firewall users in the CLI:

```
# diagnose firewall auth list
```

WiFi dashboard

The *WiFi* dashboard provides an overview of your WiFi network's performance, including FortiAP status, channel utilization, WiFi clients and associated information, login failures, and signal strength.

To access the WiFi dashboard, go to *Dashboard > WiFi*.

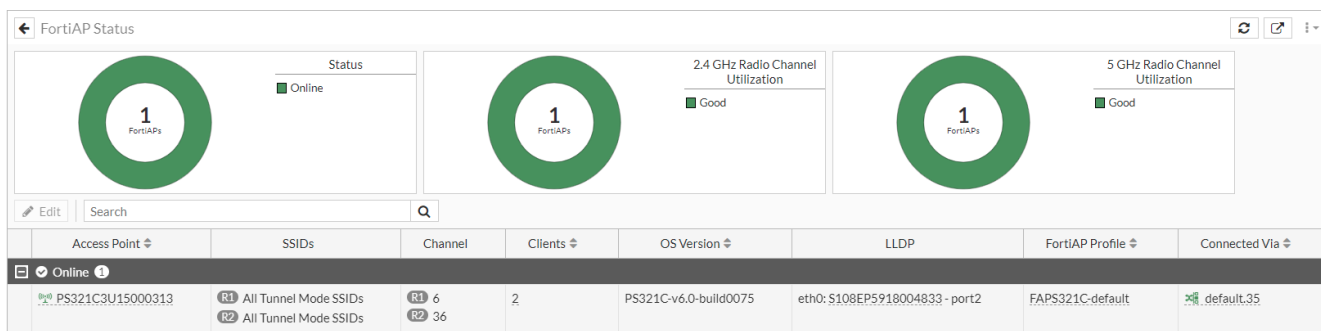

The WiFi dashboard can be customized per your requirements. To learn more about using and modifying dashboards and widgets, see [Dashboards and Monitors on page 83](#).

This section describes the following monitors available for the WiFi Dashboard:

- [FortiAP Status monitor on page 108](#)
- [Clients by FortiAP monitor on page 110](#)

FortiAP Status monitor

The *FortiAP Status* monitor displays the status and the channel utilization of the radios of FortiAP devices connected to a FortiGate. It also provides access to tools to diagnose and analyze connected APs.

To view the *FortiAP Status* monitor:

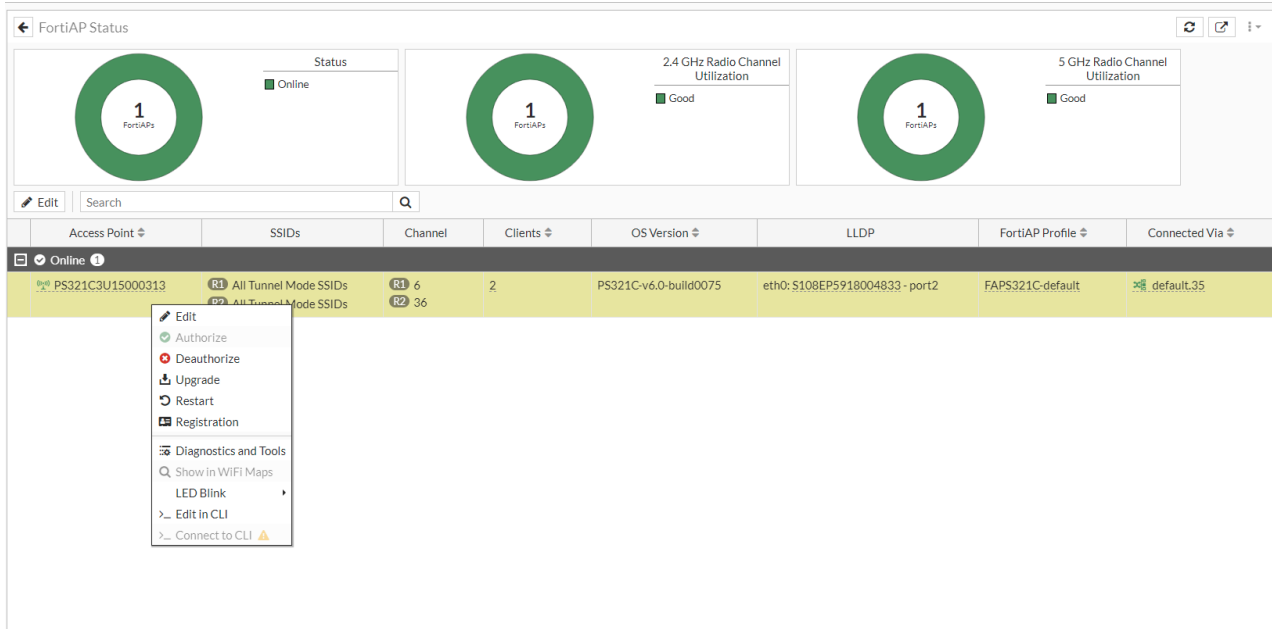

1. Go to *Dashboard > WiFi*.
2. Hover over the *FortiAP Status* widget, and click *Expand to Full Screen*. The *FortiAP Status* monitor opens.

- (Optional) Click *Save as Monitor* to save the widget as monitor.

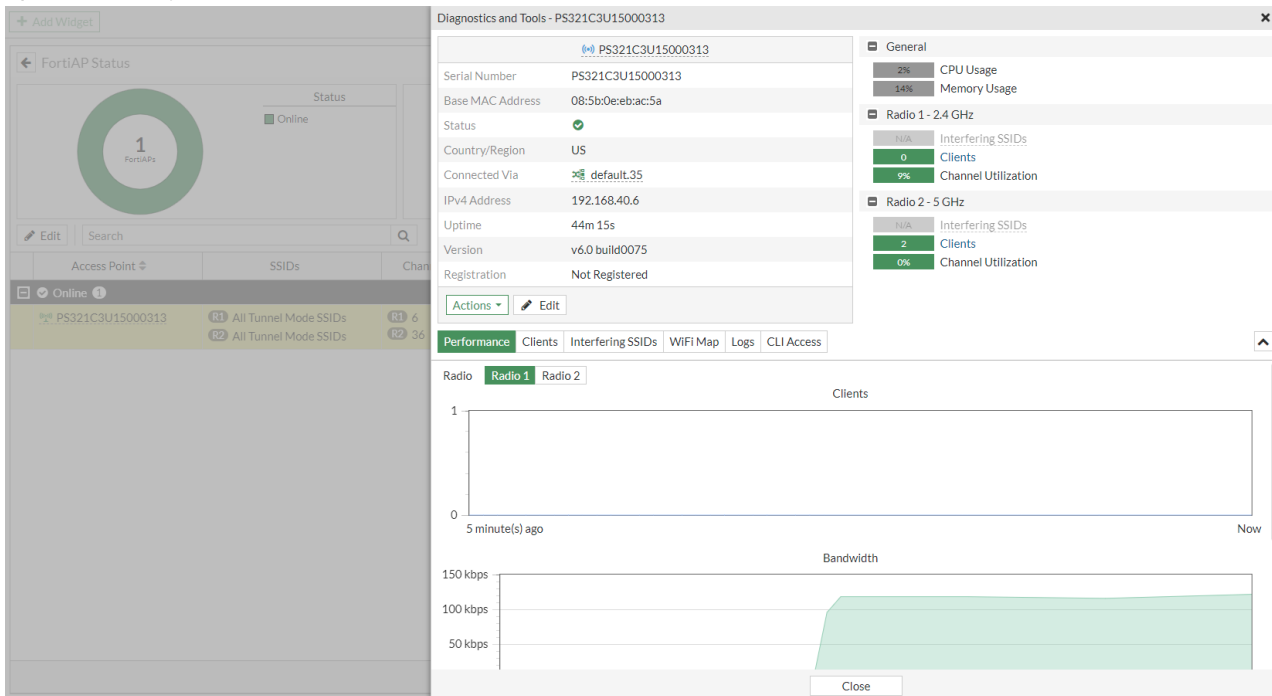

To view the Diagnostics and Tools menu:

- Right-click an *Access Point* in the table, and click *Diagnostics and Tools*. The *Diagnostics and Tools* dialog opens.

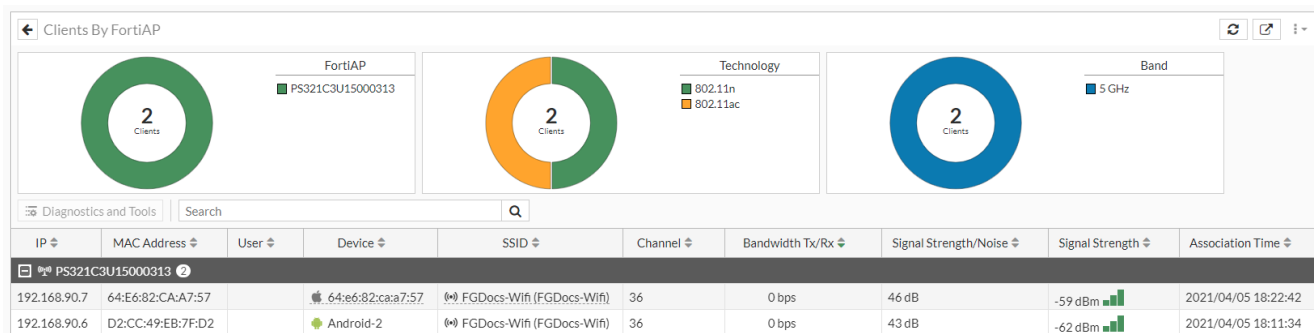

- To monitor and analyze the FortiAP device, click on the tabs in the *Diagnostics and Tools* dialog, such as *Clients*, *Spectrum Analysis*, *VLAN Probe*, and so on.

The *Diagnostics and Tools* dialog is similar to the device dialog from *WiFi & Switch Controller > Managed FortiAPs*. To learn more about the various tabs and their functions, see [Spectrum analysis of FortiAP E models](#), [VLAN probe report](#), and [Standardize wireless health metrics](#).

Clients by FortiAP monitor

The *Clients by FortiAP* monitor allows you to view detailed information about the health of individual WiFi connections in the network. It also provides access to tools to diagnose and analyze connected wireless devices.

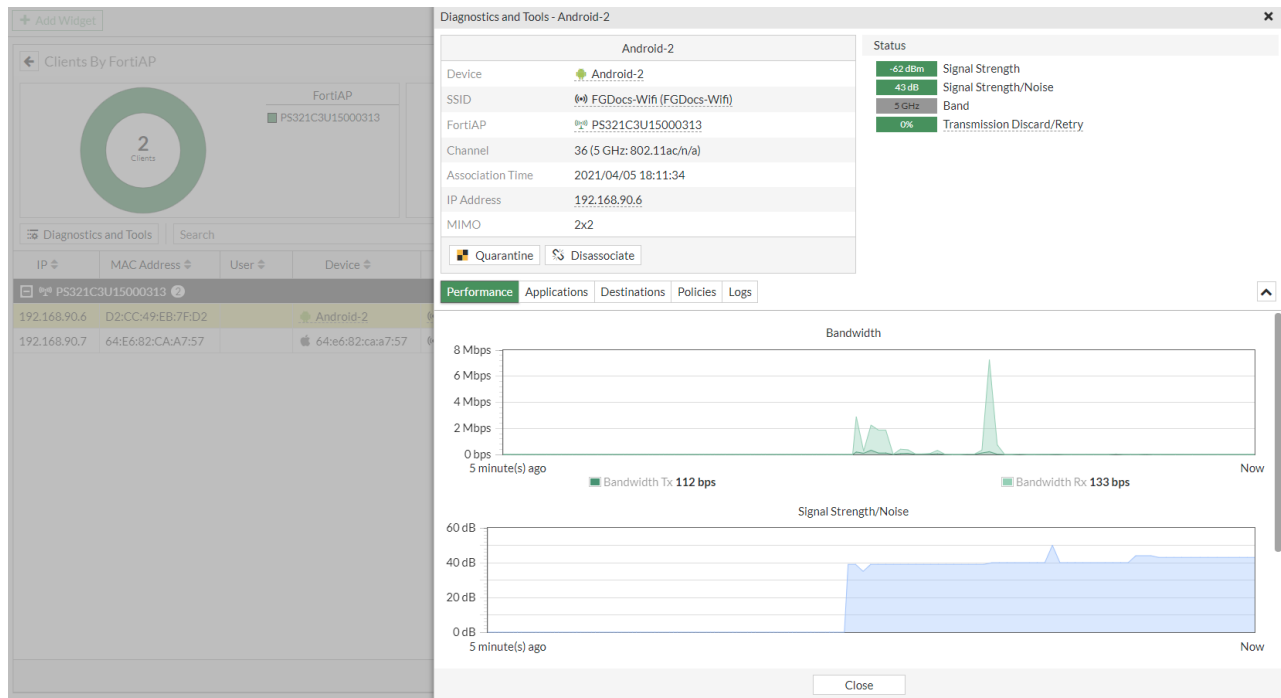

To view the *Clients by FortiAP* monitor:

1. Go to *Dashboard > WiFi*.
2. Hover over the *Clients by FortiAP* widget, and click *Expand to Full Screen*. The *Clients by FortiAP* monitor opens.
3. (Optional) Click *Save as Monitor* to save the widget as monitor.

To view the summary page for a wireless client:

1. Right-click a client in the table and select *Diagnostics and Tools*. The *Diagnostics and Tools - <device>* page is displayed.

2. (Optional) Click *Quarantine* to quarantine the client,
3. (Optional) Click *Disassociate* to disassociate the client.

Health status

The *Status* section displays the overall health for the wireless connection. The overall health of the connection is:

- Good if the value range for all three conditions are *Good*
- Fair or poor if one of the three conditions is *Fair* or *Poor* respectively.

Condition	Value Range
Signal Strength	<ul style="list-style-type: none"> • <i>Good</i> > -56dBm • -56dBm > <i>Fair</i> > -75dBm • <i>Poor</i> < -75dBm
Signal Strength/Noise	<ul style="list-style-type: none"> • <i>Good</i> > 39dBm • 20dBm < <i>Fair</i> < 39dBm • <i>Poor</i> < 20dBm
Band	<ul style="list-style-type: none"> • <i>Good</i> = 5G band • <i>Fair</i> = 2.4G band

Monitors

FortiGate supports both FortiView and Non-FortiView monitors. FortiView monitors are driven by traffic information captured from logs and real-time data. Non-FortiView monitors capture information from various real-time state tables on the FortiGate.

Non-FortiView monitors

Non-FortiView monitors capture information on various state tables, such as the routes in the routing table, devices in the device inventory, DHCP leases in the DHCP lease table, connected VPNs, clients logged into the wireless network, and much more. These monitors are useful when troubleshooting the current state of the FortiGate, and to identify whether certain objects are in the state table or not. For more information, see [Dashboards on page 90](#).

FortiView monitors

FortiView is the FortiOS log view tool and comprehensive monitoring system for your network. FortiView integrates real-time and historical data into a single view on your FortiGate. It can log and monitor network threats, keep track of administration activities, and more.

Use FortiView monitors to investigate traffic activity such as user uploads and downloads, or videos watched on YouTube. You can view the traffic on the whole network by user group or by individual. FortiView displays the information in both text and visual format, giving you an overall picture of your network traffic activity so that you can quickly decide on actionable items.

FortiView is integrated with many UTM functions. For example, you can quarantine an IP address directly in FortiView or create custom devices and addresses from a FortiView entry.

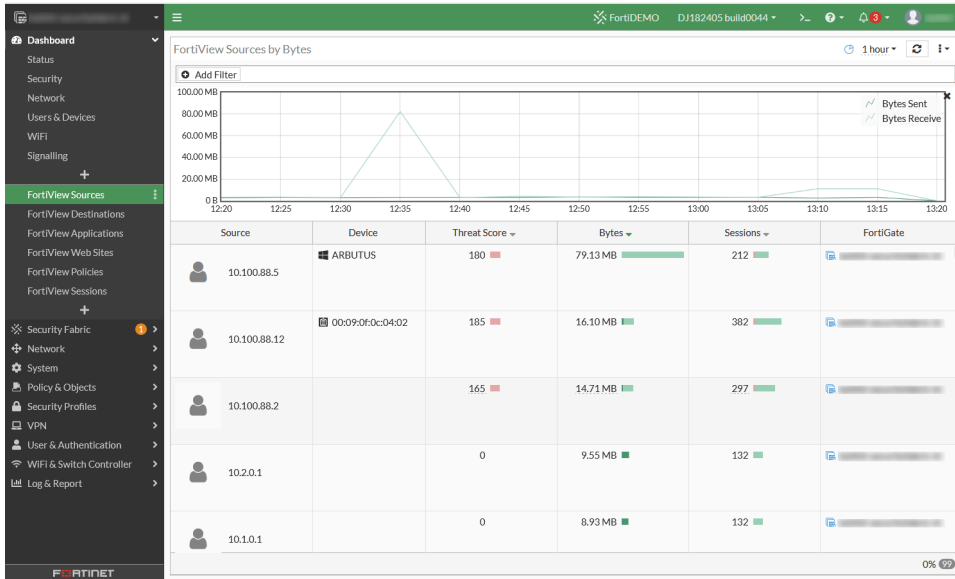

The logging range and depth will depend on the FortiGate model.

The *Optimal* template contains a set of popular default dashboards and FortiView monitors. The *Comprehensive* template contains a set of default dashboards as well as all of the FortiView monitors. See [Dashboards on page 90](#).

Template	Monitors
Optimal	<ul style="list-style-type: none"> • FortiView Sources • FortiView Destinations • FortiView Applications • FortiView Web Sites • FortiView Policies • FortiView Sessions
Comprehensive	<ul style="list-style-type: none"> • FortiView Sources • FortiView Destinations • FortiView Applications • FortiView Web Sites • FortiView Threats • FortiView Compromised Hosts • FortiView Policies • FortiView Sessions • Device Inventory Monitor • Routing Monitor • DHCP Monitor • SD-WAN Monitor • FortiGuard Quota Monitor • IPsec Monitor • SSL-VPN Monitor • Firewall User Monitor • Quarantine Monitor • FortiClient Monitor • FortiAP Clients Monitor • Rogue APs Monitor

FortiView monitors and widgets

FortiView monitors are available in the tree menu under *Dashboards*. The menu contains several default monitors for the top categories. Additional FortiView monitors are available as widgets that can be added to the dashboards. You can also add FortiView monitors directly to the tree menu with the Add (+) button.

Core FortiView monitors

The following default monitors are available in the tree menu:

Dashboard	Usage
FortiView Sources	Displays Top Sources by traffic volume and drilldown by Source.
FortiView Destinations	Displays Top Destinations by traffic volume and drilldown by Destination.
FortiView Applications	Displays Top Applications by traffic volume and drilldown by Application.
FortiView Web Sites	Displays Top Websites by session count and drilldown by Domain.
FortiView Policies	Displays Top Policies by traffic volume and drilldown by Policy number
FortiView Sessions	Displays Top Sessions by traffic source and can be used to end sessions.

Usage is based on default settings. The pages may be customized further and sorted by other fields.

You can quarantine a host and ban an IP from all of the core FortiView monitors.

Adding FortiView monitors

Non-core FortiView monitors are available in the *Add monitor* pane. You can add a FortiView widget to a dashboard or the tree menu as a monitor.

To add a monitor to the tree menu:

1. In the tree menu, under the monitors section, click *Add Monitor (+)*. The *Add Monitor* window opens.

2. Click *Add* next to a monitor. You can use the *Search* field to search for a specific monitor.
3. In the *FortiGate* area, select *All FortiGates* or *Specify* to select a FortiGate device in the security fabric.
4. (Optional) In the *Data Source* area, select *Specify* and select a source device.
5. From the *Time Period* dropdown, select the time period. This option is not available in all monitors.
6. In the *Visualization* area, select *Table View* or *Bubble Chart*.
7. From the *Sort By* dropdown, select the sorting method.
8. Click *Add Monitor*. The monitor is added to the tree menu.

Monitors by category

Usage is based on the default settings. The monitors may be customized further and sorted by other fields.

LANDMARK

Widget	Sort by	Usage
Applications	Bytes/Sessions/Bandwidth/Packets	Displays top applications and drilldown by application.
Application Bandwidth	Bytes/Bandwidth	Displays bandwidth for top applications and drilldown by application.
Cloud Applications	Bytes/Sessions/Files(Up/Down)	Displays top cloud applications and drilldown by application.
Cloud Users	Bytes/Sessions/Files(Up/Down)	Displays top cloud users and drilldown by cloud user.
Compromised Hosts	Verdict	Displays compromised hosts and drilldown by source.
Countries/Regions	Bytes/Sessions/Bandwidth/Packets	Displays top countries/regions and drilldown by countries/regions.
Destination Firewall Objects	Bytes/Sessions/Bandwidth/Packets	Displays top destination firewall objects and drilldown by destination objects.
Destination Owners	Bytes/Sessions/Bandwidth/Packets	Displays top destination owners and drilldown by destination.
Destinations	Bytes/Sessions/Bandwidth/Packets	Displays top destinations and drilldown by destination.

Widget	Sort by	Usage
Search Phrases	Count	Displays top search phrases and drilldown by search phrase.
Source Firewall Objects	Bytes/Sessions/Bandwidth/Packets	Displays top search phrases and drilldown by source object.
Sources	Bytes/Sessions/Bandwidth/Packets	Displays top sources and drilldown by source.
Threats	Threat level/Threat Score/Sessions	Displays top threats and drilldown by threat.
Traffic Shaping	Dropped Bytes/Bytes/Sessions/Bandwidth/Packets	Displays top traffic shaping and drilldown by shaper.
Web Categories	Bytes/Sessions/Bandwidth/Packets	Displays top web categories and drilldown by category.
Web Sites	Bytes/Sessions/Bandwidth/Packets	Displays top web sites and drilldown by domain.
WiFi Clients	Bytes/Sessions	Displays top WiFi clients and drilldown by source.

WAN

Widget	Sort by	Usage
Servers	Bytes/Sessions/Bandwidth/Packets	Displays top servers and drilldown by server address.
Sources	Bytes/Sessions/Bandwidth/Packets	Displays top sources and drilldown by device.
Threats	Threat Level/Threat Score/Sessions	Displays top threats and drilldown by threat.

All Segments

Widget	Sort by	Usage
Admin Logins	Configuration Changes/Logins/Failed Logins	Displays top admin logins by username.
Destination Interfaces	Bytes/Sessions/Bandwidth/Packets	Displays top destination interfaces by destination interface.
Endpoint Vulnerabilities	Severity	Displays top endpoint vulnerabilities by vulnerability name.
Failed Authentication	Failed Attempts	Displays top failed authentications by failed authentication source.
FortiSandbox Files	Submitted	Displays top FortiSandbox files by file name.

Widget	Sort by	Usage
Interface Pairs	Bytes/Sessions/Bandwidth/Packets	Displays top interface pairs by source interface.
Policies	Bytes/Sessions/Bandwidth/Packets	Displays top policies by policy.
Source Interfaces	Bytes/Sessions/Bandwidth/Packets	Displays top source interfaces by source interface.
System Events	Level/Events	Displays top system events by event name.
VPN	Connections/Bytes	Displays top VPN connections by user.
Vulnerable Endpoint Devices	Detected Vulnerabilities	Displays top vulnerable endpoint devices by device.

A maximum of 25 interfaces can be monitored at one time on a device.

Using the FortiView interface

Use the FortiView interface to customize the view and visualizations within a monitor to find the information you are looking for. The tools in the top menu bar allow you to change the time display, refresh or customize the data source, and filter the results. You can also right-click a table in the monitor to view drilldown information for an item.

Real-time and historical charts

Use the *Time Display* dropdown to select the time period to display on the current monitor. Time display options vary depending on the monitor and can include real-time information (*now*) and historical information (*1 hour*, *24 hours*, and *7 days*).

Disk logging or remote logging must be enabled to view historical information.

You can create a custom time range by selecting an area in table with your cursor.

The icon next to the time period identifies the data source (FortiGate Disk, FortiAnalyzer, or FortiGate Cloud). You can hover over the icon to see a description of the device.

Data source

FortiView gathers information from a variety of data sources. If there are no log disk or remote logging configured, the data will be drawn from the FortiGate's session table, and the *Time Period* is set to *Now*.

Other data sources that can be configured are:

- FortiGates (disk)
- FortiAnalyzer
- FortiGate Cloud

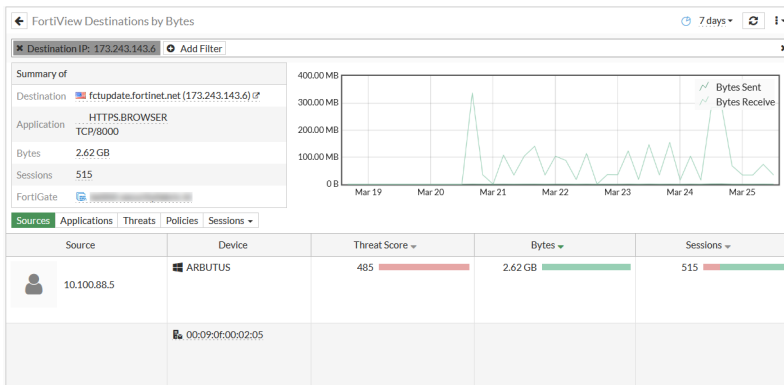

When *Data Source* is set to *Best Available Device*, FortiAnalyzer is selected when available, then FortiGate Cloud, and then FortiGate Disk.

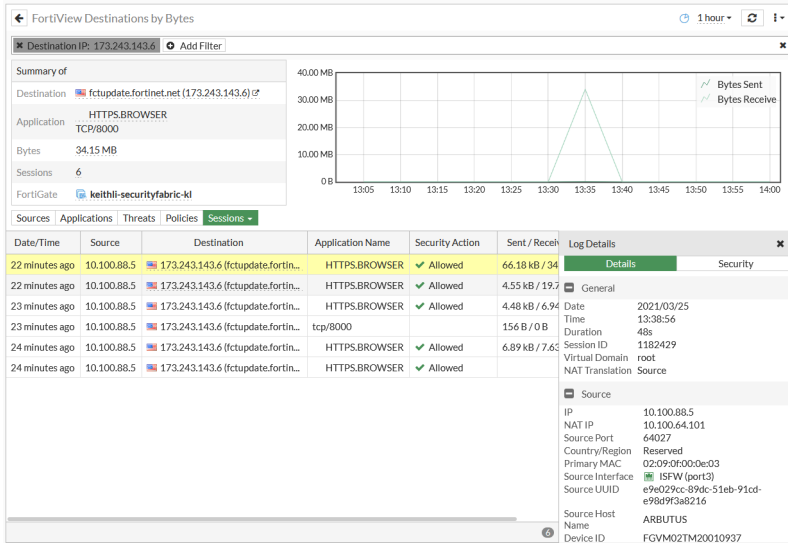

Drilldown information

Double-click or right-click an entry in a FortiView monitor and select *Drill Down to Details* to view additional details about the selected traffic activity. Click the *Back* icon in the toolbar to return to the previous view.

You can group drilldown information into different drilldown views. For example, you can group the drilldown information in the *FortiView Destinations* monitor by *Sources*, *Applications*, *Threats*, *Policies*, and *Sessions*.

Double-click an entry to view the logs in *Sessions* view. Double-click a session to view the logs.

- Graph**
 - The graph shows the bytes sent/received in the time frame. real time does not include a chart.
 - Users can customize the time frame by selecting a time period within the graph.
- Summary of**
 - Shows information such as the user/avatar, avatar/source IP, bytes, and sessions total for the time period.
 - Can quarantine host (access layer quarantine) if they are behind a FortiSwitch or FortiAP.
 - Can ban IP addresses, adds the source IP address into the quarantine list.
- Tabs**
 - Drilling down entries in any of these tabs (except sessions tab) will take you to the underlying traffic log in the sessions tab.
 - Applications* shows a list of the applications attributed to the source IP. This can include scanned applications (using Application Control in a firewall policy or unscanned applications.

```
config log gui-display
    set fortiview-unscanned-apps enable
end
```
 - Destinations* shows destinations grouped by IP address/FQDN.
 - Threats* lists the threats caught by UTM profiles. This can be from antivirus, IPS, Web Filter, Application Control, etc.
 - Web Sites* contains the websites which were detected either with webfilter, or through FQDN in traffic logs.
 - Web Categories* groups entries into their categories as dictated by the Web Filter Database.
 - Policies* groups the entries into which polices they passed through or were blocked by.
 - Sessions* shows the underlying logs (historical) or sessions (real time). Drilldowns from other tabs end up showing the underlying log located in this tab.
 - Search Phrases* shows entries of search phrases on search engines captured by a Web Filter UTM profile, with deep inspection enabled in firewall policy.
 - More information can be shown in a tooltip while hovering over these entries.

To view matching logs or download a log, click the *Security* tab in the *Log Details* .

Enabling FortiView from devices

You can enable FortiView from SSD disk, FortiAnalyzer and FortiGate Cloud.

FortiView from disk

FortiView from disk is available on all FortiGates with an SSD disk.

Restrictions

Model	Supported view
Entry-level models with SSD	Five minutes and one hour
Mid-range models with SSD	Up to 24 hours
High-end models with SSD	Up to seven days To enable seven days view: <pre>config log setting set fortiview-weekly-data enable end</pre>

Configuration

A firewall policy needs to be in place with traffic logging enabled. For optimal operation with FortiView, internal interface roles should be clearly defined as LAN. DMZ and internet facing or external interface roles should be defined as WAN.

To configure logging to disk:

```
config log disk setting
    set status enable
end
```

To include sniffer traffic and local-deny traffic when FortiView from Disk:

```
config report setting
    set report-source forward-traffic sniffer-traffic local-deny-traffic
end
```

This feature is only supported through the CLI.

Troubleshooting

Use `execute report flush-cache` and `execute report recreate-db` to clear up any irregularities that may be caused by upgrading or cache issues.

Traffic logs

To view traffic logs from disk:

1. Go to *Log & Report*, and select either the *Forward Traffic*, *Local Traffic*, or *Sniffer Traffic* views.
2. In the top menu bar, click *Log location* and select *Disk*.

FortiView from FortiAnalyzer

Connect FortiGate to a FortiAnalyzer to increase the functionality of FortiView. Adding a FortiAnalyzer is useful when adding monitors such as the *Compromised Hosts*. FortiAnalyzer also allows you to view historical information for up to seven days.

Requirements

- A FortiGate or FortiOS
- A compatible FortiAnalyzer (see [Compatibility with FortiOS](#))

To configure logging to the FortiAnalyzer, see [Configuring FortiAnalyzer on page 2371](#)

To enable FortiView from FortiAnalyzer:

1. Go to *Dashboard > FortiView Sources*.
2. Select a time range other than *Now* from the dropdown list to view historical data.
3. In top menu, click the dropdown, and select *Settings*. The *Edit Dashboard Widget* dialog is displayed.
 - a. In the *Data Source* area, click *Specify*.
 - b. From the dropdown, select *FortiAnalyzer*, and click *OK*.

All the historical information now comes from the FortiAnalyzer.

When *Data Source* is set to *Best Available Device*, FortiAnalyzer is selected when available, then FortiGate Cloud, and then FortiGate Disk.

FortiView from FortiGate Cloud

This function requires a FortiGate that is registered and logged into a compatible FortiGate Cloud. When using FortiGate Cloud, the *Time Period* can be set to up to 24 hours.

To configure logging to FortiGate Cloud, see [Configuring FortiGate Cloud on page 2373](#).

To enable FortiView with log source as FortiGate Cloud:

1. Go to *Dashboard > FortiView Sources*.
2. In the top menu, click the dropdown, and select *Settings*. The *Edit Dashboard Widget* window opens.
 - a. In the *Data Source* area, click *Specify*.
 - b. From the dropdown, select *FortiGate Cloud*, then click *OK*.

You can select FortiGate Cloud as the data source for all available FortiView pages and widgets.

FortiView sources

The *FortiView Sources* monitor displays top sources sorted by Bytes, Sessions or Threat Score. The information can be displayed in real time or historical views. You can use the monitor to create or edit a firewall device address or IP address definitions, and temporarily or permanently ban IPs.

To add a firewall device address:

1. In the *Device* column, hover over the device MAC address. An information window opens.

2. Click *Firewall Device Address*. The *New Address* dialog opens.
3. Configure the address settings, and click *Return*.

Use the *Name* field to assign a descriptive name to a device so it is easier to find it in the *Device* column. After you finish configuring the device, refresh the page to see the new name in the monitor.

To add a firewall IP address:

1. In the *Device* column, hover over the device MAC address. An information window opens.

2. Click *Firewall IP Address*. The *New Address* window opens.
3. Configure the address settings, and click *Return*.

Use the *Name* field to assign a descriptive name to a device so it is easier to find it in the *Device* column. After you finish configuring the device, refresh the page to see the new name in the monitor.

To ban an IP address:

1. In the *Device* column, hover over the device MAC address. An information window opens.

2. Click *Ban IP*. The *Ban IP* dialog is displayed.
3. Configure the ban IP settings, and click *OK*.

FortiView Sessions

The *FortiView Sessions* monitor displays *Top Sessions* by traffic source and can be used to end sessions.

To view the *FortiView Sessions* dashboard, go to *Dashboard > FortiView Sessions*.

The session table displayed on the *FortiView Sessions* monitor is useful when verifying open connections. For example, if you have a web browser open to browse the Fortinet website, you would expect a session entry from your computer on port 80 to the IP address for the Fortinet website. You can also use a session table to investigate why there are too many sessions for FortiOS to process.

You can filter the sessions displayed in the session table by setting up the available filtering options.

To filter sessions in the session table:

1. Click on the *Add Filter* button at the top of the session table.

2. Select the required filtering option. The session table updates to the filter selection.

3. You may add one or more filters depending upon your requirements. To add more filters, repeat the above steps for a different set of filters.

You can be very specific with how you use filters and target sessions based on different filter combinations. For example, you may want to view all sessions from a device with a particular IP by adding the *Source IP* filter. Similarly, you may need to target all the sessions having a particular *Destination IP* and *Destination Port*, and so on.

You may also view the session data in the CLI.

To view session data using the CLI:

```
# diagnose sys session list
```

The session table output in the CLI is very large. You can use the supported filters in the CLI to show only the data you need.

To view session data with filters using the CLI:

```
# diagnose sys session filter <option>
```

See [Using a session table on page 2884](#) to learn more about using the supported filters in the CLI.

You may also decide to end a particular session or all sessions for administrative purposes.

To end sessions from the GUI:

1. Select the session you want to end. To select multiple sessions, hold the *Ctrl* or *Shift* key on your keyboard while clicking the sessions.

The screenshot shows the FortiView Sessions interface with a table of sessions. The first three rows are highlighted in yellow, indicating they are selected. The table has columns for Source, Device, Destination, Application, Protocol, Source Port, Destination Port, Bytes, and Packets.

Source	Device	Destination	Application	Protocol	Source Port	Destination Port	Bytes	Packets
10.100.88.2	00:09:0f:00:03:04	96.45.33.73	HTTPS.BROWSER	TCP	58282	443	18.50 kB	38
10.100.88.4	00:09:0f:00:02:05	45.75.200.87	Fortiguard.Search	UDP	49396	53	4.13 kB	48
10.100.88.4	00:09:0f:00:02:05	45.75.200.88	Fortiguard.Search	UDP	49396	53	4.13 kB	48

2. Right-click on the selected sessions, click on *End Session(s)* or *End All Sessions*.

The screenshot shows the FortiView Sessions interface with the same table as above. The first three rows are still highlighted. Context menus are open over the first three rows, showing options like 'End Session(s)' and 'End All Sessions'.

Source	Device	Destination	Application	Protocol	Source Port	Destination Port	Bytes	Packets
10.100.88.2	00:09:0f:00:03:04	96.45.33.73	HTTPS.BROWSER	TCP	58282	443	18.50 kB	38
10.100.88.4	00:09:0f:00:02:05	45.75.200.87	Fortiguard.Search	UDP	49396	53	4.13 kB	48
10.100.88.4	00:09:0f:00:02:05	45.75.200.88	Fortiguard.Search	UDP	49396	53	4.13 kB	48
10.100.88.4	00:09:0f:00:02:05	45.75.200.85	Fortiguard.Search	UDP	49396	53	4.13 kB	48

3. Click *OK* in the confirmation dialog.

FortiView Top Source and Top Destination Firewall Objects monitors

The *FortiView Source Firewall Objects* and *FortiView Destination Firewall Objects* monitors leverage UUID to resolve firewall object address names for improved usability.

Requirements

To have a historical *Firewall Objects*-based view, address objects' UUIDs need to be logged.

To enable address object UUID logging in the CLI:

```
config system global
  set log-uuid-address enable
```

end

To add a firewall object monitor in the GUI:

1. Click *Add Monitor*. The *Add Monitor* window opens.

2. In the *Search* field, type *Destination Firewall Objects* and click the *Add* button next to the dashboard name.
3. In the *FortiGate* area, select the FortiGate(s) from the dropdown.
4. In the *Data Source* area, select *Best Available Device* or *Specify*. For information, see [Using the FortiView interface on page 118](#).
5. From the *Time Period* dropdown, select the time period. Select *now* for real-time information, or (*1 hour*, *24 hours*, and *7 days*) for historical information.
6. In the *Visualization* area, select *Table View* or *Bubble Chart*.
7. From the *Sort By* dropdown, select *Bytes*, *Sessions*, *Bandwidth*, or *Packets*.
8. Click *Add Monitor*. The monitor is added to the tree menu.

To drill down Firewall Objects:

1. Open the *FortiView Source Firewall Objects* or *FortiView Destination Firewall Objects* monitor.
2. Right-click on any *Source* or *Destination Object* and click *Drill Down to Details*.

Source Object	Bytes	Sessions	Bandwidth	FortiGate
all	1.19 GB	15	5.94 kbps	
all	27.73 MB	70	119.19 kbps	
MPLS-Interfaces	304 B	2	0 bps	
B01_LAN	23.43 kB	32	61.09 kbps	Branch_Office_01
B02_LAN	129.73 kB	392	137.87 kbps	Branch_Office_02
all	457.35 kB	1,352	309.10 kbps	Enterprise_Second_Floor
all	281.65 kB	954	214.22 kbps	Enterprise_First_Floor

3. Click the tabs to sort the sessions by *Application*, *Destinations*, *Web Sites*, or *Policies*.

Summary of

Source Object: all

Bytes: 28.21 MB

Sessions: 106

Bandwidth: 196.50 kbps

FortiGate: [FortiGate Icon]

Applications Destinations Web Sites Policies Sessions

Application	Category	Risk	Bytes	Sessions	Bandwidth
FortiguardSearch	Cloud.IT	Low	67.28 kB	26	0 bps
NTP	Network.Service	Low	66.80 kB	5	304 bps
DNS	Network.Service	Low	12.14 kB	43	1.05 kbps

4. To view signatures, click the entry in the *Category* column.

Applications Destinations Web Sites Policies Sessions

Application	Category	Risk	Bytes	Sessions	Bandwidth
FortiguardSearch	Cloud	Low	67.28 kB	26	0 bps
NTP	Network	Low	66.80 kB	5	304 bps
DNS	Network.Service	Low	12.14 kB	43	1.05 kbps

5. To view sessions, right-click an entry and click *View Sessions*, or click the *Sessions* tab.
6. To end a session, right-click an entry in the *Sessions* tab and select *End Sessions* or *End All Sessions*.

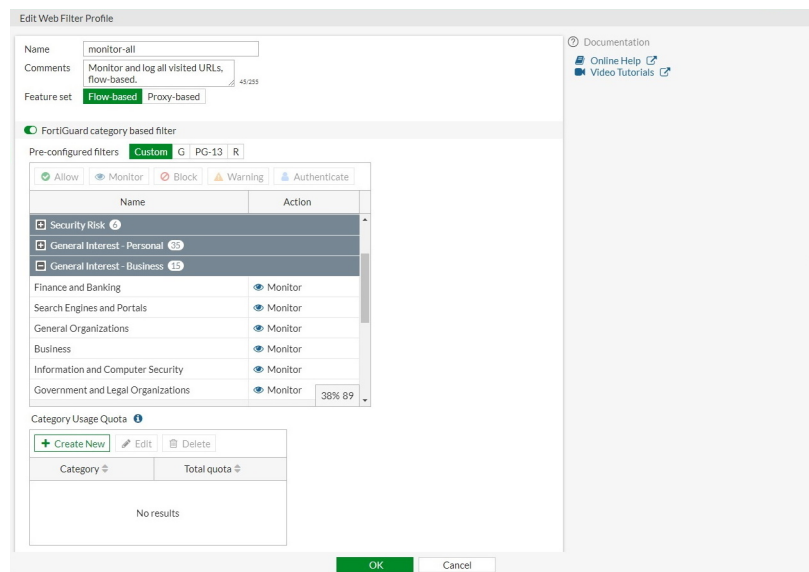

Viewing top websites and sources by category

You can use FortiGuard web categories to populate the category fields in various FortiView monitors such as *FortiView Web Categories*, *FortiView Websites* or *FortiView Sources*. To view the categories in a monitor, the web filter profile must be configured to at least monitor for a FortiGuard category based on a web filter and applied to a firewall policy for outbound traffic.

To verify the web filter profile is monitor-only:

1. Go to *Security Profiles > Web Filter*.
2. Double-click a web filter that is applied to an outbound traffic firewall policy. The *Edit Web Filter Profile* window opens.
3. Ensure *FortiGuard category based filter* is enabled.

In the image below, the *General Interest - Business* categories are monitor-only.

To create a Web categories monitor:

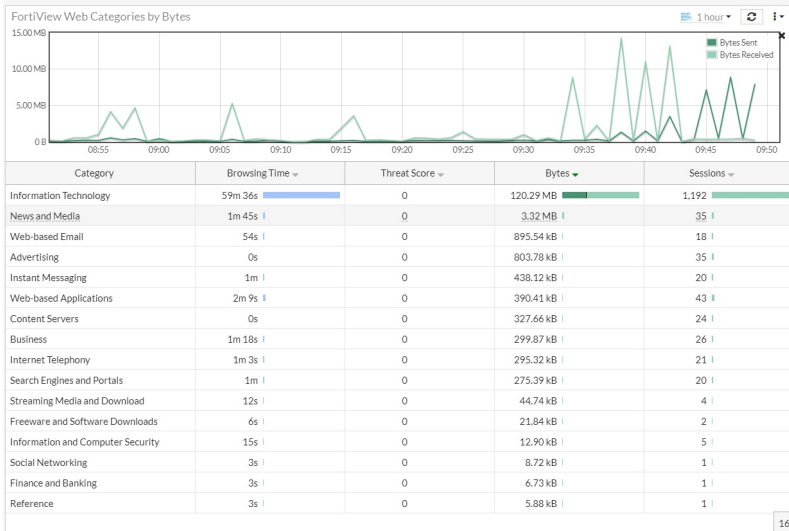

1. Click *Add Monitor*. The *Add Monitor* window opens.

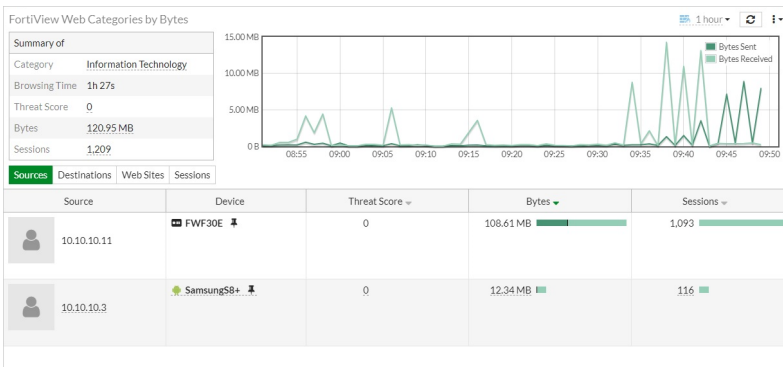

2. In the *Search* field, type *FortiView Web Categories* and click the *Add* button next to the monitor name.
3. In the *FortiGate* area, select the FortiGate(s) from the dropdown.
4. In the *Data Source* area, click *Best Available Device* or *Specify* to select a device in the security fabric.
5. From the *Time Period* dropdown, select a time period greater than *Now*.
6. From the *Sort By* dropdown, select *Bytes*, *Sessions*, *Bandwidth*, or *Packets*.
7. Click *Add Monitor*. The widget is added to the tree menu.

Viewing the web filter category

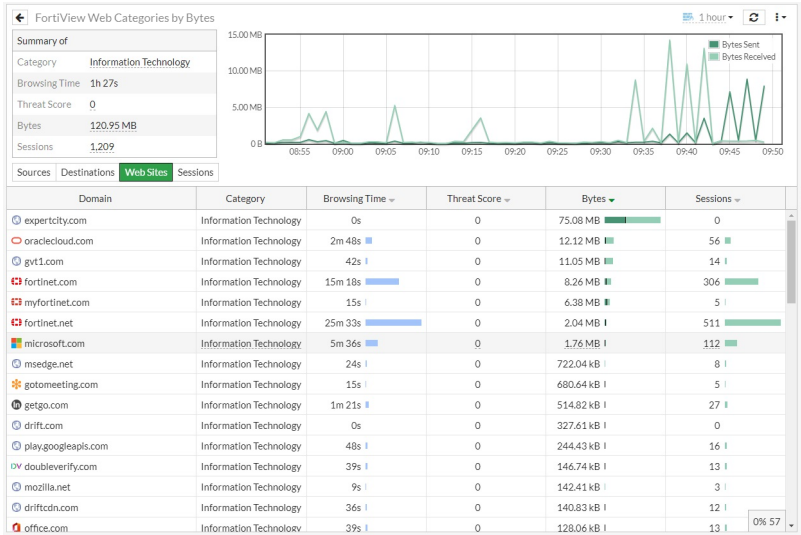

The web filter category name appears in the *Category* column of the dashboard.

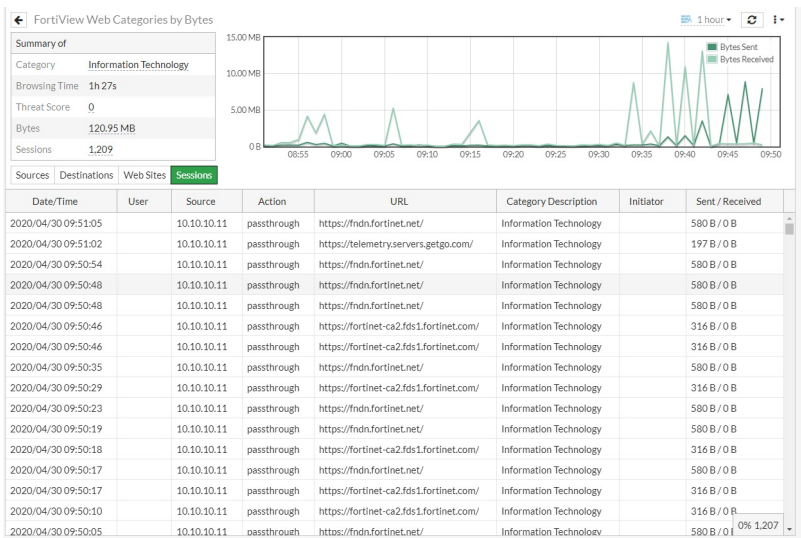

Click an entry in the table. The category name appears at the top of the *Summary of* box.

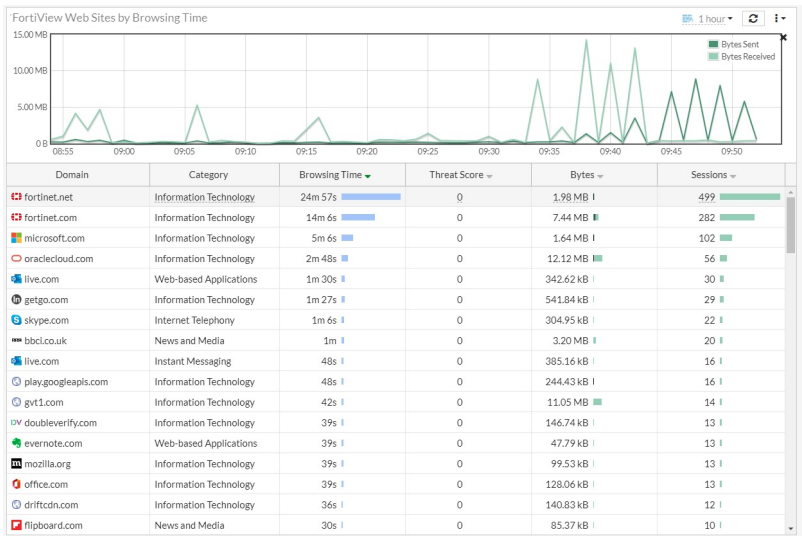

Click the *Web Sites* tab. The category name appears in the *Category* column.

Click the Sessions tab. The category name appears in the *Category Description* column.

The category name also appears in the *Category* column in the *FortiView Websites* and *FortiView Sources* monitors.

Cloud application view

To see different cloud application views, set up the following:

- A FortiGate with a firewall policy that uses the *Application Control* security profile.
- A FortiGate with log data from the local disk or FortiAnalyzer.
- Optional but highly recommended: *SSL Inspection* set to *deep-inspection* in the related firewall policies.

Viewing cloud applications

Cloud applications

All cloud applications require *SSL Inspection* set to *deep-inspection* on the firewall policy. For example, `Facebook_File.Download` can monitor Facebook download behavior which requires *SSL deep-inspection* to parse the deep information in the network packets.

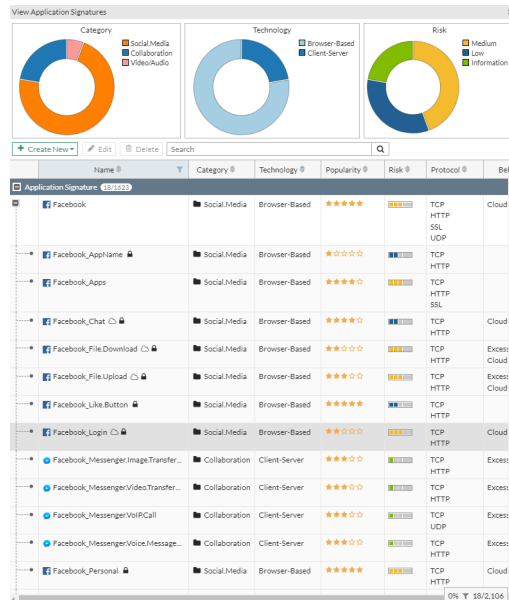

To view cloud applications:

1. Go to *Security Profiles > Application Control*.
2. Select a relative Application Control profile used by the firewall policy and click *Edit*.
3. On the *Edit Application Sensor* page, click *View Application Signatures*.
4. Hover over a column heading or the *Application Signature* bar. In the right gutter area, click the filter icon to filter the applications.

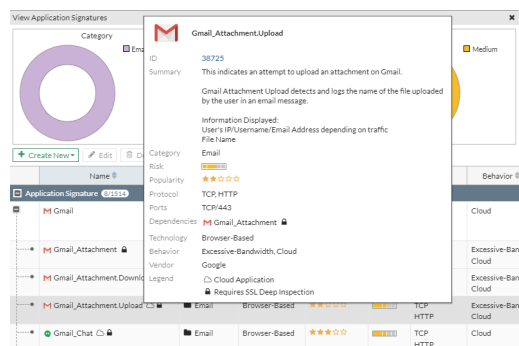

Cloud applications have a cloud icon beside them.

The lock icon indicates that the application requires SSL deep inspection.

5. Hover over an item to see its details.

This example shows *Gmail_Attachment.Download*, a cloud application signature based sensor which requires SSL deep inspection. If any local network user behind the firewall logs into Gmail and downloads a Gmail attachment, that activity is logged.

Applications with cloud behavior

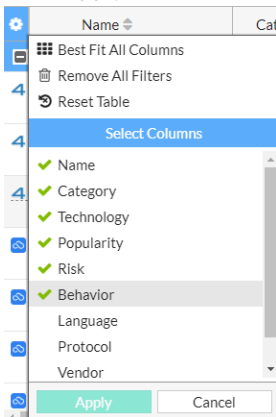

Applications with cloud behavior is a superset of cloud applications.

Some applications do not require SSL deep inspection, such as Facebook, Gmail, and YouTube. This means that if any traffic trigger application sensors for these applications, there is a FortiView cloud application view for that traffic.

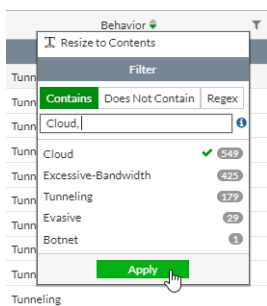

Other applications require SSL deep inspection, such as Gmail attachment, Facebook_Workplace, and so on.

To view applications with cloud behavior:

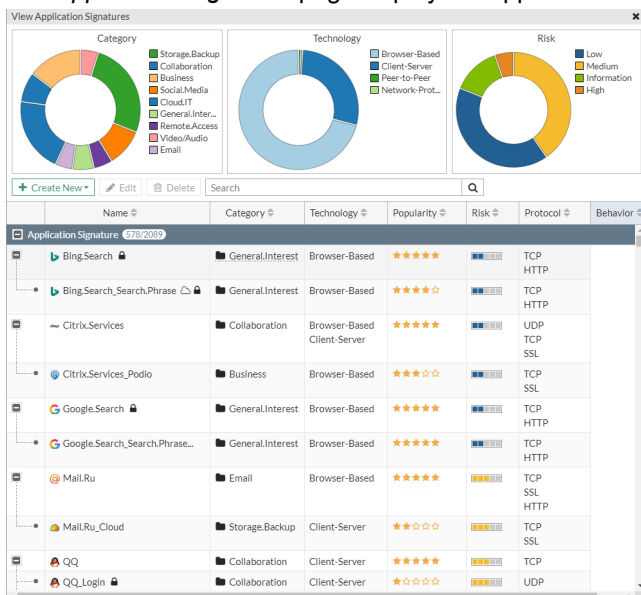

1. In the *Application Signature* page, ensure the *Behavior* column is displayed. If necessary, add the *Behavior* column.
 - a. Hover over the left side of the table column headings to display the *Configure Table* icon.
 - b. Click *Configure Table* and select *Behavior*.
 - c. Click *Apply*.

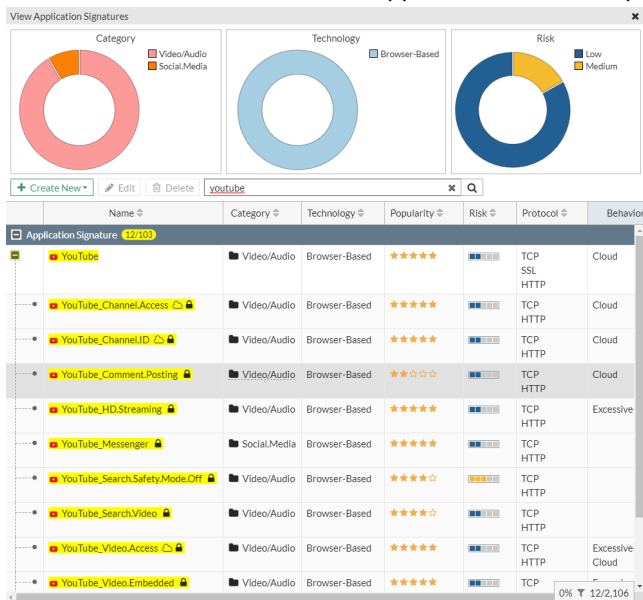

2. Click the filter icon in the *Behavior* column and select *Cloud* to filter by Cloud. Then click *Apply*.

3. The *Application Signature* page displays all applications with cloud behavior.

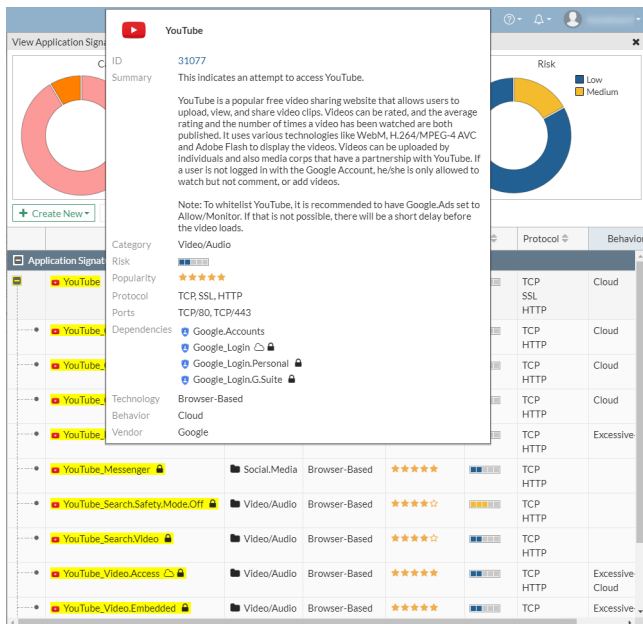

4. Use the *Search* box to search for applications. For example, you can search for *youtube*.

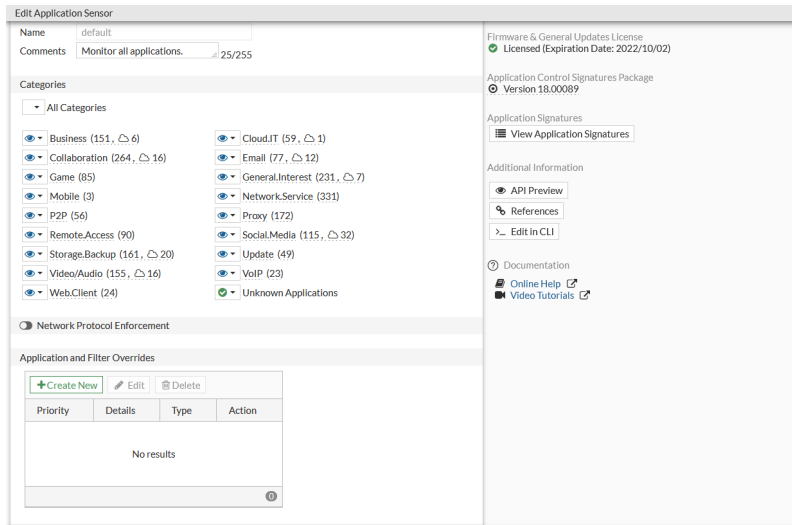

5. Hover over an item to see its details.

This example shows an application sensor with no lock icon which means that this application sensor does not require SSL deep inspection. If any local network user behind the firewall tries to navigate to the YouTube website, that activity is logged.

Configuring the Cloud Applications monitor

On the *Edit Application Sensor* page in the *Categories* section, the eye icon next to a category means that category is monitored and logged.

To add the Cloud Applications monitor in the GUI:

1. Click **Add Monitor**. The *Add monitor* window opens.

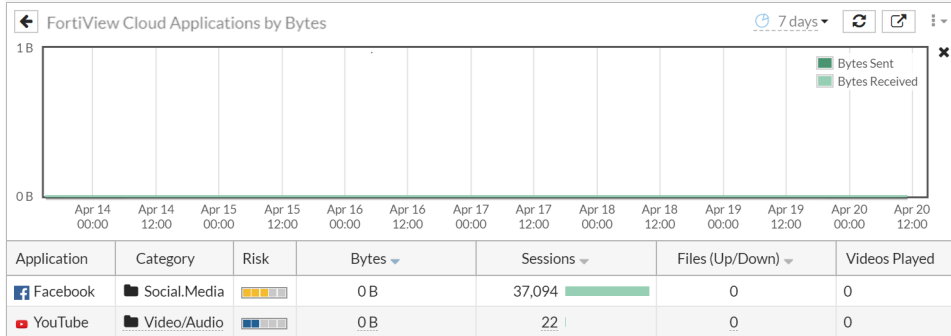

2. In the *Search* field, enter *FortiView Cloud Applications* and click the *Add* button next to the monitor.
3. In the *FortiGate* area, select the FortiGate(s) from the dropdown.
4. In the *Data Source* area, click *Best Available Device* or *Specify* to select a device in the security fabric.
5. From the *Time Period* dropdown, select a time period greater than *Now*.
6. From the *Sort By* dropdown, select *Bytes*, *Sessions*, or *Files (Up/Down)*.
7. Click *Add Monitor*. The monitor is added to the tree menu.
8. Open the monitor. If SSL deep inspection is enabled in the related firewall policy, then the monitor shows the additional details that are logged, such as *Files (Up/Down)* and *Videos Played*.
 - For YouTube, the *Videos Played* column is triggered by the *YouTube_Video.Play* cloud application sensor. This shows the number of local network users who logged into YouTube and played YouTube videos.
 - For Dropbox, the *Files (Up/Down)* column is triggered by *Dropbox_File.Download* and *Dropbox_File.Upload* cloud application sensors. This shows the number of local network users who logged into Dropbox and uploaded or downloaded files.

Application	Category	Risk	Bytes	Sessions	Files (Up/Down)	Videos Played
YouTube	Video/Audio	Low	137.53 MB	120	0	34
Dropbox	Storage Backup	Low	7.34 MB	29	1	0
Google Hangouts	Collaboration	Low	25.21 KB	3	0	0
Facebook	Social Media	Low	33.03 KB	6	0	0
Skype	Collaboration	Low	32.92 KB	1	0	0

Using the Cloud Applications monitor

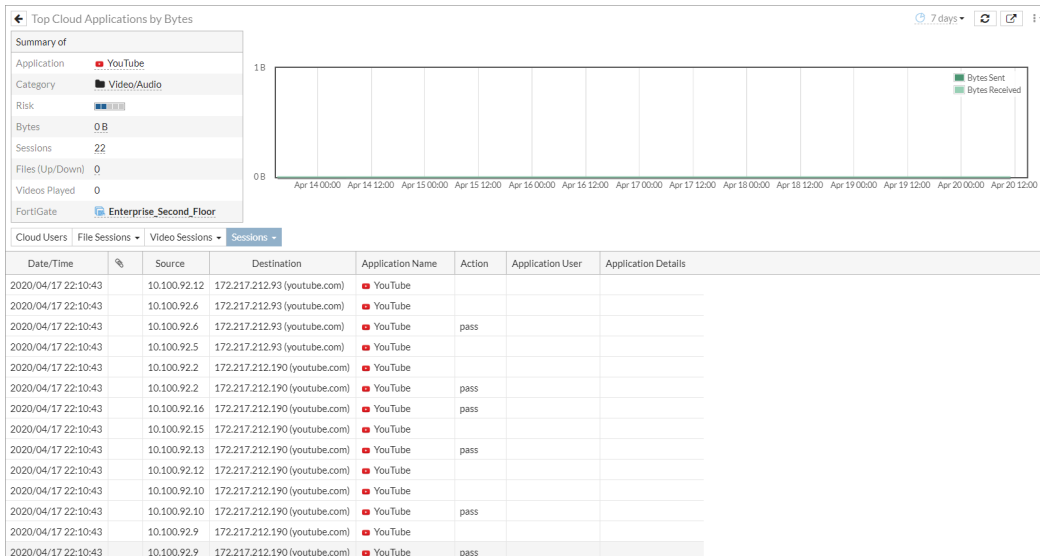

To see additional information in the Cloud Applications monitor:

1. In the tree menu, click the *FortiView Cloud Applications* monitor to open it.

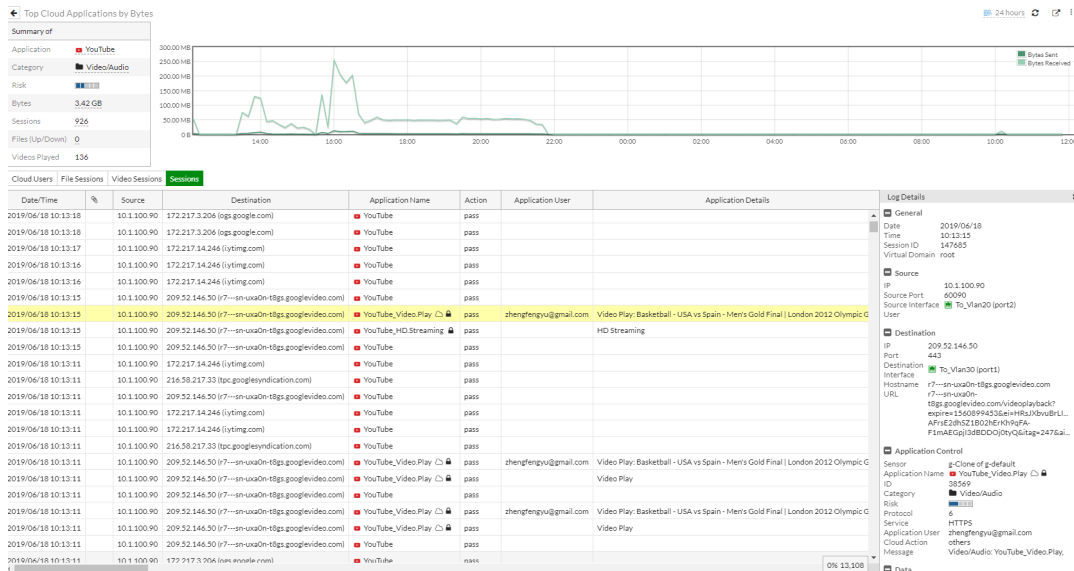

2. For details about a specific entry, double-click the entry or right-click the entry and select *Drill Down to Details*.
3. To see all the sessions for an application, click *Sessions*.

In this example, the *Application Name* column shows all applications related to YouTube.

- To view log details, double-click a session to display the *Log Details* pane. Sessions monitored by SSL deep inspection (in this example, Youtube_Video.Play) captured deep information such as *Application User*, *Application Details*, and so on. The *Log Details* pane also shows additional deep information such as *application ID*, *Message*, and so on.

Sessions not monitored by SSL deep inspection (YouTube) did not capture the deep information.

- To display a specific time period, select and drag in the timeline graph to display only the data for that time period.

Top application: YouTube example

Monitoring network traffic with SSL deep inspection

This example describes how to monitor network traffic for YouTube using *FortiView Applications* view with SSL deep inspection.

To monitor network traffic with SSL deep inspection:

- Create a firewall policy with the following settings:
 - Application Control* is enabled.
 - SSL Inspection* is set to *deep-inspection*.

- *Log Allowed Traffic* is set to *All Sessions*.

2. Go to *Security Profiles > Application Control*.
3. Select a relative Application Control profile used by the firewall policy and click *Edit*.
4. Because YouTube cloud applications are categorized into *Video/Audio*, ensure the *Video/Audio* category is monitored. Monitored categories are indicated by an eye icon.
5. Click *View Application Signatures* and hover over YouTube cloud applications to view detailed information about YouTube application sensors.
6. Expand *YouTube* to view the Application Signatures associated with the application.

Application Signature	Description	Application ID
<i>YouTube_Video.Access</i>	An attempt to access a video on YouTube.	16420
<i>YouTube_Channel.ID</i>	An attempt to access a video on a specific channel on YouTube.	44956
<i>YouTube_Comment.Posting</i>	An attempt to post comments on YouTube.	31076
<i>YouTube_HD.Streaming</i>	An attempt to watch HD videos on YouTube.	33104
<i>YouTube_Messenger</i>	An attempt to access messenger on YouTube.	47858
<i>YouTube_Video.Play</i>	An attempt to download and play a video from YouTube.	38569
<i>YouTube_Video.Upload</i>	An attempt to upload a video to YouTube.	22564
<i>YouTube</i>	An attempt to access YouTube. This application sensor does not depend on SSL deep inspection so it does not have a cloud or lock icon.	31077
<i>YouTube_Channel.Access</i>	An attempt to access a video on a specific channel on YouTube.	41598

To view the application signature description, click the ID link in the information window.

7. On the test PC, log into YouTube and play some videos.
8. On the FortiGate, go to *Log & Report > Application Control* and look for log entries for browsing and playing YouTube videos.

In this example, note the *Application User* and *Application Details*. Also note that the *Application Control ID* is 38569 showing that this entry was triggered by the application sensor *YouTube_Video.Play*.

Monitoring network traffic without SSL deep inspection

This example describes how to monitor network traffic for YouTube using FortiView cloud application view without SSL deep inspection.

To monitor network traffic without SSL deep inspection:

- Create a firewall policy with the following settings.
 - Application Control* is enabled.
 - SSL Inspection* is set to *certificate-inspection*.

- *Log Allowed Traffic* is set to *All Sessions*.

2. On the test PC, log into YouTube and play some videos.
3. On the FortiGate, go to *Log & Report > Application Control* and look for log entries for browsing and playing YouTube videos.

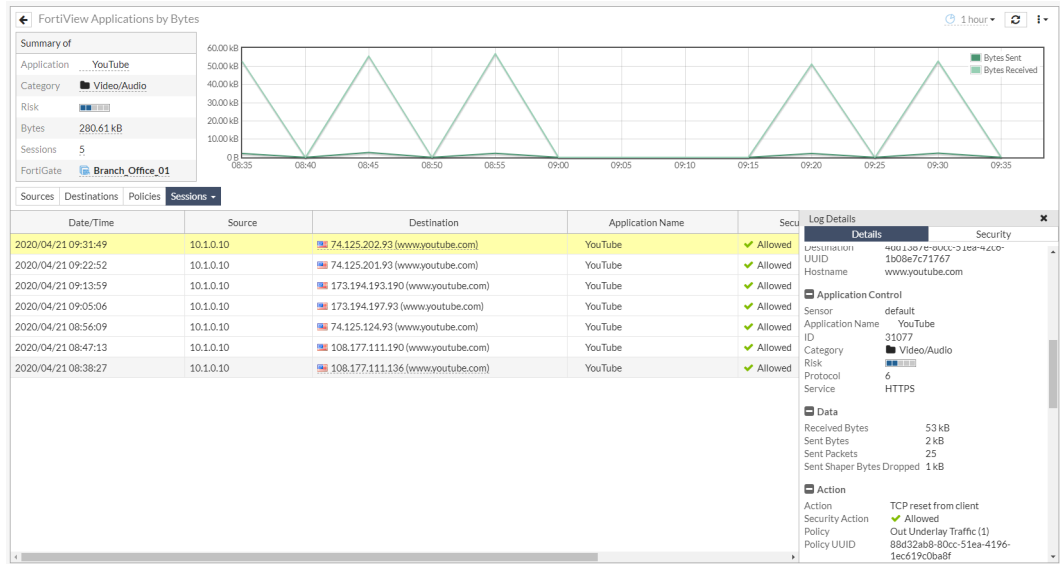

In this example, the log shows only applications with the name YouTube. The log cannot show YouTube application sensors which rely on SSL deep inspection.

4. Go to *Dashboard > FortiView Applications*.
The *FortiView Application by Bytes* monitor shows the YouTube cloud application without the video played information that requires SSL deep inspection.

5. Double-click *YouTube* and click the *Sessions* tab.

These sessions were triggered by the application sensor *YouTube* with the ID *31077*. This is the application sensor with cloud behavior which does not rely on SSL deep inspection.

Network

Interfaces

Physical and virtual interfaces allow traffic to flow between internal networks, and between the internet and internal networks. FortiGate has options for setting up interfaces and groups of subnetworks that can scale as your organization grows. You can create and edit VLAN, EMAC-VLAN, switch interface, zones, and so on.

The following topics provide information about interfaces:

Interface settings

Administrators can configure both physical and virtual FortiGate interfaces in *Network > Interfaces*. There are different options for configuring interfaces when FortiGate is in NAT mode or transparent mode.

The available options will vary depending on feature visibility, licensing, device model, and other factors. The following list is not comprehensive.

To configure an interface in the GUI:

1. Go to *Network > Interfaces*.
2. Click *Create New > Interface*.
3. Configure the interface fields:

Interface Name	Physical interface names cannot be changed.
Alias	Enter an alternate name for a physical interface on the FortiGate unit. This field appears when you edit an existing physical interface. The alias does not appear in logs. The maximum length of the alias is 25 characters.
Type	The configuration type for the interface, such as VLAN, Software Switch, 802.3ad Aggregate, and others.
Interface	This field is available when <i>Type</i> is set to <i>VLAN</i> . Select the name of the physical interface that you want to add a VLAN interface to. Once created, the VLAN interface is listed below its physical interface in the <i>Interface</i> list. You cannot change the physical interface of a VLAN interface.
VLAN ID	This field is available when <i>Type</i> is set to <i>VLAN</i> . Enter the VLAN ID. The VLAN ID can be any number between 1 and 4094 and must match the VLAN ID added by the IEEE 802.1Q-compliant router or switch that is connected to the VLAN subinterface. The VLAN ID can be edited after the interface is added.
VRF ID	Virtual Routing and Forwarding (VRF) allows multiple routing table instances to coexist on the same router. One or more interface can have a VRF, and packets are only forwarded between interfaces with the same VRF.
Virtual Domain	Select the virtual domain to add the interface to. Only administrator accounts with the <i>super_admin</i> profile can change the <i>Virtual Domain</i> .

Interface Members	<p>This section can have different formats depending on the <i>Type</i>. Members can be selected for some interface types:</p> <ul style="list-style-type: none"> • <i>Software Switch or Hardware Switch</i>: Specify the physical and wireless interfaces joined into the switch. • <i>802.3ad Aggregate or Redundant Interface</i>: This field includes the available and selected interface lists.
Role	<p>Set the role setting for the interface. Different settings will be shown or hidden when editing an interface depending on the role:</p> <ul style="list-style-type: none"> • <i>LAN</i>: Used to connected to a local network of endpoints. It is default role for new interfaces. • <i>WAN</i>: Used to connected to the internet. When WAN is selected, the <i>Estimated bandwidth</i> setting is available, and the following settings are not: <i>DHCP server</i>, <i>Create address object matching subnet</i>, <i>Device detection</i>, <i>Security mode</i>, <i>One-arm sniffer</i>, <i>Dedicate to extension/fortiap modes</i>, and <i>Admission Control</i>.and will show Estimated Bandwidth settings. • <i>DMZ</i>: Used to connected to the DMZ. When selected, <i>DHCP server</i> and <i>Security mode</i> are not available. • <i>Undefined</i>: The interface has no specific role. When selected, <i>Create address object matching subnet</i> is not available.
Estimated bandwidth	<p>The estimated WAN bandwidth.</p> <p>The values can be entered manually, or saved from a speed test executed on the interface. The values can be used in SD-WAN rules that use the Maximize Bandwidth or Best Quality strategy.</p>
Traffic mode	<p>This option is only available when <i>Type</i> is <i>WiFi SSID</i>.</p> <ul style="list-style-type: none"> • <i>Tunnel</i>: Tunnel to wireless controller • <i>Bridge</i>: Local bridge with FortiAP's interface • <i>Mesh</i>: Mesh downlink
Address	
Addressing mode	<p>Select the addressing mode for the interface.</p> <ul style="list-style-type: none"> • <i>Manual</i>: Add an IP address and netmask for the interface. If IPv6 configuration is enabled, you can add both an IPv4 and an IPv6 address. • <i>DHCP</i>: Get the interface IP address and other network settings from a DHCP server. • <i>Auto-managed by IPAM</i>: Assign subnets to prevent duplicate IP addresses from overlapping within the same Security Fabric. See Configure IPAM locally on the FortiGate on page 212. • <i>PPPoE</i>: Get the interface IP address and other network settings from a PPPoE server. This option is only available on the entry-level FortiGate models. • <i>One-Arm Sniffer</i>: Set the interface as a sniffer port so it can be used to detect attacks. See One-arm sniffer on page 220.

IP/Netmask	If <i>Addressing Mode</i> is set to <i>Manual</i> , enter an IPv4 address and subnet mask for the interface. FortiGate interfaces cannot have multiple IP addresses on the same subnet.
IPv6 addressing mode	Select the addressing mode for the interface: <ul style="list-style-type: none"> • <i>Manual</i>: Add an IP address and netmask for the interface. • <i>DHCP</i>: Get the interface IP address and other network settings from a DHCP server. • <i>Delegated</i>: Select an <i>IPv6 upstream interface</i> that has DHCPv6 prefix delegation enabled, and enter an <i>IPv6 subnet</i> if needed. The interface will get the IPv6 prefix from the upstream DHCPv6 server that is connected to the IPv6 upstream interface, and form the IPv6 address with the subnet configured on the interface.
IPv6 Address/Prefix	If <i>Addressing Mode</i> is set to <i>Manual</i> and IPv6 support is enabled, enter an IPv6 address and subnet mask for the interface. A single interface can have an IPv4 address, IPv6 address, or both.
Auto configure IPv6 address	Automatically configure an IPv6 address using Stateless Address Auto-configuration (SLAAC). This option is available when <i>IPv6 addressing mode</i> is set to <i>Manual</i> .
DHCPv6 prefix delegation	Enable/disable DHCPv6 prefix delegation, which can be used to delegate IPv6 prefixes from an upstream DHCPv6 server to another interface or downstream device. When enabled, there is an option to enable a <i>DHCPv6 prefix hint</i> that helps the DHCPv6 server provide the desired prefix.
Create address object matching subnet	This option is available when <i>Role</i> is set to <i>LAN</i> or <i>DMZ</i> . Enable this option to automatically create an address object that matches the interface subnet.
Secondary IP Address	Add additional IPv4 addresses to this interface.
Administrative Access	
IPv4 Administrative Access	Select the types of administrative access permitted for IPv4 connections to this interface. See Configure administrative access to interfaces on page 147 .
IPv6 Administrative Access	Select the types of administrative access permitted for IPv6 connections to this interface. See Configure administrative access to interfaces on page 147 .
DHCP Server	Enable a DHCP server for the interface. See DHCP servers and relays on page 323 .
Stateless Address Auto-configuration (SLAAC)	Enable to provide IPv6 addresses to connected devices using SLAAC.
DHCPv6 Server	Select to enable a DHCPv6 server for the interface. When enabled, you can configure <i>DNS service</i> settings: <i>Delegated</i> (delegate the DNS received from the upstream server), <i>Same as System DNS</i> , or <i>Specify</i> (up to four servers).

You can also enable *Stateful server* to configure the DHCPv6 server to be stateful. Manually enter the IP range, or use Delegated mode to delegate IP prefixes from an upstream DHCPv6 server connected to the upstream interface.

Network	
Device Detection	Enable/disable passively gathering device identity information about the devices on the network that are connected to this interface.
Security Mode	Enable/disable captive portal authentication for this interface. After enabling captive portal authentication, you can configure the authentication portal, user and group access, custom portal messages, exempt sources and destinations/services, and redirect after captive portal.
DSL Settings	
Physical mode	Set to <i>ADSL</i> or <i>VDSL</i> .
Transfer mode	Set to <i>PTM</i> or <i>ATM</i> . If the <i>Transfer mode</i> is set to <i>ATM</i> , the <i>Virtual channel identification</i> , <i>Virtual path identification</i> , <i>ATM protocol</i> , and <i>MUX type</i> can be configured.
Traffic Shaping	
Outbound shaping profile	Enable/disable traffic shaping on the interface. This allows you to enforce bandwidth limits on individual interfaces. See Interface-based traffic shaping profile on page 1017 for more information.
Miscellaneous	
Comments	Enter a description of the interface of up to 255 characters.
Status	Enable/disable the interface. <ul style="list-style-type: none"> • <i>Enabled</i>: The interface is active and can accept network traffic. • <i>Disabled</i>: The interface is not active and cannot accept traffic.

4. Click *OK*.

To configure an interface in the CLI:

```
config system interface
  edit <name>
    set vdom <VDOM_name>
    set mode {static | dhcp | pppoe}
    set ip <IP_address/netmask>
    set security-mode {none | captive-portal | 802.1X}
    set egress-shaping-profile <profile>
    set device-identification {enable | disable}
    set allowaccess {ping https ssh http snmp telnet fgfm radius-acct probe-response
fabric ftm}
    set secondary-IP enable
    config secondaryip
      edit 1
        set ip 9.1.1.2 255.255.255.0
        set allowaccess ping https ssh snmp http
      next
    next
  next
```

```

        end
    next
end

```

Configure administrative access to interfaces

You can configure the protocols that administrators can use to access interfaces on the FortiGate. This helps secure access to the FortiGate by restricting access to a limited number of protocols. It helps prevent users from accessing interfaces that you don't want them to access, such as public-facing ports.

As a best practice, you should configure administrative access when you're setting the IP address for a port.

To configure administrative access to interfaces in the GUI:

1. Go to *Network > Interfaces*.
2. Create or edit an interface.
3. In the *Administrative Access* section, select which protocols to enable for *IPv4* and *IPv6 Administrative Access*.

Speed Test	<p>Allow this interface to listen to speed test sender requests.</p> <p>To allow the FortiGate to be configured as speed test server, configure the following:</p> <pre> config system global set speedtest-server {enable disable} end </pre> <p>For more detail, see Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 772.</p>
HTTPS	Allow secure HTTPS connections to the FortiGate GUI through this interface. If configured, this option is enabled automatically.
HTTP	Allow HTTP connections to the FortiGate GUI through this interface. This option can only be enabled if HTTPS is already enabled.
PING	The interface responds to pings. Use this setting to verify your installation and for testing.
FMG-Access	Allow FortiManager authorization automatically during the communication exchanges between FortiManager and FortiGate devices.
SSH	Allow SSH connections to the CLI through this interface.
SNMP	Allow a remote SNMP manager to request SNMP information by connecting to this interface.
FTM	Allow FortiToken Mobile Push (FTM) access.
RADIUS Accounting	Allow RADIUS accounting information on this interface.
Security Fabric Connection	Allow Security Fabric access. This enables FortiTelemetry and CAPWAP.

FEC implementations on 10G, 25G, 40G, and 100G interfaces

Only supported FEC (forward error correction) implementations are allowed to be configured on 10G, 25G, 40G, and 100G interfaces based on the speed that is selected.

- For 1000M, 10G, or 40G interfaces, FEC is not supported and the option is disabled.
- For 25G and 100G interfaces, FEC is automatically set to `cl91-rs-fec` by default.

To configure an interface for FEC:

```
config system interface
  edit <name>
    set speed {10000full | 1000full | 100Gauto | 100Gfull | 25000auto | 25000full |
40000full}
    set mediatype {sr4 | lr4 | cr4}
    set forward-error-correction {disable | cl91-rs-fec | cl74-fc-fec}
  next
end
```

```
speed {10000full |
1000full | 100Gauto
| 100Gfull |
25000auto |
25000full |
40000full}
```

Set the interface speed:

- 10000full: 10G full-duplex
- 1000full: 1000M full-duplex
- 100Gauto: 100G auto-negotiation
- 100Gfull: 100G full-duplex
- 25000auto: 25G auto-negotiation
- 25000full: 25G full-duplex
- 40000full: 40G full-duplex

```
mediatype {sr4 | lr4 |
cr4}
```

Set the media type to use:

- sr4: short-range transceiver (4-lane)
- lr4: long-range transceiver (4-lane)
- cr4: copper transceiver (4-lane)

```
forward-error-correction
{disable | cl91-rs-
fec | cl74-fc-fec}
```

Set the forward error correction type:

- disable: disable forward error correction
- cl91-rs-fec: Reed-Solomon (FEC CL91)
- cl74-fc-fec: Firecode (FEC CL74)

To change the interface speed from 40G to 100G:

```
config system interface
  edit port26
    set speed 100Gfull
  next
end
```

The speed/mediatype/FEC of port26 will be changed from 40000full/sr4/disable to 100Gfull/sr4/cl91-rs-fec.

Do you want to continue? (y/n) y

Since the speed changed to 1000G, the `mediatype` setting automatically changes to `sr4`, and the `forward-error-correction` setting automatically changes to `cl91-rs-fec`. When the speed was 40G, the `forward-error-correction` setting was disabled.

Aggregation and redundancy

Link aggregation (IEEE 802.3ad) enables you to bind two or more physical interfaces together to form an aggregated (combined) link. This new link has the bandwidth of all the links combined. If a link in the group fails, traffic is transferred automatically to the remaining interfaces. The only noticeable effect is reduced bandwidth.

This feature is similar to redundant interfaces. The major difference is a redundant interface group only uses one link at a time, where an aggregate link group uses the total bandwidth of the functioning links in the group, up to eight (or more).

An interface is available to be an aggregate interface if:

- It is a physical interface and not a VLAN interface or subinterface.
- It is not already part of an aggregate or redundant interface.
- It is in the same VDOM as the aggregated interface. Aggregate ports cannot span multiple VDOMs.
- It does not have an IP address and is not configured for DHCP or PPPoE.
- It is not referenced in any security policy, VIP, IP Pool, or multicast policy.
- It is not an HA heartbeat interface.
- It is not one of the FortiGate-5000 series backplane interfaces.

When an interface is included in an aggregate interface, it is not listed on the *Network > Interfaces* page. Interfaces still appear in the CLI although configuration for those interfaces do not take effect. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, IP pools, or routing.

Sample configuration

This example creates an aggregate interface on a FortiGate-140D POE using ports 3-5 with an internal IP address of 10.1.1.123, as well as the administrative access to HTTPS and SSH.

To create an aggregate interface in the GUI:

1. Go to *Network > Interfaces* and select *Create New > Interface*.
2. Set *Name* to *aggregate*.
3. Set *Type* to *802.3ad Aggregate*.
4. Set *Interface members* to *port4*, *port5*, and *port6*.
5. Set *Addressing mode* to *Manual*.
6. Set *IP/Netmask* to *10.1.1.123/24*.
7. For *Administrative Access*, select *HTTPS* and *SSH*.
8. Click *OK*.

To create an aggregate interface in the CLI:

```
config system interface
  edit "aggregate"
    set vdom "root"
    set ip 10.1.1.123 255.255.255.0
    set allowaccess https ssh
    set type aggregate
    set member "port4" "port5" "port6"
    set snmp-index 45
  next
end
```

Redundancy

In a redundant interface, traffic only goes over one interface at any time. This differs from an aggregated interface where traffic goes over all interfaces for increased bandwidth. This difference means redundant interfaces can have more robust configurations with fewer possible points of failure. This is important in a fully-meshed HA configuration.

An interface is available to be in a redundant interface if:

- It is a physical interface and not a VLAN interface.
- It is not already part of an aggregated or redundant interface.
- It is in the same VDOM as the redundant interface.
- It does not have an IP address and is not configured for DHCP or PPPoE.
- It has no DHCP server or relay configured on it.
- It does not have any VLAN subinterfaces.
- It is not referenced in any security policy, VIP, or multicast policy.
- It is not monitored by HA.
- It is not one of the FortiGate-5000 series backplane interfaces.

When an interface is included in a redundant interface, it is not listed on the *Network > Interfaces* page. You cannot configure the interface individually and it is not available for inclusion in security policies, VIPs, or routing.

Sample configuration

To create a redundant interface in the GUI:

1. Go to *Network > Interfaces* and select *Create New > Interface*.
2. Set *Name* to *redundant*.
3. Set *Type* to *Redundant Interface*.
4. Set *Interface members* to *port4*, *port5*, and *port6*.
5. Set *Addressing mode* to *Manual*.
6. Set *IP/Netmask* to *10.13.101.100/24*.
7. For *Administrative Access*, select *HTTPS* and *SSH*.
8. Click *OK*.

To create a redundant interface in the CLI:

```
config system interface
  edit "redundant"
    set vdom "root"
    set ip 10.13.101.100 255.255.255.0
    set allowaccess https http
    set type redundant
    set member "port4" "port5" "port6"
    set snmp-index 9
  next
end
```

Enhanced hashing for LAG member selection

FortiGate models that have an internal switch that supports modifying the distribution algorithm can use enhanced hashing to help distribute traffic evenly, or load balance, across links on the Link Aggregation (LAG) interface.

The enhanced hashing algorithm is based on a 5-tuple of the IP protocol, source IP address, destination IP address, source port, and destination port.

Different computation methods allow for more variation in the load balancing distribution, in case one algorithm does not distribute traffic evenly between links across different XAUs. The available methods are:

xor16	Use the XOR operator to make a 16 bit hash.
xor8	Use the XOR operator to make an 8 bit hash.
xor4	Use the XOR operator to make a 4 bit hash.
crc16	Use the CRC-16-CCITT polynomial to make a 16 bit hash.

The following NP6 non-service FortiGate models support this feature: 1200D, 1500D, 1500DT, 3000D, 3100D, 3200D, 3700D, and 5001D.

To configure the enhanced hashing:

```
config system npu
  set lag-out-port-select {enable | disable}
  config sw-eh-hash
    set computation {xor4 | xor8 | xor16 | crc16}
    set ip-protocol {include | exclude}
    set source-ip-upper-16 {include | exclude}
    set source-ip-lower-16 {include | exclude}
    set destination-ip-upper-16 {include | exclude}
    set destination-ip-lower-16 {include | exclude}
    set source-port {include | exclude}
    set destination-port {include | exclude}
    set netmask-length {0 - 32}
  end
end
```

For example, to use XOR16 and include all of the fields in the 5-tuple to compute the link in the LAG interface that the packet is distributed to:

```
config system npu
  set lag-out-port-select enable
  config sw-eh-hash
    set computation xor16
    set ip-protocol include
    set source-ip-upper-16 include
    set source-ip-lower-16 include
    set destination-ip-upper-16 include
    set destination-ip-lower-16 include
    set source-port include
    set destination-port include
    set netmask-length 32
```

```
end
end
```

Failure detection for aggregate and redundant interfaces

When an aggregate or redundant interface goes down, the corresponding fail-alert interface changes to down. When an aggregate or redundant interface comes up, the corresponding fail-alert interface changes to up.

Fail-detect for aggregate and redundant interfaces can be configured using the CLI.

To configure an aggregate interface so that port3 goes down with it:

```
config system interface
  edit "aggl"
    set vdom "root"
    set fail-detect enable
    set fail-alert-method link-down
    set fail-alert-interfaces "port3"
    set type aggregate
    set member "port1" "port2"
  next
end
```

To configure a redundant interface so that port4 goes down with it:

```
config system interface
  edit "red1"
    set vdom "root"
    set fail-detect enable
    set fail-alert-method link-down
    set fail-alert-interfaces "port4"
    set type redundant
    set member "port1" "port2"
  next
end
```

VLANs

Virtual Local Area Networks (VLANs) multiply the capabilities of your FortiGate unit and can also provide added network security. VLANs use ID tags to logically separate devices on a network into smaller broadcast domains. These smaller domains forward packets only to devices that are part of that VLAN domain. This reduces traffic and increases network security.

VLANs in NAT mode

In NAT mode, the FortiGate unit functions as a layer-3 device. In this mode, the FortiGate unit controls the flow of packets between VLANs and can also remove VLAN tags from incoming VLAN packets. The FortiGate unit can also forward untagged packets to other networks such as the Internet.

In NAT mode, the FortiGate unit supports VLAN trunk links with IEEE 802.1Q-compliant switches or routers. The trunk link transports VLAN-tagged packets between physical subnets or networks. When you add VLAN subinterfaces to the FortiGate's physical interfaces, the VLANs have IDs that match the VLAN IDs of packets on the trunk link. The FortiGate unit directs packets with VLAN IDs to subinterfaces with matching IDs.

You can define VLAN subinterfaces on all FortiGate physical interfaces. However, if multiple virtual domains are configured on the FortiGate unit, you only have access to the physical interfaces on your virtual domain. The FortiGate unit can tag packets leaving on a VLAN subinterface. It can also remove VLAN tags from incoming packets and add a different VLAN tag to outgoing packets.

Normally in VLAN configurations, the FortiGate unit's internal interface is connected to a VLAN trunk, and the external interface connects to an Internet router that is not configured for VLANs. In this configuration, the FortiGate unit can apply different policies for traffic on each VLAN interface connected to the internal interface, which results in less network traffic and better security.

Sample topology

In this example, two different internal VLAN networks share one interface on the FortiGate unit and share the connection to the Internet. This example shows that two networks can have separate traffic streams while sharing a single interface. This configuration can apply to two departments in a single company or to different companies.

There are two different internal network VLANs in this example. VLAN_100 is on the 10.1.1.0/255.255.255.0 subnet, and VLAN_200 is on the 10.1.2.0/255.255.255.0 subnet. These VLANs are connected to the VLAN switch.

The FortiGate internal interface connects to the VLAN switch through an 802.1Q trunk. The internal interface has an IP address of 192.168.110.126 and is configured with two VLAN subinterfaces (VLAN_100 and VLAN_200). The external interface has an IP address of 172.16.21.2 and connects to the Internet. The external interface has no VLAN subinterfaces.

When the VLAN switch receives packets from VLAN_100 and VLAN_200, it applies VLAN ID tags and forwards the packets of each VLAN both to local ports and to the FortiGate unit across the trunk link. The FortiGate unit has policies that allow traffic to flow between the VLANs, and from the VLANs to the external network.

Sample configuration

In this example, both the FortiGate unit and the Cisco 2950 switch are installed and connected and basic configuration has been completed. On the switch, you need access to the CLI to enter commands. No VDOMs are enabled in this example.

General configuration steps include:

1. [Configure the external interface.](#)
2. [Add two VLAN subinterfaces to the internal network interface.](#)
3. [Add firewall addresses and address ranges for the internal and external networks.](#)
4. [Add security policies to allow:](#)
 - the VLAN networks to access each other.
 - the VLAN networks to access the external network.

To configure the external interface:

```
config system interface
  edit external
    set mode static
    set ip 172.16.21.2 255.255.255.0
  next
end
```

To add VLAN subinterfaces:

```
config system interface
  edit VLAN_100
    set vdom root
    set interface internal
    set type vlan
```

```
        set vlanid 100
        set mode static
        set ip 10.1.1.1 255.255.255.0
        set allowaccess https ping
    next
    edit VLAN_200
        set vdom root
        set interface internal
        set type vlan
        set vlanid 200
        set mode static
        set ip 10.1.2.1 255.255.255.0
        set allowaccess https ping
    next
end
```

To add the firewall addresses:

```
config firewall address
    edit VLAN_100_Net
        set type ipmask
        set subnet 10.1.1.0 255.255.255.0
    next
    edit VLAN_200_Net
        set type ipmask
        set subnet 10.1.2.0 255.255.255.0
    next
end
```

To add security policies:

Policies 1 and 2 do not need NAT enabled, but policies 3 and 4 do need NAT enabled.

```
config firewall policy
    edit 1
        set srcintf VLAN_100
        set srcaddr VLAN_100_Net
        set dstintf VLAN_200
        set dstaddr VLAN_200_Net
        set schedule always
        set service ALL
        set action accept
        set nat disable
        set status enable
    next
    edit 2
        set srcintf VLAN_200
        set srcaddr VLAN_200_Net
        set dstintf VLAN_100
        set dstaddr VLAN_100_Net
        set schedule always
        set service ALL
        set action accept
        set nat disable
        set status enable
    next
```

```
edit 3
    set srcintf VLAN_100
    set srcaddr VLAN_100_Net
    set dstintf external
    set dstaddr all
    set schedule always
    set service ALL
    set action accept
    set nat enable
    set status enable
next
edit 4
    set srcintf VLAN_200
    set srcaddr VLAN_200_Net
    set dstintf external
    set dstaddr all
    set schedule always
    set service ALL
    set action accept
    set nat enable
    set status enable
next
end
```

VLANs in transparent mode

In transparent mode, the FortiGate unit behaves like a layer-2 bridge but can still provide services such as antivirus scanning, web filtering, spam filtering, and intrusion protection to traffic. Some limitations of transparent mode is that you cannot use SSL VPN, PPTP/L2TP VPN, DHCP server, or easily perform NAT on traffic. The limits in transparent mode apply to IEEE 802.1Q VLAN trunks passing through the unit.

You can insert the FortiGate unit operating in transparent mode into the VLAN trunk without making changes to your network. In a typical configuration, the FortiGate unit internal interface accepts VLAN packets on a VLAN trunk from a VLAN switch or router connected to internal network VLANs. The FortiGate external interface forwards VLAN-tagged packets through another VLAN trunk to an external VLAN switch or router and on to external networks such as the Internet. You can configure the unit to apply different policies for traffic on each VLAN in the trunk.

To pass VLAN traffic through the FortiGate unit, you add two VLAN subinterfaces with the same VLAN ID, one to the internal interface and the other to the external interface. You then create a security policy to permit packets to flow from the internal VLAN interface to the external VLAN interface. If required, create another security policy to permit packets to flow from the external VLAN interface to the internal VLAN interface. Typically in transparent mode, you do not permit packets to move between different VLANs. Network protection features such as spam filtering, web filtering, and anti-virus scanning, are applied through the UTM profiles specified in each security policy, enabling very detailed control over traffic.

When the FortiGate unit receives a VLAN-tagged packet on a physical interface, it directs the packet to the VLAN subinterface with the matching VLAN ID. The VLAN tag is removed from the packet and the FortiGate unit then applies security policies using the same method it uses for non-VLAN packets. If the packet exits the FortiGate unit through a VLAN subinterface, the VLAN ID for that subinterface is added to the packet and the packet is sent to the corresponding physical interface.

Sample topology

In this example, the FortiGate unit is operating in transparent mode and is configured with two VLANs: one with an ID of 100 and the other with ID 200. The internal and external physical interfaces each have two VLAN subinterfaces, one for VLAN_100 and one for VLAN_200.

The IP range for the internal VLAN_100 network is 10.100.0.0/255.255.0.0, and for the internal VLAN_200 network is 10.200.0.0/255.255.0.0.

The internal networks are connected to a Cisco 2950 VLAN switch which combines traffic from the two VLANs onto one in the FortiGate unit's internal interface. The VLAN traffic leaves the FortiGate unit on the external network interface, goes on to the VLAN switch, and on to the Internet. When the FortiGate units receives a tagged packet, it directs it from the incoming VLAN subinterface to the outgoing VLAN subinterface for that VLAN.

In this example, we create a VLAN subinterface on the internal interface and another one on the external interface, both with the same VLAN ID. Then we create security policies that allow packets to travel between the VLAN_100_int interface and the VLAN_100_ext interface. Two policies are required: one for each direction of traffic. The same is required between the VLAN_200_int interface and the VLAN_200_ext interface, for a total of four security policies.

Sample configuration

There are two main steps to configure your FortiGate unit to work with VLANs in transparent mode:

1. [Add VLAN subinterfaces.](#)
2. [Add security policies.](#)

You can also configure the protection profiles that manage antivirus scanning, web filtering, and spam filtering.

To add VLAN subinterfaces:

```
config system interface
  edit VLAN_100_int
    set type vlan
```

```
        set interface internal
        set vlanid 100
    next
    edit VLAN_100_ext
        set type vlan
        set interface external
        set vlanid 100
    next
    edit VLAN_200_int
        set type vlan
        set interface internal
        set vlanid 200
    next
    edit VLAN_200_ext
        set type vlan
        set interface external
        set vlanid 200
    next
end
```

To add security policies:

```
config firewall policy
    edit 1
        set srcintf VLAN_100_int
        set srcaddr all
        set dstintf VLAN_100_ext
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 2
        set srcintf VLAN_100_ext
        set srcaddr all
        set dstintf VLAN_100_int
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 3
        set srcintf VLAN_200_int
        set srcaddr all
        set dstintf VLAN_200_ext
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
    next
    edit 4
        set srcintf VLAN_200_ext
        set srcaddr all
        set dstintf VLAN_200_int
        set dstaddr all
        set action accept
```

```

        set schedule always
        set service ALL
    next
end

```

Enhanced MAC VLANs

The Media Access Control (MAC) Virtual Local Area Network (VLAN) feature in Linux allows you to configure multiple virtual interfaces with different MAC addresses (and therefore different IP addresses) on a physical interface.

FortiGate implements an enhanced MAC VLAN consisting of a MAC VLAN with bridge functionality. Because each MAC VLAN has a unique MAC address, virtual IP addresses (VIPs) and IP pools are supported, and you can disable Source Network Address Translation (SNAT) in policies.

MAC VLAN cannot be used in a transparent mode virtual domain (VDM). In a transparent mode VDM, a packet leaves an interface with the MAC address of the original source instead of the interface's MAC address. FortiGate implements an enhanced version of MAC VLAN where it adds a MAC table in the MAC VLAN which learns the MAC addresses when traffic passes through.

If you configure a VLAN ID for an enhanced MAC VLAN, it won't join the switch of the underlying interface. When a packet is sent to this interface, a VLAN tag is inserted in the packet and the packet is sent to the driver of the underlying interface. When the underlying interface receives a packet, if the VLAN ID doesn't match, it won't deliver the packet to this enhanced MAC VLAN interface.

When using a VLAN ID, the ID and the underlying interface must be a unique pair, even if they belong to different VDMs. This is because the underlying, physical interface uses the VLAN ID as the identifier to dispatch traffic among the VLAN and enhanced MAC VLAN interfaces.

If you use an interface in an enhanced MAC VLAN, do not use it for other purposes such as a management interface, HA heartbeat interface, or in Transparent VDMs.

If a physical interface is used by an EMAC VLAN interface, you cannot use it in a Virtual Wire Pair.

In high availability (HA) configurations, enhanced MAC VLAN is treated as a physical interface. It's assigned a unique physical interface ID and the MAC table is synchronized with the secondary devices in the same HA cluster.

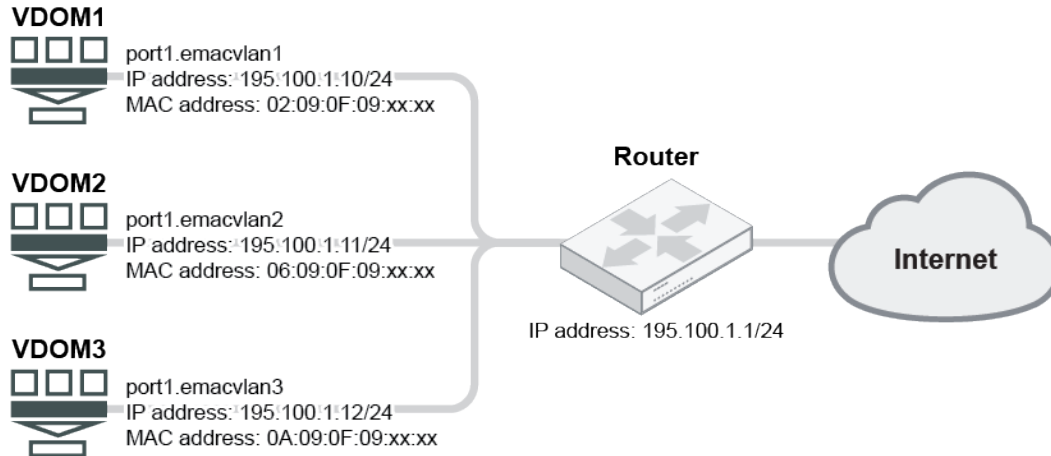

In HA configurations, FortiGate assigns a virtual MAC to each interface. Virtual interfaces, such as EMAC VLAN interfaces with underlying NPU VLINK interface, are an exception and do not get assigned virtual MAC addresses.

Example 1: Enhanced MAC VLAN configuration for multiple VDMs that use the same interface or VLAN

In this example, a FortiGate is connected, through port 1 to a router that's connected to the Internet. Three VDMs share the same interface (port 1) which connects to the same router that's connected to the Internet. Three enhanced MAC VLAN interfaces are configured on port 1 for the three VDMs. The enhanced MAC VLAN interfaces are in the same IP subnet segment and each have unique MAC addresses.

The underlying interface (port 1) can be a physical interface, an aggregate interface, or a VLAN interface on a physical or aggregate interface.

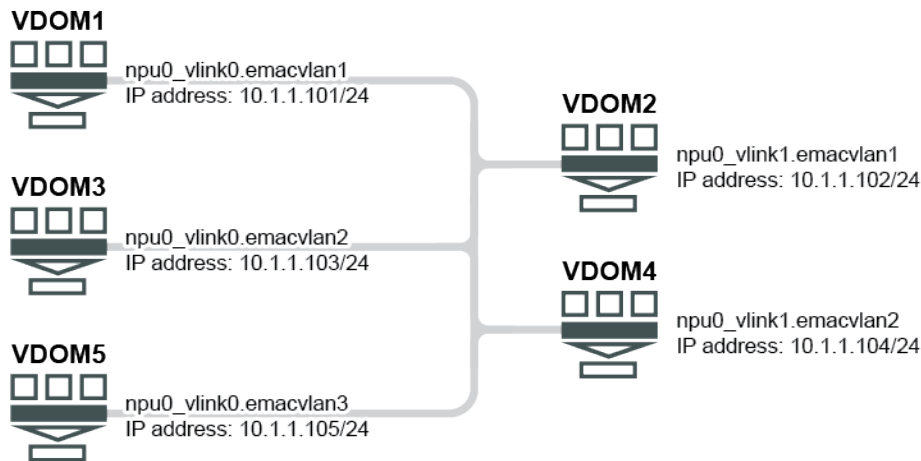

To configure enhanced MAC VLAN for this example in the CLI:

```
config system interface
  edit port1.emacvlan1
    set vdom VDOM1
    set type emac-vlan
    set interface port1
  next
  edit port 1.emacvlan2
    set vdom VDOM2
    set type emac-vlan
    set interface port1
  next
  edit port1.emacvlan3
    set vdom VDOM3
    set type emac-vlan
    set interface port1
  next
end
```

Example 2: Enhanced MAC VLAN configuration for shared VDOM links among multiple VDOMs

In this example, multiple VDOMs can connect to each other using enhanced MAC VLAN on network processing unit (NPU) virtual link (Vlink) interfaces.

FortiGate VDOM links (NPU-Vlink) are designed to be peer-to-peer connections and VLAN interfaces on NPU Vlink ports use the same MAC address. Connecting more than two VDOMs using NPU Vlinks and VLAN interfaces is not recommended.

To configure enhanced MAC VLAN for this example in the CLI:

```
config system interface
  edit npu0_vlink0.emacvlan1
    set vdom VDOM1
    set type emac-vlan
    set interface npu0_vlink0
  next
  edit npu0_vlink0.emacvlan2
    set vdom VDOM3
    set type emac-vlan
    set interface npu0_vlink0
  next
  edit npu0_vlink1.emacvlan1
    set vdom VDOM2
    set type emac-vlan
    set interface npu0_vlink1
  next
end
```

Example 3: Enhanced MAC VLAN configuration for unique MAC addresses for each VLAN interface on the same physical port

Some networks require a unique MAC address for each VLAN interface when the VLAN interfaces share the same physical port. In this case, the enhanced MAC VLAN interface is used the same way as normal VLAN interfaces.

To configure this, use the `set vlanid` command for the VLAN tag. The VLAN ID and interface must be a unique pair, even if they belong to different VDOMs.

To configure enhanced MAC VLAN:

```
config system interface
  edit <interface-name>
    set type emac-vlan
    set vlanid <VLAN-ID>
    set interface <physical-interface>
  next
end
```

FortiGate supports a maximum of 512 EMAC VLAN interfaces per underlying interface, and a maximum of 600 MAC addresses including EMAC VLAN interfaces.

Inter-VDOM routing

VDOM links allow VDOMs to communicate internally without using additional physical interfaces.

Inter-VDOM routing is the communication between VDOMs. VDOM links are virtual interfaces that connect VDOMs. A VDOM link contains a pair of interfaces, each one connected to a VDOM and forming either end of the inter-VDOM connection.

When VDOMs are configured on your FortiGate unit, configuring inter-VDOM routing and VDOM links is like creating a VLAN interface. VDOM links can be managed in either the CLI or in the network interface list in the GUI.

A VDOM link cannot share the same name as a VDOM.

VDOM link does not support traffic offload. If you want to use traffic offload, use NPU-VDOM-LINK.

To configure a VDOM link in the GUI:

1. In the Global VDOM, go to *Network > Interfaces*.
2. Click *Create New > VDOM Link*.
3. Configure the fields, including the *Name*, *Virtual Domain*, IP information, *Administrative Access*, and others, then click *OK*.

By default, VDOM links are created as point-to-point (ppp) links. If required, the link type can be changed in the CLI.

For example, when running OSPF in IPv6, a link-local address is required in order to communicate with OSPF neighbors. For a VDOM link to obtain a link-local address its type must be set to `ethernet`.

To configure a VDOM link in the CLI:

```
config global
  config system vdom-link
    edit "<vdom-link-name>"
      set type {ppp | ethernet}
    next
  end
  config system interface
    edit "<vdom-link-name0>"
      set vdom "<VDOM Name>"
```

```

        set type vdom-link
    next
    edit "<vdom-link-name1>"
        set vdom "<VDOM Name>"
        set type vdom-link
    next
end
end

```

To delete a VDOM link in the GUI:

1. In the Global VDOM, go to *Network > Interfaces*.
2. Select a *VDOM Link* and click *Delete*.

To delete a VDOM link in the CLI:

```

config global
    config system vdom-link
        delete <VDOM-LINK-Name>
    end
end

```

Example

This example shows how to configure a FortiGate unit to use inter-VDOM routing.

Two departments of a company, Accounting and Sales, are connected to one FortiGate. The company uses a single ISP to connect to the Internet.

This example includes the following general steps. We recommend following the steps in the order below.

Create the VDOMs

To enable VDOMs:

```

config system global
    set vdom-mode multi-vdom
end

```

You will be logged out of the device when VDOM mode is enabled.

To create the Sales and Accounting VDOMs:

```

config global
  config vdom
    edit Accounting
    next
    edit Sales
    next
  end
end

```

Configure the physical interfaces

Next, configure the physical interfaces. This example uses three interfaces on the FortiGate unit: port2 (internal), port3 (DMZ), and port1 (external). Port2 and port3 interfaces each have a department's network connected. Port1 is for all traffic to and from the Internet and uses DHCP to configure its IP address, which is common with many ISPs.

To configure the interfaces:

```

config global
  config system interface
    edit port2
      set alias AccountingLocal
      set vdom Accounting
      set mode static
      set ip 172.100.1.1 255.255.0.0
      set allowaccess https ping ssh
      set description "The accounting dept. internal interface"
    next
    edit port3
      set alias SalesLocal
      set vdom Sales
      set mode static
      set ip 192.168.1.1 255.255.0.0
      set allowaccess https ping ssh
      set description "The sales dept. internal interface"
    next
    edit port1
      set alias ManagementExternal
      set vdom root
      set mode dhcp
      set allowaccess https ssh snmp
      set description "The system wide management interface."
    next
  end
end

```

Configure the VDOM links

To complete the connection between each VDOM and the management VDOM, add the two VDOM links. One pair is the Accounting – management link and the other is the Sales – management link.

When configuring inter-VDOM links, you do not have to assign IP addresses to the links unless you are using advanced features such as dynamic routing that require them. Not assigning IP addresses results in faster configuration and more available IP addresses on your networks.

To configure the Accounting and management VDOM link:

```
config global
  config system vdom-link
    edit AccountVlnk
    next
  end
  config system interface
    edit AccountVlnk0
      set vdom Accounting
      set ip 11.11.11.2 255.255.255.0
      set allowaccess https ping ssh
      set description "Accounting side of the VDOM link"
    next
    edit AccountVlnk1
      set vdom root
      set ip 11.11.11.1 255.255.255.0
      set allowaccess https ping ssh
      set description "Management side of the VDOM link"
    next
  end
end
```

To configure the Sales and management VDOM link:

```
config global
  config system vdom-link
    edit SalesVlnk
    next
  end
  config system interface
    edit SalesVlnk0
      set vdom Sales
      set ip 12.12.12.2 255.255.255.0
      set allowaccess https ping ssh
      set description "Sales side of the VDOM link"
    next
    edit SalesVlnk1
      set vdom root
      set ip 12.12.12.1 255.255.255.0
      set allowaccess https ping ssh
      set description "Management side of the VDOM link"
    next
  end
end
```

Configure the firewall and security profile

With the VDOMs, physical interfaces, and VDOM links configured, the firewall must now be configured to allow the proper traffic. Firewalls are configured per-VDOM, and firewall objects and routes must be created for each VDOM separately.

To configure the firewall policies from AccountingLocal to Internet:

```
config vdom
  edit Accounting
    config firewall policy
      edit 1
        set name "Accounting-Local-to-Management"
        set srcintf port2
        set dstintf AccountVlnk0
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set nat enable
      next
    end
  next
edit root
  config firewall policy
    edit 2
      set name "Accounting-VDOM-to-Internet"
      set srcintf AccountVlnk1
      set dstintf port1
      set srcaddr all
      set dstaddr all
      set action accept
      set schedule always
      set service ALL
      set nat enable
    next
  end
next
end
```

To configure the firewall policies from SalesLocal to the Internet:

```
config vdom
  edit Sales
    config firewall policy
      edit 3
        set name "Sales-local-to-Management"
        set srcintf port3
        set dstintf SalesVlnk0
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set nat enable
      next
    end
  next
edit root
  config firewall policy
    edit 4
```

```
        set name "Sales-VDOM-to-Internet"
        set srcintf SalesVlnk1
        set dstintf port1
        set srcaddr all
        set dstaddr all
        set action accept
        set schedule always
        set service ALL
        set nat enable
    next
end
next
end
```

Test the configuration

When the inter-VDOM routing has been configured, test the configuration to confirm proper operation. Testing connectivity ensures that physical networking connections, FortiGate unit interface configurations, and firewall policies are properly configured.

The easiest way to test connectivity is to use the `ping` and `traceroute` commands to confirm the connectivity of different routes on the network.

Test both from AccountingLocal to the internet and from SalesLocal to the internet.

Software switch

A software switch is a virtual switch that is implemented at the software or firmware level and not at the hardware level. A software switch can be used to simplify communication between devices connected to different FortiGate interfaces. For example, using a software switch, you can place the FortiGate interface connected to an internal network on the same subnet as your wireless interfaces. Then devices on the internal network can communicate with devices on the wireless network without any additional configuration on the FortiGate unit, such as additional security policies.

A software switch can also be useful if you require more hardware ports for the switch on a FortiGate unit. For example, if your FortiGate unit has a 4-port switch, WAN1, WAN2, and DMZ interfaces, and you need one more port, you can create a soft switch that can include the four-port switch and the DMZ interface, all on the same subnet. These types of applications also apply to wireless interfaces, virtual wireless interfaces, and physical interfaces such as those in FortiWiFi and FortiAP units.

Similar to a hardware switch, a software switch functions like a single interface. It has one IP address and all the interfaces in the software switch are on the same subnet. Traffic between devices connected to each interface are not regulated by security policies, and traffic passing in and out of the switch are controlled by the same policy.

When setting up a software switch, consider the following:

- Ensure that you have a back up of the configuration.
- Ensure that you have at least one port or connection, such as the console port, to connect to the FortiGate unit. If you accidentally combine too many ports, you need a way to undo errors.
- The ports that you include must not have any link or relation to any other aspect of the FortiGate unit, such as DHCP servers, security policies, and so on.
- For increased security, you can create a captive portal for the switch to allow only specific user groups access to the resources connected to the switch.

Some of the difference between software and hardware switches are:

Feature	Software switch	Hardware switch
Processing	Packets are processed in software by the CPU.	Packets are processed in hardware by the hardware switch controller, or SPU where applicable.
STP	Not Supported	Supported
Wireless SSIDs	Supported	Not Supported
Intra-switch traffic	Allowed by default. Can be explicitly set to require a policy.	Allowed by default.
Active-active HA load balancing	Not supported	Supported

To create a software switch in the GUI:

1. Go to *Network > Interfaces*.
2. Click *Create New > Interface*.
3. Set *Type* to *Software Switch*.
4. Configure the *Name*, *Interface members*, and other fields as required.
To add an interface to a software switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.
5. Click *OK*.

To create a software switch in the CLI:

```

config system switch-interface
    edit <interface>
        set vdom <vdom>
        set member <interface_list>
        set type switch
    next
end
config system interface
    edit <interface>
        set vdom <vdom>
        set type switch
        set ip <ip_address>
        set allowaccess https ssh ping
    next
end

```

To add an interface to a software switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.

Example

For this example, the wireless interface (WiFi) needs to be on the same subnet as the DMZ1 interface to facilitate wireless synchronizing from an iPhone and a local computer. Because synchronizing between two subnets is problematic, putting both interfaces on the same subnet allows the synchronizing will work. The software switch will accomplish this.

1. Clear the interfaces and back up the configuration:
 - a. Ensure the interfaces are not used for other security policy or for other use on the FortiGate unit.
 - b. Check the WiFi and DMZ1 ports to ensure that DHCP is not enabled and that there are no other dependencies on these interfaces.
 - c. Save the current configuration so that it can be recovered if something goes wrong.
2. Merge the WiFi port and DMZ1 port to create a software switch named `synchro` with an IP address of 10.10.21.12 and administrative access for HTTPS, SSH and PING:

```
config system switch-interface
  edit synchro
    set vdom "root"
    set type switch
    set member dmz1 wifi
  next
end
config system interface
  edit synchro
    set ip 10.10.21.12 255.255.255.0
    set allowaccess https ssh ping
  next
end
```

After the switch is set up, you add security policies, DHCP servers, and any other settings that are required.

Hardware switch

A hardware switch is a virtual switch interface that groups different ports together so that the FortiGate can use the group as a single interface. Supported FortiGate models have a default hardware switch called either *internal* or *lan*. The hardware switch is supported by the chipset at the hardware level.

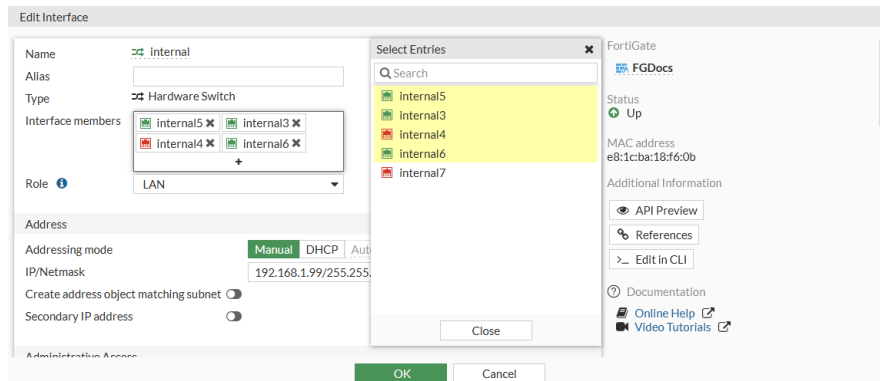

Ports that are connected to the same hardware switch behave like they are on the same physical switch in the same broadcast domain. Ports can be removed from a hardware switch and assigned to another switch or used as standalone interfaces.

Some of the difference between hardware and software switches are:

Feature	Hardware switch	Software switch
Processing	Packets are processed in hardware by the hardware switch controller, or SPU where applicable.	Packets are processed in software by the CPU.
STP	Supported	Not Supported
Wireless SSIDs	Not Supported	Supported
Intra-switch traffic	Allowed by default.	Allowed by default. Can be explicitly set to require a policy.

To change the ports in a hardware switch in the GUI:

1. Go to *Network > Interface* and edit the hardware switch.
2. Click inside the *Interface members* field.

3. Select interfaces to add or remove them from the hardware switch, then click *Close*.
To add an interface to a hardware switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.
4. Click *OK*.
Removed interfaces will now be listed as standalone interfaces in the *Physical Interface* section.

To remove ports from a hardware switch in the CLI:

```
config system virtual-switch
  edit "internal"
    config port
      delete internal2
      delete internal7
      ...
    end
  next
end
```

To add ports to a hardware switch in the CLI:

```
config system virtual-switch
  edit "internal"
    set physical-switch "sw0"
    config port
      edit "internal3"
      next
      edit "internal5"
      next
      edit "internal4"
      next
      edit "internal6"
      next
    end
  next
end
```

To add an interface to a hardware switch, it cannot be referenced by an existing configuration and its IP address must be set to 0.0.0.0/0.0.0.0.

Using 802.1X on virtual switches for certain NP6 platforms

802.1X is supported under the hardware switch interface on the following NP6 platforms: FG-30xE, FG-40xE, and FG-110xE.

In this example, port3 and port4 are part of a hardware switch interface. The hardware switch acts as a virtual switch so that devices can connect directly to these ports and perform 802.1X authentication on the port.

Prerequisites:

1. Configure a RADIUS server (see [RADIUS servers on page 1933](#)).
2. Define a user group named test to use the remote RADIUS server and for 802.1X authentication (see [User definition, groups, and settings on page 1907](#)).
3. Configure a hardware switch (named 18188) with port3 and port4 as the members.
4. Configure a firewall policy that allows traffic from the 18188 hardware switch to go to the internet.
5. Enable 802.1X authentication on the client devices.

To configure 802.1X authentication on a hardware switch in the GUI:

1. Go to *Network > Interfaces* and edit the hardware switch.
2. In the *Network* section, enable *Security mode* and select *802.1X*.

3. Click the + to add the *User group*.

The screenshot shows the 'Edit Interface' configuration window for a FortiGate. The interface is named '18188' and is a 'Hardware Switch' type. It is associated with VRF ID '0' and virtual domain 'vdom1'. The role is set to 'LAN'. The addressing mode is 'Manual' with IP/Netmask '1.1.1.1/255.255.255.0'. Administrative access is configured for IPv4 and IPv6, including protocols like HTTPS, SSH, PING, and SNMP. The 'Security mode' is set to '802.1X' and 'User groups' is set to 'test'. The 'Device detection' and 'STP' options are enabled. The 'SPAN (Port Mirroring)' option is disabled. The right sidebar shows the device status as 'Up' and provides links for API Preview, References, and Documentation.

4. Click OK.

To configure 802.1X authentication on a hardware switch in the CLI:

1. Configure the virtual hardware switch interfaces:

```
config system virtual-switch
  edit "18188"
    set physical-switch "sw0"
  config port
    edit "port3"
    next
    edit "port4"
    next
```

```

        end
    next
end

```

2. Configure 802.1X authentication:

```

config system interface
    edit "18188"
        set vdom "vdom1"
        set ip 1.1.1.1 255.255.255.0
        set allowaccess ping https ssh snmp fgfm ftm
        set type hard-switch
        set security-mode 802.1X
        set security-groups "test"
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 52
    next
end

```

To verify the that the 802.1X authentication was successful:

1. Get a client connected to port3 to authenticate to access the internet.
2. In FortiOS, verify the 802.1X authentication port status:

```

# diagnose sys 802-1x status

Virtual switch '18188' (default mode) 802.1x member status:
  port3: Link up, 802.1X state: authorized
  port4: Link up, 802.1X state: unauthorized

```

Zone

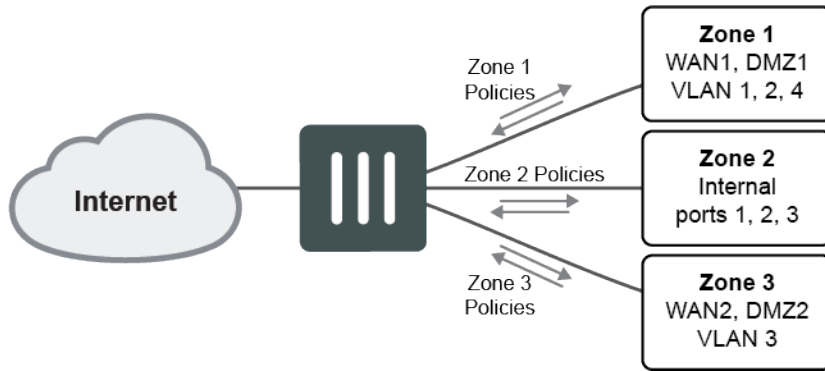

Zones are a group of one or more physical or virtual FortiGate interfaces that you can apply security policies to control inbound and outbound traffic. Grouping interfaces and VLAN subinterfaces into zones simplifies the creation of security policies where a number of network segments can use the same policy settings and protection profiles.

When you add a zone, you select the names of the interfaces and VLAN subinterfaces to add to the zone. Each interface still has its own address. Routing is still done between interfaces, that is, routing is not affected by zones. You can use security policies to control the flow of intra-zone traffic.

For example, in the sample configuration below, the network includes three separate groups of users representing different entities on the company network. While each group has its own set of ports and VLANs in each area, they can all use the same security policy and protection profiles to access the Internet. Rather than the administrator making nine separate security policies, he can make administration simpler by adding the required interfaces to a zone and creating three policies.

Sample configuration

You can configure policies for connections to and from a zone but not between interfaces in a zone. For this example, you can create a security policy to go between zone 1 and zone 3, but not between WAN2 and WAN1, or WAN1 and DMZ1.

To create a zone in the GUI:

1. Go to *Network > Interfaces*.

If VDOMs are enabled, go to the VDOM to create a zone.

2. Click *Create New > Zone*.
3. Configure the *Name* and add the *Interface Members*.
4. Enable or disable *Block intra-zone traffic* as required.
5. Click *OK*.

To configure a zone to include the internal interface and a VLAN using the CLI:

```
config system zone
  edit zone_1
    set interface internal VLAN_1
    set intrazone {deny | allow}
  next
end
```

Using zone in a firewall policy

To configure a firewall policy to allow any interface to access the Internet using the CLI:

```
config firewall policy
  edit 2
    set name "2"
    set srcintf "Zone_1"
    set dstintf "port15"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
  next
end
```

Intra-zone traffic

In the zone configuration you can set `intrazone deny` to prohibit the different interfaces in the same zone to talk to each other.

For example, if you have ten interfaces in your zone and the `intrazone` setting is `deny`. You now want to allow traffic between a very small number of networks on different interfaces that are part of the zone but you do not want to disable the intra-zone blocking.

In this example, the zone VLANs are defined as: `192.168.1.0/24, 192.168.2.0/24, ... 192.168.10.0/24`.

This policy allows traffic from `192.168.1.x` to `192.168.2.x` even though they are in the same zone and intra-zone blocking is enabled. The intra-zone blocking acts as a default deny rule and you have to specifically override it by creating a policy within the zone.

To enable intra-zone traffic, create the following policy:

Source Interface	Zone-name, e.g., <code>Vlans</code>
Source Address	<code>192.168.1.0/24</code>
Destination	Zone-name (same as Source Interface, i.e., <code>Vlans</code>)
Destination Address	<code>192.168.2.0/24</code>

Virtual wire pair

A virtual wire pair consists of two interfaces that do not have IP addressing and are treated like a transparent mode VDOM. All traffic received by one interface in the virtual wire pair can only be forwarded to the other interface, provided a virtual wire pair firewall policy allows this traffic. Traffic from other interfaces cannot be routed to the interfaces in a virtual wire pair. Redundant and 802.3ad aggregate (LACP) interfaces can be included in a virtual wire pair.

Virtual wire pairs are useful for a typical topology where MAC addresses do not behave normally. For example, port pairing can be used in a Direct Server Return (DSR) topology where the response MAC address pair may not match the request's MAC address pair.

When creating a new virtual wire pair, the *Interface members* field displays interfaces without assigned addresses. Interfaces with assigned addresses are not displayed.

Therefore, you cannot add to a virtual wire pair an interface with *Addressing mode* set to *DHCP*. If you change the interface settings to *Manual* with *IP/Netmask* set to `0.0.0.0/0.0.0.0`, you can add the interface to a virtual wire pair.

Example

In this example, a virtual wire pair (port3 and port4) makes it easier to protect a web server that is behind a FortiGate operating as an Internal Segmentation Firewall (ISFW). Users on the internal network access the web server through the ISFW over the virtual wire pair.

Interfaces used in a virtual wire pair cannot be used to access the ISFW FortiGate. Before creating a virtual wire pair, make sure you have a different port configured to allow admin access using your preferred protocol.

To add a virtual wire pair using the GUI:

1. Go to *Network > Interfaces*.
2. Click *Create New > Virtual Wire Pair*.
3. Enter a name for the virtual wire pair.
4. Select the *Interface Members* to add to the virtual wire pair (*port3* and *port 4*).
These interfaces cannot be part of a switch, such as the default LAN/internal interface.
5. If required, enable *Wildcard VLAN* and set the *VLAN Filter*.
6. Click *OK*.

To add a virtual wire pair using the CLI:

```
config system virtual-wire-pair
  edit "VWP-name"
    set member "port3" "port4"
    set wildcard-vlan disable
  next
end
```

To create a virtual wire pair policy using the GUI:

1. Go to *Policy & Objects > Firewall Virtual Wire Pair Policy*.
2. Click *Create New*.
3. In the *Virtual Wire Pair* field, click the + to add the virtual wire pair.
4. Select the direction (arrows) that traffic is allowed to flow.
5. Configure the other settings as needed.
6. Click *OK*.

To create a virtual wire pair policy using the CLI:

```
config firewall policy
  edit 1
    set name "VWP-Policy"
    set srcintf "port3" "port4"
    set dstintf "port3" "port4"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set fsso disable
```

```
next
end
```

Configuring multiple virtual wire pairs in a virtual wire pair policy

You can create a virtual wire pair policy that includes different virtual wire pairs in NGFW profile and policy mode. This reduces overhead to create multiple similar policies for each VWP. In NGFW policy mode, multiple virtual wire pairs can be configured in a *Security Virtual Wire Pair Policy* and *Virtual Wire Pair SSL Inspection & Authentication* policy.

The virtual wire pair settings must have wildcard VLAN enabled. When configuring a policy in the CLI, the virtual wire pair members must be entered in `srcintf` and `dstintf` as pairs.

To configure multiple virtual wire pairs in a policy in the GUI:

1. Configure the virtual wire pairs:

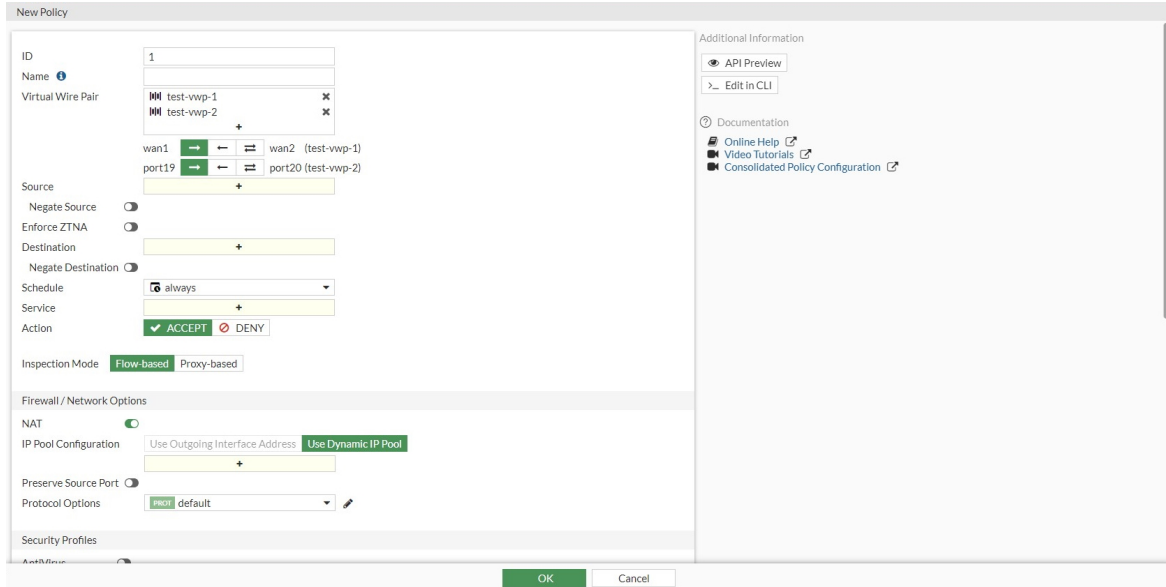

- a. Go to *Network > Interfaces* and click *Create New > Virtual Wire Pair*.
- b. Create a pair with the following settings:

Name	test-vwp-1
Interface members	wan1, wan2
Wildcard VLAN	Enable

- c. Click *OK*.
- d. Click *Create New > Virtual Wire Pair* and create another pair with the following settings:

Name	test-vwp-2
Interface members	port19, port20
Wildcard VLAN	Enable

- e. Click *OK*.
2. Configure the policy:
- a. Go to *Policy & Objects > Firewall Virtual Wire Pair Policy* and click *Create New*.
 - b. In the *Virtual Wire Pair* field, click the + to add *test-vwp-1* and *test-vwp-2*. Select the direction for each of the selected virtual wire pairs.

- c. Configure the other settings as needed.
- d. Click OK.

To configure multiple virtual wire pairs in a policy in the CLI:

1. Configure the virtual wire pairs:

```
config system virtual-wire-pair
  edit "test-vwp-1"
    set member "wan1" "wan2"
    set wildcard-vlan enable
  next
  edit "test-vwp-2"
    set member "port19" "port20"
    set wildcard-vlan enable
  next
end
```

2. Configure the policy:

```
config firewall policy
  edit 1
    set name "vwpl&2-policy"
    set srcintf "port19" "wan1"
    set dstintf "port20" "wan2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
  next
end
```

PRP handling in NAT mode with virtual wire pair

PRP (Parallel Redundancy Protocol) is supported in NAT mode for a virtual wire pair. This preserves the PRP RCT (redundancy control trailer) while the packet is processed by the FortiGate.

To configure PRP handling on a device in NAT mode:

1. Enable PRP in the VDOM settings:

```
(root) # config system settings
      set prp-trailer-action enable
end
```

2. Enable PRP in the NPU attributes:

```
(global) # config system npu
      set prp-port-in "port15"
      set prp-port-out "port16"
end
```

3. Configure the virtual wire pair:

```
(root) # config system virtual-wire-pair
      edit "test-vwp-1"
        set member "port15" "port16"
      next
end
```

Virtual VLAN switch

The hardware switch ports on FortiGate models that support virtual VLAN switches can be used as a layer 2 switch. Virtual VLAN switch mode allows 802.1Q VLANs to be assigned to ports, and the configuration of one interface as a trunk port.

The following FortiGate series are supported in FortiOS 7.0: 60F, 70F, 80F, 90G, 100E, 100F, 120G, 140E, 200F, 300E, 400E, 400F, 600F, 1100E, 1800F, 2600F, 3000F, 3500F, 4200F, and 4400F.

The `virtual-switch-vlan` option must be enabled in the CLI to configure VLAN switch mode from the GUI or CLI.

To enable VLAN switches:

```
config system global
  set virtual-switch-vlan enable
end
```

After this setting is enabled, any previously configured hardware switches will appear in the *Network > Interfaces* page under *VLAN Switch*.

To enable VLAN switch mode in the GUI:

1. Go to *System > Settings*.
2. In the *View Settings* section, enable *VLAN switch mode*.
3. Click *Apply*.

Basic configurations

Hardware switch ports can be configured as either a VLAN switch port or a trunk port. The available interfaces and allowable VLAN IDs that can be used depend on the FortiGate model. It is recommended to remove ports from the default VLAN switch before you begin configurations.

To create a new VLAN and assign ports in the GUI:

1. Go to *Network > Interfaces* and click *Create New > Interface*.
2. Enter a name and configure the following:
 - a. Set the *Type* to *VLAN Switch*.
 - b. Enter a *VLAN ID*.
 - c. Click the + and add the *Interface Members*.
 - d. Configure the *Address* and *Administrative Access* settings as needed.
3. Click *OK*.

To create a new VLAN and assign ports in the CLI:

1. Configure the VLAN:

```
config system virtual-switch
  edit "VLAN10"
    set physical-switch "sw0"
    set vlan 10
    config port
      edit "internal1"
      next
      edit "internal2"
      next
    end
  next
end
```

2. Configure the VLAN switch interface addressing:

```
config system interface
  edit "VLAN10"
    set vdom "root"
    set ip 192.168.10.99 255.255.255.0
    set allowaccess ping https ssh snmp http fgfm
    set type hard-switch
  next
end
```

To designate an interface as a trunk port:

```
config system interface
  edit internal5
    set trunk enable
  next
end
```

Example 1: HA using a VLAN switch

In this example, two FortiGates in an HA cluster are connected to two ISP routers. Instead of connecting to external L2 switches, each FortiGate connects to each ISP router on the same hardware switch port on the same VLAN. A trunk port connects the two FortiGates to deliver the 802.1Q tagged traffic to the other. A full mesh between the FortiGate cluster and the ISP routers is achieved where no single point of failure will cause traffic disruptions.

This example assumes that the HA settings are already configured. The interface and VLAN switch settings are identical between cluster members and synchronized. See [HA using a hardware switch to replace a physical switch on page 2157](#) for a similar example that does not use a VLAN switch.

To configure the VLAN switches:

1. Configure the ISP interfaces with the corresponding VLAN IDs:

```
config system virtual-switch
  edit "ISP1"
    set physical-switch "sw0"
    set vlan 2951
    config port
      edit "port1"
      next
    end
  next
  edit "ISP2"
    set physical-switch "sw0"
    set vlan 2952
    config port
      edit "port2"
      next
    end
  next
end
```

2. Configure the VLAN switch interface addressing:

```
config system interface
  edit "ISP1"
```

```
        set vdom "root"
        set ip 192.168.10.99 255.255.255.0
        set allowaccess ping
        set type hard-switch
    next
    edit "ISP2"
        set vdom "root"
        set ip 192.168.20.99 255.255.255.0
        set allowaccess ping
        set type hard-switch
    next
end
```

3. Designate port15 as the trunk port:

```
config system interface
    edit port15
        set trunk enable
    next
end
```

4. Configure firewall policies to allow outgoing traffic on the ISP1 and ISP2 interfaces:

```
config firewall policy
    edit 1
        set srcintf "port11"
        set dstintf "ISP1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
    edit 2
        set srcintf "port11"
        set dstintf "ISP2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set nat enable
    next
end
```

Example 2: LAN extension

In this example, two hardware switch ports are assigned VLAN10, and two ports are assigned VLAN20 on FortiGate B. The wan2 interface is designated as the trunk port, and is connected to the upstream FortiGate A. The corresponding VLAN subinterfaces VLAN10 and VLAN20 on the upstream FortiGate allow further access to other networks.

The available interfaces and VLAN IDs varies between FortiGate models. The FortiGate B in this example is a 60F model.

To configure FortiGate B:

1. Configure the VLAN interfaces:

```
config system virtual-switch
  edit "VLAN10"
    set physical-switch "sw0"
    set vlan 10
    config port
      edit "internal1"
      next
      edit "internal2"
      next
    end
  next
  edit "VLAN20"
    set physical-switch "sw0"
    set vlan 20
    config port
      edit "internal3"
      next
      edit "internal4"
      next
    end
  next
end
```

2. Configure the VLAN switch interface addressing:

```
config system interface
  edit "VLAN10"
    set vdom "root"
    set ip 192.168.10.99 255.255.255.0
    set allowaccess ping https ssh snmp http fgfm
```

```
        set type hard-switch
    next
    edit "VLAN20"
        set vdom "root"
        set ip 192.168.20.99 255.255.255.0
        set allowaccess ping https ssh snmp http fgfm
        set type hard-switch
    next
end
```

3. Designate wan2 as the trunk port:

```
config system interface
    edit wan2
        set trunk enable
    next
end
```

To configure FortiGate A:

1. Configure the VLAN subinterfaces:

```
config system interface
    edit "VLAN10"
        set ip 192.168.10.98 255.255.255.0
        set allowaccess ping https ssh
        set role lan
        set interface "dmz"
        set vlanid 10
    next
    edit "VLAN20"
        set ip 192.168.20.98 255.255.255.0
        set allowaccess ping https ssh
        set role lan
        set interface "dmz"
        set vlanid 20
    next
end
```

2. Configure the DHCP server on VLAN10:

```
config system dhcp server
    edit 0
        set dns-service default
        set default-gateway 192.168.10.98
        set netmask 255.255.255.0
        set interface "VLAN10 "
        config ip-range
            edit 1
                set start-ip 192.168.10.100
                set end-ip 192.168.10.254
            next
        end
        set timezone-option default
    next
end
```

3. Configure firewall policies that allow traffic from the VLAN10 and VLAN20 interfaces to the internet:

```
config firewall policy
  edit 0
    set name "VLAN10-out"
    set srcintf "VLAN10"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
  next
  edit 0
    set name "VLAN20-out"
    set srcintf "VLAN20"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
  next
end
```

To test the connection:

1. Connect a PC to internal1 on FortiGate B.
2. Verify that it receives an IP address from FortiGate A's DHCP server.
3. From the PC, ping FortiGate B on 192.168.10.99.
4. Ping FortiGate A on 192.168.10.98.
5. Connect to the internet. Traffic is allowed by the VLAN10-out policy.

VXLAN

Virtual Extensible LAN (VXLAN) is a network virtualization technology used in large cloud computing deployments. It encapsulates layer 2 Ethernet frames within layer 3 IP packets using the UDP transport protocol on port 4789. VXLAN endpoints that terminate VXLAN tunnels can be virtual or physical switch ports, and are known as VXLAN tunnel endpoints (VTEPs).

Sample VXLAN packet

A VXLAN packet encapsulation occurs by first inserting a VXLAN header in front of the original layer 2 frame. This VXLAN header uses 3 B for the VNID that is used to identify the VXLAN segment, meaning that there are 16,777,215 different possible VNIDs. This allows for more unique LAN segments than possible VLANs. The original frame and the VXLAN header are then encapsulated into the UDP payload. The outer IP header allows it to be routed and transported over a layer 3 network, thus providing a layer 2 overlay scheme over a layer 3 network.

This equates to 50 B of overhead over the original frame: 14 B (Ethernet) + 20 B (IPv4) + 8 B (UDP) + 8 B (VXLAN headers). Since fragmenting a VXLAN packet is not recommended, it is advisable to increase the MTU size to 1550 B or above if possible, or to decrease the TCP MSS size inside a firewall policy.

For more information about VXLAN, see [RFC 7348](#).

The following topics provide information about VXLAN:

- [General VXLAN configuration and topologies on page 186](#)
- [VLAN inside VXLAN on page 190](#)
- [Virtual wire pair with VXLAN on page 193](#)
- [VXLAN over IPsec tunnel with virtual wire pair on page 195](#)
- [VXLAN over IPsec using a VXLAN tunnel endpoint on page 198](#)
- [VXLAN troubleshooting on page 203](#)

General VXLAN configuration and topologies

This topic describes general VXLAN configurations and commonly used topologies. In the most basic configuration, a FortiGate is configured as a VXLAN tunnel endpoint (VTEP).

To configure a FortiGate as a VTEP:

1. Configure the local interface:

```
config system vxlan
  edit <name>
    set interface <string>
    set vni <integer>
    set ip-version {ipv4-unicast | ipv6-unicast | ipv4-multicast | ipv6-multicast}
    set dstport <integer>
    set remote-ip <IP_address>
    set remote-ip6 <IP_address>
  next
end
```

<code>interface <string></code>	Set the local outgoing interface for the VXLAN encapsulated traffic.
<code>vni <integer></code>	Set the VXLAN network ID.
<code>ip-version {ipv4-unicast ipv6-unicast ipv4-multicast ipv6-multicast}</code>	Set the IP version to use for the VXLAN device and communication over VXLAN (default = ipv4-unicast).
<code>dstport <integer></code>	Set the VXLAN destination port (default = 4789).
<code>remote-ip <IP_address></code>	Set the IPv4 address of the remote VXLAN endpoint.
<code>remote-ip6 <IP_address></code>	Set the IPv6 address of the remote VXLAN endpoint.

The VXLAN system interface is automatically created with a `vxlan` type.

2. Configure the VXLAN interface settings:

```
config system interface
  edit <name>
    set vdom <string>
    set type vxlan
    set ip <IP_address>
    set allowaccess {ping https ssh http telnet fgfm radius-acct probe-response
fabric ftm speed-test}
  next
end
```

3. Connect the internal interface and VXLAN interface to the same L2 network.

• Connect using a software switch:

```
config system switch-interface
  edit <name>
    set vdom <string>
    set member <member_1> <member_2> ... <member_n>
    set intra-switch-policy {implicit | explicit}
  next
end
```

```
member <member_1>
  <member_2> ...
  <member_n>
```

Enter the VXLAN interface and other physical or virtual interfaces that will share the L2 network.

When adding an interface member to a software switch, it cannot have an IP address or be referenced in any other settings.

```
intra-switch-policy
  {implicit |
  explicit}
```

Allow any traffic between switch interfaces or require firewall policies to allow traffic between switch interfaces:

- `implicit`: traffic between switch members is implicitly allowed.
- `explicit`: traffic between switch members must match firewall policies (explicit firewall policies are required to allow traffic between members).

When in explicit mode, traffic can be offloaded to SOC4/SOC5/NP6/NP7 processors.

• Connect using a virtual wire pair:

```
config system virtual-wire-pair
  edit <name>
    set member <member_1> <member_2>
    set wildcard-vlan {enable | disable}
    set vlan-filter <filter>
  next
end
```

```
member <member_1>
  <member_2>
```

Enter the VXLAN interface and other physical or virtual interface that will share the L2 network.

```
wildcard-vlan {enable |
  disable}
```

Enable/disable wildcard VLAN. Disable to prevent VLAN-tagged traffic between the members of the virtual wire pair (default). Enable for VLAN tags to be allowed between the members.

```
vlan-filter <filter>
```

When wildcard-vlan is enabled, set the VLAN filter to specify which VLANs are allowed. By default, an empty vlan-filter allows all VLANs.

- If using a virtual wire pair, configure a firewall policy that allows bi-directional traffic between the members of the virtual wire pair and inspection between them:

```
config firewall policy
  edit <id>
    set name <name>
    set srcintf <member_1> <member_2>
    set dstintf <member_1> <member_2>
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
  next
end
```

Topologies

Many topologies can be deployed with VXLAN. A FortiGate can connect to VXLAN endpoints that are Fortinet devices or devices from other vendors. In the following topologies, it is assumed that at least one of the VTEPs is a FortiGate. The second VTEP can be any vendor.

Basic VXLAN between two VTEPs

In this topology, a FortiGate (VTEP 1) is configured with a VXLAN interface over port1 where the `remote-ip` points to port1 of VTEP 2. The VXLAN interface and port2 can be associated with the same L2 network by making them members of either a software switch or a virtual wire pair. Devices under the L2 switches are part of the same L2 network.

See [Virtual wire pair with VXLAN on page 193](#) for an example configuration.

VXLAN between two VTEPs with wildcard VLANs

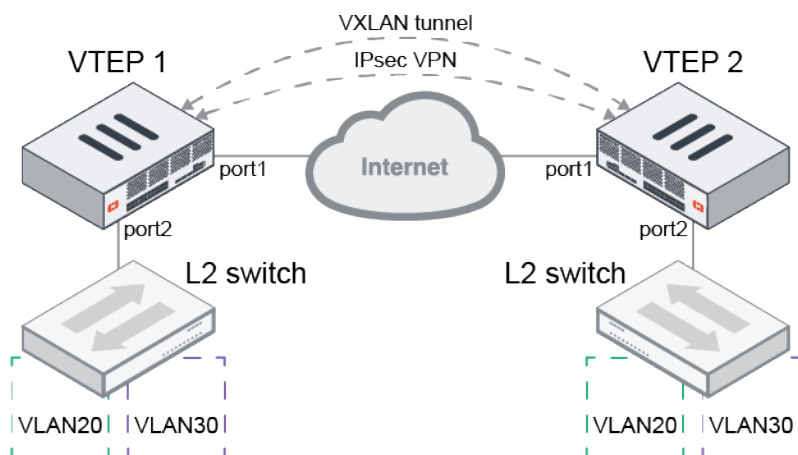

In this topology, a FortiGate (VTEP 1) is configured with a VXLAN interface over port1 where the `remote-ip` points to port1 of VTEP 2. The VXLAN interface is combined with port2 into the same L2 network using a virtual wire pair. The virtual wire pair allows wildcard VLANs to pass, which allows VLAN tags to be encapsulated over VXLAN. As a result, VLANs can span different switches over VXLAN.

Variations of these two scenarios can also be found in FortiGate to FortiSwitch FortiLink connections over VXLAN. See [Deployment procedures](#) in the FortiSwitch VXLAN Deployment Guide for example configurations.

VXLAN between two VTEPs over IPsec

In scenarios where VTEPs are located in different sites and traffic must be secured between the sites, VXLAN will need to be encrypted over IPsec. The VXLAN interface must use the IPsec interface as its outgoing interface. The `remote-ip` must be configured as the IP of the remote IPsec gateway. The VXLAN interface can be combined with port2 into the same L2 network using a software switch or virtual wire pair. Devices under the L2 switches can communicate with each other.

See [VXLAN over IPsec tunnel with virtual wire pair on page 195](#) for an example configuration. A variation of this scenario is explained in [FortiExtender as FortiGate LAN extension](#) (FortiExtender FortiGate-Managed Administration Guide).

VXLAN between multiple VTEPs in an IPsec hub and spoke topology

In this topology, an IPsec VPN hub and spoke overlay network is already configured between sites. To allow networks behind the hub and spokes to be connected together, each spoke has a VXLAN connection to the hub, and the hub allows interconnection between its private network and each of the VXLAN interfaces to the spokes. In this scenario, the private networks behind each spoke are actually on the same L2 network as the private network behind the hub.

See [VXLAN over IPsec using a VXLAN tunnel endpoint on page 198](#) for an example configuration.

VLAN inside VXLAN

VLANs can be assigned to VXLAN interfaces. In a data center network where VXLAN is used to create an L2 overlay network and for multitenant environments, a customer VLAN tag can be assigned to VXLAN interface. This allows the VLAN tag from VLAN traffic to be encapsulated within the VXLAN packet.

To configure VLAN inside VXLAN on HQ1:

1. Configure VXLAN:

```
config system vxlan
  edit "vxlan1"
    set interface port1
    set vni 1000
    set remote-ip 173.1.1.1
  next
end
```

2. Configure system interface:

```
config system interface
  edit vlan100
    set vdom root
    set vlanid 100
    set interface dmz
  next
  edit vxlan100
    set type vlan
    set vlanid 100
    set vdom root
    set interface vxlan1
  next
end
```

3. Configure software-switch:

```
config system switch-interface
  edit sw1
    set vdom root
    set member vlan100 vxlan100
    set intra-switch-policy implicit
  next
end
```

The default `intra-switch-policy implicit` behavior allows traffic between member interfaces within the switch. Therefore, it is not necessary to create firewall policies to allow this traffic.

Instead of creating a software-switch, it is possible to use a virtual-wire-pair as well. See [Virtual wire pair with VXLAN on page 193](#).

To configure VLAN inside VXLAN on HQ2:

1. Configure VXLAN:

```
config system vxlan
edit "vxlan2"
set interface port25
set vni 1000
set remote-ip 173.1.1.2
next
end
```

2. Configure system interface:

```
config system interface
edit vlan100
set vdom root
set vlanid 100
set interface port20
next
edit vxlan100
set type vlan
set vlanid 100
set vdom root
set interface vxlan2
next
end
```

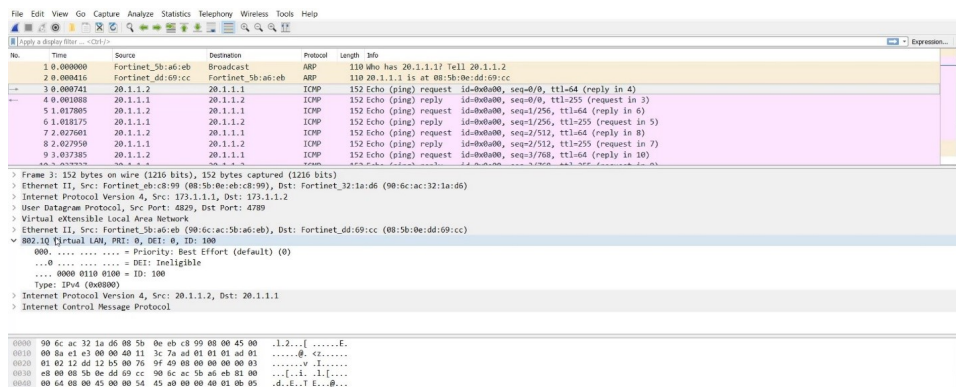

3. Configure software-switch:

```
config system switch-interface
edit sw1
set vdom root
set member vlan100 vxlan100
next
end
```

To verify the configuration:

Ping PC1 from PC2.

The following is captured on HQ2:

This captures the VXLAN traffic between 172.1.1.1 and 172.1.1.2 with the VLAN 100 tag inside.

Virtual wire pair with VXLAN

Virtual wire pairs can be used with VXLAN interfaces.

In this examples, VXLAN interfaces are added between FortiGate HQ1 and FortiGate HQ2, a virtual wire pair is added in HQ1, and firewall policies are created on both HQ1 and HQ2.

To create VXLAN interface on HQ1:

```
config system interface
  edit "port11"
    set vdom "root"
    set ip 10.2.2.1 255.255.255.0
    set allowaccess ping https ssh snmp telnet
  next
end
config system vxlan
  edit "vxlan1"
    set interface "port11"
    set vni 1000
    set remote-ip "10.2.2.2"
  next
end
```

To create VXLAN interface on HQ2:

```
config system interface
  edit "port11"
    set vdom "root"
    set ip 10.2.2.2 255.255.255.0
    set allowaccess ping https ssh snmp http
  next
end
config system vxlan
  edit "vxlan1"
    set interface "port11"
    set vni 1000
    set remote-ip "10.2.2.1"
  next
end
config system interface
  edit "vxlan1"
    set vdom "root"
    set ip 10.1.100.2 255.255.255.0
    set allowaccess ping https ssh snmp
```

```
    next
end
```

To create a virtual wire pair on HQ1:

```
config system virtual-wire-pair
    edit "vwp1"
        set member "port10" "vxlan1"
    next
end
```

To create a firewall policy on HQ1:

```
config firewall policy
    edit 5
        set name "vxlan-policy"
        set srcintf "port10" "vxlan1"
        set dstintf "port10" "vxlan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set av-profile "default"
        set webfilter-profile "default"
        set dnsfilter-profile "default"
        set ips-sensor "default"
        set application-list "default"
        set fsso disable
    next
end
```

To create a firewall policy on HQ2:

```
config firewall policy
    edit 5
        set name "1"
        set srcintf "port13"
        set dstintf "vxlan1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set fsso disable
        set nat enable
    next
end
```

VXLAN over IPsec tunnel with virtual wire pair

VXLAN can be used to encapsulate VLAN traffic over a Layer 3 network. Using IPsec VPN tunnels to secure a connection between two sites, VXLAN can encapsulate VLAN traffic over the VPN tunnel to extend the VLANs between the two sites.

In this example, a site-to-site VPN tunnel is formed between two FortiGates. A VXLAN is configured over the IPsec interface. Multiple VLANs are connected to a switch behind each FortiGate. Host1 and Host2 are connected to VLAN10 on the switches on each site, and Host21 and Host22 are connected to VLAN20. Using virtual wire pairs, the internal interface (port1) will be paired with the VXLAN interface (vxlan) to allow VLAN traffic to pass through in either direction.

To configure FGT-A:

1. Configure the WAN interface:

```
config system interface
  edit "wan1"
    set vdom "root"
    set ip 11.11.11.11 255.255.255.0
    set allowaccess ping https ssh http fgfm
    set type physical
    set role wan
    set snmp-index 1
  next
end
```

2. Configure a static route to send all traffic out the WAN interface:

```
config router static
  edit 1
    set gateway 11.11.11.1
    set device "wan1"
  next
end
```

3. Configure the IPsec tunnel:

```
config vpn ipsec phase1-interface
  edit "ipsec"
```

```

        set interface "wan1"
        set peertype any
        set proposal aes256-sha1
        set remote-gw 22.22.22.22
        set psksecret *****
    next
end
config vpn ipsec phase2-interface
    edit "ipsec"
        set phasename "ipsec"
        set proposal aes256-sha1
        set auto-negotiate enable
    next
end

```

4. Configure local and remote IP addresses for the IPsec interface:

```

config system interface
    edit "ipsec"
        set ip 10.200.0.1 255.255.255.255
        set remote-ip 10.200.0.2 255.255.255.252
    next
end

```

5. Configure the VXLAN interface and bind it to the IPsec interface:

```

config system vxlan
    edit "vxlan"
        set interface "ipsec"
        set vni 10
        set remote-ip "10.200.0.2"
    next
end

```

The remote IP address is the address of the remote IPsec peer.

6. Configure a virtual wire pair with the port1 and vxlan interfaces as members:

```

config system virtual-wire-pair
    edit "vwp"
        set member "port1" "vxlan"
        set wildcard-vlan enable
    next
end

```

The interfaces added to the virtual wire pair cannot be part of a switch, such as the default internal interface.

By enabling wildcard VLANs on the virtual wire pair, all VLAN tagged traffic that is allowed by the virtual wire pair firewall policies passes through the pair.

7. Configure a virtual wire pair firewall policy to allow traffic between the port1 and vxlan interfaces:

```

config firewall policy
    edit 4
        set name "vwp-pol"
        set srcintf "port1" "vxlan"
        set dstintf "port1" "vxlan"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
    next
end

```

```
        set schedule "always"  
        set service "ALL"  
    next  
end
```

To configure FGT-B

1. Configure the WAN interface:

```
config system interface  
    edit "wan1"  
        set vdom "root"  
        set ip 22.22.22.22 255.255.255.0 255.255.255.0  
        set allowaccess ping https ssh http fgfm  
        set type physical  
        set role wan  
        set snmp-index 1  
    next  
end
```

2. Configure a static route to send all traffic out the WAN interface:

```
config router static  
    edit 1  
        set gateway 22.22.22.2  
        set device "wan1"  
    next  
end
```

3. Configure the IPsec tunnel:

```
config vpn ipsec phase1-interface  
    edit "ipsec"  
        set interface "wan1"  
        set peertype any  
        set proposal aes256-sha1  
        set remote-gw 11.11.11.11  
        set psksecret *****  
    next  
end  
config vpn ipsec phase2-interface  
    edit "ipsec"  
        set phasename "ipsec"  
        set proposal aes256-sha1  
        set auto-negotiate enable  
    next  
end
```

4. Configure local and remote IP addresses for the IPsec interface:

```
config system interface  
    edit "ipsec"  
        set ip 10.200.0.2 255.255.255.255  
        set remote-ip 10.200.0.1 255.255.255.252  
    next  
end
```

5. Configure the VXLAN interface and bind it to the IPsec interface:

```
config system vxlan
  edit "vxlan"
    set interface "ipsec"
    set vni 10
    set remote-ip "10.200.0.1"
  next
end
```

The remote IP address is the address of the remote IPsec peer.

6. Configure a virtual wire pair with the port1 and vxlan interfaces as members:

```
config system virtual-wire-pair
  edit "vwp"
    set member "port1" "vxlan"
    set wildcard-vlan enable
  next
end
```

7. Configure a firewall policy to allow traffic between the port1 and vxlan interfaces:

```
config firewall policy
  edit 4
    set name "vwp-pol"
    set srcintf "port1" "vxlan"
    set dstintf "port1" "vxlan"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
  next
end
```

Test the configuration

To test the configuration, ping Host2 (VLAN10: 192.168.10.2/24) from Host1 (VLAN10: 192.168.10.1/24):

```
C:\>ping 192.168.10.2
```

```
Pinging 192.168.10.2 with 32 bytes of data:
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=8ms TTL=56
Reply from 192.168.10.2: bytes=32 time=11ms TTL=56
```

```
Ping statistics for 192.168.10.2:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 8ms, Maximum = 11ms, Average = 8ms
```

Host21 should also be able to ping Host22.

VXLAN over IPsec using a VXLAN tunnel endpoint

This example describes how to implement VXLAN over IPsec VPN using a VXLAN tunnel endpoint (VTEP).

This example uses a hub and spoke topology. Dialup VPN is used because it allows a single phase 1 dialup definition on the hub FortiGate. Additional spoke tunnels are added with minimal changes to the hub by adding a user account and VXLAN interface for each spoke. Spoke-to-spoke communication is established through the hub. This example assumes that the authentication users and user groups have already been created. While this topology demonstrates hub and spoke with dialup tunnels with XAuth authentication, the same logic can be applied to a static VPN with or without XAuth.

IPsec tunnel interfaces are used to support VXLAN tunnel termination. An IP address is set for each tunnel interface. Ping access is allowed for troubleshooting purposes.

VTEPs are created on the hub and each spoke to forward VXLAN traffic through the IPsec tunnels. VXLAN encapsulates OSI layer 2 Ethernet frames within layer 3 IP packets. You will need to either combine the internal port1 and VXLAN interface into a soft switch, or create a virtual wire pair so that devices behind port1 have direct layer 2 access to remote peers over the VXLAN tunnel. This example uses a switch interface on the hub and a virtual wire pair on the spokes to demonstrate the two different methods.

In order to apply an IPsec VPN interface on the VXLAN interface setting, `net-device` must be disabled in the IPsec VPN phase 1 settings.

To configure the hub FortiGate:

1. Configure the IPsec phase 1 interface:

```
config vpn ipsec phase1-interface
  edit "SPOKES"
    set type dynamic
    set interface "port2"
    set mode aggressive
    set peertype one
    set net-device disable
    set proposal aes256-sha256
    set xauthtype auto
    set authusrgrp "SPOKES"
    set peerid "SPOKES"
    set psksecret <secret>
  next
end
```

2. Configure the IPsec phase 2 interface:

```
config vpn ipsec phase2-interface
  edit "SPOKES"
    set phase1name "SPOKES"
    set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
  next
end
```

3. Configure the IPsec VPN policy that allows VXLAN traffic between the spokes:

```
config firewall policy
  edit 1
    set name "VXLAN_SPOKE_to_SPOKE"
    set srcintf "SPOKES"
    set dstintf "SPOKES"
    set srcaddr "NET_192.168.255.0"
    set dstaddr "NET_192.168.255.0"
    set action accept
    set schedule "always"
    set service "UDP_4789"
    set logtraffic all
    set fsso disable
  next
end
```

4. Configure the IPsec tunnel interfaces (the remote IP address is not used, but it is necessary for this configuration):

```
config system interface
  edit "SPOKES"
    set vdom "root"
    set ip 192.168.255.1 255.255.255.255
    set allowaccess ping
    set type tunnel
    set remote-ip 192.168.255.254 255.255.255.0
    set snmp-index 12
    set interface "port2"
  next
end
```

5. Configure the VXLAN interfaces. Each spoke requires a VXLAN interface with a different VNI. The remote IP is the tunnel interfaces IP of the spokes.**a. Spoke 1:**

```
config system VXLAN
  edit "SPOKES_VXLAN1"
    set interface "SPOKES"
    set vni 1
    set remote-ip "192.168.255.2"
  next
end
```

b. Spoke 2:

```
config system VXLAN
  edit "SPOKES_VXLAN2"
    set interface "SPOKES"
    set vni 2
```

```

        set remote-ip "192.168.255.3"
    next
end

```

To configure the spoke FortiGates:

1. Configure the IPsec phase 1 interface:

```

config vpn ipsec phase1-interface
    edit "HUB"
        set interface "port2"
        set mode aggressive
        set peertype any
        set net-device disable
        set proposal aes256-sha256
        set localid "SPOKES"
        set xauthtype client
        set authusr "SPOKE1"
        set authpasswd <secret>
        set remote-gw <hub public IP>
        set psksecret <secret>
    next
end

```

2. Configure the IPsec phase 2 interface:

```

config vpn ipsec phase2-interface
    edit "HUB"
        set phase1name "HUB"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set auto-negotiate enable
        set src-subnet 192.168.255.2 255.255.255.255
    next
end

```

The hub FortiGate inserts a reverse route pointing to newly established tunnel interfaces for any of the subnets that the spoke FortiGate's source quick mode selectors provides. This is why you should set the tunnel IP address here.

3. Configure the IPsec VPN policy:

```

config firewall policy
    edit 1
        set name "VTEP_IPSEC_POLICY"
        set srcintf "HUB"
        set dstintf "HUB"
        set srcaddr "none"
        set dstaddr "none"
        set action accept
        set schedule "always"
        set service "PING"
        set logtraffic disable
        set fssso disable
    next
end

```

4. Configure the IPsec tunnel interface:

```

config system interface
  edit "HUB"
    set vdom "root"
    set ip 192.168.255.2 255.255.255.255
    set allowaccess ping
    set type tunnel
    set remote-ip 192.168.255.1 255.255.255.0
    set snmp-index 12
    set interface "port2"
  next
end

```

5. Configure the VXLAN interfaces (the remote IP is the tunnel interface IP of the hub):**a. Spoke 1:**

```

config system VXLAN
  edit "HUB_VXLAN"
    set interface "HUB"
    set vni 1
    set remote-ip "192.168.255.1"
  next
end

```

b. Spoke 2:

```

config system VXLAN
  edit "HUB_VXLAN"
    set interface "HUB"
    set vni 2
    set remote-ip "192.168.255.1"
  next
end

```

To bind the VXLAN interface to the internal interface:**1. Configure a switch interface on the hub:**

```

config system switch-interface
  edit "SW"
    set vdom "root"
    set member "port1" "SPOKES_VXLAN1" "SPOKES_VXLAN2"
    set intra-switch-policy {implicit | explicit}
  next
end

```

Allowing intra-switch traffic is implicitly allowed by default. Use `set intra-switch-policy explicit` to require firewall policies to allow traffic between switch interfaces.

2. Configure a virtual wire pair on the spokes:

```

config system virtual-wire-pair
  edit "VWP"
    set member "HUB_VXLAN" "port1"

```

```
next
end
```

The virtual wire pair requires an explicit policy to allow traffic between interfaces.

To test the configuration:

1. Ping the hub FortiGate from the spoke FortiGate:

```
user@pc-spoke1:~$ ping 192.168.1.1 -c 3
PING 192.168.1.1 (192.168.1.1) 56(84) bytes of data.
64 bytes from 192.168.1.1: icmp_seq=1 ttl=64 time=1.24 ms
64 bytes from 192.168.1.1: icmp_seq=2 ttl=64 time=0.672 ms
64 bytes from 192.168.1.1: icmp_seq=3 ttl=64 time=0.855 ms
--- 192.168.1.1 ping statistics ---
3 packets transmitted, 3 received, 0% packet loss, time 2002 ms
rtt min/avg/max/mdev = 0.672/0.923/1.243/0.239 ms
```

2. Sniff traffic on the hub FortiGate:

```
# diagnose sniffer packet any 'icmp or (udp and port 4789)' 4 0
interfaces=[any] filters=[icmp or (udp and port 4789)]
15:00:01.438230 SPOKES in 192.168.255.2.4790 -> 192.168.255.1.4789: udp 106
15:00:01.438256 SPOKES_VXLAN1 in 192.168.1.2 -> 192.168.1.1: icmp: echo request
15:00:01.438260 port1 out 192.168.1.2 -> 192.168.1.1: icmp: echo request
15:00:01.438532 port1 in 192.168.1.1 -> 192.168.1.2: icmp: echo reply
15:00:01.438536 SPOKES_VXLAN1 out 192.168.1.1 -> 192.168.1.2: icmp: echo reply
15:00:01.438546 SPOKES out 192.168.255.1.4851 -> 192.168.255.2.4789: udp 106
```

VXLAN troubleshooting

The following commands can be used to troubleshoot VXLAN connectivity:

- `diagnose sys vxlan fdb list <VXLAN_interface>`
- `diagnose sys vxlan fdb stat <VXLAN_interface>`
- `diagnose netlink brctl name host <switch_interface>`
- `diagnose debug sniffer packet any 'udp and port 4789' 4 0 1`
- `diagnose debug enable`
- `diagnose debug flow filter port 4789`
- `diagnose debug flow trace start <repeat_#>`

Topology

The following topology is used as an example configuration to demonstrate VXLAN troubleshooting steps.

In this example, two FortiGates are configured as VXLAN tunnel endpoints (VTEPs). A VXLAN is configured to allow L2 connectivity between the networks behind each FortiGate. The VXLAN interface and port6 are placed on the same L2 network using a software switch (sw100). An L2 network is formed between PC1 and PC2.

The VTEPs have the following MAC address tables:

Interface/endpoint	VTEP 1	VTEP 2
vlan100	7e:f2:d1:84:75:0f	ca:fa:31:23:8d:c1
port6	00:0c:29:4e:5c:1c	00:0c:29:d0:3e:0d
sw100	00:0c:29:4e:5c:1c	00:0c:29:d0:3e:0d

The MAC address of PC1 is 00:0c:29:90:4f:bf. The MAC address of PC2 is 00:0c:29:f0:88:2c.

To configure the VTEP 1 FortiGate:

1. Configure the local interface:

```
config system vxlan
  edit "vxlan100"
    set interface "port2"
    set vni 100
    set remote-ip "192.168.2.87"
```

```
    next
end
```

2. Configure the interface settings:

```
config system interface
  edit "port2"
    set vdom "root"
    set ip 192.168.2.86 255.255.255.0
    set allowaccess ping https ssh http fabric
  next
  edit "vxlan100"
    set vdom "root"
    set type vxlan
    set interface "port2"
  next
end
```

3. Configure the software switch:

```
config system switch-interface
  edit "sw100"
    set vdom "root"
    set member "port6" "vxlan100"
  next
end
```

4. Configure the software switch interface settings:

```
config system interface
  edit "sw100"
    set vdom "root"
    set ip 10.10.100.86 255.255.255.0
    set allowaccess ping
    set type switch
    set device-identification enable
    set lldp-transmission enable
    set role lan
  next
end
```

To configure the VTEP 2 FortiGate:

1. Configure the local interface:

```
config system vxlan
  edit "vxlan100"
    set interface "port2"
    set vni 100
    set remote-ip "192.168.2.86"
  next
end
```

2. Configure the interface settings:

```
config system interface
  edit "port2"
    set vdom "root"
    set ip 192.168.2.87 255.255.255.0
```

```
        set allowaccess ping https ssh snmp http
    next
    edit "vxlan100"
        set vdom "root"
        set type vxlan
        set interface "port2"
    next
end
```

3. Configure the software switch:

```
config system switch-interface
    edit "sw100"
        set vdom "root"
        set member "port6" "vxlan100"
    next
end
```

4. Configure the software switch interface settings:

```
config system interface
    edit "sw100"
        set vdom "root"
        set ip 10.10.100.87 255.255.255.0
        set allowaccess ping
        set type switch
        set device-identification enable
        set lldp-transmission enable
        set role lan
        set snmp-index 42
    next
end
```

To run diagnostics and debugs:

1. Start a ping from PC1 10.10.100.10 to PC2 10.10.100.20:

```
C:\Users\fortidocs>ping 10.10.100.20

Pinging 10.10.100.20 with 32 bytes of data:
Reply from 10.10.100.20: bytes=32 time=2ms TTL=128
Reply from 10.10.100.20: bytes=32 time=1ms TTL=128
Reply from 10.10.100.20: bytes=32 time=1ms TTL=128
Reply from 10.10.100.20: bytes=32 time<1ms TTL=128

Ping statistics for 10.10.100.20:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
    Approximate round trip times in milli-seconds:
        Minimum = 0ms, Maximum = 2ms, Average = 1ms
```

2. Verify the ARP table:

```
C:\Users\fortidocs>arp /a

Interface: 10.10.100.10 --- 0x21
    Internet Address      Physical Address      Type
    10.10.100.20          00-0c-29-f0-88-2c    dynamic
    10.10.100.86          00-0c-29-4e-5c-1c    dynamic
```

```

10.10.100.255          ff-ff-ff-ff-ff-ff      static
224.0.0.22           01-00-5e-00-00-16      static
224.0.0.252          01-00-5e-00-00-fc      static

```

3. Run diagnostics on the VTEP 1 FortiGate.

a. Verify the forwarding database of VXLAN interface vxlan100:

```

# diagnose sys vxlan fdb list vxlan100
mac=00:00:00:00:00:00 state=0x0082 remote_ip=192.168.2.87 port=4789 vni=100 ifindex=6
mac=00:0c:29:f0:88:2c state=0x0002 remote_ip=192.168.2.87 port=4789 vni=100 ifindex=6

total fdb num: 2

```

The MAC address 00:0c:29:f0:88:2c is learned from PC2 10.10.100.20.

b. Verify the summary of statistics from the VXLAN's forwarding database:

```

# diagnose sys vxlan fdb stat vxlan100
fdb_table_size=256 fdb_table_used=2 fdb_entry=2 fdb_max_depth=1 cleanup_idx=0
cleanup_timer=252

```

c. Verify the software switch's forwarding table:

```

# diagnose netlink brctl name host sw100
show bridge control interface sw100 host.
fdb: hash size=32768, used=6, num=6, depth=1, gc_time=4, ageing_time=3, simple=switch
Bridge sw100 host table

```

port	no	device	devname	mac	addr	tvl	attributes
1	7	port6	port6	00:0c:29:4e:5c:1c		0	Local Static
2	33	vxlan100	vxlan100	7e:f2:d1:84:75:0f		0	Local Static
2	33	vxlan100	vxlan100	00:00:00:00:00:00		26	Hit(26)
1	7	port6	port6	00:0c:29:90:4f:bf		0	Hit(0)
1	7	port6	port6	00:0c:29:d0:3e:ef		7	Hit(7)
2	33	vxlan100	vxlan100	00:0c:29:f0:88:2c		0	Hit(0)

The MAC address of port6 is 00:0c:29:4e:5c:1c. The MAC address of vxlan100 is 7e:f2:d1:84:75:0f. The MAC address 00:0c:29:f0:88:2c of PC2 is learned from the remote network.

4. Run diagnostics on the VTEP 2 FortiGate.

a. Verify the forwarding database of VXLAN interface vxlan100:

```

# diagnose sys vxlan fdb list vxlan100
mac=00:00:00:00:00:00 state=0x0082 remote_ip=192.168.2.86 port=4789 vni=100 ifindex=6
mac=00:0c:29:90:4f:bf state=0x0002 remote_ip=192.168.2.86 port=4789 vni=100 ifindex=6

total fdb num: 2

```

The MAC address 00:0c:29:90:4f:bf is learned from PC1 10.10.100.10.

b. Verify the summary of statistics from the VXLAN's forwarding database:

```

# diagnose sys vxlan fdb stat vxlan100
fdb_table_size=256 fdb_table_used=2 fdb_entry=2 fdb_max_depth=1 cleanup_idx=0
cleanup_timer=304

```

c. Verify the software switch's forwarding table:

```

# diagnose netlink brctl name host sw100
show bridge control interface sw100 host.
fdb: hash size=32768, used=5, num=5, depth=1, gc_time=4, ageing_time=3, simple=switch
Bridge sw100 host table

```

port	no	device	devname	mac	addr	ttl	attributes
2	50	vxlan100		00:00:00:00:00:00		10	Hit(10)
2	50	vxlan100		00:0c:29:90:4f:bf		2	Hit(2)
1	7	port6		00:0c:29:d0:3e:0d		0	Local Static
2	50	vxlan100		ca:fa:31:23:8d:c1		0	Local Static
1	7	port6		00:0c:29:f0:88:2c		0	Hit(0)

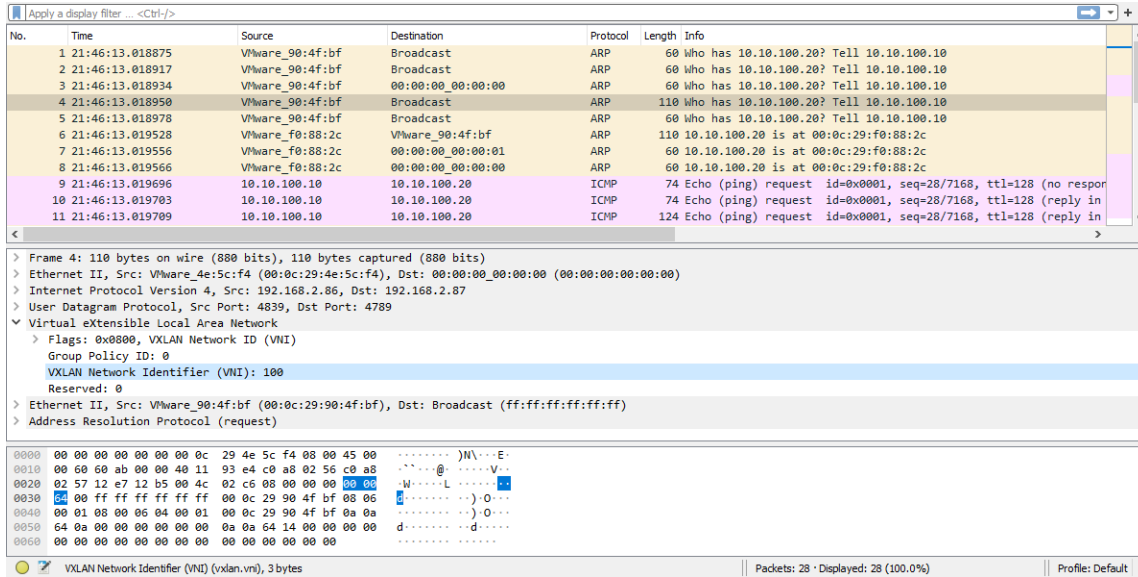

The MAC address of port6 is 00:0c:29:d0:3e:0d. The MAC address of vxlan100 is ca:fa:31:23:8d:c1. The MAC address 00:0c:29:90:4f:bf of PC1 is learned from the remote network.

5. Perform a sniffer trace on the VTEP 1 FortiGate to view the life of the packets as they pass through the FortiGate:

```
# diagnose sniffer packet any 'host 10.10.100.20 or (udp and host 192.168.2.87)' 4 0 1
Using Original Sniffing Mode
interfaces=[any]
filters=[host 10.10.100.20 or (udp and host 192.168.2.87)]
2022-11-04 14:35:18.567602 port6 in arp who-has 10.10.100.20 tell 10.10.100.10
2022-11-04 14:35:18.567629 vxlan100 out arp who-has 10.10.100.20 tell 10.10.100.10
2022-11-04 14:35:18.567642 port2 out 192.168.2.86.4804 -> 192.168.2.87.4789: udp 68

2022-11-04 14:35:18.568925 vxlan100 in arp who-has 10.10.100.10 tell 10.10.100.20
2022-11-04 14:35:18.568935 port6 out arp who-has 10.10.100.10 tell 10.10.100.20
2022-11-04 14:35:18.568945 sw100 in arp who-has 10.10.100.10 tell 10.10.100.20
2022-11-04 14:35:18.569070 port6 in arp reply 10.10.100.10 is-at 00:0c:29:90:4f:bf
2022-11-04 14:35:18.569076 vxlan100 out arp reply 10.10.100.10 is-at 00:0c:29:90:4f:bf
2022-11-04 14:35:18.569081 port2 out 192.168.2.86.4806 -> 192.168.2.87.4789: udp 68
2022-11-04 14:35:18.569417 port2 in 192.168.2.87.4789 -> 192.168.2.86.4789: udp 82
2022-11-04 14:35:18.569427 vxlan100 in 10.10.100.20 -> 10.10.100.10: icmp: echo reply
2022-11-04 14:35:18.569431 port6 out 10.10.100.20 -> 10.10.100.10: icmp: echo reply
```

In the output, the following packet sequence is seen on the FortiGate:

- a. The FortiGate receives an ARP request from PC1 10.10.100.10 on port6.
 - b. The ARP request is forwarded to vxlan100 on the same software switch, where it gets encapsulated and sent out as a UDP port 4789 packet on port2.
 - c. A reply is received on port2 from the remote VTEP with the ARP response encapsulated in UDP port 4789 again.
 - d. The ARP reply is forwarded back out of port6 to PC1.
 - e. PC1 sends the ICMP request using the same steps.
- 6. Perform the same sniffer trace filter with a level 6 verbose level. In this example, the packet capture is converted into a Wireshark file.**

The packet that leaves the physical port2 is encapsulated in UDP and has a VXLAN header with VNI 100 as the identifier. There is an additional 50 B overhead of the UDP encapsulated VXLAN packets as opposed to the unencapsulated packets (for example, packet 4 versus packets 1 and 2).

QinQ 802.1Q in 802.1ad

QinQ (802.1ad) allows multiple VLAN tags to be inserted into a single frame, and can be configured on supported FortiGate devices.

In this example, the customer connects to a provider that uses 802.1ad double-tagging to separate their customer VLANs. The FortiGate connecting to the provider double-tags its frames with an outer provider-tag (S-Tag) and an inner customer-tag (C-Tag).

Preamble & SoF 8-byte	Destination MAC 6-byte	Source MAC 6-byte	VLAN S-Tag (EtherType 0x88a8) 4-byte	VLAN C-Tag (EtherType 0x8810) 4-byte	Ether- Type 2-byte	Payload	CRC 4-byte

The customer identifies itself with the provider-tag (S-Tag) 232 and uses the customer-tag (C-Tag) 444 for traffic to its VLAN.

To configure the interfaces:

1. Configure the interface to the provider that uses the outer tag (S-Tag):

```
config system interface
  edit "vlan-8021ad"
    set vdom "root"
    set vlan-protocol 8021ad
    set device-identification enable
    set role lan
    set snmp-index 47
    set interface "PORT"
    set vlanid 232
```

```

    next
end

```

2. Configure a dynamic VLAN interface that uses the inner tag (C-Tag):

```

config system interface
    edit "DVLAN"
        set vdom "vdom1"
        set device-identification enable
        set role lan
        set snmp-index 48
        set interface "vlan-8021ad"
        set vlanid 444
    next
end

```

QinQ 802.1Q in 802.1Q

QinQ (802.1Q in 802.1Q) is supported for FortiGate VM models, where multiple VLAN tags can be inserted into a single frame.

In this example, the FortiGate VM is connected to a provider vSwitch and then a customer switch. The FortiGate encapsulates the frame with an outer 802.1Q tag of VLAN 100 and an inner 802.1Q tag of VLAN 200; port5 is used as the physical port. The provider vSwitch strips the outer tag and forwards traffic to the appropriate customer. Then the customer switch strips the inner tag and forwards the packet to the appropriate customer VLAN.

To configure the interfaces:

1. Configure the interface to the provider that uses the outer tag:

```

config system interface
    edit "vlan-8021q"
        set vdom "root"
        set device-identification enable
        set role lan
        set interface "port5"
        set vlan-protocol 8021q
        set vlanid 100
    next
end

```

2. Configure the interface to the provider that uses the inner tag:

```
config system interface
  edit "vlan-qinq8021q"
    set vdom "root"
    set ip 1.1.1.71 255.255.255.0
    set allowaccess ping https ssh snmp http
    set device-identification enable
    set role lan
    set interface "vlan-8021q"
    set vlanid 200
  next
end
```

To verify the traffic:

1. From the FortiGate, ping 1.1.1.72:

```
# execute ping 1.1.1.72
PING 1.1.1.72 (1.1.1.72): 56 data bytes
64 bytes from 1.1.1.72: icmp_seq=0 ttl=255 time=0.2 ms
64 bytes from 1.1.1.72: icmp_seq=1 ttl=255 time=0.1 ms
64 bytes from 1.1.1.72: icmp_seq=2 ttl=255 time=0.1 ms
64 bytes from 1.1.1.72: icmp_seq=3 ttl=255 time=0.1 ms
^C
--- 1.1.1.72 ping statistics ---
4 packets transmitted, 4 packets received, 0% packet loss
round-trip min/avg/max = 0.1/0.1/0.2 ms
```

2. Verify the packet capture frame header output captured from the FortiGate's port5:

```
Frame 2: 106 bytes on wire (848 bits), 106 bytes captured (848 bits)
Ethernet II, Src: VMware_93:ae:8f (00:50:56:93:ae:8f), Dst: VMware_93:e3:72
(00:50:56:93:e3:72)
  Destination: VMware_93:e3:72 (00:50:56:93:e3:72)
  Source: VMware_93:ae:8f (00:50:56:93:ae:8f)
  Type: 802.1Q Virtual LAN (0x8100)
802.1Q Virtual LAN, PRI: 0, DEI: 0, ID: 100
  000. .... = Priority: Best Effort (default) (0)
  ...0 .... = DEI: Ineligible
  ... 0000 0110 0100 = ID: 100
  Type: 802.1Q Virtual LAN (0x8100)
802.1Q Virtual LAN, PRI: 0, DEI: 0, ID: 200
  000. .... = Priority: Best Effort (default) (0)
  ...0 .... = DEI: Ineligible
  ... 0000 1100 1000 = ID: 200
  Type: IPv4 (0x0800)
Internet Protocol Version 4, Src: 1.1.1.71, Dst: 1.1.1.72
Internet Control Message Protocol
```

The outer tag (first tag) is an 802.1Q tag with VLAN ID 100. The inner tag (second tag) is also an 802.1Q tag with VLAN ID 200.

Configure IPAM locally on the FortiGate

IPAM (IP address management) is available locally on the FortiGate. A standalone FortiGate, or a Fabric root in the Security Fabric, can act as the IPAM server. Interfaces configured to be auto-managed by IPAM will receive an address from the IPAM server's address/subnet pool. *DHCP Server* is automatically enabled in the GUI, and the address range is populated by IPAM. Users can customize the address pool subnet and the size of a subnet that an interface can request.

To configure IPAM settings:

```
config system ipam
    set pool-subnet <class IP and netmask>
    set status {enable | disable}
end
```

`pool-subnet <class IP and netmask>` Set the IPAM pool subnet, class A or class B subnet.

`status {enable | disable}` Enable/disable IP address management services.

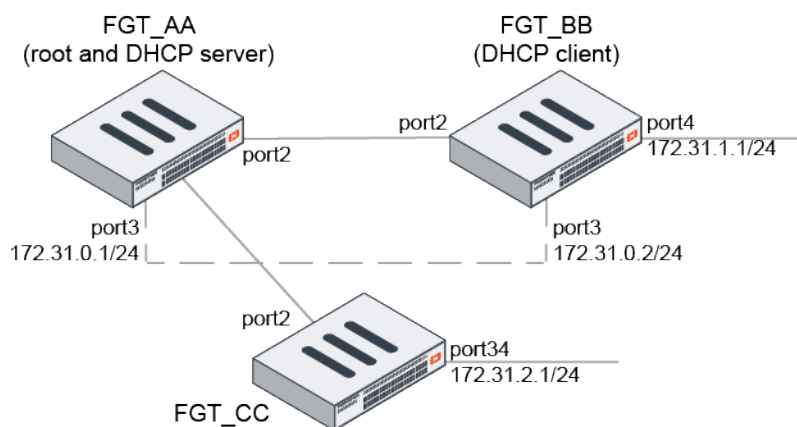

In previous FortiOS versions, the `set fortiipam-integration` option was configured under `config system global`.

The following options are available for allocating the subnet size:

```
config system interface
    set managed-subnetwork-size {32 | 64 | 128 | 256 | 512 | 1024 | 2048 | 4096 | 8192 |
16384 | 32768 | 65536}
end
```

Example

In this example, FGT_AA is the Security Fabric root with IPAM enabled. FGT_BB and FGT_CC are downstream Fabric devices and retrieve IPAM information from FGT_AA. The Fabric interface on all FortiGates is port2. FGT_AA acts as the DHCP server, and FGT_BB acts as the DHCP client.

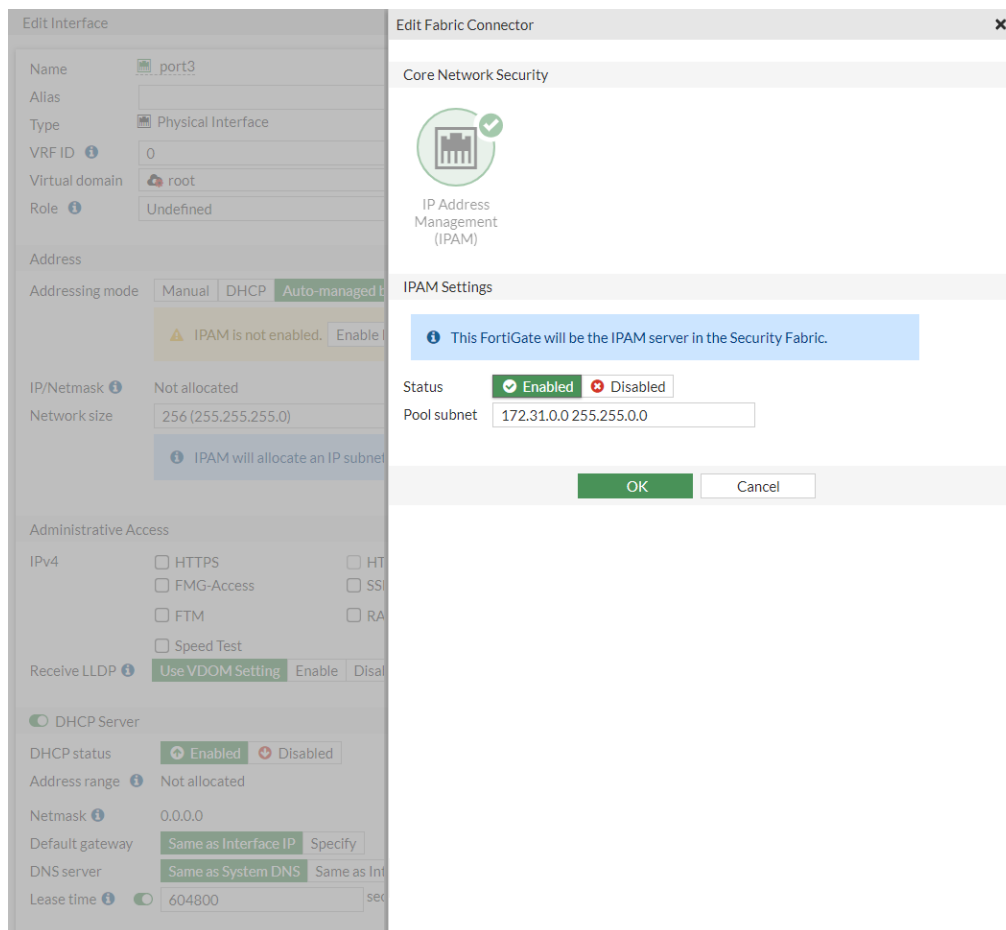

To configure IPAM locally in the Security Fabric:

1. On the root FortiGate, go to *Network > Interfaces* and edit port3.
2. For *Addressing Mode*, select *Auto-Managed by IPAM*. *DHCP Server* is automatically enabled.

The screenshot shows the 'Edit Interface' configuration for 'port3'. The interface is a physical interface in VRF 0, virtual domain 'root', and role 'Undefined'. The addressing mode is 'Auto-managed by IPAM', but IPAM is not yet enabled, as indicated by a yellow warning box with an 'Enable IPAM' button. The IP/Netmask is 'Not allocated' and the network size is set to 256. The DHCP server is enabled, with a status of 'Enabled'. Other settings include administrative access options (HTTPS, HTTP, PING, etc.) and receive LLDP settings.

3. In this example, IPAM is not enabled yet. Click *Enable IPAM*. The *Edit Fabric Connector* pane opens.

4. Enter the *Pool subnet* (only class A and B are allowed) and click **OK**. The root FortiGate is now the IPAM server in the Security Fabric. The following is configured in the backend:

```
config system interface
  edit "port3"
    set vdom "root"
    set ip 172.31.0.1 255.255.255.0
    set type physical
    set device-identification enable
    set snmp-index 5
    set ip-managed-by-fortiipam enable
  end
next
end

config system ipam
  set status enable
end
```

IPAM is managing a 172.31.0.0/16 network and assigned port3 a /24 network by default.

The *IP/Netmask* field in the *Address* section has been automatically assigned a class C IP by IPAM. The *Address range* and *Netmask* fields in the *DHCP Server* section have also been automatically configured by IPAM.

Edit Interface

Video Tutorials

5. Click **OK**.

6. Log in to FGT-BB and set the *Addressing Mode* of port4 to *Auto-Managed by IPAM*. The subnet assigned from the pool on the root is 172.31.1.1/24.

7. Log in to FG_CC and set the *Addressing Mode* of port34 to *Auto-Managed by IPAM*. The subnet assigned from the pool on the root is 172.31.2.1/24.

Any interface on a downstream FortiGate can be managed by the IPAM server. The interface does not have to be directly connected to the Fabric root FortiGate.

To edit the IPAM subnet:

1. Go to *Security Fabric > Fabric Connectors* and double-click the *IP Address Management (IPAM)* card.
2. Edit the pool subnet if needed.

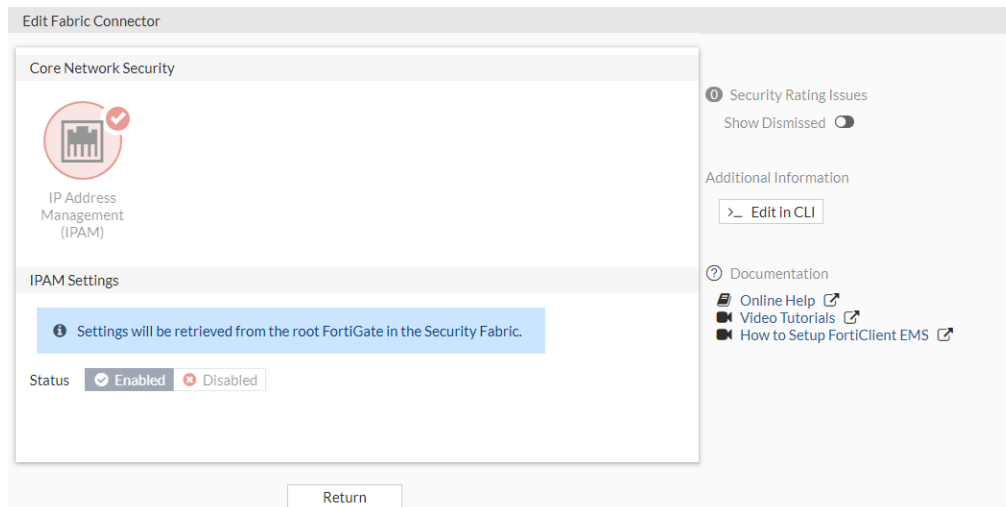

- In the right-side pane, click *View Allocated IP Addresses* to view the subnet allocations (port34, port3, and port3) and DHCP lease information. On FGT_BB, port3 is a DHCP client and the DHCP server interface (FGT_AA port3) is managed by IPAM, so it is displayed in the *Manually Configured* section.

Interfaces	IP/Netmask	FortiGate	Virtual Domain
Allocated			
port34	172.31.2.1/255.255.255.0	FGT_CC	root
port3	172.31.0.1/255.255.255.0	FGT_AA	root
port4	172.31.1.1/255.255.255.0	FGT_BB	root
Manually Configured			
port3	172.31.0.2/255.255.255.0	FGT_BB	root

The same allocated IP address information is available in the *IP Address Management (IPAM)* widget that can be added to the *Dashboard > Status* page.

- Click *OK*.
On downstream FortiGates, the settings on the *IP Address Management (IPAM)* card cannot be changed if IPAM is enabled on the root FortiGate.

Diagnostics

Use the following commands to view IPAM related diagnostics.

To view the largest available subnet size:

```
# diagnose sys ipam largest-available-subnet
Largest available subnet is a /17.
```

To verify IPAM allocation information:

```
# diagnose sys ipam dump-ipams-entries
IPAM Entries: (sn, vdom, interface, subnet/mask, flag)
F140EP4Q17000000 root port34 172.31.2.1/24 0
FG5H1E5818900001 root port3 172.31.0.1/24 0
FG5H1E5818900002 root port4 172.31.1.1/24 0
FG5H1E5818900003 root port3 172.31.0.2/24 1
```

To verify the available subnets:

```
# diagnose sys ipam dump-ipams-free-subnets
IPAM free subnets: (subnet/mask)
172.31.3.0/24
172.31.4.0/22
172.31.8.0/21
172.31.16.0/20
172.31.32.0/19
172.31.64.0/18
172.31.128.0/17
```

To remove a device from IPAM in the Security Fabric:

```
# diagnose sys ipam delete-device-from-ipams F140EP4Q17000000
Successfully removed device F140EP4Q17000000 from ipam
```

Interface MTU packet size

Changing the maximum transmission unit (MTU) on FortiGate interfaces changes the size of transmitted packets. Most FortiGate device's physical interfaces support jumbo frames that are up to 9216 bytes, but some only support 9000 or 9204 bytes.

To avoid fragmentation, the MTU should be the same as the smallest MTU in all of the networks between the FortiGate and the destination. If the packets sent by the FortiGate are larger than the smallest MTU, then they are fragmented, slowing down the transmission. Packets with the DF flag set in the IPv4 header are dropped and not fragmented.

On many network and endpoint devices, the path MTU is used to determine the smallest MTU and to transmit packets within that size.

- ASIC accelerated FortiGate interfaces, such as NP6, NP7, and SOC4 (np6xlite), support MTU sizes up to 9216 bytes.
- FortiGate VMs can have varying maximum MTU sizes, depending on the underlying interface and driver.
- Virtual interfaces, such as VLAN interfaces, inherit their MTU size from their parent interface.

To verify the supported MTU size:

```
config system interface
  edit <interface>
    set mtu-override enable
    set mtu ?
      <integer>      Maximum transmission unit (<min>--<max>)
  next
end
```

To change the MTU size:

```
config system interface
  edit <interface>
    set mtu-override enable
    set mtu <max bytes>
  next
end
```

Maximum MTU size on a path

To manually test the maximum MTU size on a path, you can use the ping command on a Windows computer.

For example, you can send ICMP packets of a specific size with a DF flag, and iterate through increasing sizes until the ping fails.

- The `-f` option specifies the Do not Fragment (DF) flag.
- The `-l` option specifies the length, in bytes, of the Data field in the echo Request messages. This does not include the 8 bytes for the ICMP header and 20 bytes for the IP header. Therefore, if the maximum MTU is 1500 bytes, then the maximum supported data size is: $1500 - 8 - 20 = 1472$ bytes.

To determine the maximum MTU size on a path:

1. In Windows command prompt, try a likely MTU size:

```
>ping 4.2.2.1 -l 1472 -f
Pinging 4.2.2.1 with 1472 bytes of data:
Reply from 4.2.2.1: bytes=1472 time=41ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=42ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=103ms TTL=52
Reply from 4.2.2.1: bytes=1472 time=38ms TTL=52

Ping statistics for 4.2.2.1:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 38ms, Maximum = 103ms, Average = 56ms
```

2. Increase the size and try the ping again:

```
>ping 4.2.2.1 -l 1473 -f
Pinging 4.2.2.1 with 1473 bytes of data:
Request timed out.

Ping statistics for 4.2.2.1:
    Packets: Sent = 1, Received = 0, Lost = 1 (100% loss),
```

The second test fails, so the maximum MTU size on the path is 1472 bytes + 8-byte ICMP header + 20-byte IP header = 1500 bytes

Maximum segment size

The TCP maximum segment size (MSS) is the maximum amount of data that can be sent in a TCP segment. The MSS is the MTU size of the interface minus the 20 byte IP header and 20 byte TCP header. By reducing the TCP MSS, you can effectively reduce the MTU size of the packet.

The TCP MSS can be configured in a firewall policy, or directly on an interface.

To configure the MSS in a policy:

```
config firewall policy
  edit <policy ID>
    set srcintf "internal"
    set dstintf "wan1"
    set srcaddr "10.10.10.6"
    set dstaddr "all"
    set schedule "always"
    set service "ALL"
    set tcp-mss-sender 1448
    set tcp-mss-receiver 1448
  next
end
```

To configure the MSS on an interface:

```
config system interface
  edit "wan2"
    set vdom "root"
```

```

    set mode dhcp
    set allowaccess ping fgfm
    set type physical
    set tcp-mss 1448
    set role wan
  next
end

```

One-arm sniffer

You can use a one-arm sniffer to configure a physical interface as a one-arm intrusion detection system (IDS). Traffic sent to the interface is examined for matches to the configured security profile. The matches are logged, and then all received traffic is dropped. Sniffing only reports on attacks; it does not deny or influence traffic.

You can also use the one-arm sniffer to configure the FortiGate to operate as an IDS appliance to sniff network traffic for attacks without actually processing the packets. To configure a one-arm IDS, enable sniffer mode on a physical interface and connect the interface to the SPAN port of a switch or a dedicated network tab that can replicate the traffic to the FortiGate.

If the one-arm sniffer option is not available, this means the interface is in use. Ensure that the interface is not selected in any firewall policies, routes, virtual IPs, or other features where a physical interface is specified. The option also does not appear if the role is set to WAN. Ensure the role is set to LAN, DMZ, or undefined.

The following table lists some of the one-arm sniffer settings you can configure:

Field	Description
Filters	<p>Enable this setting to include filters that define a more granular sniff of network traffic. Select specific hosts, ports, VLANs, and protocols.</p> <p>In all cases, enter a number or range for the filter type. The standard protocols are:</p> <ul style="list-style-type: none"> • UDP: 17 • TCP: 6 • ICMP: 1
Include IPv6 Packets	If the network is running IPv4 and IPv6 addresses, enable this setting to sniff both types; otherwise, the FortiGate will only sniff IPv4 traffic.
Include Non-IPv6 Packets	Enable this setting for a more intense content scan of the traffic.
Security Profiles	<p>The following profiles are configurable in the GUI and CLI:</p> <ul style="list-style-type: none"> • Antivirus • Web filter • Application control • IPS • File filter <p>The following profiles are only configurable in the CLI:</p> <ul style="list-style-type: none"> • Email filter • DLP • IPS DoS

Each security profile has a predefined profile for *One-Arm Sniffer* called *sniffer-profile*. The *sniffer-profile* can be viewed or edited from the GUI through the *Edit Interface* page only. Please refer to the [Sample configuration on page 221](#) for a demonstration.

CPU usage and packet loss

Traffic scanned on the one-arm sniffer interface is processed by the CPU, even if there is an SPU, such as NPU or CP, present. The one-arm sniffer may cause higher CPU usage and perform at a lower level than traditional inline scanning, which uses NTurbo or CP to accelerate traffic when present.

The absence of high CPU usage does not indicate the absence of packet loss. Packet loss may occur due to the capacity of the TAP devices hitting maximum traffic volume during mirroring, or on the FortiGate when the kernel buffer size is exceeded and it is unable to handle bursts of traffic.

Sample configuration

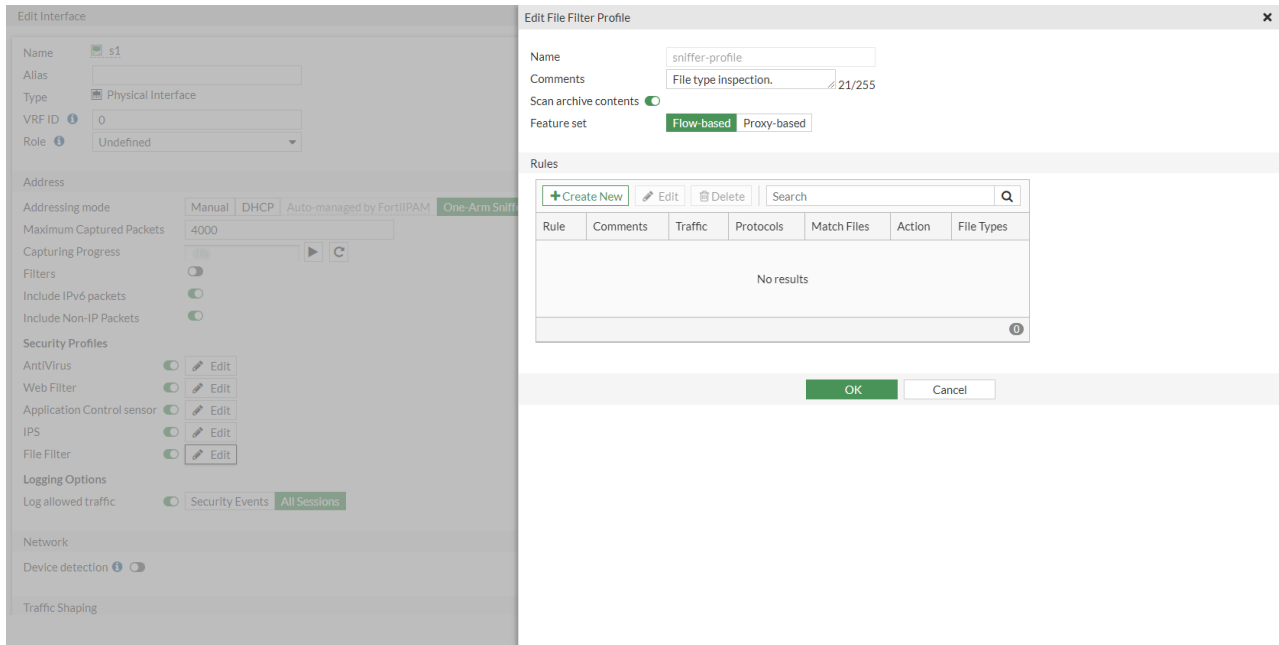

The following example shows how to configure a file filter profile that blocks PDF and RAR files used in a one-arm sniffer policy.

To configure a one-arm sniffer policy in the GUI:

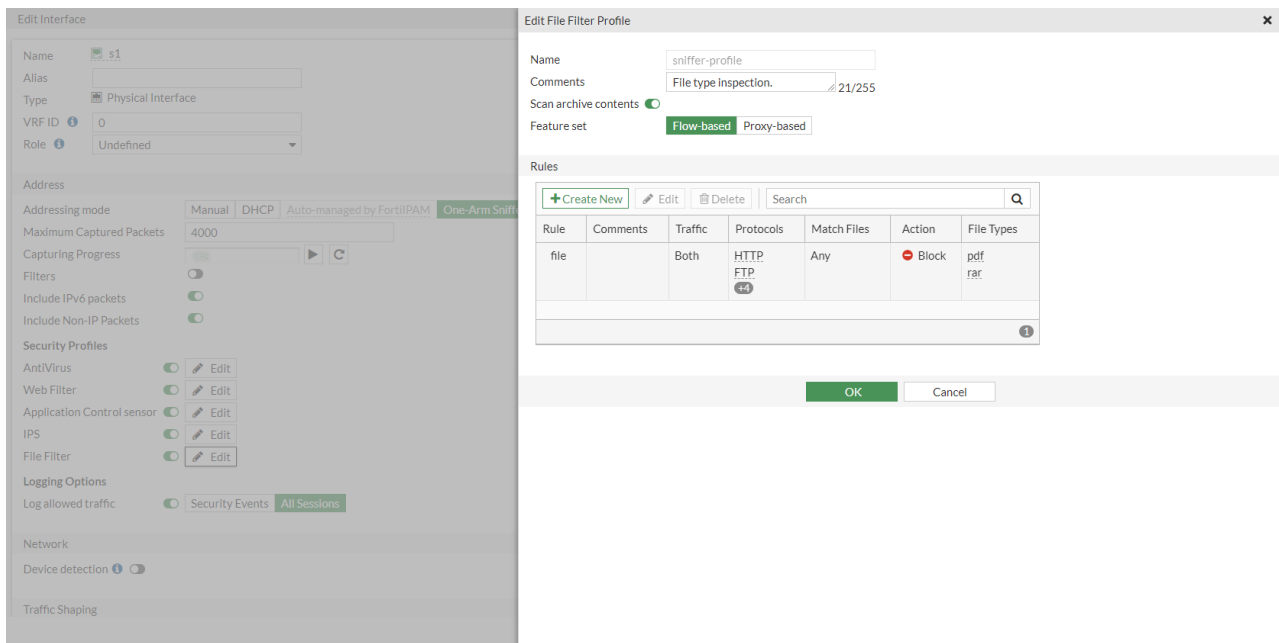

1. Go to *Network > Interfaces* and double-click a physical interface to edit it.
2. For *Role*, select either *LAN*, *DMZ*, or *Undefined*.
3. For *Addressing Mode*, select *One-Arm Sniffer*.

The screenshot shows the 'Edit Interface' configuration page for interface 's1'. The 'Addressing mode' is set to 'One-Arm Sniffer'. Under 'Security Profiles', 'File Filter' is enabled and has an 'Edit' button next to it. The 'Logging Options' section shows 'Log allowed traffic' with 'Security Events' and 'All Sessions' selected. The right sidebar shows the device name 'FortiGate-301E' and status 'Up'.

4. In the *Security Profiles* section, enable *File Filter* and click *Edit*. The *Edit File Filter Profile* pane opens.
5. In the *Rules* table, click *Create New*.

6. Configure the rule:
 - a. For *File types*, click the + and select *pdf* and *rar*.
 - b. For *Action*, select *Block*.
 - c. Click *OK* to save the rule.
7. Click *OK* to save the file filter profile.

8. Click *OK* to save the interface settings.
9. Go to *Log & Report > File Filter* to view the logs.

Date/Time	Service	Action	URL	File Name	Matched file name	File Type	Matched file type	Filter Name
9 minutes ago	FTP	passthrough		hello2.pdf		pdf		file
10 minutes ago	FTP	passthrough		test.rar		rar		file

To configure a one-arm sniffer policy in the CLI:

1. Configure the interface:

```
config system interface
  edit "s1"
    set vdom "root"
    set ips-sniffer-mode enable
    set type physical
    set role undefined
    set snmp-index 31
  next
end
```

2. Configure the file filter profile:

```
config file-filter profile
  edit "sniffer-profile"
    set comment "File type inspection."
    config rules
      edit "1"
        set protocol http ftp smtp imap pop3 cifs
        set action block
        set file-type "pdf" "rar"
      next
    end
  next
end
```

3. Configure the firewall sniffer policy:

```
config firewall sniffer
  edit 1
    set interface "s1"
    set file-filter-profile-status enable
    set file-filter-profile "sniffer-profile"
  next
end
```

4. View the log:

```
# execute log filter category 19
# execute log display
1 logs found.
1 logs returned.

1: date=2020-12-29 time=09:14:46 eventtime=1609262086871379250 tz="-0800"

```

Interface migration wizard

The *Integrate Interface* option on the *Network > Interfaces* page helps migrate a physical port into another interface or interface type such as aggregate, software switch, redundant, zone, or SD-WAN zone. The FortiGate will migrate object references either by replacing the existing instance with the new interface, or deleting the existing instance based on the user's choice. Users can also change the VLAN ID of existing VLAN sub-interface or FortiSwitch VLANs.

The interface migration wizard does not support turning an aggregate, software switch, redundant, zone, or SD-WAN zone interface back into a physical interface.

Integrating an interface

In this example, a DHCP server interface is integrated into a newly created redundant interface, which transfers the DHCP server to a redundant interface.

To integrate an interface:

1. Go to *Network > Interfaces* and select an interface in the list.
2. Click *Integrate Interface*. The wizard opens.

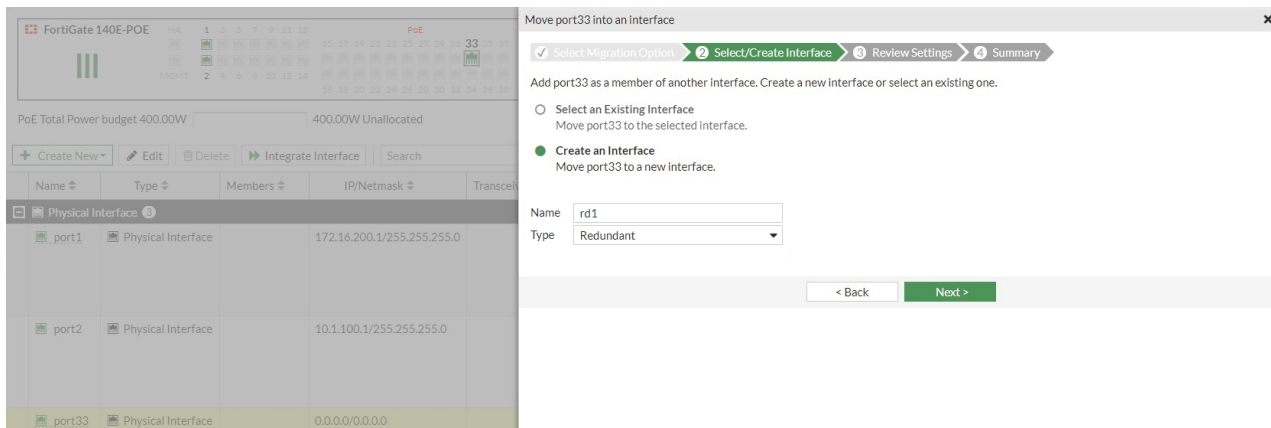

Alternatively, select an interface in the list. Then right-click and select *Integrate Interface*.

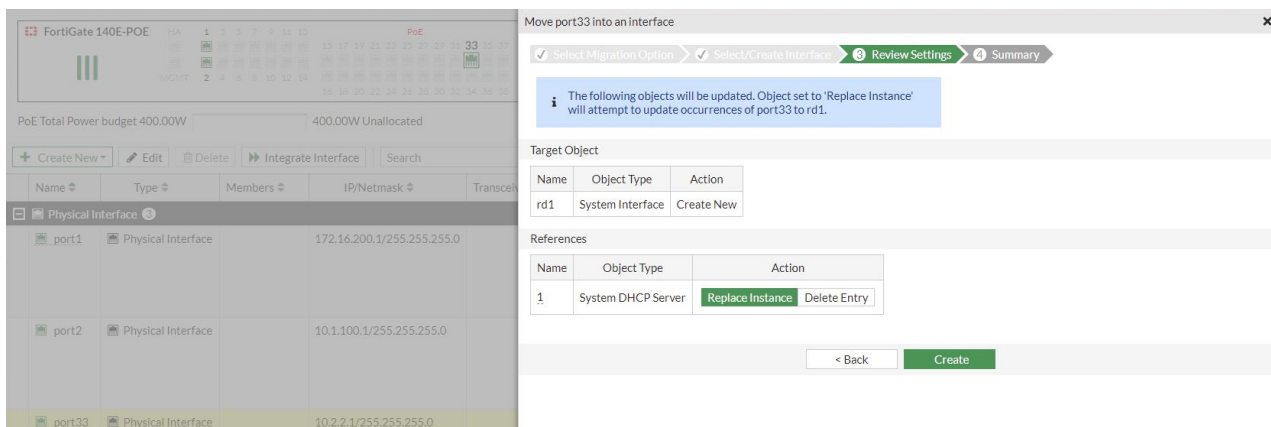

3. Select *Migrate to Interface* and click *Next*.

Name	Type	Members	IP/Netmask	Transceiver
port1	Physical Interface		172.16.200.1/255.255.255.0	
port2	Physical Interface		10.1.100.1/255.255.255.0	
port33	Physical Interface		0.0.0.0/0.0.0.0	

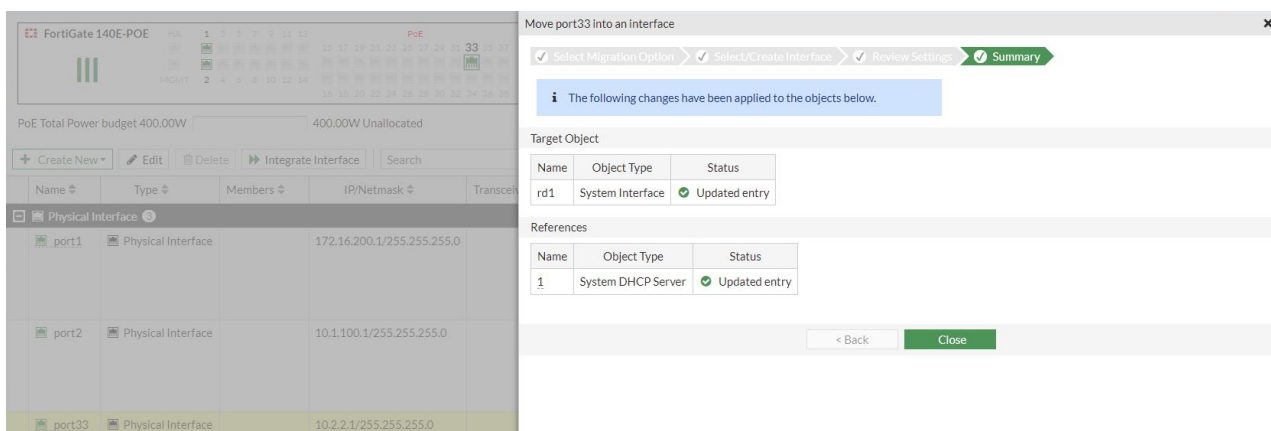

4. Select *Create an Interface*. Enter a name (*rd1*) and set the *Type* to *Redundant*.

5. Click *Next*. The *References* section lists the associated services with options to *Replace Instance* or *Delete Entry*.
6. For the DHCP server *Action*, select *Replace Instance* and click *Create*.

7. The migration occurs automatically and the statuses for the object and reference change to *Updated entry*. Click *Close*.

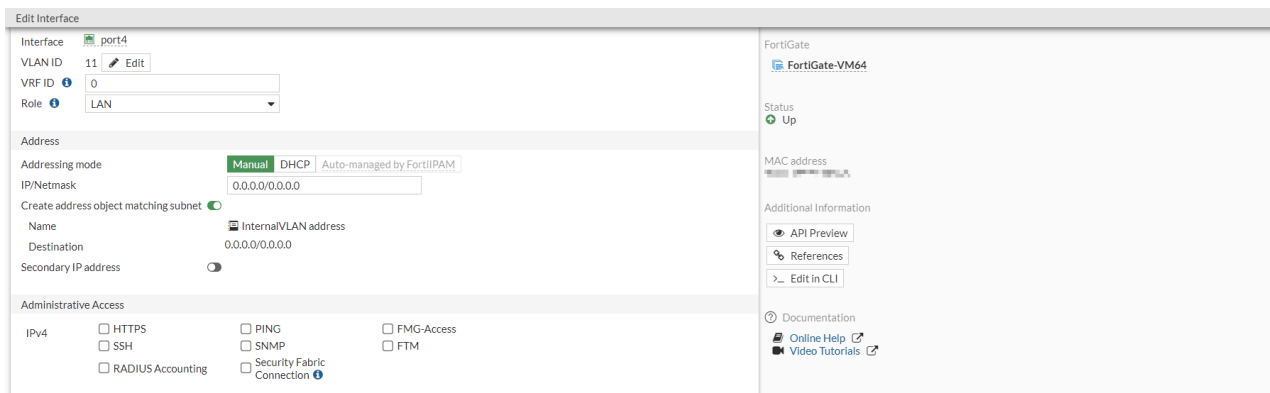

Changing the VLAN ID

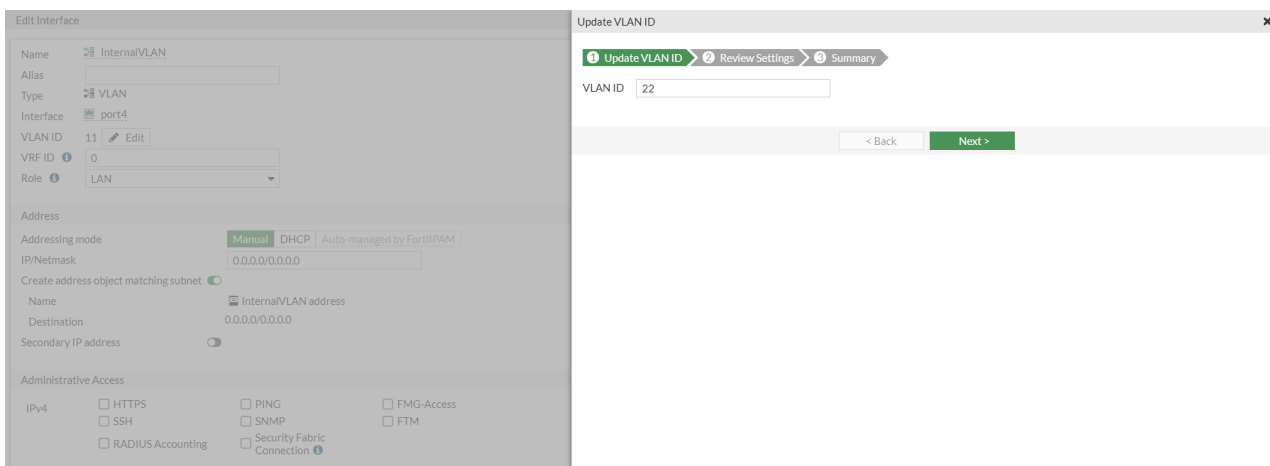

In this example, the VLAN ID of *Internal/VLAN* is changed from 11 to 22.

To change the VLAN ID:

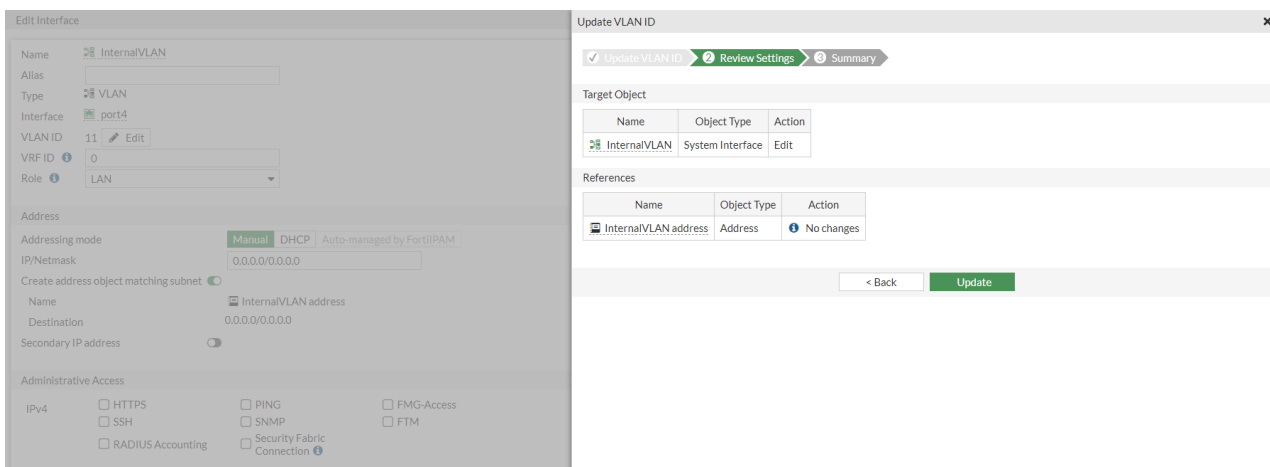

1. Go to *Network > Interfaces* and edit an existing interface.
2. Beside the *VLAN ID* field, click *Edit*. The *Update VLAN ID* window opens.

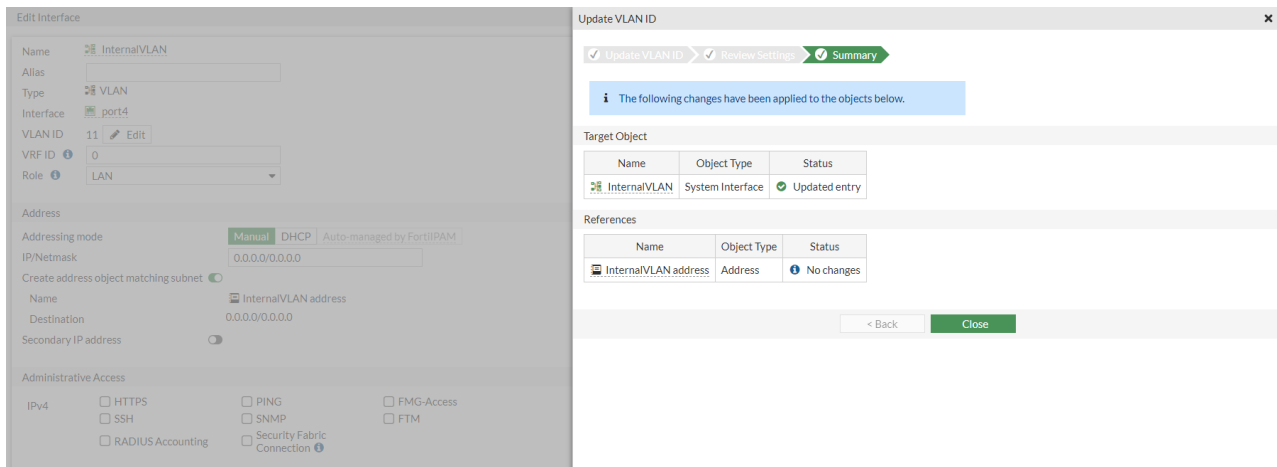

3. Enter the new ID (22) and click *Next*.

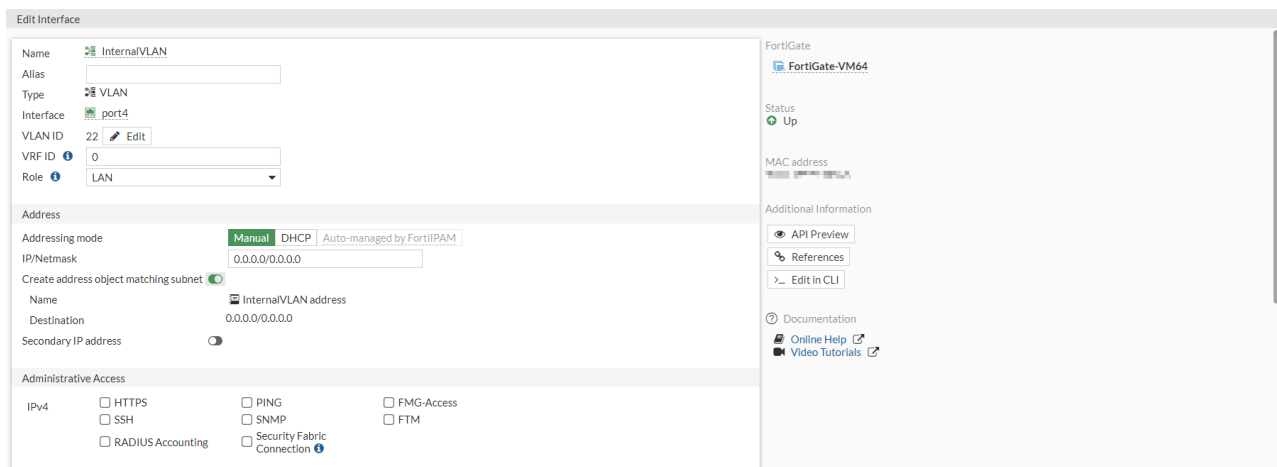

4. Verify the changes, then click *Update* and *OK*.

5. The target object status changes to *Updated entry*. Click *Close*.

In the interface settings, the ID displays as 22.

Captive portals

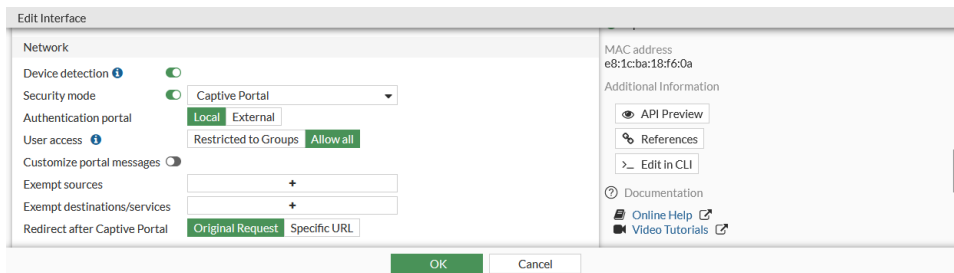

A captive portal is used to enforce authentication before web resources can be accessed. Until a user authenticates successfully, any HTTP request returns the authentication page. After successfully authenticating, a user can access the requested URL and other web resources, as permitted by policies. The captive portal can also be configured to only allow access to members of specific user groups.

Captive portals can be hosted on the FortiGate or an external authentication server. They can be configured on any network interface, including VLAN and WiFi interfaces. On a WiFi interface, the access point appears open, and the client can connect to access point with no security credentials, but then sees the captive portal authentication page. See [Captive Portal Security](#), in the [FortiWiFi and FortiAP Configuration Guide](#) for more information.

All users on the interface are required to authenticate. Exemption lists can be created for devices that are unable to authenticate, such as a printer that requires access to the internet for firmware upgrades.

To configure a captive portal in the GUI:

1. Go to *Network > Interfaces* and edit the interface that the users connect to. The interface *Role* must be *LAN* or *Undefined*.
2. Enable *Security mode*.

3. Configure the following settings, then click **OK**.

Authentication Portal	Configure the location of the portal: <ul style="list-style-type: none"> • <i>Local</i>: the portal is hosted on the FortiGate unit. • <i>External</i>: enter the FQDN or IP address of external portal.
User access	Select if the portal applies to all users, or selected user groups: <ul style="list-style-type: none"> • <i>Restricted to Groups</i>: restrict access to the selected user groups. The <i>Login page</i> is shown when a user tried to log in to the captive portal. • <i>Allow all</i>: all users can log in, but access will be defined by relevant policies. The <i>Disclaimer page</i> is shown when a user tried to log in to the captive portal.
Customize portal messages	Enable to use custom portal pages, then select a replacement message group. See Captive portals on page 227 .
Exempt sources	Select sources that are exempt from the captive portal. Each exemption is added as a rule in an automatically generated exemption list.
Exempt destinations/services	Select destinations and services that are exempt from the captive portal. Each exemption is added as a rule in an automatically generated exemption list.
Redirect after Captive Portal	Configure website redirection after successful captive portal authentication: <ul style="list-style-type: none"> • <i>Original Request</i>: redirect to the initially browsed to URL . • <i>Specific URL</i>: redirect to the specified URL.

To configure a captive portal in the CLI:

1. If required, create a security exemption list:

```
config user security-exempt-list
  edit <list>
    config rule
      edit 1
        set srcaddr <source(s)>
        set dstaddr <source(s)>
        set service <service(s)>
      next
      edit 2
        set srcaddr <source(s)>
        set dstaddr <source(s)>
        set service <service(s)>
    
```

```

        next
    end
next
end

```

2. Configure captive portal authentication on the interface:

```

config system interface
    edit <interface>
        set security-mode {none | captive-portal}
        set security-external-web <string>
        set replacemsg-override-group <group>
        set security-redirect-url <string>
        set security-exempt-list <list>
        set security-groups <group(s)>
    next
end

```

Custom captive portal pages

Portal pages are HTML files that can be customized to meet user requirements.

Most of the text and some of the HTML in the message can be changed. Tags are enclosed by double percent signs (%%); most of them should not be changed because they might carry information that the FortiGate unit needs. For information about customizing replacement messages, see [Modifying replacement messages on page 2266](#).

The images on the pages can be replaced. For example, your organization's logo can replace the Fortinet logo. For information about uploading and using new images in replacement messages, see [Replacement message images on page 2267](#).

The following pages are used by captive portals:

Login Page	Requests user credentials. The %%QUESTION%% tag provides the <i>Please enter the required information to continue.</i> text. This page is shown to users that are trying to log in when <i>User access</i> is set to <i>Restricted to Groups</i> .
Login Failed Page	Reports that incorrect credentials were entered, and requests correct credentials. The %%FAILED_MESSAGE%% tag provides the <i>Firewall authentication failed. Please try again.</i> text.
Disclaimer Page	A statement of the legal responsibilities of the user and the host organization that the user must agree to before proceeding. This page is shown users that are trying to log in when <i>User access</i> is set to <i>Allow all</i> .
Declined Disclaimer Page	Shown if the user does not agree to the statement on the Disclaimer page. Access is denied until the user agrees to the disclaimer.

DNS

Domain name system (DNS) is used by devices to locate websites by mapping a domain name to a website's IP address.

A FortiGate can serve different roles based on user requirements:

- A FortiGate can control what DNS server a network uses.
- A FortiGate can function as a DNS server.

FortiGuard Dynamic DNS (DDNS) allows a remote administrator to access a FortiGate's Internet-facing interface using a domain name that remains constant even when its IP address changes.

FortiOS supports DNS configuration for both IPv4 and IPv6 addressing. When a user requests a website, the FortiGate looks to the configured DNS servers to provide the IP address of the website in order to know which server to contact to complete the transaction.

The FortiGate queries the DNS servers whenever it needs to resolve a domain name into an IP address, such as for NTP or web servers defined by their domain names.

The following topics provide information about DNS:

- [Important DNS CLI commands on page 230](#)
- [DNS domain list on page 232](#)
- [FortiGate DNS server on page 233](#)
- [DDNS on page 239](#)
- [DNS latency information on page 243](#)
- [DNS over TLS and HTTPS on page 245](#)
- [DNS troubleshooting on page 249](#)

Important DNS CLI commands

DNS settings can be configured with the following CLI command:

```
config system dns
  set primary <ip_address>
  set secondary <ip_address>
  set protocol {cleartext dot doh}
  set ssl-certificate <string>
  set server-hostname <hostname>
  set domain <domains>
  set ip6-primary <ip6_address>
  set ip6-secondary <ip6_address>
  set timeout <integer>
  set retry <integer>
  set dns-cache-limit <integer>
  set dns-cache-ttl <integer>
  set cache-notfound-responses {enable | disable}
  set interface-select-method {auto | sdwan | specify}
  set interface <interface>
  set source-ip <class_ip>
  set server-select-method {least-rtt | failover}
```

```
set alt-primary <ip_address>
set alt-secondary <ip_address>
set log {disable |error | all}
set fqdn-cache-ttl <integer>
set fqdn-min-refresh <integer>
end
```

For a FortiGate with multiple logical CPUs, you can set the DNS process number from 1 to the number of logical CPUs. The default DNS process number is 1.

```
config system global
    set dnsproxy-worker-count <integer>
end
```

DNS protocols

The following DNS protocols can be enabled:

- `cleartext`: Enable clear text DNS over port 53 (default).
- `dot`: Enable DNS over TLS.
- `doh`: Enable DNS over HTTPS.

For more information, see [DNS over TLS and HTTPS on page 245](#).

cache-notfound-responses

When enabled, any DNS requests that are returned with `NOT FOUND` can be stored in the cache. The DNS server is not asked to resolve the host name for `NOT FOUND` entries. By default, this option is disabled.

dns-cache-limit

Set the number of DNS entries that are stored in the cache (0 to 4294967295, default = 5000). Entries that remain in the cache provide a quicker response to requests than going out to the Internet to get the same information.

dns-cache-ttl

The duration that the DNS cache retains information, in seconds (60 to 86400 (1 day), default = 1800).

VDOM DNS

When the FortiGate is in multi-vdom mode, DNS is handled by the management VDOM. However in some cases, administrators may want to configure custom DNS settings on a non-management VDOM. For example, in a multi-tenant scenario, each VDOM might be occupied by a different tenant, and each tenant might require its own DNS server.

To configure a custom VDOM within a non-management VDOM:

```
config vdom
edit <vdom>
config system vdom-dns
```

```

set vdom-dns enable
set primary <primary DNS>
set secondary <secondary_DNS>
set protocol {cleartext dot doh}
set ip6-primary <primary_IPv6_DNS>
set ip6-secondary <secondary_IPv6_DNS>
set source-ip <IP_address>
set interface-select-method {auto | sdwan | specify}
end

```

DNS domain list

You can configure up to eight domains in the DNS settings using the GUI or the CLI.

When a FortiGate requests a URL that does not include an FQDN, FortiOS resolves the URL by traversing through the DNS domain list and performing a query for each domain until the first match is found.

By default, FortiGates use FortiGuard's DNS servers:

- Primary: 96.45.45.45
- Secondary: 96.45.46.46

You can also customize the DNS timeout time and the number of retry attempts.

To configure a DNS domain list in the GUI:

1. Go to *Network > DNS*.
2. Set *DNS Servers* to *Specify*.
3. Configure the primary and secondary DNS servers as needed.
4. In the *Local Domain Name* field, enter the first domain (*sample.com* in this example).
5. Click the **+** to add more domains (*example.com* and *domainname.com* in this example). You can enter up to eight domains.
6. Configure additional DNS protocol and IPv6 settings as needed.

DNS Settings

DNS servers: Use FortiGuard Servers **Specify**

Primary DNS server: 96.45.45.45 **10 ms**

Secondary DNS server: 96.45.46.46 **10 ms**

Local domain name: sample.com, example.com, domainname.com

DNS Protocols: DNS (UDP/53) , TLS (TCP/853) , HTTPS (TCP/443)

IPv6 DNS Settings: Primary DNS server: ::, Secondary DNS server: ::

DNS Filter Rating Servers: 173.243.140.53 **10 ms**

Additional Information: API Preview, Edit in CLI, Local Out Setting

Setup guides: DNS Local Domain List, Using FortiGate as a DNS Server, FortiGuard DDNS

Documentation: Online Help, Video Tutorials

Apply

7. Click *Apply*.

To configure a DNS domain list in the CLI:

```
config system dns
  set primary 96.45.45.45
  set secondary 96.45.46.46
  set domain "sample.com" "example.com" "domainname.com"
end
```

Verify the DNS configuration

In the following example, the local DNS server has the entry for *host1* mapped to the FQDN of *host1.sample.com*, and the entry for *host2* is mapped to the FQDN of *host2.example.com*.

To verify that the DNS domain list is configured:

1. Open the FortiGate CLI.

2. Enter `execute ping host1`.

The system returns the following response:

```
PING host1.sample.com (1.1.1.1): 56 data bytes
```

As the request does not include an FQDN, FortiOS traverses the configured DNS domain list to find a match.

Because *host1* is mapped to the *host1.sample.com*, FortiOS resolves *host1* to *sample.com*, the first entry in the domain list.

3. Enter `execute ping host2`.

The system returns the following response:

```
PING host2.example.com (2.2.2.2): 56 data bytes
```

FortiOS traverses the domain list to find a match. It first queries *sample.com*, the first entry in the domain list, but does not find a match. It then queries the second entry in the domain list, *example.com*. Because *host2* is mapped to the FQDN of *host2.example.com*, FortiOS resolves *host2* to *example.com*.

DNS timeout and retry settings

The DNS timeout and retry settings can be customized using the CLI.

```
config system dns
  set timeout <integer>
  set retry <integer>
end
```

<code>timeout <integer></code>	The DNS query timeout interval, in seconds (1 - 10, default = 5).
<code>retry <integer></code>	The number of times to retry the DNS query (0 - 5, default - 2).

FortiGate DNS server

You can create local DNS servers for your network. Depending on your requirements, you can either manually maintain your entries (primary DNS server), or use it to refer to an outside source (secondary DNS server).

A local, primary DNS server requires that you to manually add all URL and IP address combinations. Using a primary DNS server for local services can minimize inbound and outbound traffic, and access time. Making it authoritative is not recommended, because IP addresses can change, and maintaining the list can become labor intensive.

A secondary DNS server refers to an alternate source to obtain URL and IP address combinations. This is useful when there is a primary DNS server where the entry list is maintained.

FortiGate as a DNS server also supports TLS and HTTPS connections to a DNS client. See [DNS over TLS and HTTPS on page 245](#) for details.

See [Basic DNS server configuration example on page 237](#) for a sample configuration.

By default, DNS server options are not available in the FortiGate GUI.

To enable DNS server options in the GUI:

1. Go to *System > Feature Visibility*.
2. Enable *DNS Database* in the *Additional Features* section.
3. Click *Apply*.

To configure the FortiGate as a DNS server in the GUI:

1. Go to *Network > DNS Servers*.
2. Enable DNS services on an interface:
 - a. In the *DNS Service on Interface* table, click *Create New*.
 - b. Configure the following:

Interface	Select the interface to enable DNS service on.
Mode	Set the DNS server mode: <ul style="list-style-type: none"> • <i>Recursive</i>: The system first checks for the requested record in the shadow DNS database. If the record is not found locally, the query is then forwarded to the system's DNS server for further lookup. This mode ensures a comprehensive search for the requested record, utilizing both local and system DNS resources. • <i>Non-Recursive</i>: Search is restricted to the Public DNS database only. If the requested record is not found, the query will not be forwarded to the system's DNS server. This mode is useful when you need to limit queries strictly to local resources. • <i>Forward to System DNS</i>: The local DNS database is bypassed and all queries are forwarded directly to the system's DNS server. This is beneficial when you need to rely solely on system-level DNS resources for resolving queries.
DNS Filter	Apply a DNS filter profile to DNS server. This option is not available when <i>Mode</i> is <i>Non-Recursive</i> . See Applying DNS filter to FortiGate DNS server on page 1282 for more information.
DNS over HTTPS	Enable DNS over HTTPS (DoH). DoH is a method of performing DNS resolution over a secure HTTPS connection. See DNS over TLS and HTTPS on page 245 for more information

- c. Click *OK*.
3. Build the DNS database:
 - a. In the *DNS Database* table, click *Create New*.
 - b. Configure the following:

Type	Select the zone type: <ul style="list-style-type: none"> • <i>Primary</i>: The primary DNS zone, to manage entries directly. • <i>Secondary</i>: The secondary DNS zone, to import entries from other DNS zones. The purpose of a secondary DNS zone is to provide redundancy and load balancing. If the primary DNS server fails, the secondary DNS server can continue to resolve queries for the domain.
View	Select the zone view: <ul style="list-style-type: none"> • <i>Shadow</i>: This type of DNS zone is designed for both internal and external clients, allowing them to resolve DNS queries with the recursive DNS server on FortiGate. It creates a shadow of your public DNS records within your private network. • <i>Public</i>: This type of DNS zone is intended to serve external clients only, allowing them to resolve DNS queries with the non-recursive DNS server on FortiGate. It contains records that map the domain names of your publicly accessible services to their respective IP addresses. These records are propagated across the internet, allowing anyone in the world to find and connect to your services.
DNS Zone	The name of the DNS zone.
Domain Name	The domain name.
Hostname of Primary DNS	The domain name of the default DNS server for this zone. This option is only available when <i>Type</i> is <i>Primary</i> .
IP of Primary	The IP address of the primary DNS server. This option is only available when <i>Type</i> is <i>Secondary</i> .
Contact Email Address	The email address of the administrator for this zone. You can specify only the username, such as admin, or the full email address, such as admin@test.com. When using only a username, the domain of the email is the zone. This option is only available when <i>Type</i> is <i>Primary</i> .
TTL	The default time-to-live value for the entries of this DNS zone. This option is only available when <i>Type</i> is <i>Primary</i> .
Authoritative	Enabling <i>Authoritative</i> makes this server is the primary and sole source of information for this specific DNS zone. It prevents the FortiGate from seeking DNS records further upstream. Enabling authoritative is not recommended.
DNS Forwarder	

c. Add DNS entries:

- i. In the *DNS Entries* table, click *Create New*.
- ii. Configure the following:

Type	The resource record type. The availability of the subsequent settings vary depending on the selected type. <ul style="list-style-type: none"> • <i>Address (A)</i>: This is the host type. It maps a hostname to an IPv4 address in the DNS system, allowing a browser or other client to
------	--

access a server using its domain name.

- *Name Server (NS)*: This is the name server type. It indicates which DNS server is authoritative for that domain
- *Canonical Name (CNAME)*: This is the canonical name type. It's used to alias one name to another.
- *Mail Exchange (MX)*: This is the mail exchange type. It routes email to a specified mail server based on the information in the record.
- *IPv6 Address (AAAA)*: This is the IPv6 host type. Similar to the A record, but it maps a hostname to an IPv6 address.
- *IPv4 Pointer (PTR)*: This is the pointer type for IPv4. It provides a mapping of the IP address to a hostname, essentially the reverse of what an A record does.
- *IPv6 Pointer (PTR)*: This is the pointer type for IPv6. It functions similarly to the IPv4 PTR record, but for IPv6 addresses.

TTL

The time-to-live for this entry.

- iii. Click **OK**.
- d. Click **OK**.

To configure the FortiGate as a DNS server in the CLI:

1. Configure DNS servers:

```
config system dns-server
  edit <name>
    set dnsfilter-profile {string}
    set doh {enable | disable}
    set mode {recursive | non-recursive | forward-only}
  next
end
```

See [config system dns-server](#) in the CLI reference for a comprehensive list of commands.

2. Configure DNS database:

```
config system dns-database
  edit <name>
    set authoritative {enable | disable}
    set contact {string}
    set domain {string}
    set forwarder {user}
    set primary-name {string}
    set ttl {integer}
    set type {primary | secondary}
    set view {shadow | public }
  config dns-entry
    edit <id>
      set status {enable | disable}
      set type {A | NS | CNAME | MX | AAAA | PTR | PTR_V6}
      set ttl {integer}
      set ip {ipv4-address-any}
      set ipv6 {ipv6-address}
      set hostname {string}
      set canonical-name {string}
    next
  next
end
```

```

        next
    end
    next
end

```

See [config system dns-database](#) in the CLI reference for a comprehensive list of commands.

Basic DNS server configuration example

This section describes how to create an unauthoritative primary DNS server. The interface mode is recursive so that, if the request cannot be fulfilled, the external DNS servers will be queried.

In this example, the Local site is configured as an unauthoritative primary DNS server.

To configure FortiGate as a primary DNS server in the GUI:

1. Go to *Network > DNS Servers*.
2. In the *DNS Database* table, click *Create New*.
3. Set *Type* to *Primary*.
4. Set *View* to *Shadow*.

The *View* setting controls the accessibility of the DNS server. If you select *Public*, external users can access or use the DNS server. If you select *Shadow*, only internal users can use it.

5. Enter a *DNS Zone*, for example, *WebServer*.
6. Enter the *Domain Name* of the zone, for example, *example.com*.
7. Enter the *Hostname* of the DNS server, for example, *corporate*.
8. Enter the *Contact Email Address* for the administrator, for example, *admin@example.com*.
9. Disable *Authoritative*.

New DNS Zone

Type	<input checked="" type="radio"/> Primary <input type="radio"/> Secondary
View	<input checked="" type="radio"/> Shadow <input type="radio"/> Public
DNS Zone	<input type="text" value="WebServer"/>
Domain Name	<input type="text" value="example.com"/>
Hostname of Primary DNS	<input type="text" value="corporate"/>
Contact Email Address ⓘ	<input type="text" value="admin@example.com"/>
TTL (86400 seconds)	<input type="text" value="1"/> Day(s) <input type="text" value="0"/> Hour(s) <input type="text" value="0"/> Minute(s) <input type="text" value="0"/> Second(s)
Authoritative	<input checked="" type="checkbox"/>
DNS Forwarder	<input type="text" value=""/>

DNS Entries

+ Create New	Edit	Delete		Type	Details	Status
No results						

10. Add DNS entries:

- a. In the *DNS Entries* table, click *Create New*.
- b. Select a *Type*, for example *Address (A)*.
- c. Set the *Hostname*, for example *web*.

- d. Configure the remaining settings as needed. The options might vary depending on the selected *Type*.
- e. Click *OK*.

11. Add more DNS entries as needed.

12. Click *OK*.

13. Enable DNS services on an interface:

- a. Go to *Network > DNS Servers*.
- b. In the *DNS Service on Interface* table, click *Create New*.
- c. Select the *Interface* for the DNS server, such as *port1*.
- d. Set the *Mode* to *Recursive*.

- e. Click *OK*.

To configure FortiGate as a primary DNS server in the CLI:

```
config system dns-database
  edit WebServer
    set domain example.com
    set type primary
    set view shadow
    set ttl 86400
    set primary-name corporate
    set contact admin@example.com
    set authoritative disable
    config dns-entry
      edit 1
        set status enable
        set hostname web
        set type A
        set ip 172.16.200.254
      next
    end
  next
end
```

```
config system dns-server
  edit port1
    set mode recursive
  next
end
```

To verify the configuration:

1. Send a DNS query for a DNS entry configured locally on the Local site FortiGate:

```
C:\Users\demo>nslookup office.microsoft.com
Server:      Unknown
Address:    172.16.200.1
Non-authoritative answer:
Name:      web.example.com
Address:   172.16.200.254
```

The query is resolved to the IP address configured in the shadow DNS database on the Local site FortiGate.

2. Send a DNS query for a domain that is not configured on the Local site FortiGate:

```
C:\Users\demo>nslookup facebook.com
Server:      Unknown
Address:    172.16.200.1
Non-authoritative answer:
Name:      facebook.com
Addresses: 157.240.22.35
```

The query is resolved by the central DNS server.

DDNS

If your external IP address changes regularly and you want a static domain name, you can configure the external interface to use a dynamic DNS (DDNS) service. This ensures that external users and customers can always connect to your company firewall. You can configure FortiGuard as the DDNS server using the GUI or CLI.

A license or subscription is not required to use the DDNS service, but configuring DDNS in the GUI is not supported if:

- The FortiGate model is a 1000-series or higher.
- The FortiGate is a VM.
- The DNS server is not using FortiGuard as the DNS.

FortiGate does not support DDNS when in transparent mode.

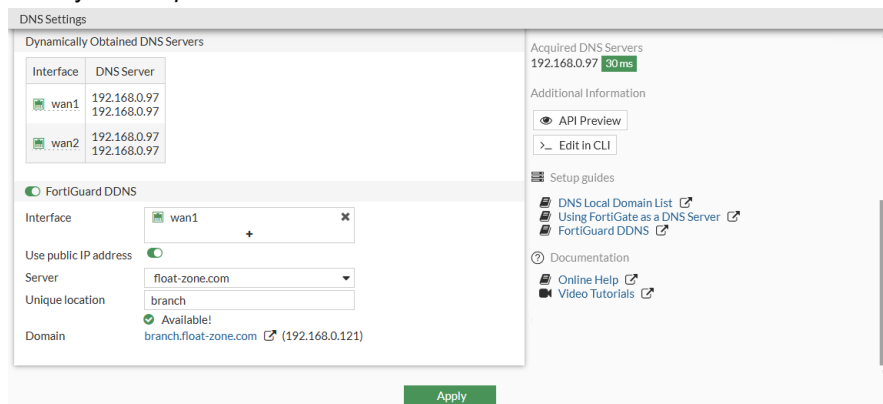

Sample topology

In this example, FortiGuard DDNS is enabled and the DDNS server is set to *float-zone.com*. Other DDNS server options include *fortiddns.com* and *fortidyndns.com*.

To configure FortiGuard DDNS service as a DDNS server in the GUI:

1. Go to *Network > DNS*
2. Enable *FortiGuard DDNS*.
3. Select the *Interface* with the dynamic connection.
4. Select the *Server* that you have an account with.
5. Enter your *Unique Location*.

6. Click *Apply*.

To configure the FortiGuard DDNS service as an IPv4 DDNS server in the CLI:

```
config system ddns
  edit 1
    set ddns-server FortiGuardDDNS
    set server-type ipv4
    set ddns-domain "branch.float-zone.com"
    set addr-type ipv4
```

```

        set use-public-ip enable
        set monitor-interface "wan1"
    next
end

```

To configure the FortiGuard DDNS service as an IPv6 DDNS server in the CLI:

```

config system ddns
    edit 1
        set ddns-server FortiGuardDDNS
        set server-type ipv6
        set ddns-domain "fgtatest001.float-zone.com"
        set addr-type ipv6
        set monitor-interface "wan1"
    next
end

```

DDNS servers other than FortiGuard

If you do not have a FortiGuard subscription, or want to use a different DDNS server, you can configure a DDNS server for each interface. Only the first configured port appears in the GUI.

The available commands vary depending on the selected DDNS server.

To configure DDNS servers other than FortiGuard in the CLI:

```

config system ddns
    edit <DDNS_ID>
        set monitor-interface <external_interface>
        set ddns-server <ddns_server_selection>
        set server-type {ipv4 | ipv6}
        set ddns-server-addr <address>
        set addr-type ipv6 {ipv4 | ipv6}
    next
end

```

To configure an IPv6 DDNS client with generic DDNS on port 3 in the CLI:

```

config system ddns
    edit 1
        set ddns-server genericDDNS
        set server-type ipv6
        set ddns-server-addr "2004:16:16:16::2" "16.16.16.2" "ddns.genericddns.com"
        set ddns-domain "test.com"
        set addr-type ipv6
        set monitor-interface "port3"
    next
end

```

Refresh DDNS IP addresses

When using a public IP that is not assigned to the FortiGate, the FortiGate cannot trigger an update when the IP address changes. The FortiGate can be configured to refresh DDNS IP addresses by periodically checking the DDNS server at

an update interval.

To configure FortiGate to refresh DDNS IP addresses in the CLI:

```
config system ddns
  edit 1
    set use-public-ip enable
    set update-interval <seconds>
  next
end
```

When `update-interval` is set to 0:

- For FortiGuard DDNS, the interval is 300 seconds.
- For third part DDNS servers, the interval is assigned by the DDNS server.

Disable cleartext

When `clear-text` is disabled, FortiGate uses the SSL connection to send and receive DDNS updates.

To disable cleartext and set the SSL certificate in the CLI:

```
config system ddns
  edit 2
    set clear-text disable
    set ssl-certificate <cert_name>
  next
end
```

DDNS update override

A DHCP server has an `override` command option that allows DHCP server communications to go through DDNS to perform updates for the DHCP client. This enforces a DDNS update of the A field every time even if the DHCP client does not request it. This allows support for the `allow`, `ignore`, and `deny` `client-updates` options.

To enable DDNS update override in the CLI:

```
config system dhcp server
  edit 1
    set ddns-update enable
    set ddns-update-override enable
    set ddns-server-ip <ddns_server_ip>
    set ddns-zone <ddns_zone>
  next
end
```

Troubleshooting

To debug DDNS:

```
# diagnose debug application ddnsd -1
# diagnose debug enable
```

To check if a DDNS server is available:

```
# diagnose test application ddnsd 3
```

Not available:

```
FortiDDNS status:
ddns_ip=0.0.0.0, ddns_ip6=::, ddns_port=443 svr_num=0 domain_num=0
```

Available:

```
FortiDDNS status:
ddns_ip=208.91.113.230, ddns_ip6=::, ddns_port=443 svr_num=1 domain_num=3
svr[0]= 208.91.113.230
domain[0]= fortiddns.com
domain[1]= fortidyndns.com
domain[2]= float-zone.com
```

DNS latency information

High latency in DNS traffic can result in an overall sluggish experience for end-users. In the *DNS Settings* pane, you can quickly identify DNS latency issues in your configuration.

Go to *Network > DNS* to view DNS latency information in the right side bar. If you use FortiGuard DNS, latency information for DNS, DNS filter, web filter, and outbreak prevention servers is also visible. Hover your pointer over a latency value to see when it was last updated.

The screenshot displays the 'DNS Settings' configuration interface. On the left, the 'DNS servers' section is active, showing 'Use FortiGuard Servers' selected and a 'Specify' button. Below this, the primary DNS server is 8.8.8.8 and the secondary is 96.45.46.46, both with a latency of 10 ms. The 'DNS Protocols' section shows DNS (UDP/53) as a toggle switch that is turned on, while TLS (TCP/853) and HTTPS (TCP/443) are turned off. The 'IPv6 DNS Settings' section shows both primary and secondary servers set to '::'. On the right side, the 'DNS Filter Rating Servers' section shows a server at 173.243.140.53 with a latency of 10 ms. Below this, there are several links for 'Additional Information' including 'API Preview', 'Edit In CLI', 'Local Out Setting', 'Setup guides', 'DNS Local Domain List', 'Using FortiGate as a DNS Server', 'FortiGuard DDNS', 'Documentation', 'Online Help', and 'Video Tutorials'. At the bottom of the configuration area, there is a green 'Apply' button.

To view DNS latency information using the CLI:

```
# diagnose test application dnsproxy 2
worker idx: 0
worker: count=1 idx=0
retry_interval=500 query_timeout=1495
DNS latency info:
vfid=0 server=2001::1 latency=1494 updated=73311
vfid=0 server=96.45.46.46 latency=1405 updated=2547
vfid=0 server=8.8.8.8 latency=19 updated=91
SDNS latency info:
vfid=0 server=173.243.140.53 latency=1 updated=707681

DNS over TLS and HTTPS

DNS over TLS (DoT) is a security protocol for encrypting and encapsulating DNS queries and responses over the TLS protocol. DoT increases user privacy and security by preventing eavesdropping and manipulation of DNS data via man-in-the-middle attacks. Similarly, DNS over HTTPS (DoH) provides a method of performing DNS resolution over a secure HTTPS connection. DoT and DoH are supported in explicit mode where the FortiGate acts as an explicit DNS server that listens for DoT and DoH requests. Local-out DNS traffic over TLS and HTTPS is also supported.

Basic configurations for enabling DoT and DoH for local-out DNS queries

Before enabling DoT or DoH, ensure that they are supported by the DNS servers. The legacy FortiGuard DNS servers (208.91.112.53 and 208.91.112.52) do not support DoT or DoH queries, and will drop these packets. At times, the latency status of the DNS servers might also appear high or unreachable.

Disabling DoT and DoH is recommended when they are not supported by the DNS servers.

To enable DoT and DoH DNS in the GUI:

1. Go to *Network > DNS*.
2. Enter the primary and secondary DNS server addresses.

- In the *DNS Protocols* section, enable *TLS (TCP/853)* and *HTTPS (TCP/443)*.

- Configure the other settings as needed.
- Click *Apply*.

To enable DoT and DoH DNS in the CLI:

```
config system dns
    set primary 1.1.1.1
    set secondary 1.0.0.1
    set protocol {cleartext dot doh}
end
```

To enable DoH on the DNS server in the GUI:

- Go to *Network > DNS Servers*.
- In the *DNS Service on Interface* section, edit an existing interface, or create a new one.
- Select a *Mode*, and *DNS Filter* profile.
- Enable *DNS over HTTPS*.

- Click *OK*.

To enable DoH on the DNS server in the CLI:

```
config system dns-server
    edit "port1"
        set dnsfilter-profile "dnsfilter"
```

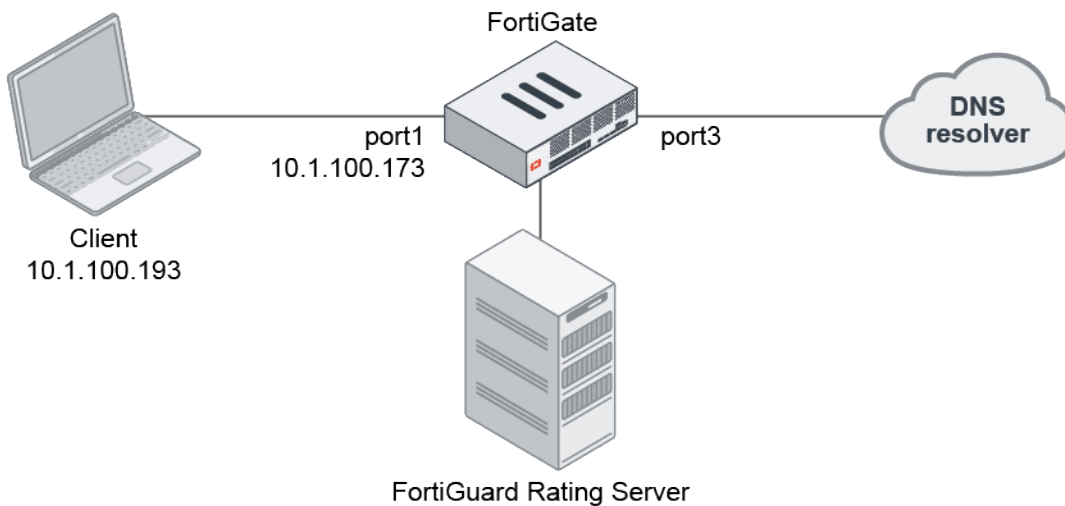

```

    set doh enable
  next
end

```

Examples

The following examples demonstrate how to configure DNS settings to support DoT and DoH queries made to the FortiGate.

DoT

The following example uses a DNS filter profile where the education category is blocked.

To enable scanning DoT traffic in explicit mode with a DNS filter:

1. Configure the DNS settings:

```

config system dns
  set primary 1.1.1.1
  set secondary 1.0.0.1
  set protocol dot
end

```

2. Configure the DNS filter profile:

```

config dnsfilter profile
  edit "dnsfilter"
    config ftgd-dns
      config filters
        edit 1
          set category 30
          set action block
        next
      end
    end
  next
end

```

3. Configure the DNS server settings:

```
config system dns-server
  edit "port1"
    set dnsfilter-profile "dnsfilter"
  next
end
```

4. Send a DNS query over TLS (this example uses kdig on an Ubuntu client) using the FortiGate as the DNS server. The www.ubc.ca domain belongs to the education category:

```
root@client:/tmp# kdig -d @10.1.100.173 +tls +header +all www.ubc.ca
;; DEBUG: Querying for owner(www.ubc.ca.), class(1), type(1), server(10.1.100.173), port
(853), protocol(TCP)
;; DEBUG: TLS, received certificate hierarchy:
;; DEBUG: #1,
C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=FortiGate,CN=FG3H1E5818903681,EMAIL=support
@fortinet.com
;; DEBUG:      SHA-256 PIN: Xhkpv9ABEhxDLtWG+lGEndNrBR7BlxjRYlGn21t1kb8=
;; DEBUG: #2, C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=Certificate
Authority,CN=fortinet-subca2001,EMAIL=support@fortinet.com
;; DEBUG:      SHA-256 PIN: 3T8EqFBjpRSkxQNPFagjUNeEUghXOEYp904ROlJM8yo=
;; DEBUG: #3, C=US,ST=California,L=Sunnyvale,O=Fortinet,OU=Certificate
Authority,CN=fortinet-ca2,EMAIL=support@fortinet.com
;; DEBUG:      SHA-256 PIN: /QfV4N3k5oxQR5RHtW/rbn/HrHgKpMLN0DEaeXY5yPg=
;; DEBUG: TLS, skipping certificate PIN check
;; DEBUG: TLS, skipping certificate verification
;; TLS session (TLS1.2)-(ECDHE-RSA-SECP256R1)-(AES-256-GCM)
;; ->>HEADER<<- opcode: QUERY; status: NOERROR; id: 56719
;; Flags: qr rd; QUERY: 1; ANSWER: 1; AUTHORITY: 0; ADDITIONAL: 0

;; QUESTION SECTION:
;; www.ubc.ca.                IN      A

;; ANSWER SECTION:
www.ubc.ca.                60      IN      A      208.91.112.55

;; Received 44 B
;; Time 2021-03-12 23:11:27 PST
;; From 10.1.100.173@853(TCP) in 0.2 ms
root@client:/tmp#
```

The IP returned by the FortiGate for ubc.ca belongs to the FortiGuard block page, so the query was blocked successfully.

DoH

The following example uses a DNS filter profile where the education category is blocked.

To configure scanning DoH traffic in explicit mode with a DNS filter:

1. Configure the DNS settings:

```
config system dns
  set primary 1.1.1.1
  set secondary 1.0.0.1
```

```

    set protocol doh
end

```

2. Configure the DNS filter profile:

```

config dnsfilter profile
  edit "dnsfilter"
    config ftgd-dns
      config filters
        edit 1
          set category 30
          set action block
        next
      end
    end
  next
end

```

3. Configure the DNS server settings:

```

config system dns-server
  edit "port1"
    set dnsfilter-profile "dnsfilter"
    set doh enable
  next
end

```

4. In your browser, enable DNS over HTTPS.

5. On your computer, edit the TCP/IP settings to use the FortiGate interface address as the DNS server.

6. In your browser, go to a website in the education category (www.ubc.ca). The website is redirected to the block page.

DNS troubleshooting

The following diagnose command can be used to collect DNS debug information. If you do not specify worker ID, the default worker ID is 0.

```

# diagnose test application dnsproxy
worker idx: 0
1. Clear DNS cache
2. Show stats
3. Dump DNS setting
4. Reload FQDN
5. Requery FQDN
6. Dump FQDN
7. Dump DNS cache
8. Dump DNS DB
9. Reload DNS DB
10. Dump secure DNS policy/profile
11. Dump Botnet domain
12. Reload Secure DNS setting

```

13. Show Hostname cache
14. Clear Hostname cache
15. Show SDNS rating cache
16. Clear SDNS rating cache
17. DNS debug bit mask
18. DNS debug obj mem
99. Restart dnsproxy worker

To view useful information about the ongoing DNS connection:

```
# diagnose test application dnsproxy 3
worker idx: 0
vdom: root, index=0, is primary, vdom dns is disabled, mip-169.254.0.1 dns_log=1 tls=0 cert=
dns64 is disabled

SERVER_LDB: gid=eb19, tz=-480, error_allow=0
FGD_REDIR_V4:208.91.112.55 FGD_REDIR_V6:
```

Important fields include:

tls	1 if the connection is TLS, 0 if the connection is not TLS.
rt	The round trip time of the DNS latency.
probe	The number of probes sent.

To dump the second DNS worker's cache:

```
diagnose test application dnsproxy 7 1
```

To enable debug on the second worker:

```
diagnose debug application dnsproxy -1 1
```

To enable debug on all workers by specifying -1 as worker ID:

```
diagnose debug application dnsproxy -1 -1
```

Explicit and transparent proxies

This section contains instructions for configuring explicit and transparent proxies.

- [Explicit web proxy on page 251](#)

Explicit web proxy

Explicit web proxy can be configured on FortiGate for proxying HTTP and HTTPS traffic.

To deploy explicit proxy, individual client browsers can be manually configured to send requests directly to the proxy, or they can be configured to download proxy configuration instructions from a Proxy Auto-Configuration (PAC) file.

When explicit proxy is configured on an interface, the interface IP address can be used by client browsers to forward requests directly to the FortiGate. FortiGate also supports PAC file configuration.

For FortiOS 7.0.1 to 7.0.12, SSL VPN web mode, explicit web proxy, and interface mode IPsec VPN features will not work with the following configuration:

1. An IP pool with ARP reply enabled is configured.
2. This IP pool is configured as the source IP address in a firewall policy for SSL VPN web mode, in a proxy policy for explicit web proxy, or as the local gateway in the Phase 1 settings for an interface mode IPsec VPN.
3. A matching blackhole route is configured for IP pool reply traffic.

Configuring an IP pool as the source NAT IP address in a regular firewall policy works as before.

For details, see [Technical Tip: IP pool and virtual IP behaviour changes in FortiOS 6.4, 7.0, 7.2, and 7.4.](#)

To configure explicit web proxy in the GUI:

1. Enable and configure explicit web proxy:
 - a. Go to *Network > Explicit Proxy*.
 - b. Enable *Explicit Web Proxy*.
 - c. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *8080*.
 - d. Configure the remaining settings as needed.

- e. Click *Apply*.
2. Create an explicit web proxy policy:
 - a. Go to *Policy & Objects > Proxy Policy*.
 - b. Click *Create New*.
 - c. Set *Proxy Type* to *Explicit Web* and *Outgoing Interface* to *port1*.
 - d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.

- e. Click **OK** to create the policy.

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. Configure a client to use the FortiGate explicit proxy:

Set the FortiGate IP address as the proxy IP address in the browser, or use an automatic configuration script for the PAC file.

To configure explicit web proxy in the CLI:

1. Enable and configure explicit web proxy:

```
config web-proxy explicit
  set status enable
  set ftp-over-http enable
  set socks enable
  set http-incoming-port 8080
  set ipv6-status enable
  set unknown-http-version best-effort
end
config system interface
  edit "port2"
    set vdom "vdom1"
    set ip 10.1.100.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet
    set type physical
    set explicit-web-proxy enable
    set snmp-index 12
  end
next
end
```

2. Create an explicit web proxy policy:

```
config firewall proxy-policy
  edit 1
    set name "proxy-policy-explicit"
    set proxy explicit-web
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set logtraffic all
  next
end
```

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. Configure a client to use the FortiGate explicit web proxy:

Set the FortiGate IP address as the proxy IP address in the browser, or use an automatic configuration script for the PAC file.

FTP proxy

FTP proxies can be configured on the FortiGate so that FTP traffic can be proxied. When the FortiGate is configured as an FTP proxy, FTP client applications should be configured to send FTP requests to the FortiGate.

To configure explicit FTP proxy in the GUI:

1. Enable and configure explicit FTP proxy:
 - a. Go to *Network > Explicit Proxy*.
 - b. Enable *Explicit FTP Proxy*.
 - c. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *21*.
 - d. Configure the *Default Firewall Policy Action* as needed.

- e. Click *Apply*.
2. Create an explicit FTP proxy policy:
 - a. Go to *Policy & Objects > Proxy Policy*.
 - b. Click *Create New*.
 - c. Set *Proxy Type* to *FTP* and *Outgoing Interface* to *port1*.

- d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, and *Action* to *ACCEPT*.

- e. Click *OK* to create the policy.

This example creates a basic policy. If required, security profiles can be enabled.

3. Configure the FTP client application to use the FortiGate IP address.

To configure explicit FTP proxy in the CLI:

1. Enable and configure explicit FTP proxy:

```
config ftp-proxy explicit
  set status enable
  set incoming-port 21
end
config system interface
  edit "port2"
    set vdom "vdom1"
    set ip 10.1.100.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet
    set type physical
    set explicit-ftp-proxy enable
    set snmp-index 12
  next
end
```

2. Create an explicit FTP proxy policy:

```
config firewall proxy-policy
  edit 4
    set name "proxy-policy-ftp"
    set proxy ftp
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
```

```
next
end
```

This example creates a basic policy. If required, security profiles can be enabled.

3. Configure the FTP client application to use the FortiGate IP address.

Transparent proxy

In a transparent proxy deployment, the user's client software, such as a browser, is unaware that it is communicating with a proxy.

Users request internet content as usual, without any special client configuration, and the proxy serves their requests. FortiGate also allows users to configure in transparent proxy mode.

To redirect HTTPS traffic, SSL inspection is required.

If the base firewall policy successfully redirects to the proxy policy then antivirus and web filter profiles configured on the firewall policy will not be applied. Security profiles should be configured on the proxy policy.

To configure transparent proxy in the GUI:

1. Configure a regular firewall policy with HTTP redirect:
 - a. Go to *Policy & Objects > Firewall Policy*.
 - b. Click *Create New*.
 - c. Name the policy appropriately, set the *Incoming Interface* to *port2*, and set the *Outgoing Interface* to *port1*.
 - d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, *Service* to *ALL*, and *Action* to *ACCEPT*.
 - e. Set *Inspection Mode* to *Proxy-based* and *SSL Inspection* to *deep-inspection*.

- f. Configure the remaining settings as needed.
- g. Click **OK**.

By default, HTTP redirect can only be enabled in the CLI. Enable *Policy Advanced Options* in *Feature Visibility* to configure it in the GUI. See [Feature visibility on page 2292](#) on page 1 for more information.

2. Configure a transparent proxy policy:
 - a. Go to *Policy & Objects > Proxy Policy*.
 - b. Click *Create New*.
 - c. Set *Proxy Type* to *Transparent Web*, set the *Incoming Interface* to *port2*, and set the *Outgoing Interface* to *port1*.
 - d. Also set *Source* and *Destination* to *all*, *Schedule* to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.

- e. Configure the remaining settings as needed.
- f. Click **OK** to create the policy.

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. No special configuration is required on the client to use FortiGate transparent proxy. As the client is using the FortiGate as its default gateway, requests will first hit the regular firewall policy, and then be redirected to the transparent proxy policy.

To configure transparent proxy in the CLI:

1. Configure a regular firewall policy with HTTP redirect:

```
config firewall policy
  edit 1
    set name "LAN To WAN"
    set srcintf "port2"
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set inspection-mode proxy
    set http-policy-redirect enable
    set fssso disable
    set ssl-ssh-profile "deep-inspection"
    set nat enable
  next
end
```

2. Configure a transparent proxy policy:

```
config firewall proxy-policy
  edit 5
    set name "proxy-policy-transparent"
    set proxy transparent-web
    set srcintf "port2"
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
  next
end
```

This example creates a basic policy. If required, security profiles can be enabled, and deep SSL inspection can be selected to inspect HTTPS traffic.

3. No special configuration is required on the client to use FortiGate transparent proxy. As the client is using the FortiGate as its default gateway, requests will first hit the regular firewall policy, and then be redirected to the transparent proxy policy.

Proxy policy addresses

Proxy addresses are designed to be used only by proxy policies. The following address types are available:

- [Host regex match on page 259](#)
- [URL pattern on page 260](#)
- [URL category on page 261](#)
- [HTTP method on page 262](#)
- [HTTP header on page 262](#)
- [User agent on page 263](#)
- [Advanced \(source\) on page 264](#)
- [Advanced \(destination\) on page 264](#)

Fast policy match

The fast policy match function improves the performance of IPv4 explicit and transparent web proxies on FortiGate devices.

When enabled, after the proxy policies are configured, the FortiGate builds a fast searching table based on the different proxy policy matching criteria. When fast policy matching is disabled, web proxy traffic is compared to the policies one at a time from the beginning of the policy list.

Fast policy matching is enabled by default, and can be configured with the following CLI command:

```
config web-proxy global
    set fast-policy-match {enable | disable}
end
```

Host regex match

In this address type, a user can create a hostname as a regular expression to match the Host field in the Layer 7 header of a packet. Once created, the hostname address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the regular expression.

This example creates a host regex match address with the pattern `qa.[a-z]*.com`.

To create a host regex match address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *Host Regex*,
 - *Type* to *Host Regex Match*, and
 - *Host Regex Pattern* to `qa.[a-z]*.com`.

The screenshot shows the 'New Address' dialog box in FortiGate. The 'Proxy Address' tab is active. The 'Name' field contains 'Host Regex', 'Type' is set to 'Host Regex Match', and the 'Host Regex Pattern' is 'qa.[a-z]*.com'. The 'Category' is 'Proxy Address'. There are 'OK' and 'Cancel' buttons at the bottom.

4. Click **OK**.

To create a host regex match address in the CLI:

```
config firewall proxy-address
  edit "Host Regex"
    set type host-regex
    set host-regex "qa.[a-z]*.com"
  next
end
```

URL pattern

In this address type, a user can create a URL path as a regular expression. Once created, the path address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the regular expression.

This example creates a URL pattern address with the pattern `/filetypes/`.

To create a URL pattern address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *URL Regex*,
 - *Type* to *URL Pattern*,
 - *Host* to *all*, and
 - *URL Path Regex* to `/filetypes/`.

The screenshot shows the 'New Address' dialog box in FortiGate. The 'Proxy Address' tab is active. The 'Name' field contains 'URL Regex', 'Type' is set to 'URL Pattern', 'Host' is 'all', and the 'URL Path Regex' is '/filetypes/'. The 'Category' is 'Proxy Address'. There are 'OK' and 'Cancel' buttons at the bottom.

4. Click **OK**.

To create a URL pattern address in the CLI:

```
config firewall proxy-address
  edit "URL Regex"
    set type url
    set host "all"
    set path "/filetypes/"
  next
end
```

URL category

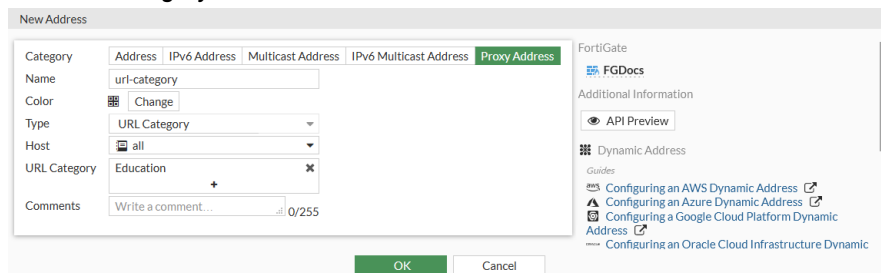

In this address type, a user can create a URL category based on a FortiGuard URL ID. Once created, the address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the URL category.

The example creates a URL category address for URLs in the *Education* category. For more information about categories, see <https://fortiguard.com/webfilter/categories>.

For information about creating and using custom local and remote categories, see [Web rating override on page 1414](#) and [Threat feeds on page 2673](#).

To create a URL category address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category to Proxy Address*,
 - *Name to url-category*,
 - *Type to URL Category*,
 - *Host to all*, and
 - *URL Category to Education*.

4. Click *OK*.

To create a URL category address in the CLI:

```
config firewall proxy-address
  edit "url-category"
    set type category
    set host "all"
    set category 30
  next
end
```

To see a list of all the categories and their numbers, when editing the address, enter `set category ?`.

HTTP method

In this address type, a user can create an address based on the HTTP request methods that are used. Multiple method options are supported, including: *CONNECT*, *DELETE*, *GET*, *HEAD*, *OPTIONS*, *POST*, *PUT*, and *TRACE*. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests that match the selected HTTP method.

The example creates a HTTP method address that uses the GET method.

To create a HTTP method address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *method_get*,
 - *Type* to *HTTP Method*,
 - *Host* to *all*, and
 - *Request Method* to *GET*.
4. Click *OK*.

To create a HTTP method address in the CLI:

```
config firewall proxy-address
  edit "method_get"
    set type method
    set host "all"
    set method get
  next
end
```

HTTP header

In this address type, a user can create a HTTP header as a regular expression. Once created, the header address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests where the HTTP header matches the regular expression.

This example creates a HTTP header address with the pattern *Q[A-B]*.

To create a HTTP header address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *HTTP-header*,

- *Type* to *HTTP Header*,
- *Host* to *all*,
- *Header Name* to *Header_Test*, and
- *Header Regex* to *Q[A-B]*.

4. Click *OK*.

To create a HTTP header address in the CLI:

```
config firewall proxy-address
  edit "method_get"
    set type header
    set host "all"
    set header-name "Header_Test"
    set header "Q[A-B]"
  next
end
```

User agent

In this address type, a user can create an address based on the names of the browsers that are used as user agents. Multiple browsers are supported, such as Chrome, Firefox, Internet Explorer, and others. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests from the specified user agent.

This example creates a user agent address for Google Chrome.

To create a user agent address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *UA-Chrome*,
 - *Type* to *User Agent*,
 - *Host* to *all*, and
 - *User Agent* to *Google Chrome*.
4. Click *OK*.

To create a user agent address in the CLI:

```
config firewall proxy-address
  edit "UA-Chrome"
    set type ua
    set host "all"
    set ua chrome
  next
end
```

Advanced (source)

In this address type, a user can create an address based on multiple parameters, including HTTP method, User Agent, and HTTP header. Once created, the address can be selected as a source of a proxy policy. This means that a policy will only allow or block requests that match the selected address.

This example creates an address that uses the get method, a user agent for Google Chrome, and an HTTP header with the pattern *Q[A-B]*.

To create an advanced (source) address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *advanced_src*,
 - *Type* to *Advanced (Source)*,
 - *Host* to *all*,
 - *Request Method* to *GET*,
 - *User Agent* to *Google Chrome*, and
 - *HTTP header* to *Header_Test : Q[A-B]*.
4. Click *OK*.

To create an advanced (source) address in the CLI:

```
config firewall proxy-address
  edit "advance_src"
    set type src-advanced
    set host "all"
    set method get
    set ua chrome
    config header-group
      edit 1
        set header-name "Header_Test"
        set header "Q[A-B]"
      next
    end
  next
end
```

Advanced (destination)

In this address type, a user can create an address based on URL pattern and URL category parameters. Once created, the address can be selected as a destination of a proxy policy. This means that a policy will only allow or block requests that match the selected address.

This example creates an address with the URL pattern */about* that are in the *Education* category. For more information about categories, see <https://fortiguard.com/webfilter/categories>.

To create an advanced (destination) address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Set the following:
 - *Category* to *Proxy Address*,
 - *Name* to *Advanced-dst*,
 - *Type* to *Advanced (Destination)*,
 - *Host* to *all*,
 - *URL Path Regex* to */about*, and
 - *URL Category* to *Education*.

The screenshot shows the 'New Address' configuration window in FortiGate. The 'Proxy Address' tab is active. The configuration fields are as follows:

- Category: Proxy Address
- Name: Advanced-dst
- Type: Advanced (Destination)
- Host: ubc
- URL Path Regex: /about
- URL Category: Education

The right sidebar contains 'Dynamic Address' guides with links to various cloud provider configurations.

4. Click *OK*.

To create an advanced (destination) address in the CLI:

```
config firewall proxy-address
  edit "Advanced-dst"
    set type dst-advanced
    set host "ubc"
    set path "/about"
    set category 30
  next
end
```

Proxy policy security profiles

Web proxy policies support most security profile types.

Security profiles must be created before they can be used in a policy, see [Security Profiles on page 1170](#) for information.

Explicit web proxy policy

The security profiles supported by explicit web proxy policies are:

- *AntiVirus*
- *Web Filter*

- *Application Control*
- *IPS*
- *DLP Sensor*
- *ICAP*
- *Web Application Firewall*
- *SSL Inspection*

To configure security profiles on an explicit web proxy policy in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	Explicit Web
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	webproxy
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Web Filter	urfilter
Application Control	app
IPS	Sensor-1
DLP Sensor	dlp
ICAP	default
Web Application Firewall	default
SSL Inspection	deep-inspection

6. Click *OK* to create the policy.

To configure security profiles on an explicit web proxy policy in the CLI:

```
config firewall proxy-policy
edit 1
set proxy explicit-web
set dstintf "port1"
set srcaddr "all"
set dstaddr "all"
```

```

    set service "web"
    set action accept
    set schedule "always"
    set utm-status enable
    set av-profile "av"
    set webfilter-profile "urlfilter"
    set dlp-sensor "dlp"
    set ips-sensor "sensor-1"
    set application-list "app"
    set icap-profile "default"
    set waf-profile "default"
    set ssl-ssh-profile "deep-inspection"
  next
end

```

Transparent proxy

The security profiles supported by transparent proxy policies are:

- *AntiVirus*
- *Web Filter*
- *Application Control*
- *IPS*
- *DLP Sensor*
- *ICAP*
- *Web Application Firewall*
- *SSL Inspection*

To configure security profiles on a transparent proxy policy in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	Transparent Web
Incoming Interfae	port2
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	webproxy
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been

created):

AntiVirus	av
Web Filter	urlfilter
Application Control	app
IPS	Sensor-1
DLP Sensor	dlp
ICAP	default
Web Application Firewall	default
SSL Inspection	deep-inspection

6. Click *OK* to create the policy.

To configure security profiles on a transparent proxy policy in the CLI:

```
config firewall proxy-policy
  edit 2
    set proxy transparent-web
    set srcintf "port2"
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set utm-status enable
    set av-profile "av"
    set webfilter-profile "urlfilter"
    set dlp-sensor "dlp"
    set ips-sensor "sensor-1"
    set application-list "app"
    set icap-profile "default"
    set waf-profile "default"
    set ssl-ssh-profile "certificate-inspection"
  next
end
```

FTP proxy

The security profiles supported by FTP proxy policies are:

- *AntiVirus*
- *Application Control*
- *IPS*
- *DLP Sensor*

To configure security profiles on an FTP proxy policy in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Click *Create New*.
3. Set the following:

Proxy Type	FTP
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Action	ACCEPT

4. In the *Firewall / Network Options* section, set *Protocol Options* to *default*.
5. In the *Security Profiles* section, make the following selections (for this example, these profiles have all already been created):

AntiVirus	av
Application Control	app
IPS	Sensor-1
DLP Sensor	dlp

6. Click *OK* to create the policy.

To configure security profiles on an FTP proxy policy in the CLI:

```
config firewall proxy-policy
  edit 3
    set proxy ftp
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set utm-status enable
    set av-profile "av"
    set dlp-sensor "dlp"
    set ips-sensor "sensor-1"
    set application-list "app"
  next
end
```

Explicit proxy authentication

FortiGate supports multiple authentication methods. This topic explains using an external authentication server with Kerberos as the primary and NTLM as the fallback.

To configure Explicit Proxy with authentication:

1. Enable and configure the explicit proxy on page 270.
2. Configure the authentication server and create user groups on page 270.
3. Create an authentication scheme and rules on page 273.
4. Create an explicit proxy policy and assign a user group to the policy on page 274.
5. Verify the configuration on page 274.

Enable and configure the explicit proxy**To enable and configure explicit web proxy in the GUI:**

1. Go to *Network > Explicit Proxy*.
2. Enable *Explicit Web Proxy*.
3. Select *port2* as the *Listen on Interfaces* and set the *HTTP Port* to *8080*.
4. Configure the remaining settings as needed.
5. Click *Apply*.

To enable and configure explicit web proxy in the CLI:

```
config web-proxy explicit
    set status enable
    set ftp-over-http enable
    set socks enable
    set http-incoming-port 8080
    set ipv6-status enable
    set unknown-http-version best-effort
end
config system interface
    edit "port2"
        set vdom "vdom1"
        set ip 10.1.100.1 255.255.255.0
        set allowaccess ping https ssh snmp http telnet
        set type physical
        set explicit-web-proxy enable
        set snmp-index 12
    end
next
end
```

Configure the authentication server and create user groups

Since we are using an external authentication server with Kerberos authentication as the primary and NTLM as the fallback, Kerberos authentication is configured first and then FSSO NTLM authentication is configured.

For successful authorization, the FortiGate checks if user belongs to one of the groups that is permitted in the security policy.

When configuring an LDAP connection to an Active Directory server, an administrator must provide Active Directory user credentials.

- To secure this connection, use LDAPS on both the Active Directory server and FortiGate. See [Configuring an LDAP server on page 1923](#).
- Apply the principle of least privilege. For the LDAP regular bind operation, do not use credentials that provide full administrative access to the Windows server when using credentials. See [Configuring least privileges for LDAP admin account authentication in Active Directory on page 1930](#).

To configure an authentication server and create user groups in the GUI:

1. Configure Kerberos authentication:

- Go to *User & Authentication > LDAP Servers*.
- Click *Create New*.
- Set the following:

Name	ldap-kerberos
Server IP	172.18.62.220
Server Port	389
Common Name Identifier	cn
Distinguished Name	dc=fortinetqa,dc=local

- Click *OK*

2. Define Kerberos as an authentication service. This option is only available in the CLI. For information on generating a keytab, see [Generating a keytab on a Windows server on page 275](#).

3. Configure FSSO NTLM authentication:

FSSO NTLM authentication is supported in a Windows AD network. FSSO can also provide NTLM authentication service to the FortiGate unit. When a user makes a request that requires authentication, the FortiGate initiates NTLM negotiation with the client browser, but does not process the NTLM packets itself. Instead, it forwards all the NTLM packets to the FSSO service for processing.

- Go to *Security Fabric > External Connectors*.
- Click *Create New* and select *FSSO Agent on Windows AD* from the *Endpoint/Identity* category.
- Set the *Name* to *FSSO, Primary FSSO Agent* to *172.16.200.220*, and enter a password.
- Click *OK*.

4. Create a user group for Kerberos authentication:

- Go to *User & Authentication > User Groups*.
- Click *Create New*.
- Set the *Name* to *Ldap-Group*, and *Type* to *Firewall*.
- In the *Remote Groups* table, click *Add*, and set the *Remote Server* to the previously created *ldap-kerberos* server.
- Click *OK*.

5. Create a user group for NTLM authentication:

- Go to *User & Authentication > User Groups*.
- Click *Create New*.

- c. Set the *Name* to *NTLM-FSSO-Group*, *Type* to *Fortinet Single Sign-On (FSSO)*, and add *FORTINETQA/FSSO* as a member.
- d. Click *OK*.

To configure an authentication server and create user groups in the CLI:

1. Configure Kerberos authentication:

```
config user ldap
  edit "ldap-kerberos"
    set server "172.18.62.220"
    set cnid "cn"
    set dn "dc=fortinetqa,dc=local"
    set type regular
    set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
    set password *****
  next
end
```

2. Define Kerberos as an authentication service:

```
config user krb-keytab
  edit "http_service"
    set pac-data disable
    set principal "HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL"
    set ldap-server "ldap-kerberos"
    set keytab
      "BQIAAABFAAIAEEZPU1RJTkVUUUEuTE9DQUwABehUVFAAFEZHVC5GT1JUSU5FVFFBLkxPQ0FMAAAAAQAAAAEAAE
      ACKLCMonpitnVAAAAARQACABBGT1JUSU5FVFFBLkxPQ0FMAARIVFRQABRGR1QuRk9SVE1ORVRRQS5MT0NBTA AAAAE
      AAAAAAADAAiiwjKJ6YrZ1QAAAE0AAgAQRk9SVE1ORVRRQS5MT0NBTAAESFRUUAUAURkdULkZPU1RJTkVUUUEuTE9
      DQUwAAAAABAAAAAAQAFwAQUHo9uqR9cSkzyxdzKCEXdwAAAF0AAgAQRk9SVE1ORVRRQS5MT0NBTAAESFRUUAUAURkd
      ULkZPU1RJTkVUUUEuTE9DQUwAAAAABAAAAAAQAEgAgzee854Aq1HhQiKJZvV4tL2Poy7hMIARQpK8MCB//BIAAAAB
      NAAIAEEZPU1RJTkVUUUEuTE9DQUwABehUVFAAFEZHVC5GT1JUSU5FVFFBLkxPQ0FMAAAAAQAAAAEABEAEG49vHE
      iiBghr63Z/lnwYrU="
  next
end
```

For information on generating a keytab, see [Generating a keytab on a Windows server on page 275](#).

3. Configure FSSO NTLM authentication:

```
config user fsso
  edit "1"
    set server "172.18.62.220"
    set password *****
  next
end
```

4. Create a user group for Kerberos authentication:

```
config user group
  edit "Ldap-Group"
    set member "ldap" "ldap-kerberos"
  next
end
```

5. Create a user group for NTLM authentication:

```
config user group
  edit "NTLM-FSSO-Group"
    set group-type fsso-service
    set member "FORTINETQA/FSSO"
  next
end
```

Create an authentication scheme and rules

Explicit proxy authentication is managed by authentication schemes and rules. An authentication scheme must be created first, and then the authentication rule.

To create an authentication scheme and rules in the GUI:

1. Create an authentication scheme:
 - a. Go to *Policy & Objects > Authentication Rules*.
 - b. Click *Create New > Authentication Schemes*.
 - c. Set the *Name* to *Auth-scheme-Negotiate* and select *Negotiate* as the *Method*.
 - d. Click *OK*.
2. Create an authentication rule:
 - a. Go to *Policy & Objects > Authentication Rules*.
 - b. Click *Create New > Authentication Rules*.
 - c. Set the *Name* to *Auth-Rule*, *Source Address* to *all*, and *Protocol* to *HTTP*.
 - d. Enable *Authentication Scheme*, and select the just created *Auth-scheme-Negotiate* scheme.
 - e. Click *OK*.

To create an authentication scheme and rules in the CLI:

1. Create an authentication scheme:

```
config authentication scheme
  edit "Auth-scheme-Negotiate"
    set method negotiate          <<< Accepts both Kerberos and NTLM as fallback
  next
end
```

2. Create an authentication rule:

```
config authentication rule
  edit "Auth-Rule"
    set status enable
    set protocol http
    set srcaddr "all"
    set ip-based enable
    set active-auth-method "Auth-scheme-Negotiate"
    set comments "Testing"
  next
end
```

Create an explicit proxy policy and assign a user group to the policy

To create an explicit proxy policy and assign a user group to it in the GUI:

1. Go to *Policy & Objects > Proxy Policy*.
2. Click *Create New*.
3. Set *Proxy Type* to *Explicit Web* and *Outgoing Interface* to *port1*.
4. Set *Source* to *all*, and the just created user groups *NTLM-FSSO-Group* and *Ldap-Group*.
5. Also set *Destination* to *all*, *Schedule* to *always*, *Service* to *webproxy*, and *Action* to *ACCEPT*.
6. Click *OK*.

To create an explicit proxy policy and assign a user group to it in the CLI:

```
config firewall proxy-policy
  edit 1
    set proxy explicit-web
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "web"
    set action accept
    set schedule "always"
    set logtraffic all
    set groups "NTLM-FSSO-Group" "Ldap-Group"
    set av-profile "av"
    set ssl-ssh-profile "deep-custom"
  next
end
```

Verify the configuration

Log in using a domain and system that would be authenticated using the Kerberos server, then enter the `diagnose wad user list` CLI command to verify:

```
# diagnose wad user list
ID: 8, IP: 10.1.100.71, VDOM: vdom1
  user name   : test1@FORTINETQA.LOCAL
  duration    : 389
  auth_type   : IP
  auth_method : Negotiate
  pol_id      : 1
  g_id        : 1
  user_based  : 0
  expire      : no
LAN:
  bytes_in=4862 bytes_out=11893
WAN:
  bytes_in=7844 bytes_out=1023
```

Log in using a system that is not part of the domain. The NTLM fallback server should be used:

```
# diagnose wad user list
ID: 2, IP: 10.1.100.202, VDOM: vdom1
```

```

user name      : TEST31@FORTINETQA
duration       : 7
auth_type      : IP
auth_method    : NTLM
pol_id         : 1
g_id           : 5
user_based     : 0
expire         : no
LAN:
  bytes_in=6156 bytes_out=16149
WAN:
  bytes_in=7618 bytes_out=1917

```

Generating a keytab on a Windows server

A keytab is used to allow services that are not running Windows to be configured with service instance accounts in the Active Directory Domain Service (AD DS). This allows Kerberos clients to authenticate to the service through Windows Key Distribution Centers (KDCs).

For an explanation of the process, see <https://docs.microsoft.com/en-us/windows-server/administration/windows-commands/ktpass>.

To generate a keytab on a Windows server:

- On the server, create a user for the FortiGate:
 - The service name is the FQDN for the explicit proxy interface, such as the hostname in the client browser proxy configuration. In this example, the service name is *FGT*.
 - The account only requires *domain users* membership.
 - The password must be very strong.
 - The password is set to never expire.
- Add the FortiGate FQDN in to the Windows DNS domain, as well as in-addr.arpa.
- Generate the Kerberos keytab using the `ktpass` command on Windows servers and many domain workstations:

```
# ktpass -princ HTTP/<domain name of test fgt>@realm -mapuser <user> -pass <password> -
crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

For example:

```
ktpass -princ HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL -mapuser FGT -pass *****
-crypto all -ptype KRB5_NT_PRINCIPAL -out fgt.keytab
```

If the FortiGate is handling multiple keytabs in Kerberos authentication, use different passwords when generating each keytab.

- Encode the keytab to base64 in a text file:
 - On Windows: `certutil -encode fgt.keytab tmp.b64 && findstr /v /c:- tmp.b64 > fgt.txt`
 - On Linux: `base64 fgt.keytab > fgt.txt`
 - On MacOS: `base64 -i fgt.keytab -o fgt.txt`
- Use the code in `fgt.txt` as the keytab parameter when configuring the FortiGate.

Transparent web proxy forwarding

In FortiOS, there is an option to enable proxy forwarding for transparent web proxy policies and regular firewall policies for HTTP and HTTPS.

In previous versions of FortiOS, you could forward proxy traffic to another proxy server (proxy chaining) with explicit proxy. Now, you can forward web traffic to the upstream proxy without having to reconfigure your browsers or publish a proxy auto-configuration (PAC) file.

Once configured, the FortiGate forwards traffic generated by a client to the upstream proxy. The upstream proxy then forwards it to the server.

To configure proxy forwarding:

1. Configure the web proxy forwarding server:

```
config web-proxy forward-server
  edit "upStream_proxy_1"
    set ip 172.16.200.20
    set healthcheck enable
    set monitor "http://www.google.ca"
  next
end
```

2. Append the web proxy forwarding server to a firewall policy:

```
config firewall policy
  edit 1
    set name "LAN To WAN"
    set srcintf "port10"
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set logtraffic all
    set webproxy-forward-server "upStream_proxy_1"
    set fsso disable
    set av-profile "av"
    set ssl-ssh-profile "deep-custom"
    set nat enable
  next
end
```

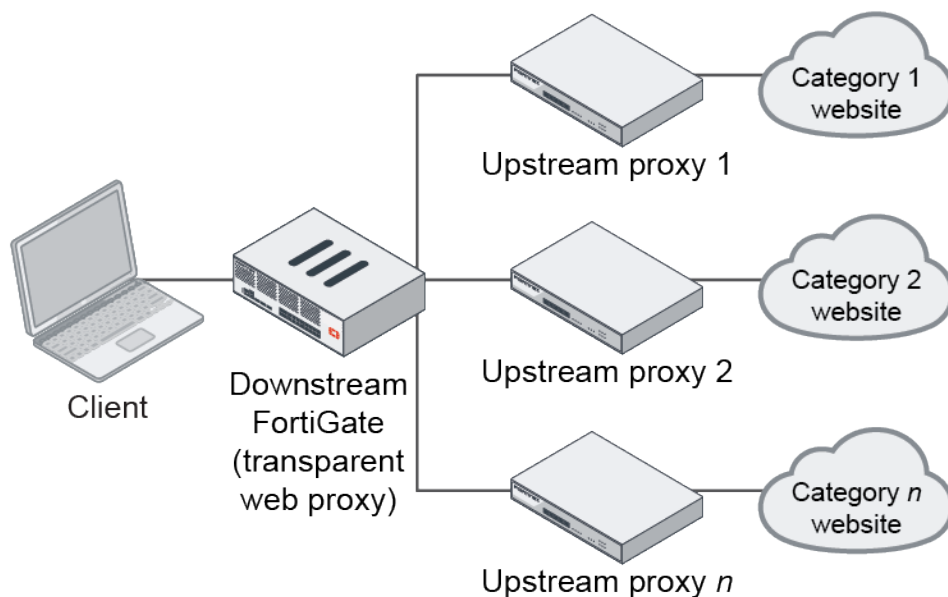

Selectively forward web requests to a transparent web proxy

Web traffic over HTTP/HTTPS can be forwarded selectively by the FortiGate's transparent web proxy to an upstream web proxy to avoid overwhelming the proxy server. Traffic can be selected by specifying the proxy address, which can be based on a FortiGuard URL category.

The FortiGuard web filter service must be enabled on the downstream FortiGate.

Topology

Forwarding behavior

The forward server will be ignored if the proxy policy matching for a particular session needs the FortiGate to see authentication information inside the HTTP (plain text) message. For example, assume that user authentication is required and a forward server is configured in the transparent web proxy, and the authentication method is an active method (such as basic). When the user or client sends the HTTP request over SSL with authentication information to the FortiGate, the request cannot be forwarded to the upstream proxy. Instead, it will be forwarded directly to the original web server (assuming deep inspection and `http-policy-redirect` are enabled in the firewall policy).

The FortiGate will close the session before the client request can be forwarded if all of the following conditions are met:

- The certificate inspection is configured in the firewall policy that has the `http-policy-redirect` option enabled.
- A previously authenticated IP-based user record cannot be found by the FortiGate's memory during the SSL handshake.
- Proxy policy matching needs the FortiGate to see the HTTP request authentication information.

This means that in order to enable user authentication and use `webproxy-forward-server` in the transparent web proxy policy at the same time, the following best practices should be followed:

- In the firewall policy that has the `http-policy-redirect` option enabled, set `ssl-ssh-profile` to use the `deep-inspection` profile.
- Use IP-based authentication rules; otherwise, the `webproxy-forward-server` setting in the transparent web proxy policy will be ignored.
- Use a passive authentication method such as FSSO. With FSSO, once the user is authenticated as a domain user by a successful login, the web traffic from the user's client will always be forwarded to the upstream proxy as long as the authenticated user remains unexpired. If the authentication method is an active authentication method (such as basic, digest, NTLM, negotiate, form, and so on), the first session containing authentication information will bypass the forward server, but the following sessions will be connected through the upstream proxy.

Sample configuration

On the downstream FortiGate proxy, there are two category proxy addresses used in two separate transparent web proxy policies as the destination address:

- In the policy with `upstream_proxy_1` as the forward server, the proxy address `category_infotech` is used to match URLs in the information technology category.
- In the policy with `upstream_proxy_2` as the forward server, the proxy address `category_social` is used to match URLs in the social media category.

To configure forwarding requests to transparent web proxies:

1. Configure the proxy forward servers:

```
config web-proxy forward-server
  edit "upStream_proxy_1"
    set ip 172.16.200.20
  next
  edit "upStream_proxy_2"
    set ip 172.16.200.46
  next
end
```

2. Configure the web proxy addresses:

```
config firewall proxy-address
  edit "category_infotech"
    set type category
    set host "all"
    set category 52
  next
  edit "category_social"
    set type category
    set host "all"
    set category 37
  next
end
```

3. Configure the firewall policy:

```
config firewall policy
  edit 1
    set srcintf "port10"
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set inspection-mode proxy
    set http-policy-redirect enable
    set ssl-ssh-profile "deep-inspection"
    set av-profile "av"
    set nat enable
  next
end
```

4. Configure the proxy policies:

```

config firewall proxy-policy
  edit 1
    set proxy transparent-web
    set srcintf "port10"
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "category_infotech"
    set service "webproxy"
    set action accept
    set schedule "always"
    set logtraffic all
    set webproxy-forward-server "upStream_proxy_1"
    set utm-status enable
    set ssl-ssh-profile "deep-inspection"
    set av-profile "av"
  next
  edit 2
    set proxy transparent-web
    set srcintf "port10"
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "category_social"
    set service "webproxy"
    set action accept
    set schedule "always"
    set logtraffic all
    set webproxy-forward-server "upStream_proxy_2"
    set utm-status enable
    set ssl-ssh-profile "deep-inspection"
    set av-profile "av"
  next
end

```

Upstream proxy authentication in transparent proxy mode

A downstream proxy FortiGate that needs to be authenticated by the upstream web proxy can use the basic authentication method to send its username and password, in the base64 format, to the upstream web proxy for authentication. If the authentication succeeds, web traffic that is forwarded from the downstream proxy FortiGate to the upstream proxy can be accepted and forwarded to its destinations.

In this example, a school has a FortiGate acting as a downstream proxy that is configured with firewall policies for each user group (students and staff). In each policy, a forwarding server is configured to forward the web traffic to the upstream web proxy.

The username and password that the upstream web proxy uses to authenticate the downstream proxy are configured on the forwarding server, and are sent to the upstream web proxy with the forwarded HTTP requests.

	Username	Password
student.proxy.local:8080	students	ABC123
staff.proxy.local:8081	staff	123456

On the downstream FortiGate, configure forwarding servers with the usernames and passwords for authentication on the upstream web proxy, then apply those servers to firewall policies for transparent proxy. For explicit web proxy, the forwarding servers can be applied to proxy policies.

When the transparent proxy is configured, clients can access websites without configuring a web proxy in their browser. The downstream proxy sends the username and password to the upstream proxy with forwarded HTTP requests to be authenticated.

To configure the forwarding server on the downstream FortiGate:

```
config web-proxy forward-server
  edit "Student_Upstream_WebProxy"
    set addr-type fqdn
    set fqdn "student.proxy.local"
    set port 8080
    set username "student"
    set password ABC123
  next
  edit "Staff_Upstream_WebProxy"
    set addr-type fqdn
    set fqdn "staff.proxy.local"
    set port 8081
    set username "staff"
    set password 123456
  next
end
```

To configure firewall policies for transparent proxy:

```
config firewall policy
  edit 1
    set srcintf "Vlan_Student"
    set dstintf "port9"
    set srcaddr "Student_Subnet"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set inspection-mode proxy
    set ssl-ssh-profile "deep-inspection"
    set av-profile "av"
    set webproxy-forward-server "Student_Upstream_WebProxy"
    set nat enable
  next
  edit 2
    set srcintf "Vlan_Staff"
    set dstintf "port9"
    set srcaddr "Staff_Subnet"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set inspection-mode proxy
    set ssl-ssh-profile "deep-inspection"
```

```

    set av-profile "av"
    set webproxy-forward-server "Staff_Upstream_WebProxy"
    set nat enable
  next
end

```

Multiple dynamic header count

Multiple dynamic headers are supported for web proxy profiles, as well as Base64 encoding and the append/new options.

Administrators only have to select the dynamic header in the profile. The FortiGate will automatically display the corresponding static value. For example, if the administrator selects the `$client-ip` header, the FortiGate will display the actual client IP address.

The supported headers are:

<code>\$client-ip</code>	Client IP address
<code>\$user</code>	Authentication user name
<code>\$domain</code>	User domain name
<code>\$local_grp</code>	Firewall group name
<code>\$remote_grp</code>	Group name from authentication server
<code>\$proxy_name</code>	Proxy realm name

To configure dynamic headers using the CLI:

Since authentication is required, FSSO NTLM authentication is configured in this example.

1. Configure LDAP:

```

config user ldap
  edit "ldap-kerberos"
    set server "172.18.62.220"
    set cnid "cn"a
    set dn "dc=fortinetqa,dc=local"
    set type regular
    set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
    set password *****
  next
end

```

2. Configure FSSO:

```

config user fsso
  edit "1"
    set server "172.18.62.220"
    set password *****
  next
end

```

3. Configure a user group:

```
config user group
  edit "NTLM-FSSO"
    set group-type fsso-service
    set member "FORTINETQA/FSSO"
  next
end
```

4. Configure an authentication scheme:

```
config authentication scheme
  edit "au-sch-ntlm"
    set method ntlm
  next
end
```

5. Configure an authentication rule:

```
config authentication rule
  edit "au-rule-fsso"
    set srcaddr "all"
    set active-auth-method "au-sch-ntlm"
  next
end
```

6. Create a web proxy profile that adds a new dynamic and custom Via header:

```
config web-proxy profile
  edit "test"
    set log-header-change enable
    config headers
      edit 1
        set name "client-ip"
        set content "$client-ip"
      next
      edit 2
        set name "Proxy-Name"
        set content "$proxy_name"
      next
      edit 3
        set name "user"
        set content "$user"
      next
      edit 4
        set name "domain"
        set content "$domain"
      next
      edit 5
        set name "local_grp"
        set content "$local_grp"
      next
      edit 6
        set name "remote_grp"
        set content "$remote_grp"
      next
      edit 7
        set name "Via"
        set content "Fortigate-Proxy"
      next
    next
  next
end
```

```

        end
    next
end

```

7. In the proxy policy, append the web proxy profile created in the previous step:

```

config firewall proxy-policy
    edit 1
        set proxy explicit-web
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set service "web"
        set action accept
        set schedule "always"
        set logtraffic all
        set groups "NTLM-FSSO"
        set webproxy-profile "test"
        set utm-status enable
        set av-profile "av"
        set webfilter-profile "content"
        set ssl-ssh-profile "deep-custom"
    next
end

```

8. Once traffic is being generated from the client, look at the web filter logs to verify that it is working.

The corresponding values for all the added header fields are shown at *Log & Report > Web Filter*, in the *Change headers* section at the bottom of the *Log Details* pane.

```

1: date=2019-02-07 time=13:57:24 logid="0344013632" type="utm" subtype="webfilter"
eventtype="http_header_change" level="notice" vd="vdom1" eventtime=1549576642 policyid=1
transid=50331689 sessionid=1712788383 user="TEST21@FORTINETQA" group="NTLM-FSSO"
profile="test" srcip=10.1.100.116 srcport=53278 dstip=172.16.200.46 dstport=80
srcintf="port2" srcintfrole="undefined" dstintf="port1" dstintfrole="undefined" proto=6
service="HTTP" url="http://172.16.200.46/" agent="curl/7.22.0" chgheaders="Added=client-
ip: 10.1.100.116|Proxy-Name: 1.1 100D.qa|user: TEST21|domain: FORTINETQA|local_grp:
NTLM-FSSO|remote_grp: FORTINETQA/FSSO|Via: Fortigate-Proxy"

```

Restricted SaaS access

Large organizations may want to restrict SaaS access to resources like Microsoft Office 365, Google Workspace, and Dropbox by tenant to block non-company login attempts and secure the users from accessing non-approved cloud resources. Many cloud vendors enable this by applying tenant restrictions for access control. For example, users accessing Microsoft 365 applications with tenant restrictions through the corporate proxy will only be allowed to log in as the company's tenant and access the organization's applications.

To implement this, access requests from the clients pass through the company's web proxy, which inserts headers to notify the SaaS service to apply tenant restrictions with the permitted tenant list. Users are redirected the SaaS service login page, and are only allowed to log in if they belong to the permitted tenant list.

For more information, refer to the vendor-specific documentation:

- Office 365: [Restrict access to a tenant](#)
- Google Workspace: [Block access to consumer accounts](#)
- Dropbox: [Network control](#)

Basic configuration

A web proxy profile can specify access permissions for Microsoft Office 365, Google Workspace, and Dropbox by inserting vendor-defined headers that restrict access to the specific accounts. Custom headers can also be inserted for any destination. The web proxy profile can then be applied to a firewall policy to control the header's insertion.

To implement Office 365 tenant restriction, Google Workspace account access control, and Dropbox network access control:

1. Configure a web proxy profile according to the vendors' specifications:
 - a. Set the header name (defined by the service provider).
 - b. Set the traffic destination (the service provider).
 - c. Set the HTTP header content to be inserted into the traffic (defined by your settings).

```
config web-proxy profile
  edit <name>
    config headers
      edit <id>
        set name <string>
        set dstaddr <address>
        set action add-to-request
        set base64-encoding disable
        set add-option new
        set protocol https http
        set content <string>
      next
    end
  next
end
```

2. Apply the web proxy profile to a policy. SSL deep inspection must be used in the firewall policy:

The following table lists the vendor-specific `config headers` settings that must be configured in the web proxy profile (`config web-proxy profile`):

Setting	Vendor specification		
	Microsoft Office 365	Google Workspace	Dropbox
name <string>	<ul style="list-style-type: none"> • Restrict-Access-To-Tenants • Restrict-Access-Context 	<ul style="list-style-type: none"> • X-GoogApps-Allowed-Domains 	<ul style="list-style-type: none"> • X-Dropbox-allowed-Team-Ids
dstaddr <address>	<ul style="list-style-type: none"> • Use the built-in Microsoft Office 365 address. 	<ul style="list-style-type: none"> • Use the built-in G Suite address. 	<ul style="list-style-type: none"> • Use the built-in wildcard.dropbox.com address.
content <string>	<ul style="list-style-type: none"> • Enter the domain for Restrict-Access-To- 	<ul style="list-style-type: none"> • Enter the domain. 	<ul style="list-style-type: none"> • Enter the Dropbox team ID.

Setting	Vendor specification		
	Microsoft Office 365	Google Workspace	Dropbox
	Tenants. • Enter the directory ID for Restrict-Access-Context.		

Due to vendors' changing requirements, these settings may no longer comply with the vendors' official guidelines. See the vendor documentation for more details.

Microsoft Office 365 example

In this example, a web proxy profile is created to control permissions for Microsoft Office 365 to allow corporate domains and deny personal accounts, such as Hotmail and Outlook that are accessed through login.live.com.

1. When a user attempts to access login.microsoftonline.com, login.microsoft.com, or login.windows.net, the traffic will match a proxy inspection mode firewall policy with the assigned web proxy profile.
2. The web proxy profile adds new headers to the customer tenant, indicating the allowed domain and restricted access for personal accounts. Next, the FortiGate starts a new connection with the Microsoft Office 365 domain controller including the new headers.
3. The Microsoft Office 365 domain controller assesses this data and will allow or deny this access, then sends a reply to the FortiGate.
4. The FortiGate sends a reply to the client.

The FortiGate will only indicate the correct domains to be allowed or denied through the headers to Microsoft. The custom sign-in portal in the browser is generated by Microsoft.

Configuration summary

The following must be configured in FortiOS:

- An FQDN address for login.live.com
- An SSL inspection profile that uses deep inspection with an exemption for login.live.com

Ensure that the firewall certificate is installed on the client machines. A company certificate signed by an internal CA is recommended.

- A web filter profile in proxy mode with static URL filters for the SNI URLs
- A web proxy profile that adds new headers to the customer tenant

- A firewall policy using proxy mode inspection that applies the configured SSL SSL inspection, web filter, and web proxy profiles

The `Restrict-Access-To-Tenants` and `Restrict-Access-Context` headers are inserted for incoming requests to: `login.microsoftonline.com`, `login.microsoft.com`, and `login.windows.net`, which are part of the Microsoft Office 365 address group.

To restrict access to personal accounts using the `login.live.com` domain, the `sec-Restrict-Tenant-Access-Policy` header is inserted and uses `restrict-msa` as the header content.

Before configuring the FortiGate, collect the information related to the company domain in the Office 365 contract.

- `Restrict-Access-To-Tenants`: your <domain.com>
- `Restrict-Access-Context`: Directory ID

To find the Directory ID related to the domain, locate it in the Azure portal, or use the whatismytenantid.com open tool.

To configure the FortiGate:

1. Add the FQDN address for `login.live.com`:

```
config firewall address
  edit "login.live.com"
    set type fqdn
    set fqdn "login.live.com"
  next
end
```

2. Configure the SSL inspection profile. In this example, the `deep-inspection` profile is cloned, and the `live.com` FQDN is removed from the exemption list.

- a. Clone the `deep-inspection` profile:

```
config firewall ssl-ssh-profile
  clone "deep-inspection" to "Tenant"
end
```

- b. Edit the `Tenant` profile and remove `live.com` from the `config ssl-exempt` list.

3. Configure the URL filter list:

```
config webfilter urlfilter
  edit 1
    set name "Auto-webfilter-urlfilter"
    config entries
      edit 1
        set url "login.microsoftonline.com"
        set action allow
      next
      edit 2
        set url "login.microsoft.com"
        set action allow
      next
      edit 3
        set url "login.windows.net"
        set action allow
    
```

```

        next
        edit 4
            set url "login.live.com"
            set action allow
        next
    end
next
end

```

4. Configure the web filter profile:

```

config webfilter profile
    edit "Tenant"
        set comment "Office 365"
        set feature-set proxy
        config web
            set urlfilter-table 1
        end
    next
end

```

5. Configure the web proxy profile (enter the header names exactly as shown):

```

config web-proxy profile
    edit "SaaS-Tenant-Restriction"
        set header-client-ip pass
        set header-via-request pass
        set header-via-response pass
        set header-x-forwarded-for pass
        set header-x-forwarded-client-cert pass
        set header-front-end-https pass
        set header-x-authenticated-user pass
        set header-x-authenticated-groups pass
        set strip-encoding disable
        set log-header-change disable
        config headers
            edit 1
                set name "Restrict-Access-To-Tenants"
                set dstaddr "login.microsoft.com" "login.microsoftonline.com"
                "login.windows.net"
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content <domain>
            next
            edit 2
                set name "Restrict-Access-Context"
                set dstaddr "login.microsoftonline.com" "login.microsoft.com"
                "login.windows.net"
                set action add-to-request
                set base64-encoding disable
                set add-option new
                set protocol https http
                set content <directory_ID>
            next
            edit 3

```

```
        set name "sec-Restrict-Tenant-Access-Policy"  
        set dstaddr "login.live.com"  
        set action add-to-request  
        set base64-encoding disable  
        set add-option new  
        set protocol https http  
        set content "restrict-msa"  
    next  
end  
next  
end
```

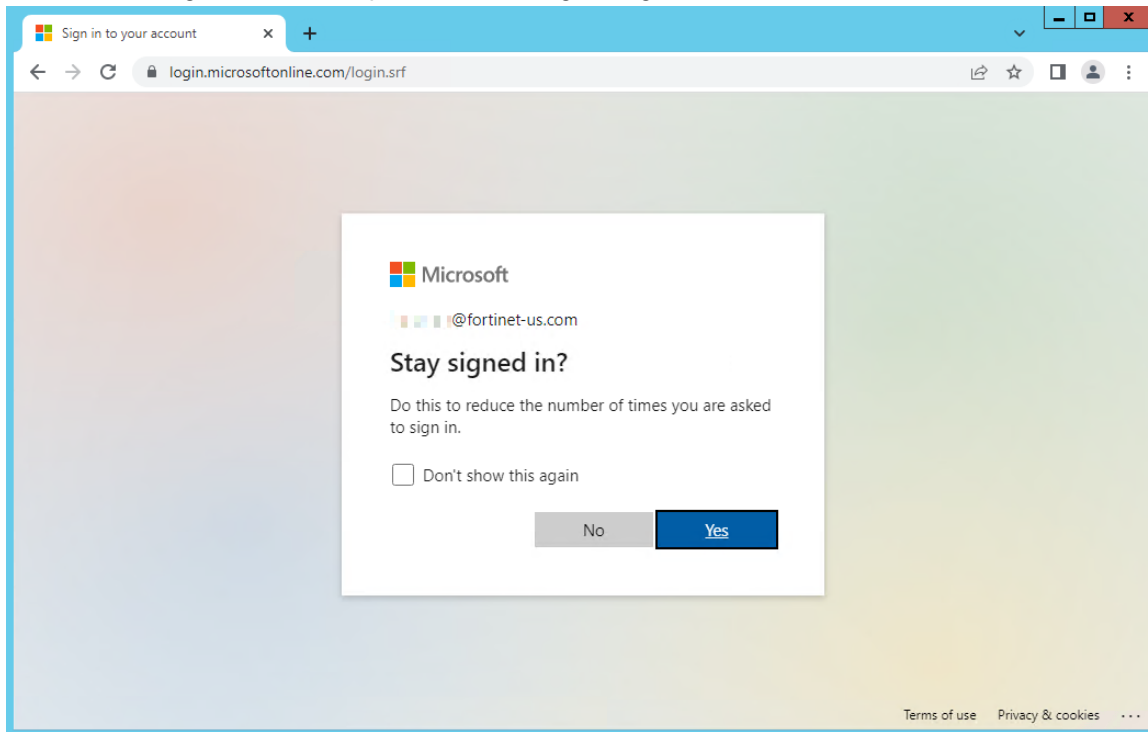

6. Configure the firewall policy:

```
config firewall policy  
    edit 10  
        set name "Tenant"  
        set srcintf "port2"  
        set dstintf "port1"  
        set action accept  
        set srcaddr "users-lan"  
        set dstaddr "login.microsoft.com" "login.microsoftonline.com"  
        "login.windows.net" "login.live.com"  
        set schedule "always"  
        set service "HTTP" "HTTPS"  
        set utm-status enable  
        set inspection-mode proxy  
        set webproxy-profile "SaaS-Tenant-Restriction"  
        set ssl-ssh-profile "Tenant"  
        set webfilter-profile "Tenant"  
        set logtraffic all  
        set nat enable  
    next  
end
```

Testing the access

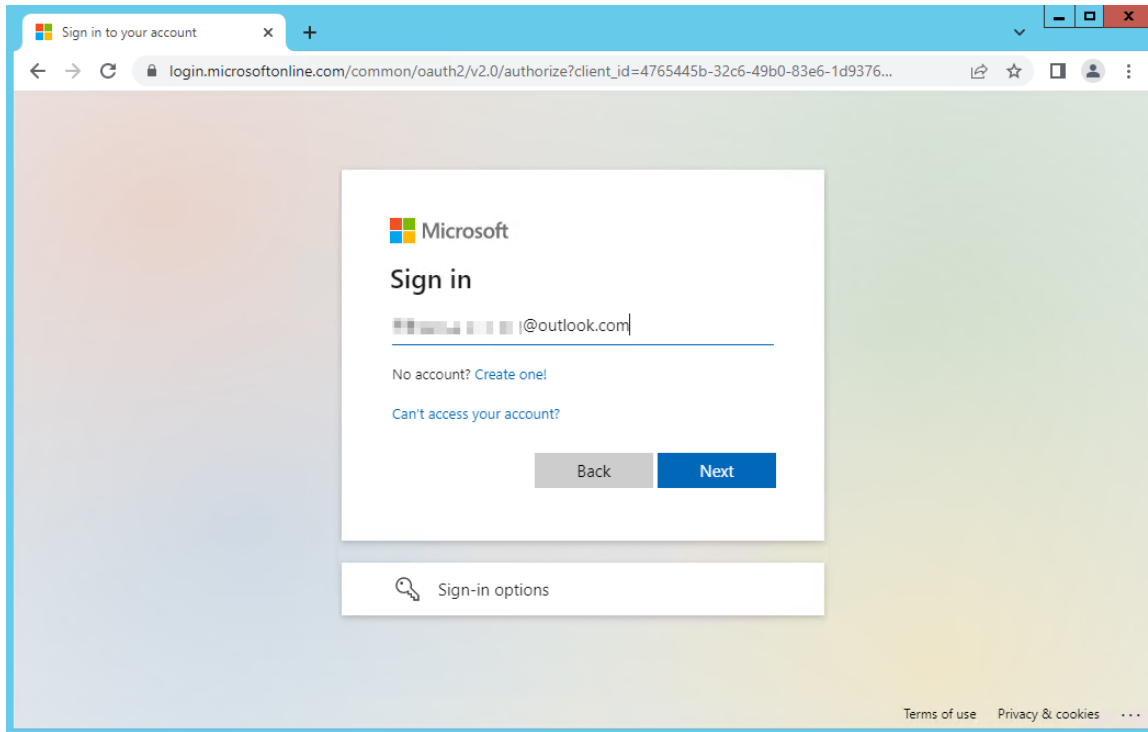

To test the access to corporate domains and personal accounts:

1. Get a client to log in with their corporate email using the login.microsoftonline.com domain.

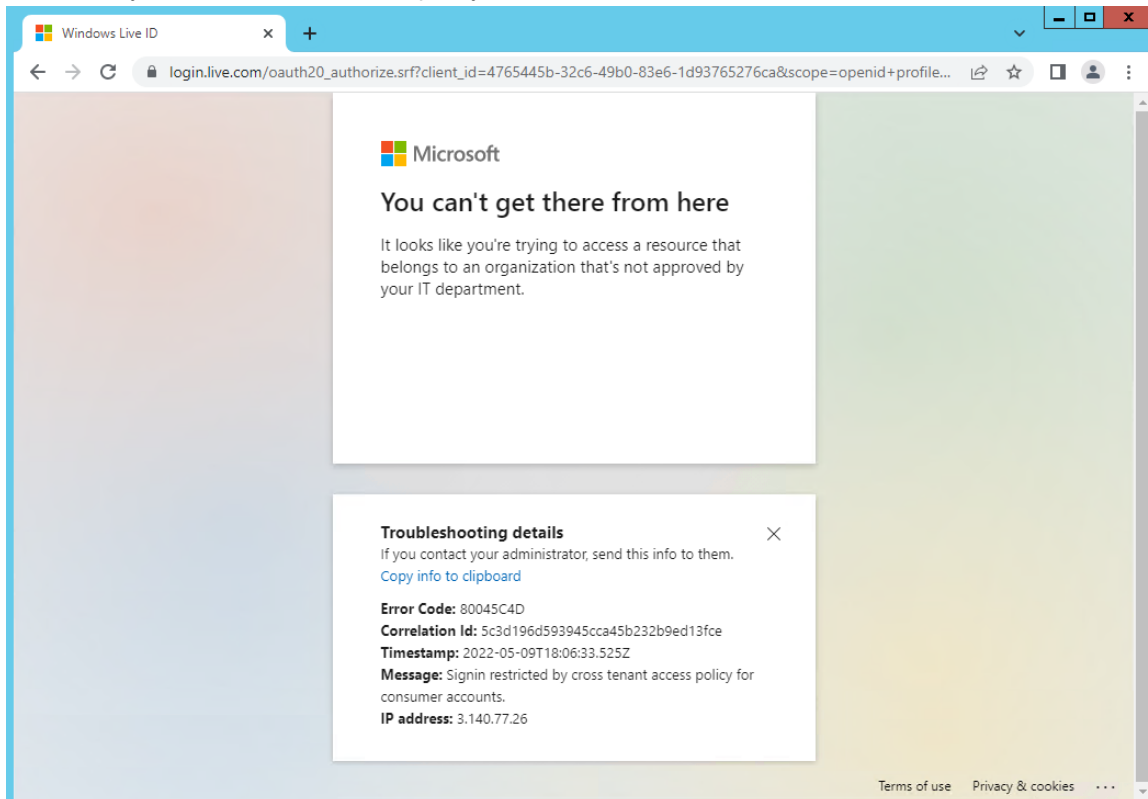

2. The client is able to enter their credentials and log in successfully.

3. Get a client to log in to their personal Outlook account.

4. After the client enters their credentials, a message appears that they cannot access this resource because it is restricted by the cross-tenant access policy.

Verifying the header insertion

To verify the header insertion for corporate domains and personal accounts:

1. On the FortiGate, start running the WAD debugs:

```
# diagnose wad debug enable category http
# diagnose wad debug enable level info
# diagnose debug enable
```

2. After a client attempts to access corporate domains, verify that the header information is sent to the Microsoft Active Directory:

```
[I][p:234][s:2481][r:33] wad_dump_fwd_http_req          :2567 hreq=0x7fc75f0cd468
Forward request to server:
POST /common/GetCredentialType?mkt=en-US HTTP/1.1

Explicit proxy and FortiGate Cloud Sandbox

Explicit proxy connections can leverage FortiGate Cloud Sandbox for advanced threat scanning and updates. This allows FortiGates behind isolated networks to connect to FortiCloud services.

To configure FortiGuard services to communicate with an explicit proxy server:

```
config system fortiguard
    set proxy-server-ip 172.16.200.44
    set proxy-server-port 3128
    set proxy-username "test1"
    set proxy-password *****
end
```

To verify the explicit proxy connection to FortiGate Cloud Sandbox:

```
# diagnose debug application forticldd -1

Proxy chaining

For the explicit web proxy you can configure web proxy forwarding servers to use proxy chaining to redirect web proxy sessions to other proxy servers. Proxy chaining can be used to forward web proxy sessions from the FortiGate unit to one or more other proxy servers on your network or on a remote network. You can use proxy chaining to integrate the FortiGate explicit web proxy with a web proxy solution that you already have in place.

A FortiGate unit can forward sessions to most web proxy servers including a remote FortiGate unit with the explicit web proxy enabled. No special configuration of the explicit web proxy on the remote FortiGate unit is required.

You can deploy the explicit web proxy with proxy chaining in an enterprise environment consisting of small satellite offices and a main office. If each office has a FortiGate unit, users at each of the satellite offices can use their local FortiGate unit as an explicit web proxy server. The satellite office FortiGate units can forward explicit web proxy sessions to an explicit web proxy server at the central office. From here the sessions can connect to web servers on the Internet.

FortiGate proxy chaining does not support web proxies in the proxy chain authenticating each other.

The following examples assume explicit web proxy has been enabled.

To enable explicit web proxy in the GUI:

1. Go to *System > Feature Visibility*.
2. In the *Security Features* column, enable *Explicit Proxy*.
3. Configure the explicit web proxy settings. See [Explicit web proxy on page 251](#).

To add a web proxy forwarding server in the GUI:

1. Go to *Network > Explicit Proxy*. The *Explicit Proxy* page opens.
2. In the *Web Proxy Forwarding Servers* section, click *Create New*.
3. Configure the server settings:

Name	Enter the name of the forwarding server.
Proxy Address Type	Select the type of IP address of the forwarding server. A forwarding server can have an <i>FQDN</i> or <i>IP</i> address.
Proxy Address	Enter the IP address of the forwarding server.
Port	Enter the port number on which the proxy receives connections. Traffic leaving the FortiGate explicit web proxy for this server has its destination port number changed to this number.
Server Down Action	Select the action the explicit web proxy will take if the forwarding server is down. <ul style="list-style-type: none"> • <i>Block</i>: Blocks the traffic if the remote server is down. • <i>Use Original Server</i>: Forwards the traffic from the FortiGate to its destination as if no forwarding server is configured.
Health Monitor	Select to enable health check monitoring.
Health Check Monitor Site	Enter the address of a remote site.

4. Click *OK*.

Example

The following example adds a web proxy forwarding server named `fwd-srv` at address `proxy.example.com` and port `8080`.

To add a web proxy forwarding server in the CLI:

```
config web-proxy forward-server
  edit fwd-srv
    set addr-type fqdn
    set fqdn proxy.example.com
    set port 8080
  next
end
```

Web proxy forwarding server monitoring and health checking

By default, a FortiGate unit monitors a web proxy forwarding server by forwarding a connection to the remote server every 10 seconds. The remote server is assumed to be down if it does not respond to the connection. FortiGate continues checking the server. The server is assumed to be back up when the server sends a response. If you enable health checking, the FortiGate unit attempts to get a response from a web server every 10 seconds by connecting through the remote forwarding server.

You can configure health checking for each remote server and specify a different website to check for each one.

If the remote server is found to be down you can configure the FortiGate unit to block sessions until the server comes back up or to allow sessions to connect to their destination, bypassing the remote forwarding server. You cannot configure the FortiGate unit to fail over to another remote forwarding server.

To configure proxy server monitor and health checking in the GUI:

1. Go to *Network > Explicit Proxy*. The *Explicit Proxy* page opens.
2. In the *Web Proxy Forwarding Servers* section, edit a server.
3. Configure the *Server Down Action* and *Health Monitor* settings.

Server Down Action	Select the action the explicit web proxy will take if the forwarding server is down. <ul style="list-style-type: none"> • <i>Block</i>: Blocks the traffic if the remote server is down. • <i>Use Original Server</i>: Forwards the traffic from the FortiGate to its destination as if no forwarding server configured.
Health Monitor	Select to enable health check monitoring.
Health Check Monitor Site	Enter the address of a remote site.

4. Click *OK*.

Example

The following example enables health checking for a web proxy forwarding server and sets the server down option to bypass the forwarding server if it is down.

To configure proxy server monitor and health checking in the CLI:

```
config web-proxy forward-server
  edit fwd-srv
    set healthcheck enable
    set monitor http://example.com
    set server-down-option pass
  next
end
```

Grouping forwarding servers and load balancing traffic to the servers

You can add multiple web proxy forwarding servers to a forwarding server group and then add the server group to an explicit web proxy policy instead of adding a single server. Forwarding server groups are created from the FortiGate CLI but can be added to policies from the web-based manager (or from the CLI).

When you create a forwarding server group you can select a load balancing method to control how sessions are load balanced to the forwarding servers in the server group. Two load balancing methods are available:

- *Weighted* load balancing sends more sessions to the servers with higher weights. You can configure the weight for each server when you add it to the group.
- *Least-session* load balancing sends new sessions to the forwarding server that is processing the fewest sessions.

When you create a forwarding server group you can also enable *affinity*. Enable affinity to have requests from the same client processed by the same server. This can reduce delays caused by using multiple servers for a single multi-step client operation. Affinity takes precedence over load balancing.

You can also configure the behavior of the group if all of the servers in the group are down. You can select to block traffic or you can select to have the traffic pass through the FortiGate explicit proxy directly to its destination instead of being sent to one of the forwarding servers.

Example

The following example adds a forwarding server group that uses weighted load balancing to load balance traffic to three forwarding servers. Server weights are configured to send most traffic to `server2`. The group has `affinity` enabled and blocks traffic if all of the forward servers are down.

To configure load balancing in the CLI:

```
config web-proxy forward-server
  edit server_1
    set ip 172.20.120.12
    set port 8080
  next
  edit server_2
    set ip 172.20.120.13
    set port 8000
  next
  edit server_3
    set ip 172.20.120.14
    set port 8090
  next
end

config web-proxy forward-server-group
  edit New-fwd-group
    set affinity enable
    set ldb-method weighted
    set group-down-option block
    config server-list
      edit server_1
        set weight 10
      next
      edit server_2
        set weight 40
      next
      edit server_3
        set weight 10
      next
    end
  next
end
```

Adding proxy chaining to an explicit web proxy policy

You can enable proxy chaining for web proxy sessions by adding a web proxy forwarding server or server group to an explicit web proxy policy. In a policy you can select one web proxy forwarding server or server group. All explicit web proxy traffic accepted by this security policy is forwarded to the specified web proxy forwarding server or server group.

To add an explicit web proxy forwarding server in the GUI:

1. Go to *Policy & Objects > Proxy Policy* and click *Create New*.
2. Configure the policy settings:

Proxy Type	Explicit Web
Outgoing Interface	wan1
Source	Internal_subnet
Destination	all
Schedule	always
Service	webproxy
Action	Accept

3. Enable *Web Proxy Forwarding Server* and select the forwarding server, (for example, *fwd-srv*).
4. Click *OK*.

Example

The following example adds a security policy that allows all users on the 10.31.101.0 subnet to use the explicit web proxy for connections through the wan1 interface to the Internet. The policy forwards web proxy sessions to a remote forwarding server named *fwd-srv*.

To add an explicit web proxy forwarding server in the CLI:

```
config firewall proxy-policy
  edit 0
    set proxy explicit-web
    set dstintf "wan1"
    set srcaddr "Internal_subnet"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set webproxy-forward-server "fwd-srv"
  next
end
```

Using TLS 1.3 with web proxy forward servers

A FortiGate can handle TLS 1.3 traffic in both deep and certificate inspection modes.

Example

The following example demonstrates that the Squid server and the FortiGate can handle TLS 1.3 traffic.

The following output from the Squid server demonstrates that the FortiGate supports TLS 1.3 traffic and forwards the hello retry request back to the client PC. The client PC then sends the client hello again, and the connection is successfully established.

No.	Time	Source	Destination	Protocol	Length	Info

WAN optimization SSL proxy chaining

An SSL server does not need to be defined for WAN optimization (WANOpt) SSL traffic offloading (traffic acceleration). The server side FortiGate uses an SSL profile to resign the HTTP server's certificate, both with and without an external proxy, without an SSL server configured. GCM and ChaCha ciphers can also be used in the SSL connection.

Examples

In these examples, HTTPS traffic is accelerated without configuring an SSL server, including with a proxy in between, and when the GCM or ChaCha ciphers are used.

Example 1

In this example, the server certificate is resigned by the server side FortiGate, and HTTPS traffic is accelerated without configuring an SSL server.

HTTPS traffic with the GCM or ChaCha cipher can pass through WANOpt tunnel.

To configure FGT_A:

1. Configure the hard disk to perform WANOpt:

```
config system storage
  edit "HDD2"
    set status enable
    set usage wanopt
    set wanopt-mode mix
  next
end
```

2. Configure the WANOpt peer and profile:

```
config wanopt peer
  edit "FGT-D"
    set ip 120.120.120.172
  next
end

config wanopt profile
  edit "test"
    config http
      set status enable
      set ssl enable
    end
  next
end
```

3. Create an SSL profile with deep inspection on HTTPS port 443:

```
config firewall ssl-ssh-profile
  edit "ssl"
    config https
      set ports 443
      set status deep-inspection
    end
  next
end
```

4. Configure a firewall policy in proxy mode with WANOpt enabled and the WANOpt profile selected:

```
config firewall policy
  edit 1
    set name "WANOPT-A"
```

```
        set srcintf "port21"
        set dstintf "port27"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
        set wanopt enable
        set wanopt-profile "test"
        set nat enable
    next
end
```

To configure FGT_D:

1. Configure the hard disk to perform WANOpt:

```
config system storage
    edit "HDD2"
        set status enable
        set usage wanopt
        set wanopt-mode mix
    next
end
```

2. Configure the WANOpt peer:

```
config wanopt peer
    edit "FGT-A"
        set ip 110.110.110.171
    next
end
```

3. Create an SSL profile with deep inspection on HTTPS port 443. The default *Fortinet_CA_SSL* certificate is used to resign the server certificate:

```
config firewall ssl-ssh-profile
    edit "ssl"
        config https
            set ports 443
            set status deep-inspection
        end
    next
end
```

4. Configure a firewall policy in proxy mode with WANOpt enabled and passive WANOpt detection:

```
config firewall policy
    edit 1
        set name "WANOPT-B"
        set srcintf "port27"
        set dstintf "port23"
        set action accept
        set srcaddr "all"
```

```

        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set inspection-mode proxy
        set wanopt enable
        set wanopt-detection passive
        set nat enable
    next
end

```

5. Configure a proxy policy to apply the SSL profile:

```

config firewall proxy-policy
    edit 100
        set proxy wanopt
        set dstintf "port23"
        set srcaddr "all"
        set dstaddr "all"
        set service "ALL"
        set action accept
        set schedule "always"
        set utm-status enable
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
    next
end

```

To confirm that traffic is accelerated:

1. On the client PC, curl a 10MB test sample for the first time:

```

root@client:/tmp# curl -k https://172.16.200.144/test_10M.pdf -O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100 9865k  100 9865k    0     0  663k      0  0:00:14  0:00:15 --:--:-- 1526k

```

It takes 15 seconds to finish the download.

2. On FGT_A, check the WAD statistics:

```

# diagnose wad stats worker.tunnel
comp.n_in_raw_bytes      10155840
comp.n_in_comp_bytes     4548728
comp.n_out_raw_bytes     29624
comp.n_out_comp_bytes    31623

# diagnose wad stats worker.protos.http
wan.bytes_in             0
wan.bytes_out            0
lan.bytes_in             760
lan.bytes_out            10140606
tunnel.bytes_in          4548728
tunnel.bytes_out         31623

```

3. Curl the same test sample a second time:

```

root@client:/tmp# curl -k https://172.16.200.144/test_10M.pdf -O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed

```

```

          Dload Upload Total Spent Left Speed
100 9865k 100 9865k 0 0 663k 0 0:00:01 0:00:01 --:--:-- 1526k

```

It now takes less than one second to finish the download.

4. On FGT_A, check the WAD statistics again:

```

# diagnose wad stats worker.tunnel
comp.n_in_raw_bytes          10181157
comp.n_in_comp_bytes         4570331
comp.n_out_raw_bytes         31627
comp.n_out_comp_bytes        34702

# diagnose wad stats worker.protos.http
wan.bytes_in                 0
wan.bytes_out                0
lan.bytes_in                 1607
lan.bytes_out                20286841
tunnel.bytes_in              4570331
tunnel.bytes_out              34702

```

The tunnel bytes are mostly unchanged, but the LAN bytes are doubled. This means that the bytes of the second curl come from the cache, showing that the traffic is accelerated.

To confirm that a curl using the GCM cipher is accepted and accelerated:

1. On the client PC, curl a 10MB test sample with the GCM cipher:

```

root@client:/tmp# curl -v -k --ciphers DHE-RSA-AES128-GCM-SHA256
https://172.16.200.144/test_10M.pdf -O
* Trying 172.16.200.144...
* TCP_NODELAY set
  % Total    % Received % Xferd Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left   Speed
  0    0    0    0    0    0    0    0  --:--:--  --:--:--  --:--:--    0*
Connected to 172.16.200.144 (172.16.200.144) port 443 (#0)

```

Example 2

In this example, an external proxy is added to the configuration in [Example 1](#).

To reconfigure FGT_A:

```
config firewall profile-protocol-options
  edit "protocol"
    config http
      set ports 80 8080
      unset options
      unset post-lang
    end
  next
end
```

To reconfigure FGT_D:

1. Configure a new firewall policy for traffic passing from port27 to port29:

```
config firewall policy
  edit 1
    set name "WANOPT-B"
    set srcintf "port27"
    set dstintf "port29"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set inspection-mode proxy
    set wanopt enable
    set wanopt-detection passive
    set nat enable
  next
end
```

2. Configure a proxy policy for traffic on destination interface port29:

```
config firewall proxy-policy
  edit 100
    set proxy wanopt
    set dstintf "port29"
    set srcaddr "all"
    set dstaddr "all"
    set service "ALL"
    set action accept
```

```

        set schedule "always"
        set profile-protocol-options "protocol"
        set ssl-ssh-profile "ssl"
    next
end

```

To confirm that HTTPS traffic is still being accelerated:

1. On the client PC, curl the same 10MB test sample through the explicit proxy:

```

root@client:/tmp# curl -x 100.100.100.174:8080 -v -k https://172.16.200.144/test_10M.pdf
-O
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left   Speed
100 9865k    100 9865k    0     0    663k      0  0:00:01  0:00:01 --:--:-- 1526k

```

It takes less than a second to finish the download.

Agentless NTLM authentication for web proxy

Agentless Windows NT LAN Manager (NTLM) authentication includes support for the following items:

- Multiple servers
- Individual users

You can use multiple domain controller servers for the agentless NTLM. They can be used for load balancing and high service stability.

You can also use user-based matching in groups for Kerberos and agentless NTLM. In these scenarios, FortiOS matches the user's group information from an LDAP server.

To support multiple domain controllers for agentless NTLM using the CLI:

1. Configure an LDAP server:

```

config user ldap
    edit "ldap-kerberos"
        set server "172.18.62.177"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password *****
    next
end

```

2. Configure multiple domain controllers:

```

config user domain-controller
    edit "dc1"
        set ip-address 172.18.62.177
        config extra-server
            edit 1
                set ip-address 172.18.62.220
            next
        end
    end

```

```
        set ldap-server "ldap-kerberos"  
    next  
end
```

3. Create an authentication scheme and rule:

```
config authentication scheme  
    edit "au-ntlm"  
        set method ntlm  
        set domain-controller "dc1"  
    next  
end  
  
config authentication rule  
    edit "ru-ntlm"  
        set srcaddr "all"  
        set ip-based disable  
        set active-auth-method "au-ntlm"  
    next  
end
```

4. In the proxy policy, append the user group for authorization:

```
config firewall proxy-policy  
    edit 1  
        set proxy explicit-web  
        set dstintf "port1"  
        set srcaddr "all"  
        set dstaddr "all"  
        set service "web"  
        set action accept  
        set schedule "always"  
        set groups "ldap-group"  
        set utm-status enable  
        set av-profile "av"  
        set ssl-ssh-profile "deep-custom"  
    next  
end
```

This configuration uses a round-robin method. When the first user logs in, the FortiGate sends the authentication request to the first domain controller. Later when another user logs in, the FortiGate sends the authentication request to another domain controller.

5. Verify the behavior after the user successfully logs in:

```
# diagnose wad user list  
ID: 1825, IP: 10.1.100.71, VDOM: vdom1  
  user name   : test1  
  duration    : 497  
  auth_type   : Session  
  auth_method : NTLM  
  pol_id      : 1    g_id      : 5  
  user_based  : 0    e  
  xpire       : 103  
LAN:  
  bytes_in=2167 bytes_out=7657  
WAN:  
  bytes_in=3718 bytes_out=270
```

To support individual users for agentless NTLM using the CLI:**1. Configure an LDAP server:**

```
config user ldap
  edit "ldap-kerberos"
    set server "172.18.62.177"
    set cnid "cn"
    set dn "dc=fortinetqa,dc=local"
    set type regular
    set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
    set password *****
  next
end
```

2. Configure the user group and allow user-based matching:

```
config user group
  edit "ldap-group"
    set member "ldap" "ldap-kerberos"
    config match
      edit 1
        set server-name "ldap-kerberos"
        set group-name "test1"
      next
    end
  next
end
```

3. Create an authentication scheme and rule:

```
config authentication scheme
  edit "au-ntlm"
    set method ntlm
    set domain-controller "dc1"
  next
end

config authentication rule
  edit "ru-ntlm"
    set srcaddr "all"
    set ip-based disable
    set active-auth-method "au-ntlm"
  next
end
```

4. In the proxy policy, append the user group for authorization:

```
config firewall proxy-policy
  edit 1
    set proxy explicit-web
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "web"
    set action accept
    set schedule "always"
    set groups "ldap-group"
    set utm-status enable
```

```

        set av-profile "av"
        set ssl-ssh-profile "deep-custom"
    next
end

```

This implementation lets you configure a single user instead of a whole group. The FortiGate will now allow the user named `test1`.

To verify the configuration using the CLI:

```

diagnose wad user list
ID: 1827, IP: 10.1.15.25, VDOM: vdom1
user name   : test1
duration    : 161
auth_type   : Session
auth_method : NTLM
pol_id      : 1
g_id        : 5
user_based  : 0
expire      : 439
LAN:
    bytes_in=1309 bytes_out=4410
WAN:
    bytes_in=2145 bytes_out=544

```

Multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers

Multiple LDAP servers can be configured in Kerberos keytabs and agentless NTLM domain controllers for multi-forest deployments.

To use multiple LDAP servers in Kerberos keytabs and agentless NTLM domain controllers:

1. Add multiple LDAP servers:

```

config user ldap
    edit "ldap-kerberos"
        set server "172.16.200.98"
        set cnid "cn"
        set dn "dc=fortinetqa,dc=local"
        set type regular
        set username "CN=root,CN=Users,DC=fortinetqa,DC=local"
        set password xxxxxxxxxx
    next
    edit "ldap-two"
        set server "172.16.106.128"
        set cnid "cn"
        set dn "OU=Testing,DC=ad864r2,DC=com"
        set type regular
        set username "cn=Testadmin,cn=users,dc=AD864R2,dc=com"
        set password xxxxxxxxxx
    next
end

```

2. Configure a Kerberos keytab entry that uses both LDAP servers:

```

config user krb-keytab
  edit "http_service"
    set pac-data disable
    set principal "HTTP/FGT.FORTINETQA.LOCAL@FORTINETQA.LOCAL"
    set ldap-server "ldap-kerberos" "ldap-two"
    set keytab xxxxxxxxxx
  next
end

```

3. Configure a domain controller that uses both LDAP servers:

```

config user domain-controller
  edit "dc1"
    set ip-address 172.16.200.98
    set ldap-server "ldap-two" "ldap-kerberos"
  next
end

```

Learn client IP addresses

Learning the actual client IP addresses is imperative for authorization. This function identifies the real client IP address when there is a NATing device between the FortiGate and the client.

```

config web-proxy global
  set learn-client-ip {enable | disable}
  set learn-client-ip-from-header {true-client-ip | x-real-ip | x-forwarded-for}
  set learn-client-ip-srcaddr <address> ... <address>
end

```

learn-client-ip {enable disable}	Enable/disable learning the client's IP address from headers.
learn-client-ip-from-header {true-client-ip x-real-ip x-forwarded-for}	Learn client IP addresses from the specified headers.
learn-client-ip-srcaddr <address> ... <address>	The source address names.

Example

In this example, the real client IP address is used to match a policy for FSSO authentication.

To enable learning the client IP address:

```

config web-proxy global
  set proxy-fqdn "default.fqdn"
  set webproxy-profile "default"
  set learn-client-ip enable
  set learn-client-ip-from-header x-forwarded-for
  set learn-client-ip-srcaddr "all"
end

```

To configure the proxy policy:

```
config firewall proxy-policy
  edit 1
    set proxy explicit-web
    set dstintf "mgmt1"
    set srcaddr "all"
    set dstaddr "all"
    set service "w"
    set action accept
    set schedule "always"
    set groups "fssol"
    set utm-status enable
    set av-profile "default"
    set dlp-sensor "default"
    set profile-protocol-options "default"
    set ssl-ssh-profile "deep-inspection"
  next
end
```

To configure the authentication scheme and rule:

```
config authentication scheme
  edit "scheme1"
    set method fsso
  next
end

config authentication rule
  edit "rule1"
    set srcaddr "all"
    set sso-auth-method "scheme1"
  next
end
```

Explicit proxy authentication over HTTPS

When a HTTP request requires authentication in an explicit proxy, the authentication can be redirected to a secure HTTPS captive portal. Once authentication is complete, the client can be redirected back to the original destination over HTTP.

Example

A user visits a website via HTTP through the explicit web proxy on a FortiGate. The user is required to authenticate by either basic or form IP-based authentication for the explicit web proxy service. The user credentials need to be transmitted over the networks in a secured method over HTTPS rather than in plain text. The user credentials are protected by redirecting the client to a captive portal of the FortiGate over HTTPS for authentication where the user credentials are encrypted and transmitted over HTTPS.

In this example, explicit proxy authentication over HTTPS is configured with form IP-based authentication. Once configured, you can enable authorization for an explicit web proxy by configuring users or groups in the firewall proxy policy.

To configure explicit proxy authentication over HTTPS:

1. Configure the authentication settings:

```
config authentication setting
  set captive-portal-type fqdn
  set captive-portal "fgt-cp"
  set auth-https enable
end
```

2. Configure the authentication scheme:

```
config authentication scheme
  edit "form"
    set method form
    set user-database "local-user-db"
  next
end
```

3. Configure the authentication rule:

```
config authentication rule
  edit "form"
    set srcaddr "all"
    set active-auth-method "form"
  next
end
```

If a session-based basic authentication method is used, enable `web-auth-cookie`.

4. Configure the firewall address:

```
config firewall address
  edit "fgt-cp"
    set type fqdn
    set fqdn "fgt.fortinetqa.local"
  next
end
```

5. Configure the interface:

```

config system interface
  edit "port10"
    set ip 10.1.100.1 255.255.255.0
    set explicit-web-proxy enable
    set proxy-captive-portal enable
  next
end

```

6. Configure a firewall proxy policy with users or groups (see [Explicit web proxy on page 251](#)).

Verification

When a client visits a HTTP website, the client will be redirected to the captive portal for authentication by HTTPS. For example, the client could be redirected to a URL by a HTTP 303 message similar to the following:

HTTP/1.1 303 See Other

Connection: close

Content-Type: text/html

Cache-Control: no-cache

Location:

https://fgt.fortinetqa.local:7831/XX/YY/ZZ/cpauth?scheme=http&Tmthd=0&host=172.16.200.46&port=80&rule=75&uri=Lw==&

Content-Length: 0

The captive portal URL used for authentication is *https://fgt.fortinetqa.local:7831/...* Once the authentication is complete with all user credentials protected by HTTPS, the client is redirected to the original HTTP website they intended to visit.

mTLS client certificate authentication

FortiGate supports client certificate authentication used in mutual Transport Layer Security (mTLS) communication between a client and server. Clients are issued certificates by the CA, and an access proxy configured on the FortiGate uses the new certificate method in the authentication scheme to identify and approve the certificate provided by the client when they try to connect to the access proxy. The FortiGate can also add the HTTP header X-Forwarded-Client-Cert to forward the certificate information to the server.

Examples

In these examples, the access proxy VIP IP address is 10.1.100.200.

Example 1

In this example, clients are issued unique client certificates from your CA. The FortiGate authenticates the clients by their user certificate before allowing them to connect to the access proxy. The access server acts as a reverse proxy for the web server that is behind the FortiGate.

This example assumes that you have already obtained the public CA certificate from your CA, the root CA of the client certificate has been imported (CA_Cert_1), and the client certificate has been distributed to the endpoints.

To configure the FortiGate:

1. Configure user authentication. Both an authentication scheme and rule must be configured, as the authentication is applied on the access proxy:

```
config authentication scheme
  edit "mtls"
    set method cert
    set user-cert enable
  next
end

config authentication rule
  edit "mtls"
    set srcintf "port2"
    set srcaddr "all"
    set dstaddr "all"
    set active-auth-method "mtls"
  next
end
```

2. Select the CA or CAs used to verify the client certificate:

```
config authentication setting
  set user-cert-ca "CA_Cert_1"
end
```

3. Configure the users. Users can be matched based on either the common-name on the certificate or the trusted issuer.

- Verify the user based on the common name on the certificate:

```
config user certificate
  edit "single-certificate"
    set type single-certificate
    set common-name "client.fortinet.com"
  next
end
```

- Verify the user based on the CA issuer:

```
config user certificate
  edit "trusted-issuer"
    set type trusted-issuer
    set issuer "CA_Cert_1"
  next
end
```

4. Configure the access proxy VIP. The SSL certificate is the server certificate that is presented to the user as they connect:

```

config firewall vip
  edit "mTLS"
    set type access-proxy
    set extip 10.1.100.200
    set extintf "port2"
    set server-type https
    set extport 443
    set ssl-certificate "Fortinet_CA_SSL"
  next
end

```

5. Configure the access proxy policy, including the real server to be mapped. To request the client certificate for authentication, `client-cert` is enabled:

```

config firewall access-proxy
  edit "mTLS-access-proxy"
    set vip "mTLS"
    set client-cert enable
    set empty-cert-action accept
    config api-gateway
      edit 1
        config realservers
          edit 1
            set ip 172.16.200.44
          next
        end
      next
    end
  next
end

```

6. Configure the proxy policy to apply authentication and the security profile, selecting the appropriate user object depending on the user type:

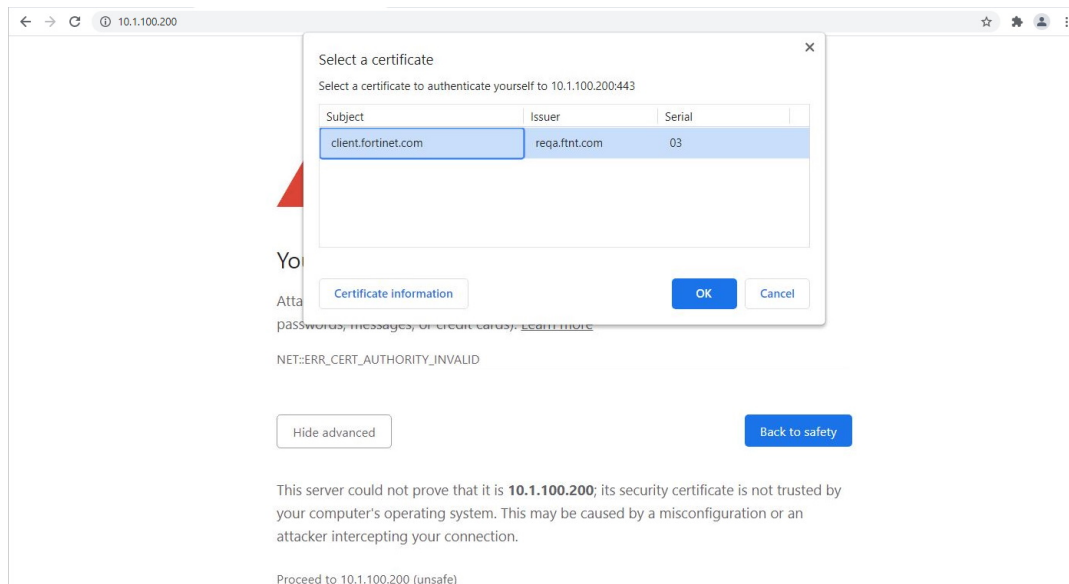

```

config firewall proxy-policy
  edit 3
    set proxy access-proxy
    set access-proxy "mTLS-access-proxy"
    set srcintf "port2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set users {"single-certificate" | "trusted-issuer"}
    set utm-status enable
    set ssl-ssh-profile "deep-inspection-clone"
    set av-profile "av"
  next
end

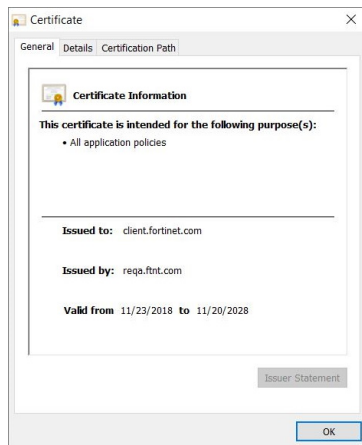

```

To verify the results:

1. In a web browser, access the VIP address. This example uses Chrome.
2. When prompted, select the client certificate, then click OK.

3. Click *Certificate information* to view details about the certificate.

4. On the FortiGate, check the traffic logs.

- If client certificate authentication passes:

```
1: date=2021-06-03 time=15:48:36 eventtime=1622760516866635697 tz="-0700"
logid="0000000010" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=45532 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=172.16.200.44 dstport=443
dstintf="vdom1" dstintfrole="undefined" sessionid=154900 service="HTTPS"
wanoptapptype="web-proxy" proto=6 action="accept" policyid=3 policytype="proxy-
policy" poluid="af5e2df2-c321-51eb-7d5d-42fa58868dcb" duration=0 user="single-
certificate" wanin=2550 rcvdbyte=2550 wanout=627 lanin=4113 sentbyte=4113 lanout=2310
appcat="unscanned"
```

- If the CA issuer is used to verify the client:

```
1: date=2021-06-03 time=15:43:02 eventtime=1622760182384776037 tz="-0700"
logid="0000000010" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=45514 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=10.1.100.200 dstport=443
dstintf="vdom1" dstintfrole="undefined" sessionid=153884 service="HTTPS"
```

```
wanoptapptype="web-proxy" proto=6 action="accept" policyid=3 policytype="proxy-policy" poluid="af5e2df2-c321-51eb-7d5d-42fa58868dcb" duration=0 user="trusted-issuer" wanin=0 rcvdbyte=0 wanout=0 lanin=4089 sentbyte=4089 lanout=7517 appcat="unscanned" utmaction="block" countweb=1 crscore=30 craction=8 utmref=65535-0
```

- If the client certificate authentication fails, and the traffic is blocked:

```
1: date=2021-06-03 time=15:45:53 eventtime=1622760353789703671 tz="-0700"
logid="0000000013" type="traffic" subtype="forward" level="notice" vd="vdom1"
srcip=10.1.100.11 srcport=45518 srcintf="port2" srcintfrole="undefined"
dstip=172.16.200.44 dstport=443 dstintf="vdom1" dstintfrole="undefined"
srccountry="Reserved" dstcountry="Reserved" sessionid=154431 proto=6 action="deny"
policyid=0 policytype="proxy-policy" user="single-certificate" service="HTTPS"
trandisp="noop" url="https://10.1.100.200/" agent="curl/7.68.0" duration=0 sentbyte=0
rcvdbyte=0 sentpkt=0 rcvdpkt=0 appcat="unscanned" crscore=30 craction=131072
crlevel="high" msg="Traffic denied because of explicit proxy policy"
```

Example 2

In this example, the same configuration as in [Example 1](#) is used, with a web proxy profile added to enable adding the client certificate to the HTTP header X-Forwarded-Client-Cert. The header is then forwarded to the server.

To configure the FortiGate:

1. Repeat steps 1 to 6 of [Example 1](#), using the common name on the certificate to verify the user.
2. Configure a web proxy profile that adds the HTTP x-forwarded-client-cert header in forwarded requests:

```
config web-proxy profile
  edit "mtls"
    set header-x-forwarded-client-cert add
  next
end
```

3. Configure the proxy policy to apply authentication, the security profile, and web proxy profile:

```
config firewall proxy-policy
  edit 3
    set uuid af5e2df2-c321-51eb-7d5d-42fa58868dcb
    set proxy access-proxy
    set access-proxy "mTLS-access-proxy"
    set srcintf "port2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set logtraffic all
    set users "single-certificate"
    set webproxy-profile "mtls"
    set utm-status enable
    set ssl-ssh-profile "deep-inspection-clone"
    set av-profile "av"
  next
end
```

To verify the results:

The WAD debug shows that the FortiGate adds the client certificate information to the HTTP header. The added header cannot be checked using the sniffer, because the FortiGate encrypts the HTTP header to forward it to the server.

1. Enable WAD debug on all categories:

```
# diagnose wad debug enable category all
```

2. Set the WAD debug level to verbose:

```
# diagnose wad debug enable level verbose
```

3. Enable debug output:

```
# diagnose debug enable
```

4. Check the debug output.

- When the FortiGate receives the client HTTP request:

```
[0x7fc8d4bc4910] Received request from client: 10.1.100.11:45544

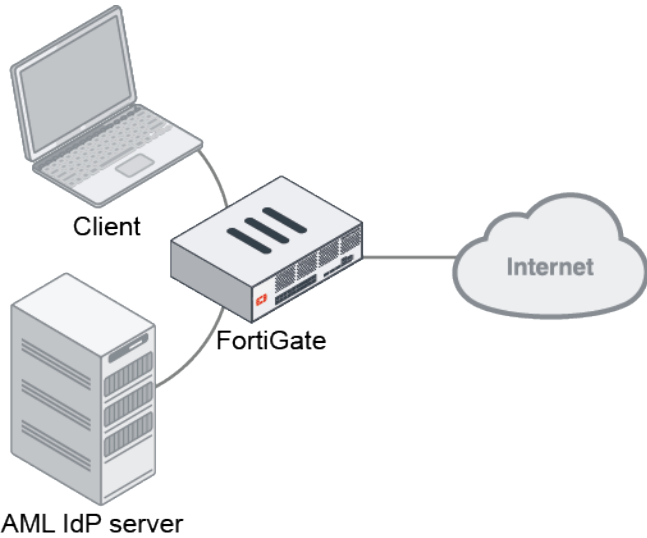

GET / HTTP/1.1
Host: 10.1.100.200
User-Agent: curl/7.68.0
Accept: */*
```

- When the FortiGate adds the client certificate in to the HTTP header and forwards the client HTTP request:

```
[0x7fc8d4bc4910] Forward request to server:
GET / HTTP/1.1
Host: 172.16.200.44
User-Agent: curl/7.68.0
Accept: */*
X-Forwarded-Client-Cert: -----BEGIN CERTIFICATE-----
MIIFXzCCA0egAwI...aCFHDHlR+wb39s=
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
MIIFpTCCA42gAwI...OtDtetkNoFLbvb
-----END CERTIFICATE-----
```

CORS protocol in explicit web proxy when using session-based, cookie-enabled, and captive portal-enabled SAML authentication

The FortiGate explicit web proxy supports the Cross-Origin Resource Sharing (CORS) protocol, which allows the FortiGate to process a CORS preflight request and an actual CORS request properly, in addition to a simple CORS request when using session-based, cookie-enabled, and captive portal-enabled SAML authentication. This allows a FortiGate explicit web proxy user with this specific configuration to properly view a web page requiring CORS with domains embedded in it other than its own domain.

To configure the FortiGate:

1. Configure the authentication rule:

```
config authentication rule
  edit "saml"
    set srcaddr "all"
    set ip-based disable
    set active-auth-method "saml"
    set web-auth-cookie enable
  next
end
```

2. Configure the captive portal:

```
config authentication setting
  set captive-portal "fgt9.myqalab.local"
end
```

3. Configure the proxy policy

```
config firewall proxy-policy
  edit 3
    set proxy explicit-web
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set logtraffic all
    set groups "ldap-group-saml"
    set utm-status enable
    set profile-protocol-options "protocol"
    set ssl-ssh-profile "deep-custom"
    set av-profile "av"
    set application-list "fff"
```

```

    next
end

```

CORS request scenarios

Preflight CORS request

The client sends the initial CORS preflight request (OPTIONS with the origin header) to the web server through FortiGate's web proxy and receives a CORS 200 OK response (with headers, such as Access-Control-Allow-Origin). The FortiGate will not redirect the client to the captive capital for authentication:

```

> OPTIONS /bidRequest HTTP/1.1
> Host: c2shb.pubgw.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Access-Control-Request-Method: GET
> Access-Control-Request-Headers: content-type,x-openrtb-version
> Origin: https://www.cnn.com
...
< HTTP/1.1 200 OK
< Date: Thu, 19 May 2022 01:49:17 GMT
< Content-Length: 0
< Server: ATS/9.1.0.46
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Methods: GET,POST,OPTIONS
< Access-Control-Allow-Headers: X-Requested-With,Content-Type,X-Openrtb-Version
< Access-Control-Allow-Credentials: true
< Access-Control-Max-Age: 600
< Age: 0
< Connection: keep-alive
< Set-Cookie: A3=d=AQABBB2ihWICEIUyD_Du5ol8tMdKKWxspR8FEgEBAQHzhmKPYgAAAAAA_
eMAAA&S=AQAAAAlU0dAheQx6euvcpS8ErK4I; Expires=Fri, 19 May 2023 07:49:17 GMT; Max-
Age=31557600; Domain=.yahoo.com; Path=/; SameSite=None; Secure; HttpOnly

```

Real CORS request

Once the initial preflight request for the client is successful, the client sends the real CORS request (GET request with origin header) to the FortiGate, The FortiGate then replies with a 30x response to redirect the client to the captive portal. The 30x response includes CORS headers such as Access-Control-Allow-Origin:

```

> GET /bidRequest HTTP/1.1
> Host: c2shb.pubgw.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Origin: https://www.cnn.com
...
< HTTP/1.1 303 See Other
< Access-Control-Max-Age: 1
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Credentials: true
< Set-Cookie: FTNT-EP-
FG900D3915800054=pqWlpdswdcCnpaWli6WlpcjEwszGmJbGksbBwMCVwcPBlpKRnMGTl52QxJeUwYPWl8aYlJWLlIu
ULZWLlJalpQ==; Path=/; Domain=.pubgw.yahoo.com; HttpOnly; SameSite=None; Secure
< Connection: close
< Content-Type: text/html

```

```

< Cache-Control: no-cache
< Location:
https://fgt9.myqalab.local:7831/test/saml/login/?cptype=ckauth&scheme=https&4Tmthd=0&host=c2
shb.pubgw.yahoo.com&port=443&rule=98&uri=L2JpZFJlcXVlc3Q=&cdata=pqWlpdswdcCnpaWli6WlpcjEwszG
mJbGksbBwMCVwcPB1pKRnMGT152QxJeUwYPW18aY1JWLL1IuU1ZWLL1JalpQ==
< Content-Length: 0

```

Redirection to captive portal

Once the client's real CORS request is redirected to the captive portal, the client sends another preflight to the captive portal. The captive portal then replies with a 20x response, which includes CORS headers such as `Access-Control-Allow-Origin`:

```

> OPTIONS
/test/saml/login/?cptype=ckauth&scheme=https&4Tmthd=1&host=gql.reddit.com&port=443&rule=98&u
ri=Lw==&cdata=pqWlpQM5dcCnpaWliqWlpcjEwszGmJbGksbAk5WT18aTwJDGnJ2T152QxpHDkYPW18aY1JWLL1IuU1Z
WLL1JGWpQ== HTTP/1.1
> Host: fgt9.myqalab.local:7831
> Connection: keep-alive
> Accept: */*
> Access-Control-Request-Method: GET
> Access-Control-Request-Headers: authorization,content-type,x-reddit-compression,x-reddit-
loid,x-reddit-session
> Origin: null
> User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64) AppleWebKit/537.36 (KHTML, like
Gecko) Chrome/100.0.4896.75 Safari/537.36 Edg/100.0.1185.36
> Sec-Fetch-Mode: cors
> Sec-Fetch-Site: cross-site
> Sec-Fetch-Dest: empty
> Referer: https://www.reddit.com/
> Accept-Encoding: gzip, deflate, br
> Accept-Language: en-US,en;q=0.9
...
< HTTP/1.1 204 No Content
< Access-Control-Max-Age: 86400
< Access-Control-Allow-Methods: GET
< Access-Control-Allow-Headers: authorization,content-type,x-reddit-compression,x-reddit-
loid,x-reddit-session
< Access-Control-Allow-Origin: null
< Access-Control-Allow-Credentials: true

```

Simple CORS request

If a simple CORS request (no preflight request sent before it) is used, when the FortiGate receives the simple request, it replies with a 30x response that includes CORS headers, such as `Access-Control-Allow-Origin`:

```

> Host: www.yahoo.com
> User-Agent: curl/7.61.1
> Accept: */*
> Origin: https://www.cnn.com
...
< HTTP/1.1 303 See Other
< Access-Control-Max-Age: 1
< Access-Control-Allow-Origin: https://www.cnn.com
< Access-Control-Allow-Credentials: true
< Set-Cookie: FTNT-EP-

```

```

```

DHCP servers and relays

A DHCP server dynamically assigns IP addresses to hosts on the network connected to the interface. The host computers must be configured to obtain their IP addresses using DHCP. You can configure one or more DHCP servers on any FortiGate interface.

A DHCP server can be in server or relay mode. In server mode, you can define one or more address ranges it assigns addresses from, and options such as the default gateway, DNS server, lease time, and other advanced options. In relay mode, the interface forwards DHCP requests from DHCP clients to an external DHCP server and returns the responses to the DHCP clients. The DHCP server must have appropriate routing so that its response packets to the DHCP clients arrive at the unit.

If an interface is connected to multiple networks through routers, you can add a DHCP server for each network. The IP range of each DHCP server must match the network address range. The routers must be configured for DHCP relay.

Default DHCP server for entry-level FortiGates

On entry-level FortiGates, a DHCP server is configured on the internal interface, by default, with the following values:

Field	Value
Address Range	192.168.1.110 to 192.168.1.210
Netmask	255.255.255.0
Default Gateway	192.168.1.99
Lease Time	7 days
DNS Server 1	192.168.1.99

These settings are appropriate for the default internal interface IP address of 192.168.1.99. If you change this address to a different network, you need to change the DHCP server settings to match.

- [Basic configuration on page 324](#)
- [DHCP options on page 327](#)
- [DHCP addressing mode on an interface on page 333](#)
- [Multiple DHCP relay servers on page 336](#)
- [FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses on page 338](#)

Basic configuration

The following contains information on basic configurations.

Configure a DHCP server on an interface

A DHCP server can be configured on an interface in the GUI from *Network > Interfaces*.

To configure a DHCP server in the GUI:

1. Go to *Network > Interfaces*.
2. Edit an interface.
3. Enable the *DHCP Server* option and configure the settings.
4. Click *OK*.

Field	Description
Address Range	By default, the FortiGate unit assigns an address range based on the address of the interface for the complete scope of the address. For example, if the interface address is 172.20.120.230, the default range created is 172.20.120.231 to 172.20.120.254. Select the range and select <i>Edit</i> to adjust the range or select <i>Create New</i> to add a different range.
Netmask	Enter the netmask of the addresses that the DHCP server assigns.
Default Gateway	Select this to use either <i>Same as Interface IP</i> or select <i>Specify</i> and enter the IP address of the default gateway that the DHCP server assigns to DHCP clients.
DNS Server	Select this to use <i>Same as system DNS</i> , <i>Same as Interface IP</i> or select <i>Specify</i> and enter the IP address of the DNS server.
Mode	Select the type of DHCP server FortiGate will be. By default, it is a <i>Server</i> . Select <i>Relay</i> if needed. When <i>Relay</i> is selected, the above configuration is replaced by a field to enter the <i>DHCP Server IP</i> address.
DHCP Server IP	This appears only when <i>Mode</i> is <i>Relay</i> . Enter the IP address of the DHCP server where FortiGate obtains the requested IP address.
Type	Select this to use the DHCP in <i>Regular</i> or <i>IPsec</i> mode.
Additional DHCP Options	Use this to create new DHCP options.
Add from DHCP Client List	If the client is currently connected and using an IP address from the DHCP server, you can select this option to select the client from the list.

To configure a DHCP server in the CLI:

```
config system dhcp server
  edit 1
    set dns-service default
    set default-gateway 192.168.1.2
    set netmask 255.255.255.0
```

```
set interface "port1"
config ip-range
  edit 1
    set start-ip 192.168.1.1
    set end-ip 192.168.1.1
  next
  edit 2
    set start-ip 192.168.1.3
    set end-ip 192.168.1.254
  next
end
set timezone-option default
set tftp-server "172.16.1.2"
next
end
```

Configure a DHCP relay on an interface

To configure a DHCP relay in the GUI:

1. Go to *Network > Interfaces*.
2. Edit an interface.
3. Expand the *Advanced* section and set *Mode* to *Relay*.
4. Enter the *DHCP Server IP*.
5. Click *OK*.

To configure a DHCP relay in the CLI:

1. Configure the interface, making sure to configure `set dhcp-relay-ip`:

```
config system interface
  edit "port2"
    set vdom "root"
    set dhcp-relay-service enable
    set ip 10.1.1.5 255.255.255.0
    set allowaccess ping https ssh fabric
    set type physical
    set snmp-index 4
    set dhcp-relay-ip "192.168.20.10"
  next
end
```

Configure a DHCP server and relay on an interface

A FortiGate interface can be configured to work in DHCP server mode to lease out addresses, and at the same time relay the DHCP packets to another device, such as a FortiNAC to perform device profiling.

The DHCP message to be forwarded to the relay server under the following conditions:

- `dhcp-relay-request-all-server` is enabled
- Message type is either `DHCPDISCOVER` or `DHCPINFORM`
- Client IP address in client message is 0
- Server ID is NULL in the client message

- Server address is a broadcast address (255.255.255.255)
- Server address is 0

Configuring a DHCP server and relay on the same interface is currently only supported in the CLI.

To configure a DHCP server and relay in the CLI:

1. Configure the interface:

```
config system interface
  edit "port2"
    set vdom "root"
    set dhcp-relay-service enable
    set ip 10.1.1.5 255.255.255.0
    set allowaccess ping https ssh fabric
    set type physical
    set snmp-index 4
    set dhcp-relay-ip "192.168.20.10"
    set dhcp-relay-request-all-server enable
  next
end
```

2. Configure the DHCP server settings:

```
config system dhcp server
  edit 17
    set status enable
    set dns-service default
    set default-gateway 10.1.1.5
    set netmask 255.255.255.0
    set interface "port2"
    config ip-range
      edit 1
        set start-ip 10.1.1.6
        set end-ip 10.1.1.254
      next
    end
  next
end
```

Excluding addresses in DHCP

If you have a large address range for the DHCP server, you can block a range of addresses that will not be included in the available addresses for the connecting users using the `config exclude-range` subcommand.

To exclude addresses in DHCP:

```
config system dhcp server
  edit <id>
    config exclude-range
      edit <sequence_number>
```

```

        set start-ip <address>
        set end-ip <address>
    next
end
next
end

```

Viewing information about DHCP server connections

To view information about DHCP server connections, go to *Dashboard > Network* and expand the *DHCP* monitor widget. On this page, you can also add IP addresses to the reserved IP address list.

DHCP options

When adding a DHCP server, you can include DHCP options. The DHCP options are BOOTP vendor information fields that provide additional vendor-independent configuration parameters to manage the DHCP server. For example, you might need to configure a FortiGate DHCP server that gives out a separate option as well as an IP address, such as an environment that needs to support PXE boot with Windows images. The *Option code* is specific to the application. The documentation for the application indicates the values to use. The *Option code* is a value between 1 and 255.

For detailed information about DHCP options, see [RFC 2132](#), DHCP Options and BOOTP Vendor Extensions.

The FortiOS DHCP server supports up to a maximum of 30 options per DHCP server. These optional fields can be set in either the GUI or CLI.

DHCP server options are not available in transparent mode.

The DHCP options include:

- [Common DHCP options on page 327](#)
- [Additional DHCP options on page 329](#)
- [IP address assignment with relay agent information option on page 331](#)

Common DHCP options

All FortiGate models come with predefined DHCP options. These DHCP options are widely used and required in most scenarios. The following DHCP options can be set straight from the *DHCP server* section of the *Edit Interface* dialog:

Option Code	Option Name	Purpose
*1	<i>Netmask</i>	Assign subnet mask to the DHCP client.
*3	<i>Default Gateway</i>	Assign default gateway to the DHCP client.
6	<i>DNS server</i>	Assign DNS server to the DHCP client.
42	<i>NTP server</i>	Assign NTP server to the DHCP client.
*51	<i>Lease time</i>	Lease time for the DHCP client.

Option Code	Option Name	Purpose
138	Wireless controllers	Assign CAPWAP Access Controller addresses to the DHCP client.
150	TFTP server(s)	Assign TFTP server to the DHCP client.

The parameter marked with an asterisk (*) are mandatory and must be filled in.

Configuring the lease time

This configuration implements DHCP option code 51. The global lease time (measured in seconds, 300 - 864000) determines the length of time an IP address remains assigned to a client. Once the lease expires, the address is released for allocation to the next client that requests an IP address.

To configure the global lease time:

```
config system dhcp server
  edit <id>
    set interface <interface>
    set netmask <netmask>
    set lease-time <integer>
  next
end
```

The default lease time is seven days (604800 seconds). To have an unlimited lease time, set the value to zero.

The lease time can also be configured in the GUI in the *Lease time* field within the *DHCP server* section of the *Edit Interface* dialog.

Breaking an address lease

If you need to end an IP address lease, you can break the lease. This is useful if you have limited addresses and longer lease times when some leases are no longer necessary, for example, with corporate visitors.

To break a lease:

```
# execute dhcp lease-clear <ip_address>
```

To break a lease for all IP addresses for the DHCP servers in the current VDOM:

```
# execute dhcp lease-clear all
```

Configuring NTP servers

This configuration implements DHCP option code 42. NTP server can be used by the client to synchronize their time which is very important as for many features to work, including scheduling, logging, and SSL-dependent features, the FortiOS system time must be accurate. This option specifies a list of the NTP servers available to the client by IP address.

To configure NTP servers:

```
config system dhcp server
  edit 2
```

```

    set ntp-service {local | default | specify}
    set ntp-server1 <class_ip>
    set ntp-server2 <class_ip>
    set ntp-server3 <class_ip>
  next
end

```

NTP servers can also be configured in the GUI in the *NTP server* field within the *DHCP server > Advanced* section of the *Edit Interface* dialog.

```

ntp-service {local |
default | specify}

```

Set the option for assigning NTP servers to DHCP clients:

- **local:** the IP address of the interface that the DHCP server is added to becomes the client's NTP server IP address.
- **default:** clients are assigned the FortiGate's configured NTP servers.
- **specify:** specify up to three NTP servers in the DHCP server configuration.

Configuring TFTP servers

This configuration implements DHCP option code 150. TFTP servers are used by VoIP phones to obtain the VoIP Configuration. You can configure multiple TFTP servers for a DHCP server. For example, you may want to configure a main TFTP server and a backup TFTP server.

The `tftp-server` command allows you to configure the TFTP servers, using either their hostnames or IP addresses. Separate multiple server entries with spaces.

To configure TFTP servers:

```

config system dhcp server
  edit <id>
    set interface <interface>
    set netmask <netmask>
    set tftp-server <hostname/IP address> <hostname/IP address>
  next
end

```

TFTP servers can also be configured in the GUI in the *TFTP server(s)* field within the *DHCP server > Advanced* section of the *Edit Interface* dialog.

Additional DHCP options

The FortiGate can be used to provide additional DHCP options that can be useful for different scenarios.

To configure the DHCP options in the GUI:

1. Go to *Network > Interfaces*, click *Create New* or *Edit* the existing interface.
2. Enable *DHCP Server*.
3. Expand the *Advanced* section and select *Create New* under *Additional DHCP options*.
4. Select a predefined *Option code* from the list or select *Specify* to enter a custom *Option code*.
5. Configure the rest of the parameters as required and click *OK* to save the options.
6. Click *OK* to save the setting.

To configure the DHCP options in the CLI:

```

config system dhcp server
  edit <id>
    config options
      edit <integer>
        set code <integer>
        set type {hex | string | ip | fqdn}
        set value <string>
      next
    end
  next
end

```

Variable	Description
code <integer>	DHCP client option code (0 - 255, default = 0). See Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) Parameters for a list of possible options.
type {hex string ip fqdn}	DHCP server option type (default = hex).
value <string>	DHCP server option value.
ip <ip address>	DHCP server option IP address. This option is only available when type is ip.

Example**To configure option 252 with value `http://192.168.1.1/wpad.dat`:**

```

config system dhcp server
  edit <id>
    config options
      edit <id>
        set code 252
        set type hex
        set value 687474703a2f2f3139322e3136382e312e312f777061642e646174
      next
    end
  next
end

```

In the example above, `687474703a2f2f3139322e3136382e312e312f777061642e646174` is the hexadecimal equivalent of the ASCII text `http://192.168.1.1/wpad.dat`.

Option 82

The DHCP relay agent information option (option 82 in [RFC 3046](#)) helps protect the FortiGate against attacks such as spoofing (forging) of IP addresses and MAC addresses, and DHCP IP address starvation.

This option is disabled by default. However, when `dhcp-relay-service` is enabled, `dhcp-relay-agent-option` becomes enabled.

To configure the DHCP relay agent option:

```

config system interface
  edit <interface>
    set vdom root
    set dhcp-relay-service enable
    set dhcp-relay-ip <ip>
    set dhcp-relay-agent-option enable
    set vlanid <id>
  next
end

```

See [IP address assignment with relay agent information option on page 331](#) for an example.

IP address assignment with relay agent information option

Option 82 (DHCP relay information option) helps protect the FortiGate against attacks such as spoofing (or forging) of IP and MAC addresses, and DHCP IP address starvation.

The following CLI variables are included in the `config system dhcp server > config reserved-address` command:

<code>circuit-id-type {hex string}</code>	DHCP option type; hex or string (default).
<code>circuit-id <value></code>	Option 82 circuit ID of the client that will get the reserved IP address. Format: <i>vlan-mod-port</i> <ul style="list-style-type: none"> vlan: VLAN ID (2 bytes) mod: 1 = snoop, 0 = relay (1 byte) port: port number (1 byte)
<code>remote-id-type {hex string}</code>	DHCP option type; hex or string (default).
<code>remote-id <value></code>	Option 82 remote ID of the client that will get the reserved IP address. Format: the MAC address of the client.
<code>type {mac option82}</code>	The DHCP reserved address type; mac (default) or option82.

To create an IP address assignment rule using option 82 in the GUI:

1. Go to *Network > Interfaces*.
2. Edit an existing port, or create a new one.

The port *Role* must be *LAN* or *Undefined*.

3. Enable *DHCP Server*.
4. Configure the address ranges and other settings as needed.
5. Click + to expand the *Advanced* options.

The screenshot shows the 'New Interface' configuration window in FortiGate. The 'DHCP Server' section is active, with 'DHCP status' set to 'Enabled'. The 'Address range' is '192.168.2.100-192.168.2.254' and the 'Netmask' is '255.255.255.0'. Under the 'Advanced' section, 'Mode' is 'Server' and 'Type' is 'Regular'. The 'Additional DHCP Options' table is visible at the bottom, with columns for Code, Type, and Value.

6. In the *IP Address Assignment Rules* table, click *Create New*. The *Create New IP Address Assignment Rule* pane opens.
7. Configure the new rule:
 - a. For the *Type*, select *DHCP Relay Agent*.
 - b. Enter the *Circuit ID* and *Remote ID*.
 - c. Enter the *IP* address that will be reserved.

8. Click **OK**.

To create an IP address assignment rule using option 82 with the CLI:

```
config system dhcp server
  edit 1
    set netmask 255.255.255.0
    set interface "port4"
    config ip-range
      edit 1
        set start-ip 192.168.2.100
        set end-ip 192.168.2.254
      next
    end
    config reserved-address
      edit 1
        set type option82
        set ip 192.168.2.100
        set circuit-id-type hex
        set circuit-id "00010102"
        set remote-id-type hex
        set remote-id "704ca5e477d6"
      next
    end
  next
end
```

DHCP addressing mode on an interface

Any FortiGate interface can be configured to obtain an IP address dynamically using DHCP. If you configure DHCP on an interface on the FortiGate, the FortiGate automatically broadcasts a DHCP request from the interface. The interface is configured with the IP address, any DNS server addresses, and the default gateway address that the DHCP server provides.

Configuring an Interface as a DHCP Client

You can configure interface as a DHCP client.

To configure an interface as a DHCP client in the GUI:

1. Go to *Network > Interfaces*.
2. Edit an interface.
3. Select the *DHCP* option in the *Addressing mode*.
4. Configure the rest of the setting as required.
5. Click *OK*.

The following table describes the DHCP status information when DHCP is configured for an interface.

Field	Description
Status	<p>Displays DHCP status messages as the interface connects to the DHCP server and gets addressing information.</p> <p>Status can be one of the following values:</p> <ul style="list-style-type: none"> • <i>Initializing</i>: No activity. • <i>Connecting</i>: Interface attempts to connect to the DHCP server. • <i>Connected</i>: Interface retrieves an IP address, netmask, and other settings from the DHCP server. • <i>Failed</i>: Interface was unable to retrieve an IP address and other settings from the DHCP server.
Obtained IP/Netmask	The IP address and netmask leased from the DHCP server. This is only displayed if the <i>Status</i> is <i>Connected</i> .
Renew	Select this to renew the DHCP license for this interface. This is only displayed if the <i>Status</i> is <i>Connected</i> .
Expiry Date	The time and date when the leased IP address and netmask is no longer valid for the interface. The IP address is returned to the pool to be allocated to the next user request for an IP address. This is only displayed if the <i>Status</i> is <i>Connected</i> .
Default Gateway	The IP address of the gateway defined by the DHCP server. This is displayed only if the <i>Status</i> is <i>Connected</i> , and if <i>Retrieve default gateway from server</i> is enabled.
Acquired DNS	The DNS server IP defined by the DHCP server. This is displayed only if the <i>Status</i> is <i>Connected</i> .
Retrieve default gateway from server	Enable this to retrieve a default gateway IP address from the DHCP server. The default gateway is added to the static routing table.
Distance	Enter the administrative distance for the default gateway retrieved from the DHCP server. The administrative distance is an integer from 1 to 255, and specifies the relative priority of a route when there are multiple routes to the same destination. A lower administrative distance indicates a more preferred route.
Override internal DNS	<p>Enable this to use the DNS addresses retrieved from the DHCP server instead of the DNS server IP addresses on the DNS page.</p> <p>When VDOMs are enabled, you can override the internal DNS only on the management VDOM.</p>

To configure an interface as a DHCP client in the CLI:

```
config system interface
  edit <name>
    set mode dhcp
    set defaultgw {enable | disable}
    set distance <integer>
    set dns-server-override {enable | disable}
  next
end
```

Configuring the DHCP renew time

You can set a minimum DHCP renew time for an interface acting as a DHCP client. This option is available only when mode is set to DHCP.

To set the DHCP renew time:

```
config system interface
  edit <name>
    set vdom <vdom>
    set interface <interface>
    set mode dhcp
    set dhcp-renew-time <integer>
  next
end
```

The possible values for `dhcp-renew-time` are 300 to 605800 seconds (five minutes to seven days). To use the renew time that the server provides, set this entry to 0.

DHCP client options

When an interface is in DHCP addressing mode, DHCP client options can be configured in the CLI. For example, a vendor class identifier (usually DHCP client option 60) can be specified so that a request can be matched by a specific DHCP offer.

Multiple options can be configured, but any options not recognized by the DHCP server are discarded.

To configure client option 60 - vendor class identifier:

```
config system interface
  edit port1
    set vdom vdom1
    set mode dhcp
    config client-options
      edit 1
        set code 60
        set type hex
        set value aabbccdd
      next
    end
    set type physical
    set snmp-index 4
```

```

next
end

```

Variable	Description
code <integer>	DHCP client option code (0 - 255, default = 0). See Dynamic Host Configuration Protocol (DHCP) and Bootstrap Protocol (BOOTP) Parameters for a list of possible options.
type {hex string ip fqdn}	DHCP client option type (default = hex).
value <string>	DHCP client option value.
ip <ip>	DHCP client option IP address. This option is only available when type is ip.

Multiple DHCP relay servers

Multiple DHCP relays can be configured on an interface. After receiving a DHCP request from a client, the FortiGate forwards it to all configured servers simultaneously without waiting for any response. Each server sends back an IP address for the client, but the client usually uses the IP address from the first response that it receives.

This allows the FortiGate to forward DHCP requests to all configured servers simultaneously, reducing wait times and potential bottlenecks.

```

config system interface
  edit <name>
    set dhcp-relay-service {enable | disable}
    set dhcp-relay-ip <ip-address>
  next
end

```

Example

In this example, two DHCP relay servers are configured on port2, with DHCP relay IP addresses 10.1.1.1 and 10.2.2.1.

To configure the DHCP relay servers:

```

config system interface
  edit "port2"
    set dhcp-relay-service enable
    set dhcp-relay-ip 10.1.1.1 10.2.2.1
  next
end

```

To check the debug messages to verify that the DHCP relay is working:

```
# diagnose debug application dhcprelay -1

Debug messages will be on for 30 minutes.
# (xid:d7d00b58) L2 socket: received request message from 0.0.0.0:68 to 255.255.255.255 at
port2
(xid:d7d00b58) got a DHCPDISCOVER
(xid:d7d00b58) Warning! can't get server id from client message
Insert option(82), len(7)
found route to 10.1.1.1 via 10.1.1.254 iif=6 oif=9/port3, mode=auto, ifname=
(xid:d7d00b58) forwarding dhcp request from 10.10.10.12:67 to 10.1.1.1:67
found route to 10.2.2.1 via 10.2.2.254 iif=6 oif=11/port4, mode=auto, ifname=
(xid:d7d00b58) forwarding dhcp request from 10.10.10.12:67 to 10.2.2.1:67
(xid:d7d00b58) got a DHCPOFFER
(xid:d7d00b58) from server 10.1.1.1
(xid:d7d00b58) sending dhcp reply from 10.10.10.12:67 to 255.255.255.255:68
(xid:d7d00b58) L2 socket: received request message from 0.0.0.0:68 to 255.255.255.255 at
port2
(xid:d7d00b58) got a DHCPREQUEST
Insert option(82), len(7)
found route to 10.1.1.1 via 10.1.1.254 iif=6 oif=9/port3, mode=auto, ifname=
(xid:d7d00b58) forwarding dhcp request from 10.10.10.12:67 to 10.1.1.1:67
found route to 10.2.2.1 via 10.2.2.254 iif=6 oif=11/port4, mode=auto, ifname=
(xid:d7d00b58) forwarding dhcp request from 10.10.10.12:67 to 10.2.2.1:67
(xid:d7d00b58) got a DHCPOFFER
(xid:d7d00b58) from server 10.2.2.1
(xid:d7d00b58) sending dhcp reply from 10.10.10.12:67 to 255.255.255.255:68
(xid:d7d00b58) got a DHCPACK
(xid:d7d00b58) from server 10.1.1.1
(xid:d7d00b58) sending dhcp reply from 10.10.10.12:67 to 255.255.255.255:68
```

The debug output shows the following information:

got a DHCPDISCOVER forwarding dhcp request from 10.10.10.12:67 to 10.1.1.1:67 forwarding dhcp request from 10.10.10.12:67 to 10.2.2.1:67	FortiGate received a DHCPDISCOVER message from the DHCP client and forwarded it to both DHCP servers.
got a DHCPOFFER from server 10.1.1.1	FortiGate received a DHCPOFFER message from server 10.1.1.1.
got a DHCPREQUEST forwarding dhcp request from 10.10.10.12:67 to 10.1.1.1:67 forwarding dhcp request from 10.10.10.12:67 to 10.2.2.1:67	FortiGate received a DHCPREQUEST message from the client and forwarded it to both servers again.
got a DHCPOFFER from server 10.2.2.1	FortiGate received another DHCPOFFER message from server 10.2.2.1.
got a DHCPACK from server 10.1.1.1	FortiGate received a DHCPACK message from server 10.1.1.1. Because the DHCP server 10.1.1.1 was the first to send response, the client accepts the DHCP configuration from this server.

FortiGate DHCP works with DDNS to allow FQDN connectivity to leased IP addresses

As clients are assigned IP addresses, they send back information that would be found in an A record to the FortiGate DHCP server, which can take this information and pass it back to a corporate DNS server so that even devices using leased IP address can be reached using FQDNs. You can configure the settings for this feature using the `ddns-update` CLI command and some other DDNS related options. Please refer to *DDNS update override* in the [DDNS on page 239](#) topic for further details.

Static routing

Static routing is one of the foundations of firewall configuration. It is a form of routing in which a device uses manually-configured routes. In the most basic setup, a firewall will have a default route to its gateway to provide network access. In a more complex setup with dynamic routing, ADVPN, or SD-WAN involved, you would still likely find static routes being deployed.

This section explores concepts in using static routing and provides examples in common use cases:

- [Routing concepts on page 339](#)
- [Policy routes on page 351](#)
- [Equal cost multi-path on page 353](#)
- [Dual internet connections on page 357](#)

The following topics include additional information about static routes:

- [Reverse path look-up on page 347](#)
- [Asymmetric routing on page 348](#)
- [Routing changes on page 350](#)

Default route

The default route has a destination of `0.0.0.0/0.0.0.0`, representing the least specific route in the routing table. It is a catch all route in the routing table when traffic cannot match a more specific route. Typically this is configured with a static route with an administrative distance of `10`. In most instances, you will configure the next hop interface and the gateway address pointing to your next hop. If your FortiGate is sitting at the edge of the network, your next hop will be your ISP gateway. This provides internet access for your network.

Sometimes the default route is configured through DHCP. On some entry-level models, the WAN interface is preconfigured in DHCP mode. Once the WAN interface is plugged into the network modem, it will receive an IP address, default gateway, and DNS server. FortiGate will add this default route to the routing table with a distance of `5`, by default. This will take precedence over any default static route with a distance of `10`. Therefore, take caution when you are configuring an interface in DHCP mode, where *Retrieve default gateway from server* is enabled. You may disable it and/or change the distance from the *Network > Interfaces* page when you edit an interface.

Adding or editing a static route

To add a static route using the GUI:

1. Go to *Network > Static Routes* and click *Create New*.
2. Enter the following information:

Dynamic Gateway	When enabled, a selected DHCP/PPPoE interface will automatically retrieve its dynamic gateway.
Destination	<ul style="list-style-type: none"> • Subnet Enter the destination IP address and netmask. A value of <code>0.0.0.0/0.0.0.0</code> creates a default route. • Named Address Select an address or address group object. Only addresses with static

	<p>route configuration enabled will appear on the list. This means a geography type address cannot be used.</p> <ul style="list-style-type: none"> • Internet Service <p>Select an Internet Service. These are known IP addresses of popular services across the Internet.</p>
Interface	Select the name of the interface that the static route will connect through.
Gateway Address	Enter the gateway IP address. When selecting an IPsec VPN interface or SD-WAN creating a blackhole route, the gateway cannot be specified.
Administrative Distance	Enter the distance value, which will affect which routes are selected first by different protocols for route management or load balancing. The default is 10.
Advanced Options	Optionally, expand <i>Advanced Options</i> and enter a <i>Priority</i> . When two routes have an equal distance, the route with a lower priority number will take precedence. The default is 1.

3. Click *OK*.

Configuring FQDNs as a destination address in static routes

You can configure FQDN firewall addresses as destination addresses in a static route, using either the GUI or the CLI.

In the GUI, to add an FQDN firewall address to a static route in the firewall address configuration, enable the *Static Route Configuration* option. Then, when you configure the static route, set *Destination* to *Named Address*.

To configure an FQDN as a destination address in a static route using the CLI:

```
config firewall address
  edit 'Fortinet-Documentation-Website'
    set type fqdn
    set fqdn docs.fortinet.com
    set allow-routing enable
  next
end

config router static
  edit 0
    set dstaddr Fortinet-Documentation-Website
    ...
  next
end
```

Routing table

A routing table consists of only the best routes learned from the different routing protocols. The most specific route always takes precedence. If there is a tie, then the route with a lower administrative distance will be injected into the routing table. If administrative distances are also equal, then all the routes are injected into the routing table, and *Cost* and *Priority* become the deciding factors on which a route is preferred. If these are also equal, then FortiGate will use [Equal cost multi-path on page 353](#) to distribute traffic between these routes.

Viewing the routing table in the GUI

You can view routing tables in the FortiGate GUI under *Dashboard > Network > Static & Dynamic Routing* by default. Expand the widget to see the full page. Additionally, if you want to convert the widget into a dashboard, click on the *Save as Monitor* icon on the top right of the page.

You can also monitor policy routes by toggling from *Static & Dynamic* to *Policy* on the top right corner of the page. The active policy routes include policy routes that you created, SD-WAN rules, and Internet Service static routes. It also supports downstream devices in the Security Fabric.

The following figure show an example of the static and dynamic routes in the Routing Monitor:

To view more columns, right-click on the column header to select the columns to be displayed:

Field	Description
IP Version	Shows whether the route is IPv4 or IPv6.
Network	The IP addresses and network masks of destination networks that the FortiGate can reach.
Gateway IP	The IP addresses of gateways to the destination networks.
Interfaces	The interface through which packets are forwarded to the gateway of the destination network.
Distance	The administrative distance associated with the route. A lower value means the route is preferable compared to other routes to the same destination.
Type	<p>The type values assigned to FortiGate routes (Static, Connected, RIP, OSPF, or BGP):</p> <ul style="list-style-type: none"> Connected: All routes associated with direct connections to FortiGate interfaces Static: The static routes that have been added to the routing table manually RIP: All routes learned through RIP RIPNG: All routes learned through RIP version 6 (which enables the sharing of routes through IPv6 networks) BGP: All routes learned through BGP OSPF: All routes learned through OSPF OSPF6: All routes learned through OSPF version 6 (which enables the sharing of routes through IPv6 networks) IS-IS: All routes learned through IS-IS HA: RIP, OSPF, and BGP routes synchronized between the primary unit and the

Field	Description
	subordinate units of a high availability (HA) cluster. HA routes are maintained on subordinate units and are visible only if you're viewing the router monitor from a virtual domain that is configured as a subordinate virtual domain in a virtual cluster.
Metric	The metric associated with the route type. The metric of a route influences how the FortiGate dynamically adds it to the routing table. The following are types of metrics and the protocols they are applied to: <ul style="list-style-type: none"> • <i>Hop count</i>: Routes learned through RIP • <i>Relative cost</i>: Routes learned through OSPF • <i>Multi-Exit Discriminator (MED)</i>: Routes learned through BGP. By default, the MED value associated with a BGP route is zero. However, the MED value can be modified dynamically. If the value was changed from the default, the Metric column displays a non-zero value.
Priority	In static routes, priorities are 0 by default. When two routes have an equal distance, the route with the lower priority number will take precedence.
VRF	Virtual routing and forwarding (VRF) allows multiple routing table instances to co-exist. VRF can be assigned to an Interface. Packets are only forwarded between interfaces with the same VRF.
Up Since	The total accumulated amount of time that a route learned through RIP, OSPF, or BGP has been reachable.

Viewing the routing table in the CLI

Viewing the routing table using the CLI displays the same routes as you would see in the GUI.

If VDOMs are enabled on the FortiGate, all routing-related CLI commands must be run within a VDOM and not in the global context.

To view the routing table using the CLI:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
* - candidate default
Routing table for VRF=0
S*    0.0.0.0/0 [1/0] via 172.31.0.1, MPLS [1/0]via 192.168.2.1, port1 [1/0] via
192.168.122.1, port2
S     1.2.3.4/32 [10/0] via 172.16.100.81, VLAN100
C     10.10.2.0/24 is directly connected, hub
C     10.10.2.1/32 is directly connected, hub
O     10.10.10.0/24 [110/101] via 192.168.2.1, port1, 01:54:18
C     10.253.240.0/20 is directly connected, wqt.root
S     110.2.2.122/32 [22/0] via 2.2.2.2, port2, [3/3]
C     172.16.50.0/24 is directly connected, WAN1-VLAN50
```

```

C      172.16.60.0/24 is directly connected, WAN2-VLAN60
C      172.16.100.0/24 is directly connected, VLAN100
C      172.31.0.0/30 is directly connected, MPLS
C      172.31.0.2/32 is directly connected, MPLS
B      192.168.0.0/24 [20/0] via 172.31.0.1, MPLS, 00:31:43
C      192.168.2.0/24 is directly connected, port1
C      192.168.20.0/24 is directly connected, port3
C      192.168.99.0/24 is directly connected, Port1-VLAN99
C      192.168.122.0/24 is directly connected, port2
Routing table for VRF=10
C      172.16.101.0/24 is directly connected, VLAN101

```

Examining an entry:

```
B      192.168.0.0/24 [20/0] via 172.31.0.1, MPLS, 00:31:43
```

Value	Description
B	BGP. The routing protocol used.
192.168.0.0/24	The destination of this route, including netmask.
[20/0]	20 indicates an administrative distance of 20 out of a range of 0 to 255. 0 is an additional metric associated with this route, such as in OSPF.
172.31.0.1	The gateway or next hop.
MPLS	The interface that the route uses.
00:31:43	The age of the route in HH:MM:SS.

Viewing the routing database

The routing database consists of all learned routes from all routing protocols before they are injected into the routing table. This likely lists more routes than the routing table as it consists of routes to the same destinations with different distances. Only the best routes are injected into the routing table. However, it is useful to see all learned routes for troubleshooting purposes.

To view the routing database using the CLI:

```

# get router info routing-table database
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
     E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       > - selected route, * - FIB route, p - stale info
Routing table for VRF=0
S    *> 0.0.0.0/0 [1/0] via 172.31.0.1, MPLS
      *>          [1/0] via 192.168.2.1, port1
      *>          [1/0] via 192.168.122.1, port2
S    *> 1.2.3.4/32 [10/0] via 172.16.100.81, VLAN100
C    *> 10.10.2.0/24 is directly connected, hub

```

```

C    *> 10.10.2.1/32 is directly connected, hub
O    *> 10.10.10.0/24 [110/101] via 192.168.2.1, port1, 02:10:17
C    *> 10.253.240.0/20 is directly connected, wqt.root
S    *> 110.2.2.122/32 [22/0] via 2.2.2.2, port2, [3/3]
C    *> 172.16.50.0/24 is directly connected, WAN1-VLAN50
C    *> 172.16.60.0/24 is directly connected, WAN2-VLAN60
C    *> 172.16.100.0/24 is directly connected, VLAN100
O    172.31.0.0/30 [110/201] via 192.168.2.1, port1, 00:47:36
C    *> 172.31.0.0/30 is directly connected, MPLS

```

Selected routes are marked by the > symbol. In the above example, the OSPF route to destination 172.31.0.0/30 is not selected.

Kernel routing table

The kernel routing table makes up the actual Forwarding Information Base (FIB) that used to make forwarding decisions for each packet. The routes here are often referred to as kernel routes. Parts of this table are derived from the routing table that is generated by the routing daemon.

To view the kernel routing table using the CLI:

```

# get router info kernel
tab=254 vf=0 scope=0 type=1 proto=11 prio=0 0.0.0.0/0.0.0.0/0->0.0.0.0/0 pref=0.0.0.0
    gwy=172.31.0.1 flag=04 hops=0 oif=31(MPLS)
    gwy=192.168.2.1 flag=04 hops=0 oif=3(port1)
    gwy=192.168.122.1 flag=04 hops=0 oif=4(port2)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.122.98/255.255.255.255/0->1.1.1.1/32
pref=0.0.0.0 gwy=192.168.122.1 dev=4(port2)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 172.31.0.2/255.255.255.255/0->1.1.1.1/32
pref=0.0.0.0 gwy=172.31.0.1 dev=31(MPLS)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.2.5/255.255.255.255/0->1.1.1.1/32
pref=0.0.0.0 gwy=192.168.2.1 dev=3(port1)
tab=254 vf=0 scope=0 type=1 proto=11 prio=0 0.0.0.0/0.0.0.0/0->1.2.3.4/32 pref=0.0.0.0
gwy=172.16.100.81 dev=20(VLAN100)
tab=254 vf=0 scope=0 type=1 proto=17 prio=0 192.168.122.98/255.255.255.255/0->8.8.8.8/32
pref=0.0.0.0 gwy=192.168.122.1 dev=4(port2)

```

The kernel routing table entries are:

Value	Description
tab	Table number: It will either be 254 (unicast) or 255 (multicast).
vf	Virtual domain of the firewall: It is the VDOM index number. If VDOMs are not enabled, this number is 0.
type	Type of routing connection. Valid values include: <ul style="list-style-type: none"> 0 - unspecified 1 - unicast 2 - local 3 - broadcast 4 - anycast 5 - multicast

Value	Description
	<ul style="list-style-type: none"> • 6 - blackhole • 7 - unreachable • 8 - prohibited
proto	Type of installation that indicates where the route came from. Valid values include: <ul style="list-style-type: none"> • 0 - unspecific • 2 - kernel • 11 - ZebOS routing module • 14 - FortiOS • 15 - HA • 16 - authentication based • 17 - HA1
prio	Priority of the route. Lower priorities are preferred.
->0.0.0.0/0 (->x.x.x.x/mask)	The IP address and subnet mask of the destination.
pref	Preferred next hop along this route.
gwy	Gateway: The address of the gateway this route will use.
dev	Outgoing interface index: This number is associated with the interface for this route. If VDOMs are enabled, the VDOM is also included here. If an interface alias is set for this interface, it is also displayed here.

Route cache

The route cache contains recently used routing entries in a table. It is consulted before the routing table to speed up the route look-up process.

To view the route cache using the CLI:

```
# diagnose ip rtcache list
family=02 tab=254 vrf=0 vf=0 type=01 tos=0 flag=00000200
0.0.0.0@0->208.91.113.230@3(port1) gwy=192.168.2.1 prefsrc=192.168.2.5
ci: ref=0 lastused=1 expire=0 err=00000000 used=5 br=0 pmtu=1500

family=02 tab=254 vrf=0 vf=0 type=01 tos=0 flag=00000200
192.168.2.5@0->8.8.8.8@3(port1) gwy=192.168.2.1 prefsrc=0.0.0.0
ci: ref=0 lastused=0 expire=0 err=00000000 used=2 br=0 pmtu=1500

family=02 tab=254 vrf=0 vf=0 type=02 tos=8 flag=80000200
8.8.8.8@31(MPLS)->172.31.0.2@6(root) gwy=0.0.0.0 prefsrc=172.31.0.2
ci: ref=1 lastused=0 expire=0 err=00000000 used=0 br=0 pmtu=16436

family=02 tab=254 vrf=0 vf=0 type=02 tos=0 flag=84000200
192.168.20.6@5(port3)->192.168.20.5@6(root) gwy=0.0.0.0 prefsrc=192.168.20.5
```

```
ci: ref=2 lastused=0 expire=0 err=00000000 used=1 br=0 pmtu=16436
...
```

The size of the route cache is calculated by the kernel, but can be modified.

To modify the size of the route cache:

```
config system global
    set max-route-cache-size <number_of_cache_entries>
end
```

Route look-up

Route look-up typically occurs twice in the life of a session. Once when the first packet is sent by the originator and once more when the first reply packet is sent from the responder. When a route look-up occurs, the routing information is written to the session table and the route cache. If routing changes occur during the life of a session, additional routing look-ups may occur.

FortiGate performs a route look-up in the following order:

1. Policy-based routes: If a match occurs and the action is to forward, traffic is forwarded based on the policy route.
2. Route Cache: If there are no matches, FortiGate looks for the route in the route cache.
3. Forwarding Information Base, otherwise known as the kernel routing table.
4. If no match occurs, the packet is dropped.

Searching the routing table

When there are many routes in your routing table, you can perform a quick search by using the search bar to specify your criteria, or apply filters on the column header to display only certain routes. For example, if you want to only display static routes, you may use "static" as the search term, or filter by the *Type* field with value *Static*.

Route look-up on the other hand provides a utility for you to enter criteria such as *Destination*, *Destination Port*, *Source*, *Protocol* and/or *Source Interface*, in order to determine the route that a packet will take. Once you click *Search*, the corresponding route will be highlighted.

You can also use the CLI for a route look-up. The CLI provides a basic route look-up tool.

To look-up a route in the CLI:

```
# get router info routing-table details 4.4.4.4
Routing table for VRF=0
Routing entry for 0.0.0.0/0
    Known via "static", distance 1, metric 0, best
    * 172.31.0.1, via MPLS distance 0
    * 192.168.2.1, via port1 distance 0
    * 192.168.122.1, via port2 distance 0
```

Blackhole routes

Sometimes upon routing table changes, it is not desirable for traffic to be routed to a different gateway. For example, you may have traffic destined for a remote office routed through your IPsec VPN interface. When the VPN is down, traffic will try to re-route to another interface. However, this may not be viable and traffic will instead be routed to your default route

through your WAN, which is not desirable. Traffic may also be routed to another VPN, which you do not want. For such scenarios, it is good to define a blackhole route so that traffic is dropped when your desired route is down. Upon reconnection, your desired route is once again added to the routing table and your traffic will resume routing to your desired interface. For this reason, blackhole routes are created when you configure an IPsec VPN using the IPsec wizard.

For FortiOS 7.0.1 to 7.0.12, SSL VPN web mode, explicit web proxy, and interface mode IPsec VPN features will not work with the following configuration:

1. An IP pool with ARP reply enabled is configured.
2. This IP pool is configured as the source IP address in a firewall policy for SSL VPN web mode, in a proxy policy for explicit web proxy, or as the local gateway in the Phase 1 settings for an interface mode IPsec VPN.
3. A matching blackhole route is configured for IP pool reply traffic.

Configuring an IP pool as the source NAT IP address in a regular firewall policy works as before.

For details, see [Technical Tip: IP pool and virtual IP behaviour changes in FortiOS 6.4, 7.0, 7.2, and 7.4](#).

To create a blackhole route in the GUI:

1. Go to *Network > Static Routes*.
2. Click *Create New*. The *New Static Route* screen appears.
3. Specify a *Destination* type.
4. Select *Blackhole* from the *Interface* field.
5. Type the desired *Administrative Distance*.
6. Click *OK*.

Route priority for a *Blackhole* route can only be configured from the CLI.

Reverse path look-up

Whenever a packet arrives at one of the interfaces on a FortiGate, the FortiGate determines whether the packet was received on a legitimate interface by doing a reverse look-up using the source IP address in the packet header. This protects against IP spoofing attacks. If the FortiGate does not have a route to the source IP address through the interface on which the packet was received, the FortiGate drops the packet as per Reverse Path Forwarding (RPF) check. There are two modes of RPF – feasible path and strict. The default feasible RPF mode checks only for the existence of at least one active route back to the source using the incoming interface. The strict RPF check ensures the best route back to the source is used as the incoming interface.

To configure a strict Reverse Path Forwarding check in the CLI:

```
config system settings
  set strict-src-check enable
```

```
end
```

You can remove RPF state checks without needing to enable asymmetric routing by disabling state checks for traffic received on specific interfaces. Disabling state checks makes a FortiGate less secure and should only be done with caution for troubleshooting purposes.

To remove Reverse Path Forwarding checks from the state evaluation process in the CLI:

```
config system interface
  edit <interface_name>
    set src-check disable
  next
end
```

Asymmetric routing

Asymmetric routing occurs when request and response packets follow different paths that do not cross the same firewall.

In the following topology, traffic between PC1 and PC2 takes two different paths.

Traffic from PC1 to PC2 goes through the FortiGate, while traffic from PC2 to PC1 does not.

In TCP, if the packets in the request and response directions follow different paths, the FortiGate will block the packets, since the TCP three-way handshake is not established through the FortiGate.

Scenario 1: PC1 starts a TCP connection with PC2

1. The TCP SYN is allowed by the FortiGate.
2. The TCP SYN/ACK bypasses the FortiGate.
3. The TCP ACK is blocked by the FortiGate.
4. Subsequent TCP packets are blocked by the FortiGate.

Scenario 2: PC2 starts a TCP connection with PC1

1. The TCP SYN bypasses the FortiGate.
2. The TCP SYN/ACK is blocked by the FortiGate.
3. Subsequent TCP packets are blocked by the FortiGate.

In ICMP, consider the following scenarios.

Scenario 1: PC1 pings PC2

1. The ICMP request passes through the FortiGate. A session is created.
2. The ICMP reply bypasses the FortiGate, but reaches PC1. The ping is successful.

3. The ICMP request passes through the FortiGate, and it matches the previous session.
4. The ICMP reply bypasses the FortiGate, but it reaches PC1. The ping is successful.
5. Subsequent ICMP requests are allowed by the FortiGate.

Scenario 2: PC2 pings PC1

1. The ICMP request bypasses the FortiGate, but it reaches PC1.
2. The ICMP reply passes through the FortiGate. No session is matched, and the packet is dropped.
3. Subsequent ICMP replies are blocked by the FortiGate.

If an ICMP request does not pass through the FortiGate, but the response passes through the FortiGate, then by default it blocks the packet as invalid.

Permitting asymmetric routing

If required, the FortiGate can be configured to permit asymmetric routing.

To permit asymmetric routing:

```
config system settings
    set asymroute enable
end
```

This setting should be used only when the asymmetric routing issue cannot be resolved by ensuring both directions of traffic pass through the FortiGate.

When asymmetric routing is enabled and occurs, the FortiGate cannot inspect all traffic. Potentially malicious traffic may pass through and compromise the security of the network.

Asymmetric routing behaves as follows when it is permitted by the FortiGate:

TCP packets

Scenario 1: PC1 starts a TCP connection with PC2

1. The TCP SYN is allowed by the FortiGate. The FortiGate creates a session, checks the firewall policies, and applies the configuration from the matching policy (UTM inspection, NAT, traffic shaping, and so on).
2. The TCP SYN/ACK bypasses the FortiGate.
3. The TCP ACK is allowed by the FortiGate. The packet matches the previously created session.
4. Subsequent TCP packets are allowed by the FortiGate. The packets in the session can also be offloaded where applicable.

Scenario 2: PC2 starts a TCP connection with PC1

1. The TCP SYN bypasses the FortiGate.
2. The TCP SYN/ACK is allowed by the FortiGate. No session is matched. The packet passes to the CPU and is forwarded based on the routing table.
3. The TCP ACK bypasses the FortiGate.
4. Subsequent TCP packets are allowed by the FortiGate. The FortiGate acts as a router that only makes routing decisions. No security inspection is performed.

ICMP packets

Scenario 1: PC1 pings PC2

1. There is no difference from when asymmetric routing is disabled.

Scenario 2: PC2 pings PC1

1. The ICMP request bypasses the FortiGate, but it reaches PC1.
2. The ICMP reply passes through the FortiGate. No session is matched. The packet passes to the CPU and is forwarded based on the routing table.
3. Subsequent ICMP replies are allowed by the FortiGate. The FortiGate acts as a router that only makes routing decisions. No security inspection is performed.

UDP packets

Asymmetric routing does not affect UDP packets. UDP packets are checked by the session table regardless of asymmetric routing. A policy is required to allow UDP.

Routing changes

When routing changes occur, routing look-up may occur on an existing session depending on certain configurations.

Routing changes without SNAT

When a routing change occurs, FortiGate flushes all routing information from the session table and performs new routing look-up for all new packets on arrival by default. You can modify the default behavior using the following commands:

```
config system interface
  edit <interface>
    set preserve-session-route enable
  next
end
```

By enabling `preserve-session-route`, the FortiGate marks existing session routing information as persistent. Therefore, routing look-up only occurs on new sessions.

Routing changes with SNAT

When SNAT is enabled, the default behavior is opposite to that of when SNAT is not enabled. After a routing change occurs, sessions with SNAT keep using the same outbound interface as long as the old route is still active. This may be the case if the priority of the static route was changed. You can modify this default behavior using the following commands:

```
config system global
  set snat-route-change enable
end
```

By enabling `snat-route-change`, sessions with SNAT will require new route look-up when a routing change occurs. This will apply a new SNAT to the session.

Policy routes

Policy routing allows you to specify an interface to route traffic. This is useful when you need to route certain types of network traffic differently than you would if you were using the routing table. You can use the incoming traffic's protocol, source or destination address, source interface, or port number to determine where to send the traffic.

When a packet arrives, the FortiGate starts at the top of the policy route list and attempts to match the packet with a policy. For a match to be found, the policy must contain enough information to route the packet. At a minimum, this requires the outgoing interface to forward the traffic, and the gateway to route the traffic to. If one or both of these are not specified in the policy route, then the FortiGate searches the routing table to find the best active route that corresponds to the policy route. If no routes are found in the routing table, then the policy route does not match the packet. The FortiGate continues down the policy route list until it reaches the end. If no matches are found, then the FortiGate does a route lookup using the routing table.

Policy routes are sometimes referred to as Policy-based routes (PBR).

Configuring a policy route

In this example, a policy route is configured to send all FTP traffic received at port1 out through port4 and to a next hop router at 172.20.120.23. To route FTP traffic, the protocol is set to TCP (6) and the destination ports are set to 21 (the FTP port).

To configure a policy route in the GUI:

1. Go to *Network > Policy Routes*.
2. Click *Create New > Policy Route*.
3. Configure the following fields:

Incoming interface	port1
Source Address	0.0.0.0/0.0.0.0
Destination Address	0.0.0.0/0.0.0.0
Protocol	TCP
Destination ports	21 - 21
Type of service	0x00
Bit Mask	0x00
Outgoing interface	Enable and select port4
Gateway address	172.20.120.23

The screenshot shows the 'New Routing Policy' configuration window in FortiGate. The configuration is as follows:

- If incoming traffic matches:**
 - Incoming Interface: port1
 - Source Address: IP/Netmask 0.0.0.0/0.0.0.0
 - Destination Address: IP/Netmask 0.0.0.0/0.0.0.0
 - Protocol: TCP, UDP, SCTP, ANY, Specify (6 selected)
 - Source ports: 0 - 65535
 - Destination ports: 21 - 21
 - Type of service: 0x00, Bit Mask 0x00
- Then:**
 - Action: Forward Traffic (selected), Stop Policy Routing
 - Outgoing interface: port4
 - Gateway address: 172.20.120.23
 - Comments: Write a comment... (0/255)
 - Status: Enabled (selected), Disabled

The 'OK' button is highlighted in green, and the 'Cancel' button is visible below it.

4. Click **OK**.

To configure a policy route in the CLI:

```
config router policy
  edit 1
    set input-device "port1"
    set src "0.0.0.0/0.0.0.0"
    set dst "0.0.0.0/0.0.0.0"
    set protocol 6
    set start-port 21
    set end-port 21
    set gateway 172.20.120.23
    set output-device "port4"
    set tos 0x00
    set tos-mask 0x00
  next
end
```

Moving a policy route

A routing policy is added to the bottom of the table when it is created. Routing policies can be moved to a different location in the table to change the order of preference. In this example, routing policy 3 will be moved before routing policy 2.

To move a policy route in the GUI:

1. Go to *Network > Policy Routes*.
2. In the table, select the policy route.

Seq.#	Incoming Interface	Outgoing Interface	Source	Destination	Hit Count
1	VPN_A_Tunnel (Branch-HQ-A)	VPN_A_Tunnel (Branch-HQ-A)			0
2	VPN_B_Tunnel (Branch-HQ-B)	VPN_B_Tunnel (Branch-HQ-B)			0
3	HQ-MPLS (HQ-MPLS)	HQ-MPLS (HQ-MPLS)			0

Updated: 13:27:34

3. Drag the selected policy route to the desired position.

Seq.#	Incoming Interface	Outgoing Interface	Source	Destination	Hit Count
1	VPN_A_Tunnel (Branch-HQ-A)	VPN_A_Tunnel (Branch-HQ-A)			0
3	HQ-MPLS (HQ-MPLS)	HQ-MPLS (HQ-MPLS)			0
2	VPN_B_Tunnel (Branch-HQ-B)	VPN_B_Tunnel (Branch-HQ-B)			0

Updated: 13:26:38

To move a policy route in the CLI:

```
config router policy
  move 3 after 1
end
```

Equal cost multi-path

Equal cost multi-path (ECMP) is a mechanism that allows a FortiGate to load-balance routed traffic over multiple gateways. Just like routes in a routing table, ECMP is considered after policy routing, so any matching policy routes will take precedence over ECMP.

ECMP pre-requisites are as follows:

- Routes must have the same destination and costs. In the case of static routes, costs include distance and priority
- Routes are sourced from the same routing protocol. Supported protocols include static routing, OSPF, and BGP

ECMP and SD-WAN implicit rule

ECMP and SD-WAN implicit rule are essentially similar in the sense that an SD-WAN implicit rule is processed after SD-WAN service rules are processed. See [Implicit rule on page 658](#) to learn more.

The following table summarizes the different load-balancing algorithms supported by each:

ECMP	SD-WAN		Description
	GUI	CLI	
source-ip-based	Source IP	source-ip-based	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address use the same path. This is the default selection.

ECMP	SD-WAN		Description
	GUI	CLI	
weight-based	Sessions	weight-based	The workload is distributed based on the number of sessions that are connected through the interface. The weight that you assign to each interface is used to calculate the percentage of the total sessions allowed to connect through an interface, and the sessions are distributed to the interfaces accordingly.
usage-based	Spillover	usage-based	The interface is used until the traffic bandwidth exceeds the ingress and egress thresholds that you set for that interface. Additional traffic is then sent through the next interface member.
source-dest-ip-based	Source-Destination IP	source-dest-ip-based	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address and go to the same destination IP address use the same path.
Not supported	Volume	measured-volume-based	This mode is supported in SD-WAN only. The workload is distributed based on the number of packets that are going through the interface.

To configure the ECMP algorithm from the CLI:

- At the VDOM level:

```
config system settings
    set v4-ecmp-mode {source-ip-based* | weight-based | usage-based | source-dest-ip-based}
end
```

- If SD-WAN is enabled, the above option is not available and ECMP is configured under the SD-WAN settings:

```
config system sdwan
    set status enable
    set load-balance-mode {source-ip-based* | weight-based | usage-based | source-dest-ip-based | measured-volume-based}
end
```

For ECMP in IPv6, the mode must also be configured under SD-WAN:

```
# diagnose sys vd list
system fib version=63
list virtual firewall info:
name=root/root index=0 enabled fib_ver=40 use=168 rt_num=46 asym_rt=0 sip_helper=0, sip_nat_trace=1, mc_fwd=0, mc_ttl_nc=0, tpmc_sk_pl=0
ecmp=source-ip-based, ecmp6=source-ip-based asym_rt6=0 rt6_num=55 strict_src_check=0 dns_log=1 ses_num=20 ses6_num=0 pkt_num=19154477
```

To change the number of paths allowed by ECMP:

```
config system settings
  set ecmp-max-paths <number of paths>
end
```

Setting `ecmp-max-paths` to the lowest value of 1 is equivalent to disabling ECMP.

ECMP configuration examples

The following examples demonstrate the behavior of ECMP in different scenarios:

- [Example 1: Default ECMP on page 355](#)
- [Example 2: Same distance, different priority on page 356](#)
- [Example 3: Weight-based ECMP on page 356](#)
- [Example 4: Load-balancing BGP routes on page 357](#)

Example 1: Default ECMP

```
config router static
  edit 1
    set gateway 172.16.151.1
    set device "port1"
  next
  edit 2
    set gateway 192.168.2.1
    set device "port2"
  next
end

# get router info routing-table all
Routing table for VRF=0
S*   0.0.0.0/0 [10/0] via 172.16.151.1, port1
      [10/0] via 192.168.2.1, port2
C    172.16.151.0/24 is directly connected, port1
C    192.168.2.0/24 is directly connected, port2
```

Result:

Both routes are added to the routing table and load-balanced based on the source IP.

Example 2: Same distance, different priority

```

config router static
  edit 1
    set gateway 172.16.151.1
    set priority 5
    set device "port1"
  next
  edit 2
    set gateway 192.168.2.1
    set device "port2"
  next
end

# get router info routing-table all
Routing table for VRF=0
S* 0.0.0.0/0 [10/0] via 192.168.2.1, port2
      [10/0] via 172.16.151.1, port1, [5/0]
C 172.16.151.0/24 is directly connected, port1
C 192.168.2.0/24 is directly connected, port2

```

Result:

Both routes are added to the routing table, but traffic is routed to `port2` which has a lower priority value with a default of 0.

Example 3: Weight-based ECMP

```

config router static
  edit 3
    set dst 10.10.30.0 255.255.255.0
    set weight 80
    set device "vpn2HQ1"
  next
  edit 5
    set dst 10.10.30.0 255.255.255.0
    set weight 20
    set device "vpn2HQ2"
  next
end

# get router info routing-table all
Routing table for VRF=0
...
S 10.10.30.0/24 [10/0] is directly connected, vpn2HQ1, [0/80]
      [10/0] is directly connected, vpn2HQ2, [0/20]
C 172.16.151.0/24 is directly connected, port1
C 192.168.0.0/24 is directly connected, port3
C 192.168.2.0/24 is directly connected, port2

```

Result:

Both routes are added to the routing table, but 80% of the sessions to `10.10.30.0/24` are routed to `vpn2HQ1`, and 20% are routed to `vpn2HQ2`.

Example 4: Load-balancing BGP routes

```

config router bgp
  set as 64511
  set router-id 192.168.2.86
  set ebgp-multipath enable
  config neighbor
    edit "192.168.2.84"
      set remote-as 64512
    next
    edit "192.168.2.87"
      set remote-as 64512
    next
  end
end
# get router info routing-table all
Routing table for VRF=0
...
C 172.16.151.0/24 is directly connected, port1
C 192.168.0.0/24 is directly connected, port3
C 192.168.2.0/24 is directly connected, port2
B 192.168.80.0/24 [20/0] via 192.168.2.84, port2, 00:00:33
  [20/0] via 192.168.2.87, port2, 00:00:33

```

Result:

The network 192.168.80.0/24 is advertised by two BGP neighbors. Both routes are added to the routing table, and traffic is load-balanced based on Source IP.

For multiple BGP paths to be added to the routing table, you must enable `ebgp-multipath` for eBGP or `ibgp-multipath` for iBGP. These settings are disabled by default.

Dual internet connections

Dual internet connections, also referred to as dual WAN or redundant internet connections, refers to using two FortiGate interfaces to connect to the Internet. This is generally accomplished with SD-WAN, but this legacy solution provides the means to configure dual WAN without using SD-WAN. You can use dual internet connections in several ways:

- Link redundancy: If one interface goes down, the second interface automatically becomes the main connection.
- Load sharing: This ensures better throughput.
- Use a combination of link redundancy and load sharing.

This section describes the following dual internet connection scenarios:

- [Scenario 1: Link redundancy and no load-sharing on page 358](#)
- [Scenario 2: Load-sharing and no link redundancy on page 360](#)
- [Scenario 3: Link redundancy and load-sharing on page 361](#)

Scenario 1: Link redundancy and no load-sharing

Link redundancy ensures that if your Internet access is no longer available through a certain port, the FortiGate uses an alternate port to connect to the Internet.

In this scenario, two interfaces, WAN1 and WAN2, are connected to the Internet using two different ISPs. WAN1 is the primary connection. In the event of a failure of WAN1, WAN2 automatically becomes the connection to the Internet. For this configuration to function correctly, you must configure the following settings:

- [Link health monitor on page 358](#): To determine when the primary interface (WAN1) is down and when the connection returns.
- [Routing on page 359](#): Configure a default route for each interface.
- [Security policies on page 360](#): Configure security policies to allow traffic through each interface to the internal network.

Link health monitor

Adding a link health monitor is required for routing failover traffic. A link health monitor confirms the device interface connectivity by probing a gateway or server at regular intervals to ensure it is online and working. When the server is not accessible, that interface is marked as down.

Set the `interval` (how often to send a ping) and `failtime` (how many lost pings are considered a failure). A smaller interval value and smaller number of lost pings results in faster detection, but creates more traffic on your network.

The link health monitor supports both IPv4 and IPv6, and various other protocols including ping, tcp-echo, udp-echo, http, and twamp.

To add a link health monitor (IPv4) using the CLI:

```
config system link-monitor
  edit <link-monitor-name>
    set addr-mode ipv4
    set srcintf <interface-name>
    set server <server-IP-address>
    set protocol {ping tcp-echo udp-echo http twamp}
    set gateway-ip <gateway-IP-address>
    set interval <seconds>
    set failtime <retry-attempts>
    set recoverytime <number-of-successful-responses>
    set status enable
  next
end
```

Option	Description
<code>set update-cascade-interface {enable disable}</code>	This option is used in conjunction with fail-detect and fail-alert options in interface settings to cascade the link failure down to another interface. See the Bring other interfaces down when link monitor fails KB article for details.
<code>set update-static-route {enable disable}</code>	When the link fails, all static routes associated with the interface will be removed.

Routing

You must configure a default route for each interface and indicate your preferred route as follows:

- Specify different distances for the two routes. The lower of the two distance values is declared active and placed in the routing table.

Or

- Specify the same distance for the two routes, but give a higher priority to the route you prefer by defining a lower value. Both routes will be added to the routing table, but the route with a higher priority will be chosen as the best route

In the following example, we will use the first method to configure different distances for the two routes. You might not be able to connect to the backup WAN interface because the FortiGate does not route traffic out of the backup interface. The FortiGate performs a reverse path look-up to prevent spoofed traffic. If an entry cannot be found in the routing table that sends the return traffic out through the same interface, the incoming traffic is dropped.

To configure the routing of the two interfaces using the GUI:

- Go to *Network > Static Routes*, and click *Create New*.
- Enter the following information:

Destination	For an IPv4 route, enter a subnet of 0.0.0.0/0.0.0.0. For an IPv6 route, enter a subnet of ::/0.
Interface	Select the primary connection. For example, wan1.
Gateway Address	Enter the gateway address.
Administrative Distance	Leave as the default of 10.

- Click *OK*.
- Repeat the above steps to set *Interface* to wan2 and *Administrative Distance* to 20.

To configure the routing of the two interfaces using the CLI:

```
config router {static | static6}
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set device wan1
    set gateway <gateway_address>
    set distance 10
```

```
next
edit 2
    set dst 0.0.0.0 0.0.0.0
    set device wan2
    set gateway <gateway_address>
    set distance 20
next
end
```

Security policies

When you create security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic is allowed to pass through WAN2, as it did with WAN1. This ensures that failover occurs with minimal effect to users.

Scenario 2: Load-sharing and no link redundancy

Load sharing may be accomplished in a few of the following ways of the many possible ways:

- By defining a preferred route with a lower distance, and specifying policy routes to route certain traffic to the secondary interface.
- By defining routes with same distance values but different priorities, and specifying policy routes to route certain traffic to the secondary interface.
- By defining routes with same distance values and priorities, and use equal-cost multi-path (ECMP) routing to equally distribute traffic between the WAN interfaces.

In our example, we will use the first option for our configuration. In this scenario, because link redundancy is not required, you do not have to configure a link monitor.

Traffic behaviour without a link monitor is as follows:

- If the remote gateway is down but the primary WAN interface of a FortiGate is still up, the FortiGate will continue to route traffic to the primary WAN. This results in traffic interruptions.
 - If the primary WAN interface of a FortiGate is down due to physical link issues, the FortiGate will remove routes to it and the secondary WAN routes will become active. Traffic will failover to the secondary WAN.
-

Routing

Configure routing as you did in [Scenario 1: Link redundancy and no load-sharing on page 358](#) above.

Policy routes

By configuring policy routes, you can redirect specific traffic to the secondary WAN interface. This works in this case because policy routes are checked before static routes. Therefore, even though the static route for the secondary WAN is not in the routing table, traffic can still be routed using the policy route.

In this example, we will create a policy route to route traffic from one address group to the secondary WAN interface.

To configure a policy route from the GUI:

1. Go to *Network > Policy Routes*, and click *Create New*.
2. Enter the following information:

Incoming interface	Define the source of the traffic. For example, <code>internal</code> .
Source Address	If we prefer to route traffic only from a group of addresses, define an address or address group, and add here.
Destination Address	Because we want to route all traffic from the address group here, we do not specify a destination address.
Protocol	Specify any protocol.
Action	Forward traffic.
Outgoing interface	Select the secondary WAN as the outbound interface. For example, <code>wan2</code> .
Gateway address	Input the gateway address for your secondary WAN. Because its default route has a higher distance value and is not added to the routing table, the gateway address must be added here.

3. Click OK.

To configure a policy route from the CLI:

```
config router policy
  edit 1
    set input-device "internal"
    set srcaddr "Laptops"
    set gateway <gateway_address>
    set output-device "wan2"
  next
end
```

Security policies

Your security policies should allow all traffic from `internal` to WAN1. Because link redundancy is not needed, you do not need to duplicate all WAN1 policies to WAN2. You will only need to define policies used in your policy route.

Scenario 3: Link redundancy and load-sharing

In this scenario, both the links are available to distribute Internet traffic with the primary WAN being preferred more. Should one of the interfaces fail, the FortiGate will continue to send traffic over the other active interface. The configuration is a combination of both the link redundancy and the load-sharing scenarios. The main difference is that the configured routes have equal distance values, with the route with a higher priority being preferred more. This ensures both routes are active in the routing table, but the route with a higher priority will be the best route.

Link health monitor

Link monitor must be configured for both the primary and the secondary WAN interfaces. This ensures that if the primary or the secondary WAN fails, the corresponding route is removed from the routing table and traffic re-routed to the other

WAN interface.

For configuration details, see sample configurations in [Scenario 1: Link redundancy and no load-sharing on page 358](#).

Routing

Both WAN interfaces must have default routes with the same distance. However, preference is given to the primary WAN by giving it a higher priority.

To configure the routing of the two interfaces using the CLI:

```
config router {static | static6}
  edit 1
    set dst 0.0.0.0 0.0.0.0
    set device wan1
    set gateway <gateway_address>
    set distance 10
    set priority 1
  next
  edit 2
    set dst 0.0.0.0 0.0.0.0
    set device wan2
    set gateway <gateway_address>
    set distance 10
    set priority 10
  next
end
```

Policy routes

The policy routes configuration is very similar to that of the policy routes in [Scenario 2: Load-sharing and no link redundancy on page 360](#), except that the gateway address should not be specified. When a policy route is matched and the gateway address is not specified, the FortiGate looks at the routing table to obtain the gateway. In case the secondary WAN fails, traffic may hit the policy route. Because there is no gateway specified and the route to the secondary WAN is removed by the link monitor, the policy route will be bypassed and traffic will continue through the primary WAN. This ensures that the policy route is not active when the link is down.

Security policies

When you create security policies, you need to configure duplicate policies to ensure that after traffic fails over WAN1, regular traffic is allowed to pass through WAN2, as it was with WAN1. This ensures that failover occurs with minimal effect to users.

Dynamic routing

Dynamic routing protocols attempt to build a map of the network topology to identify the best routes to reach different destinations. Instead of manually defining static routes, which is not scalable, dynamic routing typically involves defining neighbors and peer routers that share their network topology and routing updates with each other. Protocols like distance vector, link state, and path vector are used by popular routing protocols. FortiGate supports RIP, OSPF, BGP,

and IS-IS, which are interoperable with other vendors. When different dynamic routing protocols are used, the administrative distance of each protocol helps the FortiGate decide which route to pick.

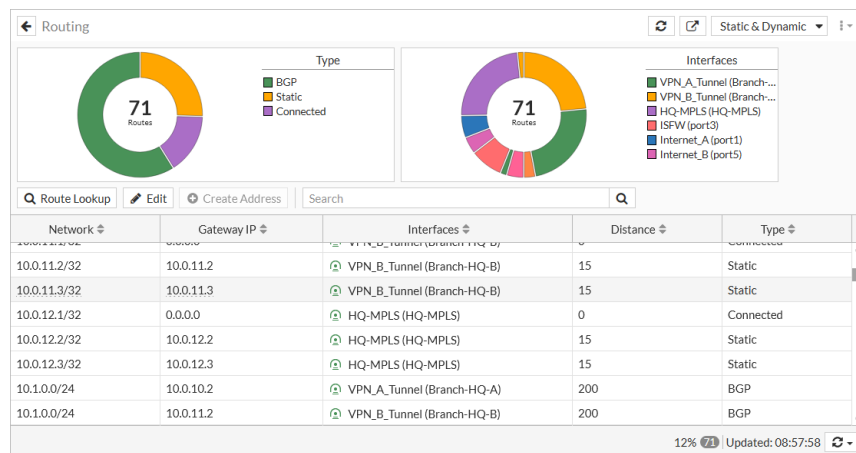

Go to *System > Feature Visibility* and enable *Advanced Routing* to configure dynamic routing options in the GUI. See [Feature visibility on page 2292](#) for more information.

This section includes:

- [RIP on page 364](#)
- [OSPF on page 383](#)
- [BGP on page 395](#)
- [BFD on page 431](#)
- [Routing objects on page 440](#)

To view the routing table and perform route look-ups in the GUI, go to *Dashboard > Network* and expand the *Routing* widget.

To view the routing table in the CLI:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
S*  0.0.0.0/0 [5/0] via 192.168.0.1, wan1
C   10.10.10.0/24 is directly connected, internal
C   169.254.2.1/32 is directly connected, Dialup-test
C   172.31.0.0/30 is directly connected, toKVM-MPLS
C   172.31.0.1/32 is directly connected, toKVM-MPLS
C   192.168.0.0/24 is directly connected, wan1
O   192.168.2.0/24 [110/101] via 10.10.10.11, internal, 00:00:26
S   192.168.20.0/24 [10/0] via 172.31.0.2, toKVM-MPLS
    [10/0] via 10.10.10.11, internal
```

RIP

Routing Information Protocol (RIP) is a distance-vector routing protocol that is intended for small and relatively homogeneous networks. It works well when there are minimal redundant paths and limited hop counts. FortiGate supports RIP version 1 ([RFC 1058](#)), RIP version 2 ([RFC 2453](#)), and RIPvng ([RFC 2080](#)).

Basic configuration

To configure the FortiGate to participate in RIP using the most basic configurations in the GUI:

1. Go to *Network > RIP*.
2. Set the *Version*.
3. Add the networks that the FortiGate will advertise in and that will participate in RIP.
4. If the interface settings, such as passive interface, authentication, or enabling send/receive updates, must be edited, add the interfaces to the *Interface* table.
5. Click *Apply*.

To configure the FortiGate to participate in RIP using the most basic configurations in the CLI:

```
config router rip
  config network
    edit 1
      set prefix <subnet> <netmask>
    next
  end
  config interface
    edit <interface>
      set receive-version 2
      set send-version 2
    next
  end
end
```

Default route injection

Enabling *Inject default route* (`default-information-originate`) advertises a default route into the FortiGate's RIP network.

To enable/disable default route injection in the GUI:

1. Go to *Network > RIP*.
2. Expand the *Advanced Options*.
3. Enable/disable *Inject Default Route*.
4. Click *OK*.

To enable/disable default route injection in the CLI:

```
config router rip
  set default-information-originate {enable | disable}
```

```
end
```

Default metric

The default metric setting sets the default metric for all redistributed routes. If the default metric is set to five, and static routes are redistributed, then static routes have a metric of five. This value can be overridden by setting a specific metric value for a protocol. For example, the static route metric can be set to two, overriding the default metric.

```
config router rip
    set default-metric 5
    config redistribute "static"
        set status enable
        set metric 2
    end
end
```

The default metric is five, but redistributed static routes have a metric of two. So, the default metric is overridden and the metric for redistributed static routes is two.

Timers

RIP uses the update, timeout, and garbage timers to regulate its performance. The default timer settings are effective in most configurations. When customizing the settings, you must ensure that the new settings are compatible with your local routers and access servers.

Go to *Network > RIP* and expand the *Advanced Options* to configure the timers in the GUI, or use the CLI:

```
config router rip
    set timeout-timer <seconds>
    set update-timer <seconds>
    set garbage-timer <seconds>
end
```

Update timer

The update timer sets the interval between routing updates. The default value is 30 seconds. Randomness is added to help prevent network congestion due to multiple routers trying to update their neighbors simultaneously. The update timer must be at least three times shorter than the timeout timer.

If there is significant RIP traffic on the network, you can increase the update timer to send fewer updates. You must apply the same increase to all routers on the network to avoid timeouts that degrade your network speed.

Timeout timer

The timeout timer is the maximum amount of time that a reachable route is kept in the routing table since its last update. The default value is 180 seconds. If an update for the route is received before the timeout period elapses, then the timer is reset. The timeout timer should be at least three times longer than the update timer.

If routers are not responding to updates in time, increasing the timeout timer can help. A longer timeout timer results in longer update periods, and the FortiGate could wait a considerable amount of time for all of the timers to expire on an unresponsive route.

Garbage timer

The garbage timer is the amount of time that the FortiGate advertises a route as unreachable before deleting the route from the routing table. The default value is 120 seconds.

If the timer is short, older routes are removed from the routing table more quickly, resulting in a smaller routing table. This can be useful for large networks, or if the network changes frequently.

Authentication and key chain

RIP version 1 (RIPv1) has no authentication. RIP version 2 (RIPv2) uses text passwords or authentication keys to ensure that the routing information exchanged between routers is reliable. For authentication to work, both the sending and receiving routers must be set to use authentication and must be configured with the same password or keys. An authentication key that uses authentication key chains is more secure than a text password because the intervals when the key is valid can be configured.

A key chain is a list of one or more authentication keys that each have send and receive lifetimes. Keys are used to authenticate routing packets only during the keys specified lifetimes. The FortiGate migrates from one key to the next according to the scheduled lifetimes. The sending and receiving routers should have synchronized system dates and times to ensure that both ends are using the same keys at the same times. You can overlap the key lifetimes to make sure that a key is always available, even if there is some difference in the system times.

To configure a text password in the GUI:

1. Go to *Network > RIP*.
2. In the *Interfaces* table, click *Create New*, or edit an existing interface.
3. Enable *Authentication* and select *Text* or *MD5*.
4. Click *Change*, and enter the password.
5. Configure the remaining settings as needed.
6. Click *OK*.
7. Click *Apply*.

To configure a text password in the CLI:

```
config router rip
  config interface
    edit <interface>
      set auth-mode {text | md5}
      set auth-string *****
    next
  end
end
```

To configure a key chain with two sequentially valid keys and use it in a RIP interface:

```
config router key-chain
  edit rip_key
    config key
      edit 1
        set accept-lifetime 09:00:00 23 02 2020 09:00:00 17 03 2020
        set send-lifetime 09:00:00 23 02 2020 09:00:00 17 03 2020
      next
    next
  end
end
```

```

        set key-string *****
    next
    edit 2
        set accept-lifetime 09:01:00 17 03 2020 09:00:00 1 04 2020
        set send-lifetime 09:01:00 17 03 2020 09:00:00 1 04 2020
        set key-string *****
    next
end
next
end
config router rip
    config interface
        edit port1
            set auth-keychain "rip_key"
        next
    end
end

```

Passive RIP interfaces

By default, an active RIP interface keeps the FortiGate routing table current by periodically asking neighbors for routes and sending out route updates. This can generate a significant amount of extra traffic in a large network.

A passive RIP interface listens to updates from other routers, but does not send out route updates. This can reduce network traffic when there are redundant routers in the network that would always send out essentially the same updates.

This example shows how to configure a passive RIPv2 interface on port1 using MD5 authentication.

To configure a passive RIP interface in the GUI:

1. Go to *Network > RIP*.
2. In the *Interfaces* table, click *Create New*.
3. Set *Interface* to the required interface.
4. Enable *Passive*.
5. Enable *Authentication* and set it to *MD5*.
6. Click *Change* and enter a password.
7. Set *Receive Version* to *2*.
8. Click *OK*.

To configure a passive RIP interface in the CLI:

```

config router rip
    set passive-interface "port1"
    config interface
        edit "port1"
            set auth-mode md5
            set auth-string *****
            set receive-version 2
            set send-version 2
        next
    end
end

```

```

end
end

```

RIP and IPv6

RIP next generation (RIPng) is an extension of RIPv2 that includes support for IPv6. See [Basic RIPng example on page 381](#) and [IPv6 tunneling on page 549](#) for more information.

Basic RIP example

In this example, a medium-sized network is configured using RIPv2.

- Two core routers, RIP Router2 and RIP Router3, connect to the ISP router for two redundant paths to the internet.
- Two other routers, RIP Router1 and RIP Router4, connect to the two core routers and to different local networks.
- The ISP router is using RIP for its connections to the core routers, and redistributes its default route to the network - that is, default route injection is enabled.
- The ISP router uses NAT and has a static route to the internet. None of the other routers use NAT or static routes.

All of the FortiGate routers are configured as shown, using netmask 255.255.255.0. Firewall policies have been configured to allow the required traffic to flow across the interfaces.

Router	Interface	Interface name	IP address
Router1	port1	LoSales	10.11.101.101
	port2	vd12link0	10.11.201.101
	port3	vd13link0	10.11.202.101
Router2	port1	vd23link0	10.12.101.102
	port2	vd12link1	10.11.201.102
	port3	vd42link1	10.14.201.102
	port4	vdr2link1	172.20.120.102
Router3	port1	vd23link1	10.12.101.103
	port2	vd13link1	10.11.202.103
	port3	vd43link1	10.14.202.103
	port4	vdr3link1	172.20.121.103
Router4	port1	LoAccounting	10.14.101.104
	port2	vd42link0	10.14.201.104
	port3	vd43link0	10.14.202.104
ISP Router	port1	port1	To internet
	port2	vdr2link0	172.20.120.5
	port3	vdr3link0	172.20.121.5

After configuring each router, you can check the status of the connections by viewing the RIP database, RIP interfaces, and routing table. See [Verifying the configuration on page 374](#).

After the network is configured, you can test it to ensure that when network events occur, such as a downed link, routing updates are triggered and converge as expected. See [Testing the configuration and routing changes on page 378](#).

ISP router

To configure the ISP Router in the GUI:

1. Go to *Network > RIP*.
2. Set the *Version* to 2.
3. Under *Networks*, add two networks:
 - 172.20.120.0/255.255.255.0
 - 172.20.121.0/255.255.255.0
4. Add the interfaces:
 - a. In the *Interfaces* table, click *Create New*.
 - b. Set *Interface* to *port2*.
 - c. Leave the remaining settings as their default values.

- d. Click *OK*.
 - e. Repeat these steps for *port3*.
5. Under *Advanced Options*, enable *Inject Default Route*.
This setting allows the ISP router to share its default 0.0.0.0 routes with other routers in the RIP network.
6. Click *Apply*.

To configure the ISP Router in the CLI:

```

config router rip
  set default-information-originate enable
  config network
    edit 1
      set prefix 172.20.121.0 255.255.255.0
    next
    edit 2
      set prefix 172.20.120.0 255.255.255.0
    next
  end
  config interface
    edit "port2"
      set receive-version 2
      set send-version 2
    next
    edit "port3"
      set receive-version 2
      set send-version 2
    next
  end
end
end

```

Router2 and Router3

Router2 and Router3 RIP configurations have different IP addresses, but are otherwise the same.

To configure Router2 and Router3 in the GUI:

1. Go to *Network > RIP*.
2. Set the *Version* to 2.
3. Under *Networks*, add the IP addresses for each port:

Router2	10.12.101.0/255.255.255.0
	10.11.201.0/255.255.255.0
	10.14.201.0/255.255.255.0
	172.20.120.0/255.255.255.0

Router3	10.12.101.0/255.255.255.0
	10.11.202.0/255.255.255.0
	10.14.202.0/255.255.255.0
	172.20.121.0/255.255.255.0

4. Add the interfaces:
 - a. In the *Interfaces* table, click *Create New*.
 - b. Set *Interface* to *port1*.
 - c. Leave the remaining settings as their default values.
 - d. Click *OK*.
 - e. Repeat these steps for *port2*, *port3*, and *port4*.
5. Click *Apply*.

To configure Router2 in the CLI:

```

config router rip
  config network
    edit 1
      set prefix 10.12.101.0 255.255.255.0
    next
    edit 2
      set prefix 10.11.201.0 255.255.255.0
    next
    edit 3
      set prefix 10.14.201.0 255.255.255.0
    next
    edit 4
      set prefix 172.20.120.0 255.255.255.0
    next
  end
config interface
  edit "port1"
    set receive-version 2
    set send-version 2
  next
  edit "port2"
    set receive-version 2
    set send-version 2
  next
  edit "port3"
    set receive-version 2
    set send-version 2
  next
  edit "port4"
    set receive-version 2
    set send-version 2
  next
end
end

```

To configure Router3 in the CLI:

```

config router rip
  config network
    edit 1
      set prefix 10.12.101.0 255.255.255.0
    next
    edit 2
      set prefix 10.11.202.0 255.255.255.0
    next
    edit 3
      set prefix 10.14.202.0 255.255.255.0
    next
    edit 4
      set prefix 172.20.121.0 255.255.255.0
    next
  end
config interface
  edit "port1"
    set receive-version 2
    set send-version 2
  next
  edit "port2"
    set receive-version 2
    set send-version 2
  next
  edit "port3"
    set receive-version 2
    set send-version 2
  next
  edit "port4"
    set receive-version 2
    set send-version 2
  next
end
end

```

Router1 and Router4

Router1 and Router4 RIP configurations have different IP addresses, but are otherwise the same.

To configure Router1 and Router4 in the GUI:

1. Go to *Network > RIP*.
2. Set the *Version* to 2.
3. Under *Networks*, add the IP addresses for each port:

Router1	10.11.101.0/255.255.255.0
	10.11.201.0/255.255.255.0
	10.11.202.0/255.255.255.0

Router4	10.14.101.0/255.255.255.0
	10.14.201.0/255.255.255.0
	10.14.202.0/255.255.255.0

4. Add the interfaces:

- a. In the *Interfaces* table, click *Create New*.
- b. Set *Interface* to *port1*.
- c. For port1 only, enable *Passive*.
- d. Leave the remaining settings as their default values.
- e. Click *OK*.
- f. Repeat these steps for *port2* and *port3*, making sure that *Passive* is disabled.

5. Click *Apply*.

To configure Router1 in the CLI:

```
config router rip
  config network
    edit 1
      set prefix 10.11.101.0 255.255.255.0
    next
    edit 2
      set prefix 10.11.201.0 255.255.255.0
    next
    edit 3
      set prefix 10.11.202.0 255.255.255.0
    next
  end
  set passive-interface "port1"
  config interface
    edit "port1"
      set receive-version 2
      set send-version 2
    next
    edit "port2"
      set receive-version 2
      set send-version 2
    next
    edit "port3"
      set receive-version 2
      set send-version 2
    next
  end
end
```

To configure Router4 in the CLI:

```
config router rip
  config network
    edit 1
      set prefix 10.14.101.0 255.255.255.0
    next
```

```

    edit 2
      set prefix 10.14.201.0 255.255.255.0
    next
    edit 3
      set prefix 10.14.202.0 255.255.255.0
    next
  end
  set passive-interface "port1"
  config interface
    edit "port1"
      set receive-version 2
      set send-version 2
    next
    edit "port2"
      set receive-version 2
      set send-version 2
    next
    edit "port3"
      set receive-version 2
      set send-version 2
    next
  end
end

```

Verifying the configuration

The interface's names are shown in the debugs. The same commands should also be run on the other routers.

To verify the configuration after the ISP router, Router2, and Router3 have been configured:

This verification can be done after the ISP router, Router2, and Router3 have been configured. Only Router2's debugs are shown.

1. Check the RIP interface information:

```

# get router info rip interface
Router2 is up, line protocol is up
  RIP is not enabled on this interface
ssl.Router2 is up, line protocol is up
  RIP is not enabled on this interface
vdr2link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      172.20.120.102/24
vd12link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.201.102/24

```

```

vd42link1 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.14.201.102/24
vd23link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.12.101.102/24

```

RIP starts exchanging routes as soon as the networks are added to the Router2 and Router3 configurations because the RIP interfaces are active by default, and start sending and receiving RIP updates when a matching interface on the subnet is found. The interface configuration allows the interface settings to be fine tuned, in this case to specify only RIPv2 support.

2. Check the RIP database:

```

# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network      Next Hop      Metric From      If      Time
R  0.0.0.0/0    172.20.120.5    2 172.20.120.5    vdr2link1 02:55
Rc 10.11.201.0/24
R  10.11.202.0/24 10.12.101.103    2 10.12.101.103    vd23link0 02:33
Rc 10.12.101.0/24
Rc 10.14.201.0/24
R  10.14.202.0/24 10.12.101.103    2 10.12.101.103    vd23link0 02:33
Rc 172.20.120.0/24
R  172.20.121.0/24 10.12.101.103    2 10.12.101.103    vd23link0 02:33

```

3. Check the routing table:

```

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
R*  0.0.0.0/0 [120/2] via 172.20.120.5, vdr2link1, 13:37:23
C   10.11.201.0/24 is directly connected, vd12link1
R   10.11.202.0/24 [120/2] via 10.12.101.103, vd23link0, 14:10:01
C   10.12.101.0/24 is directly connected, vd23link0
C   10.14.201.0/24 is directly connected, vd42link1
R   10.14.202.0/24 [120/2] via 10.12.101.103, vd23link0, 14:10:01
C   172.20.120.0/24 is directly connected, vdr2link1
R   172.20.121.0/24 [120/2] via 10.12.101.103, vd23link0, 13:20:36

```

Router2 has learned the default gateway from the ISP router, and has learned of other networks from Router3.

4. If firewall policies are correctly configured, the outside network can be reached:

```
# execute ping-options source 10.11.201.102
# execute ping 8.8.8.8
PING 8.8.8.8 (8.8.8.8): 56 data bytes
64 bytes from 8.8.8.8: icmp_seq=0 ttl=115 time=4.5 ms
64 bytes from 8.8.8.8: icmp_seq=1 ttl=115 time=4.2 ms
64 bytes from 8.8.8.8: icmp_seq=2 ttl=115 time=4.2 ms
64 bytes from 8.8.8.8: icmp_seq=3 ttl=115 time=4.2 ms
64 bytes from 8.8.8.8: icmp_seq=4 ttl=115 time=4.1 ms
--- 8.8.8.8 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 4.1/4.2/4.5 ms

# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1 172.20.120.5 0.101 ms 0.030 ms 0.014 ms
 2 172.16.151.1 0.169 ms 0.144 ms 0.131 ms
 3 * * *
```

To verify the configuration after Router1 and Router4 have also been configured:

This verification can be done after Router1 and Router4 have been configured. Only Router1's debugs are shown.

1. Check the RIP interface information:

```
# get router info rip interface
Router1 is up, line protocol is up
  RIP is not enabled on this interface
ssl.Router1 is up, line protocol is up
  RIP is not enabled on this interface
vd12link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.201.101/24
vd13link0 is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Disabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.202.101/24
LoSales is up, line protocol is up
  Routing Protocol: RIP
    Receive RIPv2 packets only
    Send RIPv2 packets only
    Passive interface: Enabled
    Split horizon: Enabled with Poisoned Reversed
    IP interface address:
      10.11.101.101/24
      127.0.0.1/8
```

2. Check the RIP database:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network          Next Hop          Metric From          If          Time
R  0.0.0.0/0        10.11.202.103          3 10.11.202.103      vd13link0 02:35
Rc 10.11.101.0/24          1                      LoSales
Rc 10.11.201.0/24          1                      vd12link0
Rc 10.11.202.0/24          1                      vd13link0
R  10.12.101.0/24        10.11.202.103          2 10.11.202.103      vd13link0 02:35
R  10.14.101.0/24        10.11.202.103          3 10.11.202.103      vd13link0 02:35
R  10.14.201.0/24        10.11.201.102          2 10.11.201.102      vd12link0 02:30
R  10.14.202.0/24        10.11.202.103          2 10.11.202.103      vd13link0 02:35
R  172.20.120.0/24       10.11.201.102          2 10.11.201.102      vd12link0 02:30
R  172.20.121.0/24       10.11.202.103          2 10.11.202.103      vd13link0 02:35
```

3. Check the routing table:

```
# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
Routing table for VRF=0
R*   0.0.0.0/0 [120/3] via 10.11.202.103, vd13link0, 00:09:42
C    10.11.101.0/24 is directly connected, LoSales
C    10.11.201.0/24 is directly connected, vd12link0
C    10.11.202.0/24 is directly connected, vd13link0
R    10.12.101.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
R    10.14.101.0/24 [120/3] via 10.11.202.103, vd13link0, 00:09:42
R    10.14.201.0/24 [120/2] via 10.11.201.102, vd12link0, 00:09:42
R    10.14.202.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
R    172.20.120.0/24 [120/2] via 10.11.201.102, vd12link0, 00:09:42
R    172.20.121.0/24 [120/2] via 10.11.202.103, vd13link0, 00:09:42
```

4. If firewall policies are correctly configured, the accounting network and the internet are reachable from the sales network:

```
# execute ping-options source 10.11.101.101
# execute ping 10.14.101.104
PING 10.14.101.104 (10.14.101.104): 56 data bytes

 2  172.20.121.5  0.216 ms  0.045 ms  0.038 ms
```

Testing the configuration and routing changes

After the network is configured, test it to ensure that when network events occur, such as a downed link, routing updates are triggered and converge as expected.

In the following examples, we disable certain links to simulate network outages, then verify that routing and connectivity is restored after the updates have converged.

Example 1 - ISP router port3 interface goes down

In this example, a link outage occurs on port3 of the ISP router. Consequently, all routers must use Router2, and not Router3, to reach the internet. Note the RIP database before and after the link failure, and the time taken for the route updates to propagate and return to a functioning state.

Router4's debugs are shown.

Before:

```
# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network          Next Hop          Metric From          If          Time

 3  * * *

```

After:

- You might see different routes, and the routes might change, while convergence is occurring. During convergence, the metric for your default route increases to 16.

```

# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network          Next Hop          Metric From      If      Time
R  0.0.0.0/0        10.14.202.103          16 10.14.202.103  vd43link0 01:50

```

- After convergence is complete, the RIP database will look similar to the following:

```

# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network          Next Hop          Metric From      If      Time
R  0.0.0.0/0        10.14.201.102          3 10.14.201.102  vd42link0 02:53
R  10.11.101.0/24   10.14.202.103          3 10.14.202.103  vd43link0 03:00
R  10.11.201.0/24   10.14.201.102          2 10.14.201.102  vd42link0 02:53
R  10.11.202.0/24   10.14.202.103          2 10.14.202.103  vd43link0 03:00
R  10.12.101.0/24   10.14.202.103          2 10.14.202.103  vd43link0 03:00
Rc 10.14.101.0/24   1                          LoAccounting
Rc 10.14.201.0/24   1                          vd42link0
Rc 10.14.202.0/24   1                          vd43link0
R  172.20.120.0/24  10.14.201.102          2 10.14.201.102  vd42link0 02:53

```

- The default router should point to Router2, with the same number of hops:

```

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
R*  0.0.0.0/0 [120/3] via 10.14.201.102, vd42link0, 00:05:24

C   10.14.101.0/24 is directly connected, LoAccounting
C   10.14.201.0/24 is directly connected, vd42link0

```

```

C      10.14.202.0/24 is directly connected, vd43link0
R      172.20.120.0/24 [120/2] via 10.14.201.102, vd42link0, 02:58:39

# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.14.201.102  0.167 ms  0.063 ms  0.029 ms
 2  172.20.120.5  0.117 ms  0.073 ms  0.041 ms
 3  172.16.151.1  0.303 ms  0.273 ms  0.253 ms

```

Example 2- Additional link failures on Router2

In addition to the link failure on the ISP router in example, port1 and port3 on Router2 have also failed. This means that Router4 must go through Router3, Router1, Router2, then the ISP router to reach the internet. Note that, for a period of time, some routes' metrics increase to 16. If no better routes are found for these networks, then they eventually disappear.

After the convergence completes, the RIP database and routing table on Router4 should resemble the following:

```

# get router info rip database
Codes: R - RIP, Rc - RIP connected, Rs - RIP static, K - Kernel,
       C - Connected, S - Static, O - OSPF, I - IS-IS, B - BGP
   Network          Next Hop          Metric From          If          Time
R  0.0.0.0/0         10.14.202.103      5 10.14.202.103     vd43link0 02:54
R  10.11.101.0/24    10.14.202.103      3 10.14.202.103     vd43link0 02:54
R  10.11.201.0/24    10.14.202.103      3 10.14.202.103     vd43link0 02:54
R  10.11.202.0/24    10.14.202.103      2 10.14.202.103     vd43link0 02:54
Rc 10.14.101.0/24    1                   LoAccounting
Rc 10.14.202.0/24    1                   vd43link0
R  172.20.120.0/24   10.14.202.103      4 10.14.202.103     vd43link0 02:54

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

Routing table for VRF=0
R*   0.0.0.0/0 [120/5] via 10.14.202.103, vd43link0, 00:03:54
R    10.11.101.0/24 [120/3] via 10.14.202.103, vd43link0, 03:10:12
R    10.11.201.0/24 [120/3] via 10.14.202.103, vd43link0, 00:03:54
R    10.11.202.0/24 [120/2] via 10.14.202.103, vd43link0, 03:10:38
C    10.14.101.0/24 is directly connected, LoAccounting
C    10.14.202.0/24 is directly connected, vd43link0

```

Reaching the internet on the default gateway now requires five hops from Router4:

```

# execute traceroute 8.8.8.8
traceroute to 8.8.8.8 (8.8.8.8), 32 hops max, 3 probe packets per hop, 84 byte packets
 1  10.14.202.103  0.087 ms  0.026 ms  0.012 ms
 2  10.11.202.101  0.045 ms  0.024 ms  0.025 ms
 3  10.11.201.102  0.048 ms  0.024 ms  0.015 ms
 4  172.20.120.5  0.050 ms  0.028 ms  0.019 ms
 5  * * *

```

Basic RIPng example

In this example, a small network is configured with RIP next generation (RIPng). Two FortiGates are connected to the internal network and the ISP, providing some redundancy to help ensure that the internal network can always reach the internet.

The FortiGates are running in NAT mode with VDOMs disabled, and firewall policies have already been configured to allow traffic to flow across the interfaces.

All of the internal computers and other network devices support IPv6 addressing and are running RIPng (where applicable), so no static routing is required. Internal network devices only need to know the FortiGate's internal interface network addresses.

Router	Interface (alias)	IPv6 address
Router1	port1 (internal)	2002:A0B:6565:0:0:0:0:0
	port2 (ISP)	2002:AC14:7865:0:0:0:0:0
Router2	port1 (internal)	2002:A0B:6566:0:0:0:0:0
	port2 (ISP)	2002:AC14:7866:0:0:0:0:0

On each FortiGate, the interfaces are configured first, and then RIPng. No redistribution or authentication is configured.

In the RIPng configuration, only the interface names are required. The ISP router and the other FortiGate are configured as neighbors. Declaring the neighbors reduces the discovery traffic when the routers start. There is no specific command to include a subnet in the RIP broadcast, and RIPng can only be configured using the CLI.

To configure Router1:

1. Configure the interfaces:

```
config system interface
  edit port1
    set allowaccess ping https ssh
    set type physical
    set description "Internal RnD network"
    set alias "internal"
    config ipv6
      set ip6-address 2002:a0b:6565::/0
    end
  end
```

```
next
edit port2
    set allowaccess ping https ssh
    set type physical
    set description "ISP and Internet"
    set alias "ISP"
    config ipv6
        set ip6-address 2002:ac14:7865::/0
    end
next
end
```

2. Configure RIPng:

```
config router ripng
    config neighbor
        edit 1
            set ip6 2002:a0b:6566::
            set interface port1
        next
        edit 2
            set ip6 2002:ac14:7805::
            set interface port2
        next
    end
config interface
    edit port1
    next
    edit port2
    next
end
end
```

To configure Router2:

1. Configure the interfaces:

```
config system interface
    edit port1
        set allowaccess ping https ssh
        set type physical
        set description "Internal RnD network"
        set alias "internal"
        config ipv6
            set ip6-address 2002:a0b:6566::/0
        end
    next
    edit port2
        set allowaccess ping https ssh
        set type physical
        set description "ISP and Internet"
        set alias "ISP"
        config ipv6
            set ip6-address 2002:ac14:7866::/0
        end
    next
end
```

2. Configure RIPng:

```
config router ripng
  config neighbor
    edit 1
      set ip6 2002:a0b:6565::
      set interface port1
    next
  edit 2
    set ip6 2002:ac14:7805::
    set interface port2
  next
end
config interface
  edit port1
  next
  edit port2
  next
end
end
```

Testing the configuration

The following commands can be used to check the RIPng information on the FortiGates, and can help track down issues:

To view the local scope IPv6 addresses used as next-hops by RIPng on the FortiGate:

```
# diagnose ipv6 address list
```

To view IPv6 addresses that are installed in the routing table:

```
# diagnose ipv6 route list
```

To view the IPv6 routing table:

```
# get router info6 routing-table
```

This information is similar to the `diagnose ipv6 route list` command, but it is presented in an easier to read format.

To view the brief output on the RIP information for the interface listed:

```
# get router info6 rip interface external
```

This includes information such as, if the interface is up or down, what routing protocol is being used, and whether passive interface or split horizon is enabled.

OSPF

Open Shortest Path First (OSPF) is a link state routing protocol that is commonly used in large enterprise networks with L3 switches, routers, and firewalls from multiple vendors. It can quickly detect link failures, and converges network traffic

without networking loops. It also has features to control which routes are propagated, allowing for smaller routing tables, and provides better load balancing on external links when compared to other routing protocols.

To configure OSPF in the GUI, go to *Network > OSPF*:

Option	Description
Router ID	A unique ID to identify your router in the network, typically in the format x.x.x.x.
Areas	The areas that the router is part of. For each area, define the <i>Area ID</i> , <i>Type</i> , and <i>Authentication</i> method.
Networks	The networks that OSPF is enabled in, and the area that they belong to.
Interfaces	OSPF interfaces for transmitting and receiving packets. Configure interface properties, such as <i>Network Type</i> , <i>Cost</i> , <i>Hello interval</i> , and others.
Advanced Options	Settings for <i>Inject Default Route</i> , <i>Passive Interfaces</i> , and <i>Redistribute</i> . Redistribution can be enabled by protocol and the metric for each protocol can be configured.

This section includes the following topics:

- [Basic OSPF example on page 384](#)

Basic OSPF example

In this example, three FortiGate devices are configured in an OSPF network.

- Router1 is the Designated Router (DR). It has the highest priority and the lowest IP address, to ensure that it becomes the DR.
- Router2 is the Backup Designated Router (BDR). It has a high priority to ensure that it becomes the BDR.
- Router3 is the Autonomous System Border Router (ASBR). It routes all traffic to the ISP BGP router for internet access. It redistributes routes from BGP and advertises a default route to its neighbors. It can allow different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics can be assigned to these routes to make them more or less preferred than regular OSPF routes. Route maps could be used to further control what prefixes are advertised or received from the ISP.

FortiGate	Interface	IP address
Router1 (DR)	port1	10.11.101.1
	port2	10.11.102.1
	port3	192.168.102.1
Router2 (BDR)	port1	10.11.101.2
	port2	10.11.103.2
	port3	192.168.103.2
Router3 (ASBR)	port1	10.11.102.3
	port2	10.11.103.3
	port3	172.20.120.3

- Firewall policies are already configured to allow unfiltered traffic in both directions between all of the connected interfaces.
- The interfaces are already configured, and NAT is only used for connections to public networks. The costs for all of the interfaces is left at 0.
- The OSPF network belongs to Area 0, and is not connected to any other OSPF networks. All of the routers are part of the backbone 0.0.0.0 area, so no inter-area communications are needed.
- Router3 redistributes BGP routes into the OSPF AS and peers with the ISP BGP Router over eBGP. For information about configuring BGP, see [BGP on page 395](#).
- The advertised networks - 10.11.101.0, 10.11.102.0, and 10.11.103.0 - are summarized by 10.11.0.0/16. Additional networks are advertised individually by the /24 subnet.

Router1

To configure Router1 in the GUI:

1. Go to *Network > OSPF*.
2. Set *Router ID* to *10.11.101.1*.
3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.
5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

6. Click *OK*.
7. In the *Networks* table, click *Create New* again and set the following:

Area	0.0.0.0
IP/Netmask	192.168.102.0 255.255.255.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router1-Internal-DR
Interface	port1
Cost	0
Priority	255
Authentication	None
Timers	<ul style="list-style-type: none"> • Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router1-External
Interface	port2
Cost	0
Authentication	None
Timers	<ul style="list-style-type: none"> • Hello Interval: 10 • Dead Interval: 40

12. Click *OK*.
13. Click *Apply*.

To configure Router1 in the CLI:

```
config router ospf
  set router-id 10.11.101.1
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit "Router1-Internal-DR"
      set interface "port1"
      set priority 255
      set dead-interval 40
      set hello-interval 10
    next
    edit "Router1-External"
      set interface "port2"
      set dead-interval 40
      set hello-interval 10
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0 255.255.0.0
    next
    edit 2
      set prefix 192.168.102.0 255.255.255.0
    next
  end
end
```

Router2

To configure Router2 in the GUI:

1. Go to *Network > OSPF*.
2. Set *Router ID* to *10.11.101.2*.
3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.
5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

6. Click *OK*.
7. In the *Networks* table, click *Create New* again and set the following:

Area	0.0.0.0
IP/Netmask	192.168.103.0 255.255.255.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router2-Internal
Interface	port1
Cost	0
Priority	250
Authentication	None
Timers	<ul style="list-style-type: none"> • Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router2-External
Interface	port2
Cost	0
Authentication	None
Timers	<ul style="list-style-type: none"> • Hello Interval: 10 • Dead Interval: 40

12. Click *OK*.
13. Click *Apply*.

To configure Router2 in the CLI:

```

config router ospf
  set router-id 10.11.101.1
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit "Router2-Internal"
      set interface "port1"
      set priority 250
      set dead-interval 40
      set hello-interval 10
    next
    edit "Router2-External"
      set interface "port2"
  
```

```

        set dead-interval 40
        set hello-interval 10
    next
end
config network
    edit 1
        set prefix 10.11.0.0 255.255.0.0
    next
    edit 2
        set prefix 192.168.103.0 255.255.255.0
    next
end
end

```

Router3

To configure Router3 in the GUI:

1. Go to *Network > OSPF*.
2. Set *Router ID* to *10.11.103.3*.
3. Under *Default Settings*, set *Inject default route* to *Regular Areas*.
A default route must be present on Router3 to advertise it to other routers.
4. Enable *Redistribute BGP* and use the default settings.
5. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

6. Click *OK*.
7. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.0.0 255.255.0.0

8. Click *OK*.
9. In the *Interfaces* table, click *Create New* and set the following:

Name	Router3-Internal
Interface	port1
Cost	0
Authentication	None
Timers	<ul style="list-style-type: none"> • Hello Interval: 10 • Dead Interval: 40

10. Click *OK*.
11. In the *Interfaces* table, click *Create New* again and set the following:

Name	Router3-Internal2
Interface	port2
Cost	0
Authentication	None
Timers	<ul style="list-style-type: none">• Hello Interval: 10• Dead Interval: 40

12. Click *OK*.

13. Click *Apply*.

To configure Router3 in the CLI:

```
config router ospf
  set default-information-originate enable
  set router-id 10.11.103.3
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit "Router3-Internal"
      set interface "port1"
      set dead-interval 40
      set hello-interval 10
    next
    edit "Router3-Internal2"
      set interface "port2"
      set dead-interval 40
      set hello-interval 10
    next
  end
  config network
    edit 1
      set prefix 10.11.0.0 255.255.0.0
    next
  end
  config redistribute "bgp"
    set status enable
  end
end
```

To configure BGP on Router3 in the CLI:

```
config router bgp
  set as 64511
  set router-id 1.1.1.1
  config neighbor
    edit "172.20.120.5"
      set remote-as 64512
    next
  end
  config network
```

```

edit 1
    set prefix 172.20.120.0 255.255.255.0
next
end
end

```

For more information on configuring BGP, see [BGP on page 395](#).

Testing the configuration

Both the network connectivity and OSPF routing are tested. When a link goes down, routes should converge as expected.

Working state

- Router3:

```

Router3 # get router info ospf neighbor
OSPF process 0, VRF 0:
Neighbor ID      Pri   State           Dead Time   Address      Interface
10.11.101.1     1    Full/Backup     00:00:34   10.11.102.1  port1
10.11.101.2     1    Full/Backup     00:00:38   10.11.103.2  port2

Router3 # get router info ospf status
Routing Process "ospf 0" with ID 10.11.103.3
Process uptime is 18 hours 52 minutes
Process bound to VRF default
Conforms to RFC2328, and RFC1583Compatibility flag is disabled
Supports only single TOS(TOS0) routes
Supports opaque LSA
Do not support Restarting
This router is an ASBR (injecting external routing information)
SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
Refresh timer 10 secs
Number of incoming current DD exchange neighbors 0/5
Number of outgoing current DD exchange neighbors 0/5
Number of external LSA 3. Checksum 0x021B78
Number of opaque AS LSA 0. Checksum 0x000000
Number of non-default external LSA 2
External LSA database is unlimited.
Number of LSA originated 16
Number of LSA received 100
Number of areas attached to this router: 1
  Area 0.0.0.0 (BACKBONE)
    Number of interfaces in this area is 2(2)
    Number of fully adjacent neighbors in this area is 2
    Area has no authentication
    SPF algorithm last executed 00:37:36.690 ago
    SPF algorithm executed 13 times
    Number of LSA 6. Checksum 0x03eafa

```

BGP

Border Gateway Protocol (BGP) is a standardized routing protocol that is used to route traffic across the internet. It exchanges routing information between Autonomous Systems (AS) on the internet and makes routing decisions based on path, network policies, and rule sets. BGP contains two distinct subsets: internal BGP (iBGP) and external BGP (eBGP). iBGP is intended for use within your own networks. eBGP is used to connect different networks together and is the main routing protocol for the internet backbone.

To configure BGP in the GUI, go to *Network > BGP*:

Option	Description
Local AS	The AS number for the local router.
Router ID	A unique ID to identify your router in the network, typically in the format x.x.x.x.
Neighbors	The neighbors that the FortiGate will be peering with. Configure the remote router's AS number, any other properties used for peering with the neighbor, and IPv4 and IPv6 filtering.
Neighbor Groups	The neighbor groups that share the same outbound policy configurations.
Neighbor Ranges	The source address range of BGP neighbors that will be automatically assigned to a neighbor group.
IPv4 & IPv6 Networks	The networks to be advertised to other BGP routers.
IPv4 & IPv6 Redistribute	Enable redistribution by protocol. Specify either <i>All</i> routes, or <i>Filter</i> by route map.
Dampening	Enable route flap dampening to reduce the propagation of flapping routes.
Graceful Restart	Enable BGP graceful restart, which causes the adjacent routers to keep routes active while the BGP peering is restarted on the FortiGate. This is useful in HA instances when failover occurs.
Advanced Options	Various advanced settings, such as <i>Local Preference</i> , <i>Distance internal</i> , <i>Keepalive</i> , <i>Holdtime</i> , and others
Best Path Selection	Configure path selection attributes on this router.

Currently, FortiGates do not support BGP graceful restart when peering with neighbor routers operating in graceful restart helper-only mode.

This section includes the following topics:

Basic BGP example

In this example, BGP is configured on two FortiGate devices. The FortiGates are geographically separated, and form iBGP peering over a VPN connection. FGT_A also forms eBGP peering with ISP2.

FGT_A learns routes from ISP2 and redistributes them to FGT_B while preventing any iBGP routes from being advertised.

The internal networks behind the FortiGates can communicate with each other, and the internal networks behind FGT_B can traverse FGT_A to reach networks that are advertised by ISP2.

- FGT_A and FGT_B have static routes to each other through ISP1. ISP1 does not participate in BGP.
- The IPsec VPN tunnel between FGT_A and FGT_B is configured with wildcard 0.0.0.0/0 networks for phase2 local and remote selectors. The VPN interfaces have IP addresses already configured and are used for peering between FGT_A and FGT_B.
- FGT_A is configured to peer with ISP2 on 10.10.108.86.
- The firewall policies between FGT_A and FGT_B are not NATed. The firewall policies egressing on wan2 are NATed.

Configuring iBGP peering

To configure FGT_A to establish iBGP peering with FGT_B in the GUI:

1. Go to *Network > BGP*.
2. Set *Local AS* to 64511
3. Set *Router ID* to 1.1.1.1.
4. In the *Neighbors* table, click *Create New* and set the following:

IP	10.100.201.88
Remote AS	64511

5. Click *OK*.
6. Under *Networks*, set *IP/Netmask* to *192.168.86.0/24*.
7. Click *Apply*.
8. In the CLI, set the interface used as the source IP address of the TCP connection (where the BGP session, TCP/179, is connecting from) for the neighbor (*update-source*) to *toFGTB*.

To configure FGT_A to establish iBGP peering with FGT_B in the CLI:

```
config router bgp
  set as 64511
  set router-id 1.1.1.1
  config neighbor
    edit "10.100.201.88"
      set remote-as 64511
      set update-source "toFGTB"
    next
  end
  config network
    edit 1
      set prefix 192.168.86.0 255.255.255.0
    next
  end
end
```

To configure FGT_B to establish iBGP peering with FGT_A in the GUI:

1. Go to *Network > BGP*.
2. Set *Local AS* to *64511*
3. Set *Router ID* to *2.2.2.2*.
4. In the *Neighbors* table, click *Create New* and set the following:

IP	10.100.201.86
Remote AS	64511

5. Click *OK*.
6. Under *Networks*, set *IP/Netmask* to *192.168.88.0/24*.
7. Click *Apply*.
8. In the CLI, set the interface used as the source IP address of the TCP connection (where the BGP session, TCP/179, is connecting from) for the neighbor (*update-source*) to *toFGTA*.

To configure FGT_B to establish iBGP peering with FGT_A in the CLI:

```
config router bgp
  set as 64511
  set router-id 2.2.2.2
  config neighbor
    edit "10.100.201.86"
```

```
        set remote-as 64511
        set update-source "toFGTA"
    next
end
config network
    edit 1
        set prefix 192.168.88.0 255.255.255.0
    next
end
end
```

To check the FGT_A and FGT_B peering:

1. Check the BGP neighbors:

```
# get router info bgp neighbors
```

2. Check the networks learned from neighbors:

```
# get router info bgp network
```

3. Check that the routes are added to the routing table:

```
# get router info routing-table all
```

To see the neighborhood status, network, and routing table command outputs for the completed example, see [Troubleshooting and debugging on page 400](#).

Configuring eBGP peering

By establishing eBGP peering with ISP2, learned routes will have a distance of 20 and will automatically be propagated to iBGP peers. iBGP peers do not change the next hop when they advertise a route. To make FGT_B receive a route with FGT_A as the next hop, and not ISP 2's network, *Next hop self* (`next-hop-self`) is enabled for routes advertised to FGT_B.

Additionally, to peer with another router that is multiple hops away, enable `ebg-enforce-multihop` in the neighbor configuration.

In this example, the iBGP routes are automatically advertised to the eBGP neighbor, so a route map is created to deny iBGP routes from being advertised to ISP 2. Prefixes from ISP 2 are advertised to FGT_A and FGT_B, but no prefixes are advertised from FGT_A to ISP 2.

To configure FGT_A to establish eBGP peering with ISP 2 in the GUI:

1. Configure a route map to prevent advertisement of iBGP routes to ISP 2:
 - a. Go to *Network > Routing Objects* and click *Create New > Route Map*.
 - b. Set *Name* to *exclude1*.
 - c. In the *Rules* table, click *Create New*.
 - d. Set *Action* to *Deny*.
 - e. Under *Other Rule Variables*, enable *Match origin* and set it to *IGP*.
 - f. Click *OK*.
 - g. Click *OK*.
2. Update the BGP configuration:

- a. Go to *Network > BGP*.
- b. In the *Neighbors* table, click *Create New* and set the following:

IP	10.10.102.87
Remote AS	64512
Route map out	exclude1

- c. Click *OK*.
- d. In the *Neighbors* table, edit the previously created entry, *10.100.201.88*.
- e. Under *IPv4 Filtering*, select *Next hop self*.
- f. Click *OK*.
- g. Click *Apply*.

To configure FGT_A to establish eBGP peering with ISP 2 in the CLI:

1. Configure a route map to prevent advertisement of iBGP routes to ISP 2:

```
config router route-map
  edit "exclude1"
    config rule
      edit 1
        set action deny
        set match-origin igp
      next
    end
  next
end
```

2. Update the BGP configuration:

```
config router bgp
  config neighbor
    edit "10.10.102.87"
      set remote-as 64512
      set route-map-out "exclude1"
    next
    edit "10.100.201.88"
      set next-hop-self enable
    next
  end
end
```

To see the neighborhood status, network, and routing table command outputs for the completed example, see [Troubleshooting and debugging on page 400](#).

Firewall policies

On FGT_A configure the following policies:

- Allow the internal subnet to the VPN interface. Do not enable NAT. Enable security profiles as required.
- Allow the VPN interface to the internal subnet. Do not enable NAT. Enable security profiles as required.
- Allow the internal subnet to wan2. Enable NAT and security profiles as required.
- Allow VPN traffic from toFGTA to wan2. Enable NAT and security profiles as required.

On FGT_B configure the following policies:

- Allow the internal subnet to the VPN interface. Do not enable NAT. Enable security profiles as required.
- Allow the VPN interface to the internal subnet. Do not enable NAT. Enable security profiles as required.

To verify that pinging from FGT_B to FGT_A is successful:

```
FGT_B # execute ping-options source 192.168.88.88
FGT_B # execute ping 192.168.86.86
PING 192.168.86.86 (192.168.86.86): 56 data bytes
64 bytes from 192.168.86.86: icmp_seq=0 ttl=255 time=0.5 ms
...
--- 192.168.86.86 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.3/0.3/0.5 ms
```

To verify that pinging from FGT_B to a subnet in ISP 2 is successful:

```
FGT_B # execute ping-options source 192.168.88.88
FGT_B # execute ping 172.16.201.87
PING 172.16.201.87 (172.16.201.87): 56 data bytes
64 bytes from 172.16.201.87: icmp_seq=0 ttl=254 time=0.6 ms
...
--- 172.16.201.87 ping statistics ---
5 packets transmitted, 5 packets received, 0% packet loss
round-trip min/avg/max = 0.4/0.4/0.6 ms

FGT_B # execute traceroute-options source 192.168.88.88
FGT_B # execute traceroute 172.16.201.87
traceroute to 172.16.201.87 (172.16.201.87), 32 hops max, 3 probe packets per hop, 84 byte
packets
 1  10.100.201.86  0.315 ms  0.143 ms  0.110 ms
 2  172.16.201.87  0.258 ms  0.144 ms  0.222 ms
```

Troubleshooting and debugging

When troubleshooting issues, logically step through the debugs. For example, if peering cannot be established between FGT_A and FGT_B:

1. Verify the basic connectivity between the FGT_A wan1 interface and the FGT_B port1 interface.
2. Verify that the VPN between FGT_A and FGT_B is established.
3. Verify the connectivity between the VPN interfaces.
4. Check the neighborhood status on each peer. Use the BGP state to help determine the possible issue, for example:

Idle state	The local FortiGate has not started the BGP process with the neighbor. This could be because the eBGP peer is multiple hops away, but multihop is not enabled.
Connect	The local FortiGate has started the BGP process, but has not initiated a TCP connection, possibly due to improper routing.
Active	The local FortiGate has initiated a TCP connection, but there is no response. This might indicate issues with the delivery or the response from the remote peer.

5. If there are issues establishing the TCP connection, use the command `diagnose sniffer packet any 'tcp and port 179'` to identify the problem at the packet level.

The following outputs show instances where all of the configurations are completed, peering has formed, and routes have been exchanged. The debug output during each configuration step might differ from these outputs. These debug outputs can be used to help identify what might be missing or misconfigured on your device.

To verify the status of the neighbors:

```
FGT_A # get router info bgp neighbors
VRF 0 neighbor table:
BGP neighbor is 10.10.102.87, remote AS 64512, local AS 64511, external link

```

Route filtering with a distribution list

During BGP operations, routes can be propagated between BGP peers and redistributed from other routing protocols. In some situations, advertising routes from one peer to another might need to be prevented.

The [Basic BGP example on page 396](#) explains using a route map to filter routes that are learned from iBGP to prevent them from propagating to an eBGP peer. In this example, a distribution list is used to prevent certain routes from one peer from being advertised to another peer.

- A company has its own web and email servers in an OSPF area, and needs to advertise routes to these resources to external peers. Users, routers, and other server all reside in the OSPF area.
- The FortiGate acts as the BGP border router, redistributing routes from the company's network to its BGP peers. It is connected to the OSPF area using its DMZ interface.
- Two ISP managed BGP peers in an AS (Peer 1 and Peer 2) are used to access the internet, and routes must not to be advertised from Peer 1 to Peer 2. The manufacturers of these routers, and information about other devices on the external BGP AS, are not known.
- Routes to the BGP peers are redistributed so that external locations can access the web and email servers in the OSPF area. The FortiGate device's external interfaces and the BGP peers are in different ASs, and form eBGP peers.
- Other networking devices must be configured for BGP. The peer routers must be updated with the FortiGate device's BGP information, including IP addresses, AS number, and any specific capabilities that are used, such as IPv6, graceful restart, BFD, and so on.
- It is assumed that security policies have been configured to allow traffic between the networks and NAT is not used. To tighten security, only the required services should be allowed inbound to the various servers.
- In a real life scenario, public IP addresses would be used in place of private IP addresses.

Configuring BGP

In this example, Peer 1 routes are blocked from being advertised to Peer 2 using an access list. All incoming routes from Peer 1 are blocked when updates are sent to Peer 2.

Routes learned from OSPF are redistributed into BGP. EBGP multi path is enabled to load-balance traffic between the peers using ECMP. See [Equal cost multi-path on page 353](#) for more information.

To configure BGP in the GUI:

1. Configure an access list to block Peer 1 routes:
 - a. Go to *Network > Routing Objects* and click *Create New > Access List*.
 - b. Set *Name* to *block_peer1*.
 - c. In the *Rules* table, click *Create New*.
 - d. Set *Action* to *Deny*.
 - e. Enable *Exact Match* and specify the prefix *172.21.111.0 255.255.255.0*.
 - f. Click *OK*.
 - g. Click *OK*.
2. Configure BGP:
 - a. Go to *Network > BGP*.
 - b. Set *Local AS* to *65001*
 - c. Set *Router ID* to *10.11.201.110*.
 - d. In the *Neighbors* table, click *Create New* and set the following:

IP	172.21.111.5
Remote AS	65001

- e. Click *OK*.
- f. In the *Neighbors* table, click *Create New* again and set the following:

IP	172.22.222.5
Remote AS	65001
Distribute list out	Enable, and select the <i>block_peer1</i> access list.

- g. Click *OK*.
- h. Under *IPv4 Redistribute*, enable *OSPF* and select *ALL*.
- i. Expand *Best Path Selection* and enable *EBGP multi path*.
- j. Click *Apply*.

To configure BGP in the CLI:

1. Configure an access list to block Peer 1 routes:

```
config router access-list
  edit "block_peer1"
    config rule
      edit 1
        set action deny
        set prefix 172.21.111.0 255.255.255.0
        set exact-match enable
      next
    end
  next
end
```

2. Configure BGP:

```

config router bgp
  set as 65001
  set router-id 10.11.201.110
  set ebgp-multipath enable
  config neighbor
    edit "172.21.111.5"
      set remote-as 65001
    next
    edit "172.22.222.5"
      set distribute-list-out "block_peer1"
      set remote-as 65001
    next
  end
  config redistribute "ospf"
    set status enable
  end
end

```

Configuring OSPF

In this example, all of the traffic is within the one OSPF area, and there are other OSPF routers in the network. When adjacencies are formed, other routers receive the routes advertised from the FortiGate that are redistributed from BGP.

To configure OSPF in the GUI:

1. Go to *Network > OSPF*.
2. Set *Router ID* to *10.11.201.110*.
3. In the *Areas* table, click *Create New* and set the following:

Area ID	0.0.0.0
Type	Regular
Authentication	None

4. Click *OK*.
5. In the *Networks* table, click *Create New* and set the following:

Area	0.0.0.0
IP/Netmask	10.11.201.0 255.255.255.0

6. Click *OK*.
7. In the *Interfaces* table, click *Create New* and set the following:

Name	OSPF_dmz_network
Interface	dmz

8. Click *OK*.
9. Enable *Redistribute BGP* and set *Metric value* to *1*.
10. Click *Apply*.

To configure OSPF in the CLI:

```
config router ospf
  set router-id 10.11.201.110
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit "OSPF_dmz_network"
      set interface "dmz"
    next
  end
  config network
    edit 1
      set prefix 10.11.201.0 255.255.255.0
    next
  end
  config redistribute "bgp"
    set status enable
    set metric 1
  end
end
```

Testing the configuration

To test this configuration, run the standard connectivity checks, and also make sure that routes are being passed between protocols as expected. Use the following checklist to help verify that the FortiGate is configured successfully:

1. Check that the FortiGate has established peering with BGP Peer 1 and Peer 2:

```
# get router info bgp summary
# get router info bgp neighbors
```

2. Check that the FortiGate has formed adjacency with OSPF neighbors:

```
# get router info ospf status
# get router info ospf neighbors
```

3. Check the routing table on the FortiGate to make sure that routes from both OSPF and BGP are included:

```
# get router info routing-table all
```

4. Check devices in the OSPF network for internet connectivity and to confirm that routes redistributed from BGP are in their routing tables.
5. Check the routing table on Peer 2 to confirm that no routes from Peer 1 are included.
6. Check that the routes from the internal OSPF network are redistributed to Peer 1 and Peer 2.
7. Verify connectivity to the HTTP and email servers.

Next hop recursive resolution using other BGP routes

By default, BGP routes are not considered when a BGP next hop requires recursive resolution. They are considered when `recursive-next-hop` is enabled. Recursive resolution will resolve to one level.

To consider BGP routes for recursive resolution of next hops:

```
config router bgp
  set recursive-next-hop enable
end
```

Example**To see the change in the routing table when the option is enabled:****1. Check the BGP routing table:**

```
# get router info routing-table bgp
Routing table for VRF=0
B 10.100.1.4/30 [200/0] via 10.100.1.14 (recursive is directly connected, R560),
00:02:06
```

2. Enable BGP routes for recursive resolution of next hops:

```
config router bgp
  set recursive-next-hop enable
end
```

3. Check the BGP routing table again:

```
# get router info routing-table bgp
Routing table for VRF=0
B 10.100.1.4/30 [200/0] via 10.100.1.14 (recursive is directly connected, R560),
00:02:15
B 172.16.203.0/24 [200/0] via 10.100.1.6 (recursive via 10.100.1.14, R560),
00:00:06
```

The second BGP route's next hop is now recursively resolved by another BGP route.

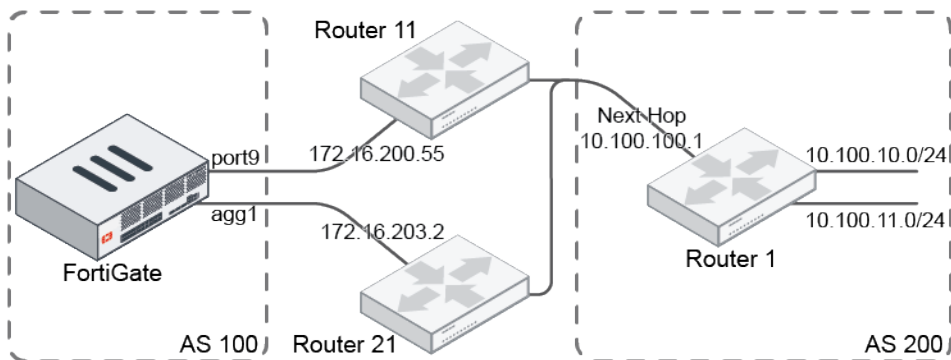

Next hop recursive resolution using ECMP routes

When there are multiple ECMP routes to a BGP next hop, all of them are considered for the next hop recursive resolution. This ensures that the outgoing traffic can be load balanced.

To support multipath, either EGBP or IGBP multipath must be enabled:

```
config router bgp
  set ebgp-multipath enable
  set ibgp-multipath enable
end
```

In this example, there are two static routes. The FortiGate has learned two BGP routes from Router 1 that have the same next hop at 10.100.100.1. The next hop is resolved by the two static routes.

To verify that the routes are added to the BGP routing table:

1. Check the two static routes:

```
# get router info routing-table static
Routing table for VRF=0
S      10.100.100.0/24 [10/0] via 172.16.200.55, port9
      [10/0] via 172.16.203.2, agg1
```

2. Confirm that both routes are in the BGP routing table:

```
# get router info routing-table bgp
Routing table for VRF=0
B      10.100.10.0/24 [20/200] via 10.100.100.1 (recursive via 172.16.200.55, port9),
00:00:07                                     (recursive via 172.16.203.2, agg1),
00:00:07
B      10.100.11.0/24 [20/200] via 10.100.100.1 (recursive via 172.16.200.55, port9),
00:00:07                                     (recursive via 172.16.203.2, agg1),
00:00:07
```

BGP conditional advertisement

BGP conditional advertisement allows the router to advertise a route only when certain conditions are met. Multiple conditions can be used together, with conditional route map entries treated as an AND operator, and IPv6 is supported.

Multiple conditions example

In this example, the FortiGate only advertises routes to its neighbor 2.2.2.2 if it learns multiple BGP routes defined in its conditional route map entry. All conditionals must be met.

To configure multiple conditions in BGP conditional advertisements:**1. Configure the IPv4 prefix list:**

```
config router prefix-list
  edit "281"
    config rule
      edit 1
        set prefix 172.28.1.0 255.255.255.0
        unset ge
        unset le
      next
    end
  next
  edit "282"
    config rule
      edit 1
        set prefix 172.28.2.0 255.255.255.0
        unset ge
        unset le
      next
    end
  next
  edit "222"
    config rule
      edit 1
        set prefix 172.22.2.0 255.255.255.0
        unset ge
        unset le
      next
    end
  next
end
```

2. Configure the IPv4 route maps:

```
config router route-map
  edit "2814"
    config rule
      edit 1
        set match-ip-address "281"
      next
    end
  next
  edit "2224"
    config rule
      edit 1
        set match-ip-address "222"
      next
    end
  next
  edit "2824"
    config rule
      edit 1
        set match-ip-address "282"
      next
    end
end
```

```
    next
end
```

3. Configure the IPv6 prefix list:

```
config router prefix-list6
  edit "adv-2226"
    config rule
      edit 1
        set prefix6 2003:172:22:1::/64
        unset ge
        unset le
      next
    end
  next
edit "list6-1"
  config rule
    edit 1
      set prefix6 2003:172:28:1::/64
      unset ge
      unset le
    next
  end
next
edit "list6-2"
  config rule
    edit 1
      set prefix6 2003:172:28:2::/64
      unset ge
      unset le
    next
  end
next
end
```

4. Configure the IPv6 route maps:

```
config router route-map
  edit "map-2226"
    config rule
      edit 1
        set match-ip6-address "adv-2226"
      next
    end
  next
edit "map-2816"
  config rule
    edit 1
      set match-ip6-address "list6-1"
    next
  end
next
edit "map-2826"
  config rule
    edit 1
      set match-ip6-address "list6-2"
    next
  end
```

```

        end
    next
end

```

5. Configure the BGP settings:

```

config router bgp
  config neighbor
    edit "2.2.2.2"
      config conditional-advertise
        edit "2224"
          set condition-routemap "2814" "2824"
          set condition-type non-exist
        next
      end
    next
  edit "2003::2:2:2:2"
    config conditional-advertise6
      edit "map-2226"
        set condition-routemap "map-2816" "map-2826"
      next
    end
    set route-reflector-client6 enable
  next
end
end

```

To verify the IPv4 conditional advertisements:

```

# get router info bgp neighbors 2.2.2.2
...
Conditional advertise-map:
  Adv-map 2224root 2814root, cond-state 0-1
          2824root, cond-state 0-1
...

```

In this output, the condition is that the routes in route maps 2814 and 2824 do not exist. However, routes for 2814 and 2224 exist, so the conditions are not met.

To verify the IPv6 conditional advertisements:

```

# get router info6 bgp neighbors 2003::2:2:2:2
...
Conditional advertise-map:
  Adv-map map-2226root map-2816root, cond-state 1-1
          map-2826root, cond-state 1-0
...

```

In this output, the condition is that the routes in route maps map-2816 and map-2826 exist. However, routes for map-2816 exist, but map-2826 does not, so the conditions are not met.

To view the conditional route maps:

```

# diagnose ip router command show-vrf root show running router bgp
...
neighbor 2.2.2.2 advertise-map 2224root exist-map 2814root
neighbor 2.2.2.2 advertise-map 2224root exist-map 2824root

```

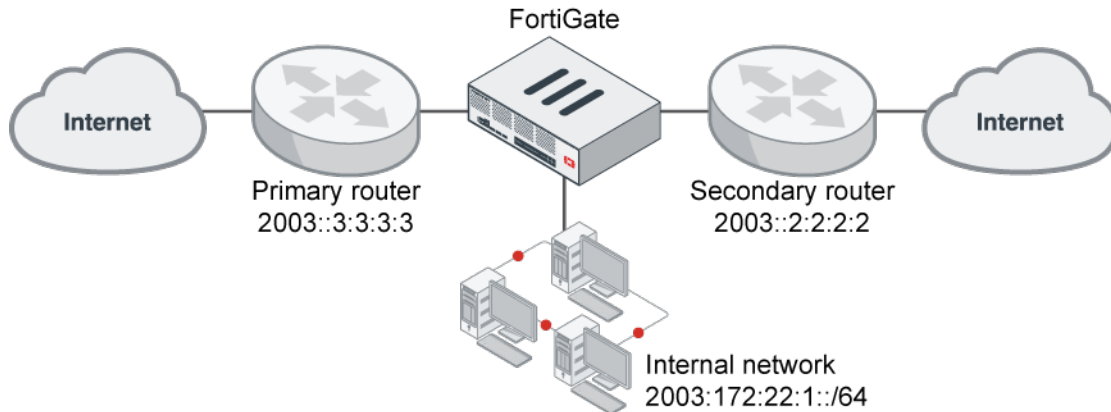

```

... ..
!
address-family ipv6
neighbor 2003::2:2:2:2 advertise-map map-2226root non-exist-map map-2816root
neighbor 2003::2:2:2:2 advertise-map map-2226root non-exist-map map-2826root
!

```

IPv6 example 1

In this example, the FortiGate advertises its local network to the secondary router when the primary router is down. The FortiGate detects the primary router is down in the absence of a learned route.

- When the FortiGate learns route 2003:172:28:1::/64 from the primary router, it does not advertise its local route (2003:172:22:1::/64) to the secondary router.
- When the FortiGate does not learn route 2003:17:28:1::/64 from the primary router, advertises its local route (2003:172:22:1::/64) to the secondary router.
- The BGP conditional advertisement condition is set to be true if the condition route map (2003:172:28:1::/64) is not matched (non-exist).

To configure BGP conditional advertisement with IPv6:

1. Configure the IPv6 prefix lists:

```

config router prefix-list6
  edit "adv-222"
    config rule
      edit 1
        set prefix6 2003:172:22:1::/64
        unset ge
        unset le
      next
    end
  next
  edit "lrn-281"
    config rule
      edit 1
        set prefix6 2003:172:28:1::/64
        unset ge
        unset le
      next
    end
  next
end

```

```
        end
    next
end
```

2. Configure the route maps:

```
config router route-map
    edit "map-221"
        config rule
            edit 1
                set match-ip6-address "adv-222"
            next
        end
    next
    edit "map-281"
        config rule
            edit 1
                set match-ip6-address "lrn-281"
            next
        end
    next
end
```

3. Configure BGP:

```
config router bgp
    set as 65412
    set router-id 1.1.1.1
    set ibgp-multipath enable
    set network-import-check disable
    set graceful-restart enable
    config neighbor
        edit "2003::2:2:2:2"
            set soft-reconfiguration6 enable
            set remote-as 65412
            set update-source "loopback1"
            config conditional-advertise6
                edit "map-221"
                    set condition-routemap "map-281"
                    set condition-type non-exist
                next
            end
        next
    edit "2003::3:3:3:3"
        set soft-reconfiguration6 enable
        set remote-as 65412
        set update-source "loopback1"
    next
end
```

In this configuration, if route map `map-281` does not exist, then the FortiGate advertises route map `map-221` to neighbor `2003::2:2:2:2`.

4. Verify the routing table:

```
# get router info6 routing-table bgp
B      2003:172:28:1::/64 [200/0] via 2003::3:3:3:3 (recursive via
****:***:***:****:****, port9), 01:23:45
```

```
B          2003:172:28:2::/64 [200/0] via 2003::3:3:3:3 (recursive via
****:.*:***:***:***:***:****, port9), 23:09:22
```

When the FortiGate learns 2003:172:28:1::/64, it will not advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2. If the FortiGate has not learned 2003:172:28:1::/64, it will advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2.

IPv6 example 2

With the same IPv6 prefix lists and route maps, when the FortiGate does learn 2003:172:28:1::/64, it advertises local route 2003:172:22:1::/64 to the secondary router. The BGP conditional advertisement condition is set to be true if the condition route map is matched (`exist`).

To configure BGP conditional advertisement with IPv6:

1. Configure BGP:

```
config router bgp
  config neighbor
    edit "2003::2:2:2"
      config conditional-advertise6
        edit "map-221"
          set condition-routemap "map-281"
          set condition-type exist
        next
      end
    next
  end
end
```

2. Verify the routing table:

```
# get router info6 routing-table bgp
B          2003:172:28:1::/64 [200/0] via 2003::3:3:3:3 (recursive via
****:.*:***:***:***:***:****, port9), 01:23:45
B          2003:172:28:2::/64 [200/0] via 2003::3:3:3:3 (recursive via
****:.*:***:***:***:***:****, port9), 23:09:22
```

When the FortiGate learns 2003:172:28:1::/64, it will advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2. If the FortiGate has not learned route 2003:172:28:1::/64, it will not advertise its local route 2003:172:22:1::/64 to neighbor 2003::2:2:2.

BGP error handling per RFC 7606

The FortiGate uses one of the three approaches to handle malformed attributes in BGP UPDATE messages, in order of decreasing severity:

1. Notification and Session reset
2. Treat-as-withdraw
3. Attribute discard

When a BGP UPDATE message contains multiple malformed attributes, the most severe approach that is triggered by one of the attributes is followed. See [RFC 7606](#) for more information.

The following table lists the BGP attributes, and how FortiGate handles a malformed attribute in the UPDATE message:

BGP attribute	Handling
origin	Handled by the treat-as-withdraw approach.
AS path	Handled by the treat-as-withdraw approach.
AS 4 path	Handled by the attribute discard approach.
aggregator	Handled by the attribute discard approach.
aggregator 4	Handled by the attribute discard approach.
next-hop	Handled by the treat-as-withdraw approach.
multiple exit discriminator	Handled by the treat-as-withdraw approach.
local preference	Handled by the treat-as-withdraw approach.
atomic aggregate	Handled by the attribute discard approach.
community	Handled by the treat-as-withdraw approach.
extended community	Handled by the treat-as-withdraw approach.
originator	Handled by the treat-as-withdraw approach.
cluster	Handled by the treat-as-withdraw approach.
PMSI	Handled by the treat-as-withdraw approach.
MP reach	Handled by the notification message approach.
MP unreachable	Handled by the notification message approach.
attribute set	Handled by the treat-as-withdraw approach.
AIGP	Handled by the treat-as-withdraw approach.
Unknown	If the BGP flag does not indicate that this is an optional attribute, this malformed attribute is handled by the notification message approach.

BGP next hop tag-match mode

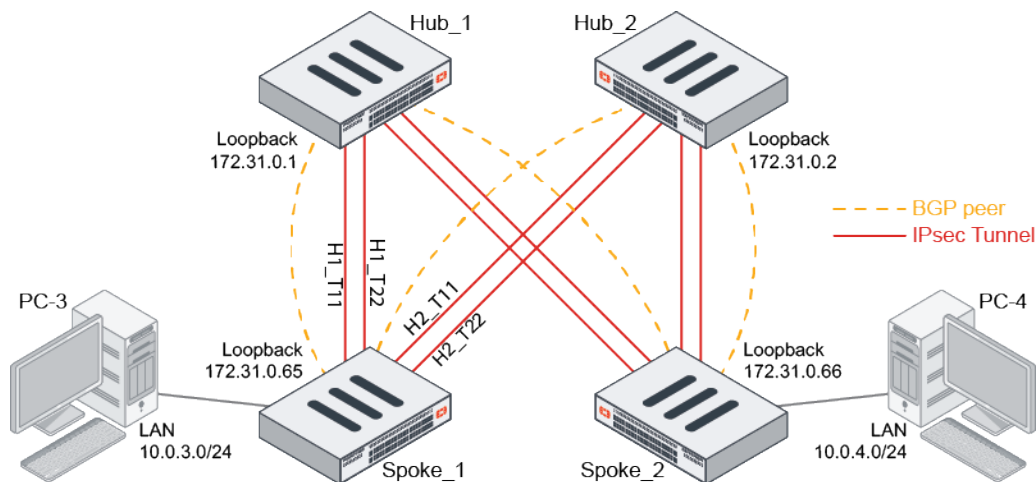

Tag-match mode can be configured to increase flexibility when controlling how BGP routes' next hops are resolved:

```
config router bgp
    set tag-resolve-mode {disable | preferred | merge}
end
```

Best-match (<code>disable</code>)	Resolve the BGP route's next hops with best-matched routes. This is the default setting.
Tag-match (<code>preferred</code>)	Resolve the BGP route's next hops with routes that have the same tag. If there are no results, resolve the next hops with best-matched routes.
Tag-and-best-match (<code>merge</code>)	Merge tag-match with best-match if they are using different routes, then let shortcuts hide their parents. The results exclude the next hops of tag-match whose interfaces have appeared in best-match.

In these examples:

- Each spoke has two IPsec tunnels to each hub, and one BGP peer on loopback interface to each hub (route-reflector).
- The loopbacks are exchanged with IKE between the spokes and hubs. They are installed as static routes that are used to provide reachability for establishing BGP neighbors.
- The summary BGP routes from the loopback IP address ranges that originated on the hubs are advertised to the spokes for resolving the BGP next hops on the spokes.
- The spokes' PC LAN subnets are reflected by the hubs.
- Spoke_1 receives BGP routes (the LAN subnet and loopback IP summary) from Hub_1 with tag 1 and from Hub_2 with tag 2.
- SD-WAN is enabled on Spoke_1, and all of the tunnels are SD-WAN members.

Example 1: Connection between Hub and Spoke down

If the connections between Hub_1 and Spoke_2 are down, traffic from PC_3 to PC_4 can still go through Hub_1 because of the best-match resolving on Spoke_1, but packets will be dropped on Hub_1. When tag-match is enabled on Spoke_1, the spoke will resolve the PC_4 LAN route to Hub2, and traffic will be forwarded to Hub_2 and reach its destination.

To test the tag-match mode:

1. View the key routes on Spoke_1:

```
Spoke_1(root) # get router info routing-table all
C    10.0.3.0/24 is directly connected, port4
B    10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11 tunnel
172.31.1.1), 20:09:52
      (recursive via H1_T22 tunnel 10.0.0.2), 20:09:52
      (recursive via H2_T11 tunnel 172.31.1.101), 20:09:52
      (recursive via H2_T22 tunnel 10.0.0.4), 20:09:52
B    172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
23:25:37
      (recursive via H1_T22 tunnel 10.0.0.2), 23:25:37
      [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 23:25:37
      (recursive via H2_T22 tunnel 10.0.0.4), 23:25:37
S    172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
      [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
```

```
S      172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
      [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C      172.31.0.65/32 is directly connected, Loopback0
...
```

172.31.0.0/25 is the loopback IP summary originated by both Hub_1 and Hub_2. The next hop of the PC_4 LAN route is resolved to Hub_1 (H1_T11, H1_T22) and Hub_2 (H2_T11, H2_T22) based on the loopback IP summary route.

- When connections between Spoke_2 and Hub_1 fails due to the BGP neighbor, tunnels, or physical ports going down, the PC_4 LAN route can be still resolved to Hub_1 and Hub_2 because the loopback IP summary can still be received from both Hub_1 and Hub_2:

```
Spoke_1(root) # get router info routing-table all
C      10.0.3.0/24 is directly connected, port4
B      10.0.4.0/24 [200/0] via 172.31.0.66 (recursive via H1_T11 tunnel 172.31.1.1),
00:03:06
      (recursive via H1_T22 tunnel 10.0.0.2), 00:03:06
      (recursive via H2_T11 tunnel 172.31.1.101), 00:03:06
      (recursive via H2_T22 tunnel 10.0.0.4), 00:03:06
B      172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
23:55:34
      (recursive via H1_T22 tunnel 10.0.0.2), 23:55:34
      [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 23:55:34
      (recursive via H2_T22 tunnel 10.0.0.4), 23:55:34
...
```

- If traffic sent from PC_3 to PC_4 goes through Hub_1, packets are dropped because there is no PC_4 LAN route on Hub_1:

```
Spoke_1 (root) # diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
filters=[host 10.0.4.2]
11.261264 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
11.261349 H1_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request
12.260268 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
12.260291 H1_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request

Hub_1 (root) # diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
filters=[host 10.0.4.2]
6.966064 EDGE_T1 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.965012 EDGE_T1 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
```

- If the tag-match mode is set to tag-match (preferred) on Spoke_1, then the PC_4 LAN route can only be resolved to Hub_2 because of tag-match checking:

```
Spoke_1(root) # get router info routing-table all
C      10.0.3.0/24 is directly connected, port4
B      10.0.4.0/24 [200/0] via 172.31.0.66 tag 2 (recursive via H2_T11 tunnel
172.31.1.101), 00:02:35
      (recursive via H2_T22 tunnel 10.0.0.4), 00:02:35
B      172.31.0.0/25 [200/0] via 172.31.0.1 tag 1 (recursive via H1_T11 tunnel
172.31.1.1), 03:18:41
      (recursive via H1_T22 tunnel 10.0.0.2), 03:18:41
      [200/0] via 172.31.0.2 tag 2 (recursive via H2_T11 tunnel 172.31.1.101),
03:18:41
```

```

(recursive via H2_T22 tunnel 10.0.0.4), 03:18:41
...
Spoke_1 (root) # get router info routing-table details 10.0.4.0/24

Routing table for VRF=0
Routing entry for 10.0.4.0/24
  Known via "bgp", distance 200, metric 0, best
  Last update 00:01:11 ago
  * 172.31.0.66, tag 2 (recursive via H2_T11 tunnel 172.31.1.101), tag-match
    (recursive via H2_T22 tunnel 10.0.0.4), tag-match

```

5. If traffic is again sent from PC_3 to PC_4, it will go through Hub_2 and reach the destination:

```

Spoke_1 (root) # diagnose sniffer packet any 'host 10.0.4.2' 4
interfaces=[any]
filters=[host 10.0.4.2]
7.216948 port4 in 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.217035 H2_T11 out 10.0.3.2 -> 10.0.4.2: icmp: echo request
7.217682 H2_T11 in 10.0.4.2 -> 10.0.3.2: icmp: echo reply
7.217729 port4 out 10.0.4.2 -> 10.0.3.2: icmp: echo reply

```

Example 2: SD-WAN failover when shortcut down

After the shortcut from Spoke_1 to Spoke_2 is established, Spoke_1 will only resolve the PC_4 LAN route to the shortcut, because of best-match resolving, prohibiting SD-WAN failover. When tag-and-best-match is enabled on Spoke_1, the spoke can resolve the PC_4 LAN route to the shortcut and to other alternative tunnels, allowing SD-WAN failover.

To test the tag-and-best-match mode:

1. Unset tag-resolve-mode and resume the connections between Spoke_2 and Hub_1. The routing table on Spoke_1 changes to the initial state:

```

Spoke_1(root) # get router info routing-table all
C    10.0.3.0/24 is directly connected, port4
B    10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11 tunnel
172.31.1.1), 00:01:54
      (recursive via H1_T22 tunnel 10.0.0.2), 00:01:54
      (recursive via H2_T11 tunnel 172.31.1.101), 00:01:54
      (recursive via H2_T22 tunnel 10.0.0.4), 00:01:54
B    172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
03:30:35
      (recursive via H1_T22 tunnel 10.0.0.2), 03:30:35
      [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 03:30:35
      (recursive via H2_T22 tunnel 10.0.0.4), 03:30:35
S    172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
      [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S    172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
      [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C    172.31.0.65/32 is directly connected, Loopback0
...

```

2. Send traffic from PC_3 to PC_4.

The shortcut from Spoke_1 o Spoke_2 is established.

The PC_4 LAN route is only resolved to the shortcut because of best-match resolving. If the shortcut is out of SLA, then the traffic cannot switch over to another, alternative tunnel.

```
Spoke_1 (root) # get router info routing-table all
C    10.0.3.0/24 is directly connected, port4
B    10.0.4.0/24 [200/0] via 172.31.0.66 [2] (recursive via H1_T11_0 tunnel
10.0.0.40), 00:09:22
B    172.31.0.0/25 [200/0] via 172.31.0.1 (recursive via H1_T11 tunnel 172.31.1.1),
03:40:12
      (recursive via H1_T22 tunnel 10.0.0.2), 03:40:12
      [200/0] via 172.31.0.2 (recursive via H2_T11 tunnel 172.31.1.101), 03:40:12
      (recursive via H2_T22 tunnel 10.0.0.4), 03:40:12
S    172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
      [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S    172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
      [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C    172.31.0.65/32 is directly connected, Loopback0
S    172.31.0.66/32 [15/0] via H1_T11_0 tunnel 10.0.0.40, [1/0]
...
```

- If the tag-match mode is set to tag-and-best-match (merge) on Spoke_1, then the PC_4 LAN route is resolved to the H1_T11_0 shortcut based on best-match resolving, and to H1_T11, H1_T22, H2_T11, H2_T22 based on tag-match resolving. It is then resolved to H1_T11, H1_T22, H2_T11, H2_T22 after letting the shortcut hide its parent tunnel.

```
Spoke_1 (root) # get router info routing-table all
C    10.0.3.0/24 is directly connected, port4
B    10.0.4.0/24 [200/0] via 172.31.0.66 tag 1 (recursive via H1_T11_0 tunnel
10.0.0.40), 00:07:36
      (recursive via H1_T22 tunnel 10.0.0.2), 00:07:36
      [200/0] via 172.31.0.66 tag 2 (recursive via H1_T11_0 tunnel 10.0.0.40),
00:07:36
      (recursive via H2_T11 tunnel 172.31.1.101), 00:07:36
      (recursive via H2_T22 tunnel 10.0.0.4), 00:07:36
B    172.31.0.0/25 [200/0] via 172.31.0.1 tag 1 (recursive via H1_T11 tunnel
172.31.1.1), 03:48:26
      (recursive via H1_T22 tunnel 10.0.0.2), 03:48:26
      [200/0] via 172.31.0.2 tag 2 (recursive via H2_T11 tunnel 172.31.1.101),
03:48:26
      (recursive via H2_T22 tunnel 10.0.0.4), 03:48:26
S    172.31.0.1/32 [15/0] via H1_T11 tunnel 172.31.1.1, [1/0]
      [15/0] via H1_T22 tunnel 10.0.0.2, [1/0]
S    172.31.0.2/32 [15/0] via H2_T11 tunnel 172.31.1.101, [1/0]
      [15/0] via H2_T22 tunnel 10.0.0.4, [1/0]
C    172.31.0.65/32 is directly connected, Loopback0
S    172.31.0.66/32 [15/0] via H1_T11_0 tunnel 10.0.0.40, [1/0]
...
```

```

BGP multi-exit discriminator

Border Gateway Protocol (BGP) is the routing protocol that governs how internet traffic is efficiently routed between autonomous systems (AS). BGP uses path attributes for its best path calculation to a network.

Multi-Exit Discriminator (MED) is a BGP path attribute that discriminates among multiple exit or entry points to the same neighboring AS. MED is also known as Optional Non-Transitive path attribute. The lower the MED value, the more preferred the path is to the receiving router.

MED is typically utilized when an AS has multiple exit points to another AS. In such cases, the AS may want to influence incoming traffic by advertising different MED values for the same route.

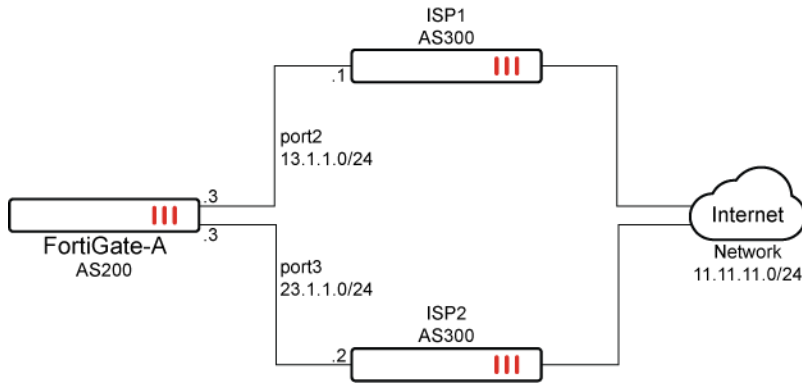

Common use case

A common use case for MED is in the context of a dual-homed AS. In a dual-homed AS scenario, the FortiGate connects to two different ISPs belonging to the same AS for redundancy and load balancing. By manipulating the MED value, the AS can direct traffic to one ISP over the other. For instance, if one link is congested, the AS can advertise a higher MED value for that link, making the other link more suitable to incoming traffic.

MED is a BGP path attribute that discriminates among multiple exit or entry points to the same neighboring AS. If an administrator has two or more eBGP peering to different AS then the local preference can be used to influence the routing decision.

The following example discusses the use of MED in dual-homed AS network and the configuration of MED Path Attribute on FortiOS.

Characteristics of the topology include the following:

- FortiGate-A has two internet service providers: ISP1 and ISP2.
- FortiGate-A belongs to AS 200.
- ISP1 and ISP2 both belong to AS 300.
- FortiGate-A will establish eBGP peering relationships with ISP1 and ISP2.
- Network 11.11.11.0/24 resides on the Internet and is reachable by both ISP1 and ISP2.
- eBGP multipath is enabled on FortiGate-A if FortiGate-A needs to perform equal cost load-balancing of traffic between both ISP1 and ISP2 to reach to 11.11.11.0/24.
- The network 11.11.11.0/24 on the Internet is being advertised by both ISP1 and ISP2 to FortiGate-A through eBGP.

For this example, the traffic originating from behind the FortiGate-A should prefer ISP1 rather than ISP2 to reach 11.11.11.0/24, and needs to use the BGP MED Path Attribute. This is done by configuring `set set-metric` in a route map configuration and ensuring the MED value of ISP1 is less than that of ISP2.

To configure MED in a dual-homed AS network using the CLI:

1. Configure eBGP peering on FortiGate-A by specifying the BGP neighbors:

```

config router bgp
  set as 200
  set router-id 2.2.2.2
  config neighbor
    edit "13.1.1.1"
      set remote-as 300
    next
    edit "23.1.1.2"
      set remote-as 300
    next
  end
end

```

2. Configure eBGP on ISP1 and ISP2, and advertise the 11.11.11.0/24 network:

```

config router bgp
  set as 300
  set router-id 3.3.3.3
  config neighbor
    edit "13.1.1.3"
      set remote-as 200
    next
  end
end

```

```

end
config network
  edit 1
    set prefix 11.11.11.0 255.255.255.0
  next
end
end

```

3. Verify the eBGP neighbors on Fortigate-A with ISP1 and ISP2:

```

# get router info bgp summary
VRF 0 BGP router identifier 2.2.2.2, local AS number 200
BGP table version is 6
1 BGP AS-PATH entries
0 BGP community entries

Neighbor V          AS MsgRcvd MsgSent  TblVer  InQ OutQ Up/Down  State/PfxRcd
13.1.1.1 4            300    48     50       0    0    0 00:25:45      1
23.1.1.2 4            300    56     60       6    0    0 00:26:30      1

```

4. Configure the prefix list to filter and select the 11.11.11.0/24 subnet inside the prefix list:

a. Configure ISP1:

```

config router prefix-list
  edit "ISP1_Prefix_List"
    config rule
      edit 1
        set prefix 11.11.11.0 255.255.255.0
      next
    end
  next
end

```

b. Configure ISP2:

```

config router prefix-list
  edit "ISP2_Prefix_List"
    config rule
      edit 1
        set prefix 11.11.11.0 255.255.255.0
      next
    end
  next
end

```

5. Configure route maps and configure the MED value:

a. Configure ISP1:

```

config router route-map
  edit "MED_Route_MAP"
    config rule
      edit 1
        set match-ip-address "ISP1_Prefix_List"
        set set-metric 300
      next
    end
  next
end

```

b. Configure ISP2:

```

config router route-map
  edit "MED_Route_MAP_2"
    config rule
      edit 1
        set match-ip-address "ISP2_Prefix_List"
        set set-metric 400
      next
    end
  next
end

```

6. Apply the route map in the outbound direction:

Applying the configuration in the outbound direction ensures that the MED is changed to the respective value for the route 11.11.11.0/24 specified in the prefix list.

a. Configure the ISP1 BGP:

```

config router bgp
  set as 300
  set router-id 3.3.3.3
  config neighbor
    edit "13.1.1.3"
      set remote-as 200
      set route-map-out "MED_Route_MAP"
    next
  end
end

```

b. Configure the ISP2 BGP:

```

config router bgp
  set as 300
  set router-id 4.4.4.4
  config neighbor
    edit "23.1.1.3"
      set remote-as 200
      set route-map-out "MED_Route_MAP_2"
    next
  end
end

```

7. Verify that ISP1 is selected as the best path to reach the 11.11.11.0/24 network:

The neighbor that is considered the best, valid route is marked with a *>.

```

# get router info bgp network
VRF 0 BGP table version is 6, local router ID is 2.2.2.2
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete

```

Network	Next Hop	Metric	LocPrf	Weight	RouteTag	Path
*> 11.11.11.0/24	13.1.1.1	300		0	0 300 i	<-/1>
*	23.1.1.2	400		0	0 300 i	<-/->

Total number of prefixes 1

8. Verify the routing table of FortiGate-A:

The routing table only contains the best and valid paths.

```
# get router info routing-table details
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default
```

```
Routing table for VRF=0
B      11.11.11.0/24 [20/300] via 13.1.1.1, port2, 00:37:47
C      13.1.1.0/24 is directly connected, port2
C      23.1.1.0/24 is directly connected, port3
```

Troubleshooting BGP

There are some features in BGP that are used to deal with problems that may arise. Typically, the problems with a BGP network that has been configured involve routes going offline frequently. This is called route flap and causes problems for the routers using that route.

Clearing routing table entries

To see if a new route is being properly added to the routing table, you can clear all or some BGP neighbor connections (sessions) using the `execute router clear bgp` command.

For example, if you have 10 routes in the BGP routing table and you want to clear the specific route to IP address 10.10.10.1, enter the following CLI command:

```
# execute router clear bgp ip 10.10.10.1
```

To remove all routes for AS number 650001, enter the following CLI command:

```
# execute router clear bgp as 650001
```

Route flap

When routers or hardware along a route go offline and back online that is called a route flap. Flapping is the term that is used if these outages continue, especially if they occur frequently.

Route flap is a problem in BGP because each time a peer or a route goes down, all the peer routers that are connected to that out-of-service router advertise the change in their routing tables. This creates a lot of administration traffic on the network and the same traffic re-occurs when that router comes back online. If the problem is something like a faulty

network cable that alternates online and offline every 10 seconds, there could easily be an overwhelming amount of routing updates sent out unnecessarily.

Another possible reason for route flap occurs with multiple FortiGate devices in HA mode. When an HA cluster fails over to the secondary unit, other routers on the network may see the HA cluster as being offline, resulting in route flap. While this doesn't occur often, or more than once at a time, it can still result in an interruption in traffic which is disruptive for network users. The easy solution for this problem is to increase the timers on the HA cluster, such as TTL timers, so they don't expire during the failover process. Also, configuring graceful restart on the HA cluster helps with a smooth failover.

The first method of dealing with route flap is to check your hardware. If a cable is loose or bad, it can easily be replaced and eliminate the problem. If an interface on the router is bad, either avoid using that interface or swap in a functioning router. If the power source is bad on a router, either replace the power supply or use a power conditioning backup power supply. These quick and easy fixes can save you from configuring more complex BGP options. However, if the route flap is from another source, configuring BGP to deal with the outages will ensure your network users uninterrupted service.

Some methods of dealing with route flap in BGP include:

- [Holdtime timer on page 428](#)
- [Dampening on page 429](#)
- [Graceful restart on page 429](#)
- [BFD on page 431](#)

Holdtime timer

The first step to troubleshooting a flapping route is the holdtime timer. This timer reduces how frequently a route going down will cause a routing update to be broadcast.

Once activated, the holdtime timer won't allow the FortiGate to accept any changes to that route for the duration of the timer. If the route flaps five times during the timer period, only the first outage will be recognized by the FortiGate. For the duration of the other outages, there won't be changes because the Fortigate is essentially treating this router as down. If the route is still flapping after the timer expires, it will start again.

If the route isn't flapping (for example, if it goes down, comes up, and stays back up) the timer will still count down and the route is ignored for the duration of the timer. In this situation, the route is seen as down longer than it really is but there will be only the one set of route updates. This isn't a problem in normal operation because updates are not frequent.

The potential for a route to be treated as down when it's really up can be viewed as a robustness feature. Typically, you don't want most of your traffic being routed over an unreliable route. So if there's route flap going on, it's best to avoid that route if you can. This is enforced by the holdtime timer.

How to configure the holdtime timer

There are three different route flapping situations that can occur: the route goes up and down frequently, the route goes down and back up once over a long period of time, or the route goes down and stays down for a long period of time. These can all be handled using the holdtime timer.

For example, your network has two routes that you want to set the timer for. One is your main route (to 10.12.101.4) that all of your Internet traffic goes through, and it can't be down for long if it's down. The second is a low speed connection to a custom network that's used infrequently (to 10.13.101.4). The timer for the main route should be fairly short (for example, 60 seconds). The second route timer can be left at the default, since it's rarely used.

To configure the BGP holdtime timer:

```
config router bgp
  config neighbor
    edit 10.12.101.4
      set holdtime-timer 60
      set keep-alive-timer 60
    next
    edit 10.13.101.4
      set holdtime-timer 180
      set keep-alive-timer 60
    next
  end
end
```

Dampening

Dampening is a method that's used to limit the amount of network problems due to flapping routes. With dampening, the flapping still occurs but the peer routers pay less and less attention to that route as it flaps more often. One flap doesn't start dampening, but the second flap starts a timer where the router won't use that route because it is considered unstable. If the route flaps again before the timer expires, the timer continues to increase. There's a period of time called the reachability half-life, after which a route flap will be suppressed for only half the time. This half-life comes into effect when a route has been stable for a while but not long enough to clear all the dampening completely. For the flapping route to be included in the routing table again, the suppression time must expire.

If the route flapping was temporary, you can clear the flapping or dampening from the FortiGate device's cache by using one of the `execute router clear bgp` CLI commands:

```
# execute router clear bgp dampening {<ip_address> | <ip_address/netmask>}
```

or

```
# execute router clear bgp flap-statistics {<ip_address> | <ip_address/netmask>}
```

For example, to remove route flap dampening information for the 10.10.0.0/16 subnet, enter the following CLI command:

```
# execute router clear bgp dampening 10.10.0.0/16
```

To configure BGP route dampening:

```
config router bgp
  set dampening {enable | disable}
  set dampening-route-map <routemap-name_str>
end
```

Graceful restart

BGP4 has the capability to gracefully restart.

In some situations, route flap is caused by routers that appear to be offline but the hardware portion of the router (control plane) can continue to function normally. One example of this is when some software is restarting or being upgraded but the hardware can still function normally.

Graceful restart is best used for these situations where routing won't be interrupted, but the router is unresponsive to routing update advertisements. Graceful restart doesn't have to be supported by all routers in a network, but the network will benefit when more routers support it.

FortiGate HA clusters can benefit from graceful restart. When a failover takes place, the HA cluster advertises that it is going offline, and will not appear as a route flap. It will also enable the new HA main unit to come online with an updated and usable routing table. If there is a flap, the HA cluster routing table will be out-of-date.

For example, the FortiGate is one of four BGP routers that send updates to each other. Any of those routers may support graceful starting. When a router plans to go offline, it sends a message to its neighbors stating how long it expects to be offline. This way, its neighboring routers don't remove it from their routing tables. However, if that router isn't back online when expected, the routers will mark it offline. This prevents routing flap and its associated problems.

FortiGate devices support both graceful restart of their own BGP routing software and neighboring BGP routers.

Currently, FortiGates do not support BGP graceful restart when peering with neighbor routers operating in graceful restart helper-only mode.

To configure BGP graceful restart:

```
config router bgp
  set graceful-restart {disable | enable}
  set graceful-restart-time <seconds_integer>
  set graceful-stalepath-time <seconds_integer>
  set graceful-update-delay <seconds_integer>
  config neighbor
    edit 10.12.101.4
      set capability-graceful-restart {enable | disable}
    next
  end
end
```

Before the restart, the router sends its peers a message to say it's restarting. The peers mark all the restarting router's routes as stale, but they continue to use the routes. The peers assume the router will restart, check its routes, and take care of them, if needed, after the restart is complete. The peers also know what services the restarting router can maintain during its restart. After the router completes the restart, the router sends its peers a message to say it's done restarting.

To restart the router:

```
# execute router restart
```

Scheduled time offline

Graceful restart is a means for a router to advertise that it is going to have a scheduled shutdown for a very short period of time. When neighboring routers receive this notice, they will not remove that router from their routing table until after a set time elapses. During that time, if the router comes back online, everything continues to function as normal. If that router remains offline longer than expected, then the neighboring routers will update their routing tables as they assume that the router will be offline for a long time.

The following example demonstrates if you want to configure graceful restart on the FortiGate where you expect the FortiGate to be offline for no more than two minutes, and after three minutes the BGP network should consider the FortiGate to be offline.

To configure graceful restart time settings:

```
config router bgp
    set graceful-restart enable
    set graceful-restart-time 120
    set graceful-stalepath-time 180
end
```

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD communicate with each other and if a timer runs out on a connection then that router is declared down. BFD then communicates this information to the routing protocol and the routing information is updated.

For more information about BFD, see [BFD on page 431](#).

BGP path selection process

Sometimes the FortiGate may receive multiple BGP paths from neighbors and must decide which is the best path to take. The following criteria are used to determine the best path.

Consider only routes with no AS loops and a valid next hop, and then:

1. Prefer the highest weight (this attribute is local to the FortiGate).
2. Prefer the highest local preference (applicable within AS).
3. Prefer the route originated by the local router (next hop = 0.0.0.0).
4. Prefer the shortest AS path.
5. Prefer the lowest origin code (IGP > EGP > incomplete).
6. Prefer the lowest MED (exchanged between autonomous systems).
7. Prefer the EBGP path over IBGP path.
8. Prefer the path through the closest IGP neighbor.
9. Prefer the oldest route for EBGP paths.
10. Prefer the path with the lowest neighbor BGP router ID.
11. Prefer the path with the lowest neighbor IP address.

BFD

Bidirectional Forwarding Detection (BFD) is a protocol that you can use to quickly locate hardware failures in the network. Routers running BFD send packets to each other at a negotiated rate. If packets from a BFD-enabled router fail to arrive, that router is declared to be down. BFD communicates this information to the associated routing protocols and the routing information is updated. It helps detect one way device failure and is used for fast convergence of routing protocols.

BFD can run on an entire FortiGate, selected interfaces, or on a protocol, such as BGP, for all configured interfaces. The configuration hierarchy allows each lower level to override the BFD setting of the upper level. For example, if you enable BFD for an entire FortiGate, you can disable BFD for an interface or for BGP.

Echo mode and authentication are not supported for BFD on the FortiGate.

BFD can be enabled per device, VDOM, or interface. Once enabled, a BFD neighbor should be defined. Finally, enable BFD on a route or routing protocol.

To configure BFD for an entire FortiGate:

```
config system settings
    set bfd {enable | disable}
    set bfd-desired-min-tx <ms>
    set bfd-required-min-rx <ms>
    set bfd-detect-mult <multiplier>
    set bfd-dont-enforce-src-port {enable | disable}
end
```

To configure BFD for an interface:

```
config system interface
    edit <interface-name>
        set bfd {global | enable | disable}
        set bfd-desired-min-tx <ms>
        set bfd-required-min-rx <ms>
        set bfd-detect-mult <multiplier>
    next
end
```

To configure BFD neighbors:

```
config router {bfd | bfd6}
    config neighbor
        edit <IP-address>
            set interface <interface-name>
        next
    end
end
```

To show BFD neighbors:

```
# get router {info | info6} bfd neighbor
```

To show BFD requests:

```
# get router {info | info6} bfd requests
```

BFD and static routes

BFD for static routes allows you to configure routing failover based on remote path failure detection. BFD removes a static route from the routing table if the FortiGate can't reach the route's destination and returns the route to the routing table if the route's destination is restored.

For example, you can add two static routes with BFD enabled. If one of the routes has a higher priority, all matching traffic uses that route. If BFD determines that the link to the gateway of the route with the higher priority is down, the higher priority route is removed from the routing table and all matching traffic uses the lower priority route. If the link to the gateway for the higher priority route comes back up, BFD adds the route back into the routing table and all matching traffic switches to use the higher priority route.

You can configure BFD for IPv4 and IPv6 static routes.

To configure BFD for static routes:

```
config router {static | static6}
  edit <sequence-number>
    set bfd {enable | disable}
  next
end
```

Example

The following example demonstrates the configuration of static routes between two FortiGates. There is a host behind FortiGate 2 with an IP address of 1.1.1.1. FortiGate 1 has multiple paths to reach the host.

To configure static routes:

1. Configure FortiGate 1:

```
config system interface
  edit "port1"
    set vdom "root"
    set ip 10.180.6.237 255.255.240.0
    set allowaccess ping
    set bfd enable
  next
end
config router bfd
  config neighbor
    edit 10.180.4.136
      set interface "port1"
    next
  end
end
```

2. Configure FortiGate 2:

```
config system interface
  edit "port1"
    set vdom "root"
    set ip 10.180.4.136 255.255.240.0
    set allowaccess ping
```

```

        set bfd enable
    next
end
config router bfd
    config neighbor
        edit 10.180.6.237
            set interface "port1"
        next
    end
end
end

```

3. Configure two static routes:

```

config router static
    edit 2
        set dst 1.1.1.1 255.255.255.255
        set gateway 10.180.4.136
        set device "port1"
        set bfd enable
    next
    edit 3
        set dst 1.1.1.1 255.255.255.255
        set gateway 10.180.2.44
        set distance 20
        set device "port1"
    next
end

```

4. Confirm that BFD neighborship is established:

```

# get router info bfd neighbor
OurAddress      NeighAddress    State           Interface        LDesc/RDesc
10.180.6.237    10.180.4.136    UP              port1            1/1

```

5. Review the active route in the routing table:

```

# get router info routing-table all
S      1.1.1.1/32 [10/0] via 10.180.4.136, port1
C      10.180.0.0/20 is directly connected, port1

```

The route with the lower distance is preferred in the routing table.

If port1 on FortiGate 2 goes down or FortiGate 1 is unable to reach 10.180.4.126, the BFD neighborship will go down.

```

# get router info bfd neighbor
OurAddress      NeighAddress    State           Interface        LDesc/RDesc
10.180.6.237    10.180.4.136    DOWN           port1            1/1

```

With BFD neighborship down, the FortiGate is unable to reach 1.1.1.1/32 through gateway 10.180.4.136. The routing table will be updated so that the route through gateway 10.180.2.44 is active in the routing table.

```

# get router info routing-table all
S      1.1.1.1/32 [20/0] via 10.180.2.44, port1
C      10.180.0.0/20 is directly connected, port1

```

BFD removes a static route from the routing table if the FortiGate cannot reach the route's destination. The static route will be returned to the routing table if the route's destination is restored.

BFD and OSPF

You can configure BFD for Open Shortest Path First (OSPF) on a FortiGate. FortiGate supports BFD for OSPF for both IPv4 and IPv6. BFD must be configured globally and per interface.

To configure BFD for OSPF:

```
config router {ospf | ospf6}
    set bfd {enable | disable}
end
```

To enable BFD on a specific OSPF interface:

```
config router {ospf | ospf6}
    set bfd enable
    config {ospf-interface | ospf6-interface}
        edit <ID>
            set bfd {global | enable | disable}
            set interface <interface-name>
            set area-id <IP address>
        next
    end
end
```

If BFD is configured when OSPF is not, no BFD packets will be sent. When both BFD and OSPF are configured, the neighbors for both will be the same. Use the following commands to confirm that the neighbor IP addresses match:

```
# get router info ospf neighbor
# get router info bfd neighbor
```

BFD and BGP

While BGP can detect route failures, BFD can be configured to detect these failures more quickly, which allows for faster responses and improved convergence. This can be balanced with the bandwidth BFD uses in its frequent route checking.

The `config router bgp` commands allow you to set the addresses of the neighbor units that are also running BFD. Both units must be configured with BFD in order to use it.

To configure BFD for BGP:

```
config router bgp
    config neighbor
        edit <neighbor-IP-address>
            set bfd {enable | disable}
        next
    end
end
```

BFD for Multihop paths

FortiGate BFD can support neighbors connected over multiple hops. When BFD is down, BGP sessions will be reset and will try to re-establish neighbor connection immediately. See [BFD for multihop path for BGP on page 436](#) for more information.

To configure BFD for multihop paths:

```
config router {bfd | bfd6}
  config multihop-template
    edit <ID>
      set src <IP address/netmask>
      set dst <IP address/netmask>
      set bfd-desired-min-tx <integer>
      set bfd-required-min-rx <integer>
      set bfd-detect-mult <integer>
      set auth-mode {none | md5}
      set md5-key <password>
    next
  end
end
```

Troubleshooting BFD

You can troubleshoot BFD using the following commands:

```
# get router {info | info6} bfd neighbor
# get router {info | info6} bfd requests
# diagnose sniffer packet any <filter> <sniffer count>
# diagnose debug application bfdd <debug level>
# diagnose debug enable
```

BFD for multihop path for BGP

In BFD, a FortiGate can support neighbors connected over multiple hops. When BFD is down, BGP sessions are reset and will try to immediately re-establish neighbor connections. Previously, BFD was only supported when two routers or FortiGates were directly connected on the same network.

```
config router {bfd | bfd6}
  config multihop-template
    edit <ID>
      set src <class_IP/netmask>
      set dst <class_IP/netmask>
      set bfd-desired-min-tx <integer>
      set bfd-required-min-rx <integer>
      set bfd-detect-mult <integer>
      set auth-mode {none | md5}
      set md5-key <password>
    next
  end
end
```

src <class_IP/netmask>	Enter the source prefix.
dst <class_IP/netmask>	Enter the destination prefix.
bfd-desired-min-tx <integer>	Set the BFD desired minimal transmit interval, in milliseconds (100 - 30000, default = 250).
bfd-required-min-rx <integer>	Set the BFD required minimal transmit interval, in milliseconds (100 - 30000, default = 250).
bfd-detect-mult <integer>	Set the BFD detection multiplier (3 - 50, default = 3).
auth-mode {none md5}	Set the authentication mode (none or meticulous MD5).
md5-key <password>	Enter the password.

Example

This example includes IPv4 and IPv6 BFD neighbor configurations. The BFD neighbor is also a BGP neighbor that is in a different AS.

To configure BFD with multihop BGP paths:

1. Enable BFD on all interfaces:

```
config system settings
    set bfd enable
end
```

2. Enable BFD on port1 and ignore the global configuration:

```
config system interface
    edit "port1"
        set bfd enable
    next
end
```

3. Configure the BGP neighbors:

```
config router bgp
    set as 65412
    set router-id 1.1.1.1
    config neighbor
        edit "172.16.201.2"
            set bfd enable
            set ebgp-enforce-multihop enable
            set soft-reconfiguration enable
            set remote-as 65050
        next
    next
```

```

        edit "2000:172:16:201::2"
            set bfd enable
            set ebgp-enforce-multihop enable
            set soft-reconfiguration enable
            set remote-as 65050
        next
    end
end

```

4. Configure the IPv4 BFD:

```

config router bfd
    config multihop-template
        edit 1
            set src 172.16.200.0 255.255.255.0
            set dst 172.16.201.0 255.255.255.0
            set auth-mode md5
            set md5-key *****
        next
    end
end

```

5. Configure the IPv6 BFD:

```

config router bfd6
    config multihop-template
        edit 1
            set src 2000:172:16:200::/64
            set dst 2000:172:16:201::/64
        next
    end
end

```

Testing the connection

1. Verify the BFD status for IPv4 and IPv6:

```

# get router info bfd requests
BFD Peer Requests:
    client types(ct in 0x): 01=external 02=static
                          04=ospf 08=bgp 10=pim-sm
src=172.16.200.1      dst=172.16.201.2      ct=08 ifi=9 type=SM

# get router info bfd neighbor
OurAddress      NeighAddress      State      Interface      LDesc/RDesc
172.16.200.1    172.16.201.2      UP         port1          5/3/M

# get router info6 bfd requests
BFD Peer Requests:
    client types(ct in 0x): 01=external 02=static
                          04=ospf 08=bgp 10=pim-sm
src=2000:172:16:200::1
dst=2000:172:16:201::2
ct=08 ifi=9 type=SM

# get router info6 bfd neighbor
OurAddress: 2000:172:16:200::1
NeighAddress: 2000:172:16:201::2
State: UP Interface: port1 Desc: 6/4 Multi-hop

```

2. Verify the BGP status and the BGP routing table:

```
# get router info bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 11
3 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
172.16.201.2	4	65050	185	187	10	0	0	00:54:20	4
2000:172:16:201::2	4	65050	159	160	10	0	0	00:54:24	4

Total number of neighbors 2

```
# get router info routing-table bgp
Routing table for VRF=0
```

```
B 172.28.1.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
B 172.28.2.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
B 172.28.5.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
B 172.28.6.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:54:32
```

```
# get router info6 bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 8
3 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
172.16.201.2	4	65050	185	187	7	0	0	00:54:24	3
2000:172:16:201::2	4	65050	159	160	7	0	0	00:54:28	3

Total number of neighbors 2

```
# get router info6 routing-table bgp
Routing table for VRF=0
```

```
B 2000:172:28:1::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:54:40
B 2000:172:28:2::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:54:40
B 2000:172:28:3::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:54:40
```

3. Simulate a disruption to the BFD connection. The BFD neighbor is lost:

```
# get router info bfd neighbor
OurAddress      NeighAddress    State           Interface       LDesc/RDesc
# get router info6 bfd neighbor
```

4. The BGP neighbor is reset, and the FortiGate attempts to re-establish a connection with the neighbor. The timers are reset once the neighbor connection is re-established:

```
# get router info bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 12
```

```
4 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
172.16.201.2	4	65050	189	192	11	0	0	00:00:11	4
2000:172:16:201::2	4	65050	165	167	12	0	0	00:00:08	4

Total number of neighbors 2

```
# get router info6 bgp summary
VRF 0 BGP router identifier 1.1.1.1, local AS number 65412
BGP table version is 10
4 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
172.16.201.2	4	65050	189	192	8	0	0	00:00:15	3
2000:172:16:201::2	4	65050	165	167	9	0	0	00:00:12	3

Total number of neighbors 2

5. The BGP routes are learned again, and there are new timers in the route tables:

```
# get router info routing-table bgp
Routing table for VRF=0
B      172.28.1.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15
B      172.28.2.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15
B      172.28.5.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15
B      172.28.6.0/24 [20/0] via 172.16.201.2 (recursive via 172.16.200.4, port1),
00:00:15

# get router info6 routing-table bgp
Routing table for VRF=0
B      2000:172:28:1::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:00:13
B      2000:172:28:2::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:00:13
B      2000:172:28:3::/64 [20/0] via 2000:172:16:201::2 (recursive via
2000:172:16:200::4, port1), 00:00:13
```

Routing objects

The following objects can be configured from the *Network > Routing Objects* page:

- [Route maps on page 441](#)
- [Access lists on page 443](#)
- [Prefix lists on page 446](#)
- [AS path lists on page 448](#)
- [Community lists on page 449](#)

Route maps

Route maps are a powerful tool to apply custom actions to dynamic routing protocols based on specific conditions. They are used primarily in BGP to manipulate routes advertised by the FortiGate (`route-map-out`) or received routes from other BGP routers (`route-map-in`).

Route maps can be used in OSPF for conditional `default-information-originate`, filtering external routes, or matching specific routes for redistribution. Similarly, route maps can be used by RIP to match routes for redistribution.

A route map may have multiple rules that are processed from the top down. Each rule has an action to permit or deny. If the action is not set, the default action is to permit. The rules have criteria for matching a route based on various attributes, or setting attributes based on a matched route.

For example, a route map can be used to match BGP routes with a certain community string, and then set an AS path to the matching route. This can be applied to a BGP neighbor by configuring the route map in setting for that neighbor.

To configure a route map that matches criteria based on other routing objects:

```
config router route-map
  edit <name>
    config rule
      edit <id>
        set action {permit | deny}
        set match-as-path <string>
        set match-community <string>
        set match-ip-address <string>
        set match-ip6-address <string>
        set match-ip-nexthop <string>
        set match-ip6-nexthop <string>
      next
    end
  next
end
```

<code>match-as-path <string></code>	Match a BGP AS path list.
<code>match-community <string></code>	Match a BGP community list.
<code>match-ip-address <string></code>	Match an IPv4 address permitted by <code>access-list</code> or <code>prefix-list</code> .
<code>match-ip6-address <string></code>	Match an IPv6 address permitted by <code>access-list6</code> or <code>prefix-list6</code> .
<code>match-ip-nexthop <string></code>	Match a next hop IPv4 address passed by <code>access-list</code> or <code>prefix-list</code> .
<code>match-ip6-nexthop <string></code>	Match a next hop IPv6 address passed by <code>access-list6</code> or <code>prefix-list6</code> .

Route maps can be used by various routing protocols, such as RIP, OSPF, and BGP.

To use a route map with RIP:

```
config router rip
  config redistribute
    edit <name>
      set routemap <string>
    next
  next
end
```

```

end
end

```

To use a route map with OSPF:

```

config router ospf
  set default-information-route-map <string>
  set distribute-route-map-in <string>
  config redistribute <string>
    set routemap <string>
  end
end

```

default-information-route-map <string>	Enter the default information route map.
distribute-route-map-in <string>	Enter the route map to filter incoming external routes.
redistribute <string>	Configure the redistribute protocol.

To use a route map with BGP:

```

config router bgp
  config neighbor
    edit <ip>
      set route-map-in <string>
      set route-map-in6 <string>
      set route-map-in-vpn4 <string>
      set route-map-out <string>
      set route-map-out-preferable <string>
      set route-map-out6 <string>
      set route-map-out6-preferable <string>
      set route-map-out-vpn4 <string>
      set route-map-out-vpn4-preferable <string>
    next
  end
  config network
    edit <id>
      set prefix <IP/netmask>
      set route-map <string>
    next
  end
  config redistribute <string>
    set route-map <string>
  end
end

```

route-map-in <string>	Enter the IPv4 inbound route map filter.
route-map-in6 <string>	Enter the IPv6 inbound route map filter.
route-map-in-vpn4 <string>	Enter the VPNv4 inbound route map filter.
route-map-out <string>	Enter the IPv4 outbound route map filter.

route-map-out-preferable <string>	Enter the IPv4 outbound route map filter if the peer is preferred.
route-map-out6 <string>	Enter the IPv6 outbound route map filter.
route-map-out6-preferable <string>	Enter the IPv6 outbound route map filter if the peer is preferred.
route-map-out-vpn4 <string>	Enter the VPNv4 outbound route map filter.
route-map-out-vpn4- preferable <string>	Enter the VPNv4 outbound route map filter if the peer is preferred.
route-map <string>	Enter the route map to modify the generated route.
redistribute <string>	Configure the redistribute protocol.

To use a route map with BGP conditional advertisement:

```

config router bgp
  set as <AS_number>
  config neighbor
    edit <ip>
      set remote-as <AS_number>
      config conditional-advertise
        edit <advertise-routemap>
          set condition-routemap <name1>, <name2>, ...
          set condition-type {exist | non-exist}
        next
      end
    next
  end
end

```

<advertise-routemap>	Edit the advertising route map.
condition-routemap <name1>, <name2>, ...	Enter the list of conditional route maps.

Access lists

Access lists are simple lists used for filtering routes based on a prefix consisting of an IPv4 or IPv6 address and netmask.

To configure an IPv4 access list:

```

config router access-list
  edit <name>
    config rule
      edit <id>
        set action {permit | deny}
        set prefix <IPv4_address>
        set wildcard <wildcard_filter>
        set exact-match {enable | disable}
      next
    next
  end
end

```

```

    end
  next
end

```

To configure an IPv6 access list:

```

config router access-list6
  edit <name>
    config rule
      edit <id>
        set action {permit | deny}
        set prefix <IPv6_address>
        set exact-match {enable | disable}
      next
    end
  next
end

```

In RIP, an access list can be used in the `distribute-list` setting to filter received or advertised routes, or in an `offset-list` to offset the hop count metric for a specific prefix.

To use an access list in RIP:

```

config router rip
  config distribute-list
    edit <id>
      set direction {in | out}
      set listname <string>
    next
  end
  config offset-list
    edit <id>
      set direction {in | out}
      set access-list <string>
      set offset <integer>
    next
  end
end

```

<code>listname <string></code>	Enter the distribute access or prefix list name.
--------------------------------------	--

<code>access-list <string></code>	Enter the access list name.
---	-----------------------------

In OSPF, an access list can be used in the `distribute-list-in` setting to act as a filter to prevent a certain route from being inserted into the routing table. An access list can also be used in the `distribute-list` to filter the routes that can be distributed from other protocols.

To use an access list in OSPF:

```

config router ospf
  set distribute-list-in <string>
  config distribute-list
    edit <id>
      set access-list <string>
      set protocol {connected | static | rip}
    next
  end
end

```

```

    next
  end
end

```

distribute-list-in <string>	Enter the filter for incoming routes.
--------------------------------	---------------------------------------

access-list <string>	Enter the access list name.
----------------------	-----------------------------

In BGP, an access list can be used to filter updates from a neighbor or to a neighbor.

To use an access list in BGP:

```

config router bgp
  config neighbor
    edit <ip>
      set distribute-list-in <string>
      set distribute-list-in6 <string>
      set distribute-list-in-vpn4 <string>
      set distribute-list-out <string>
      set distribute-list-out6 <string>
      set distribute-list-out-vpn4 <string>
    next
  end
end

```

distribute-list-in <string>	Enter the filter for IPv4 updates from this neighbor.
--------------------------------	---

distribute-list-in6 <string>	Enter the filter for IPv6 updates from this neighbor.
---------------------------------	---

distribute-list-in-vpn4 <string>	Enter the filter for VPNv4 updates from this neighbor.
-------------------------------------	--

distribute-list-out <string>	Enter the filter for IPv4 updates to this neighbor.
---------------------------------	---

distribute-list-out6 <string>	Enter the filter for IPv6 updates to this neighbor.
----------------------------------	---

distribute-list-out-vpn4 <string>	Enter the filter for VPNv4 updates to this neighbor.
--------------------------------------	--

In a route map, an access list can be used to match IP addresses and next hops.

To use an access list in a route map:

```

config router route-map
  edit <name>
    config rule
      edit <id>
        set match-ip-address <string>
        set match-ip6-address <string>
        set match-ip-nexthop <string>
        set match-ip6-nexthop <string>
      next
    end
  end

```

```

    next
end

```

<code>match-ip-address <string></code>	Match an IPv4 address permitted by <code>access-list</code> or <code>prefix-list</code> .
<code>match-ip6-address <string></code>	Match an IPv6 address permitted by <code>access-list6</code> or <code>prefix-list6</code> .
<code>match-ip-nexthop <string></code>	Match a next hop IPv4 address passed by <code>access-list</code> or <code>prefix-list</code> .
<code>match-ip6-nexthop <string></code>	Match a next hop IPv6 address passed by <code>access-list6</code> or <code>prefix-list6</code> .

Prefix lists

Similar to access lists, prefix lists are simple lists used for filtering routes based on a prefix consisting of an IPv4 or IPv6 address and netmask, but they use settings to specify the minimum (`ge`, greater than or equal) and maximum (`le`, less than or equal) prefix length to be matched. For example, a prefix of 10.0.0.0/8 with a `ge` of 16 will match anything in the 10.0.0.0/8 network with /16 or above; 10.10.0.0/16 will match, and 10.10.0.0/12 will not match.

To configure an IPv4 prefix list:

```

config router prefix-list
  edit "prefix-list1"
    config rule
      edit 1
        set action {permit | deny}
        set prefix <IPv4_address>
        set ge <integer>
        set le <integer>
      next
    end
  next
end

```

To configure an IPv6 prefix list:

```

config router prefix-list6
  edit "prefix-list-IPv6"
    config rule
      edit 1
        set action {permit | deny}
        set prefix6 <IPv6_address>
        set ge <integer>
        set le <integer>
      next
    end
  next
end

```

In RIP, an prefix list can be used in the `distribute-list` setting to filter received or advertised routes.

To use a prefix list in RIP:

```

config router rip
  config distribute-list
    edit <id>
      set listname <string>
    next
  end
end

```

<code>listname <string></code>	Enter the distribute access or prefix list name.
--------------------------------------	--

In OSPF, a prefix list can be used in the `distribute-list-in` setting to act as a filter to prevent a certain route from being inserted into the routing table.

To use a prefix list in OSPF:

```

config router ospf
  set distribute-list-in <string>
end

```

<code>distribute-list-in <string></code>	Enter the filter for incoming routes.
--	---------------------------------------

In BGP, a prefix list can be used to filter updates from a neighbor or to a neighbor.

To use a prefix list in BGP:

```

config router bgp
  config neighbor
    edit <ip>
      set prefix-list-in <string>
      set prefix-list-in6 <string>
      set prefix-list-in-vpn4 <string>
      set prefix-list-out <string>
      set prefix-list-out6 <string>
      set prefix-list-out-vpn4 <string>
    next
  end
end

```

<code>prefix-list-in <string></code>	Enter the IPv4 inbound filter for updates from this neighbor.
--	---

<code>prefix-list-in6 <string></code>	Enter the IPv6 inbound filter for updates from this neighbor.
---	---

<code>prefix-list-in-vpn4 <string></code>	Enter the inbound filter for VPNv4 updates from this neighbor.
---	--

<code>prefix-list-out <string></code>	Enter the IPv4 outbound filter for updates to this neighbor.
---	--

<code>prefix-list-out6 <string></code>	Enter the IPv6 outbound filter for updates to this neighbor.
--	--

<code>prefix-list-out-vpn4 <string></code>	Enter the outbound filter for VPNv4 updates to this neighbor.
--	---

In a route map, a prefix list can be used to match IP addresses and next hops.

To use a prefix list in a route map:

```

config router route-map
  edit <name>
    config rule
      edit <id>
        set match-ip-address <string>
        set match-ip6-address <string>
        set match-ip-nexthop <string>
        set match-ip6-nexthop <string>
      next
    end
  next
end

```

match-ip-address <string>	Match an IPv4 address permitted by access-list or prefix-list.
match-ip6-address <string>	Match an IPv6 address permitted by access-list6 or prefix-list6.
match-ip-nexthop <string>	Match a next hop IPv4 address passed by access-list or prefix-list.
match-ip6-nexthop <string>	Match a next hop IPv6 address passed by access-list6 or prefix-list6.

AS path lists

AS path lists use regular expressions to compare and match the AS_PATH attribute for a BGP route. They can be used to filter inbound or outbound routes from a BGP neighbor, or as matching criteria in a route map to match an AS_PATH in a BGP route.

To configure an AS path list:

```

config router aspath-list
  edit <name>
    config rule
      edit <id>
        set action {deny | permit}
        set regexp <string>
      next
    end
  next
end

```

To use an AS path list in BGP:

```

config router bgp
  config neighbor
    edit <ip>
      set filter-list-in <string>
      set filter-list-in6 <string>
      set filter-list-out <string>
      set filter-list-out6 <string>
    next
  next
end

```

```

    end
end

```

<code>filter-list-in <string></code>	Enter the BGP filter for IPv4 inbound routes.
<code>filter-list-in6 <string></code>	Enter the BGP filter for IPv6 inbound routes.
<code>filter-list-out <string></code>	Enter the BGP filter for IPv4 outbound routes.
<code>filter-list-out6 <string></code>	Enter the BGP filter for IPv6 outbound routes.

To use an AS path list in a route map:

```

config router route-map
  edit <name>
    config rule
      edit <id>
        set match-as-path <string>
      next
    end
  next
end

```

<code>match-as-path <string></code>	Match a BGP AS path list.
---	---------------------------

Community lists

Community lists provide a means to filter BGP routes using a community string. They can be applied in a route map to match routes that have the community string defined in the community list.

To configure a community list:

```

config router community-list
  edit <name>
    set type {standard | expanded}
    config rule
      edit <id>
        set action {deny | permit}
        set regexp <string>
        set match <string>
      next
    end
  next
end

```

To use a community list in a route map to match a BGP community:

```

config router route-map
  edit <name>
    config rule
      edit <id>
        set match-community <string>
      next
    end
  next
end

```

```
next
end
```

```
match-community <string> Match a BGP community list.
```

In an SD-WAN deployment, a remote BGP router or spoke may communicate a preferred interface or path to route traffic using a community string. See [Using BGP tags with SD-WAN rules on page 721](#) and [Controlling traffic with BGP route mapping and service rules on page 727](#) for examples.

Multicast

The following topics include information about multicast:

- [Multicast routing and PIM support on page 450](#)
- [Configuring multicast forwarding on page 451](#)

Multicast routing and PIM support

Multicasting (also called IP multicasting) consists of using a single multicast source to send data to many receivers. Multicasting can be used to send data to many receivers simultaneously while conserving bandwidth and reducing network traffic. Multicasting can be used for one-way delivery of media streams to multiple receivers and for one-way data transmission for news feeds, financial information, and so on. Many dynamic routing protocols such as RIPv2, OSPF, and EIGRP use multicasting to share hello packets and routing information.

A FortiGate can operate as a Protocol Independent Multicast (PIM) version 2 router. FortiGates support PIM sparse mode ([RFC 4601](#)) and PIM dense mode ([RFC 3973](#)), and can service multicast servers or receivers on the network segment to which a FortiGate interface is connected. Multicast routing is not supported in transparent mode.

To support PIM communications, the sending and receiving applications, and all connecting PIM routers in between, must be enabled with PIM version 2. PIM can use static routes, RIP, OSPF, or BGP to forward multicast packets to their destinations. To enable source-to-destination packet delivery, sparse mode or dense mode must be enabled on the PIM router interfaces. Sparse mode routers cannot send multicast messages to dense mode routers. If the FortiGate is located between a source and a PIM router, between two PIM routers, or is connected directly to a receiver, you must manually create a multicast policy to pass encapsulated (multicast) packets or decapsulated data (IP traffic) between the source and destination.

PIM domains

A PIM domain is a logical area comprising a number of contiguous networks. The domain contains at least one bootstrap router (BSR), and if sparse mode is enabled, a number of rendezvous points (RPs) and designated routers (DRs). When PIM is enabled, the FortiGate can perform any of these functions at any time as configured.

A PIM domain can be configured in the GUI by going to *Network > Multicast*, or in the CLI using `config router multicast`. Note that PIM version 2 must be enabled on all participating routers between the source and receivers. Use `config router multicast` to set the global operating parameters.

When PIM is enabled, the FortiGate allocates memory to manage mapping information. The FortiGate communicates with neighboring PIM routers to acquire mapping information and, if required, processes the multicast traffic associated with specific multicast groups.

Instead of sending multiple copies of generated IP traffic to more than one specific IP destination address, PIM-enabled routers encapsulate the data and use a Class D multicast group address (224.0.0.0 to 239.255.255.255) to forward multicast packets to multiple destinations. A single stream of data can be sent because one destination address is used. Client applications receive multicast data by requesting that the traffic destined for a certain multicast group address be delivered to them.

Configuring multicast forwarding

There is sometimes confusion between the terms forwarding and routing. These two functions should not take place at the same time. Multicast forwarding should be enabled when the FortiGate is in NAT mode and you want to forward multicast packets between multicast routers and receivers. However, this function should not be enabled when the FortiGate itself is operating as a multicast router, or has an applicable routing protocol that uses multicast.

Multicast forwarding is not supported on enhanced MAC VLAN interfaces. To use multicast with enhanced MAC VLAN interfaces, use PIM ([Multicast routing and PIM support on page 450](#)).

There are two steps to configure multicast forwarding:

1. [Enabling multicast forwarding on page 451](#)
2. [Configuring multicast policies on page 452](#)

Enabling multicast forwarding

Multicast forwarding is enabled by default. If a FortiGate is operating in transparent mode, adding a multicast policy enables multicast forwarding. In NAT mode you must use the `multicast-forward` setting to enable or disable multicast forwarding.

Multicast forwarding in NAT mode

When `multicast-forward` is enabled, the FortiGate forwards any multicast IP packets in which the TTL is 2 or higher to all interfaces and VLAN interfaces, except the receiving interface. The TTL in the IP header will be reduced by 1. Even though the multicast packets are forwarded to all interfaces, you must add multicast policies to allow multicast packets through the FortiGate.

To enable multicast forwarding in NAT mode:

```
config system settings
    set multicast-forward enable
end
```

Prevent the TTL for forwarded packets from being changed

You can use the `multicast-ttl-notchange` option so that the FortiGate does not increase the TTL value for forwarded multicast packets. Use this option only if packets are expiring before reaching the multicast router.

To prevent the TTL for forwarded packets from being changed:

```
config system settings
    set multicast-ttl-notchange enable
end
```

Disable multicast traffic from passing through the FortiGate without a policy check in transparent mode

In transparent mode, the FortiGate does not forward frames with multicast destination addresses. The FortiGate should not interfere with the multicast traffic used by routing protocols, streaming media, or other multicast communication. To avoid any issues during transmission, you can disable `multicast-skip-policy` and configure multicast security policies.

To disable multicast traffic from passing through the FortiGate without a policy check in transparent mode:

```
config system settings
    set multicast-skip-policy disable
end
```

Configuring multicast policies

Multicast packets require multicast policies to allow packets to pass from one interface to another. Similar to firewall policies, in a multicast policy you specify the source and destination interfaces, and the allowed address ranges for the source and destination addresses of the packets. You can also use multicast policies to configure source NAT and destination NAT for multicast packets.

Keep the following in mind when configuring multicast policies:

- The matched forwarded (outgoing) IP multicast source IP address is changed to the configured IP address.
- The `snat` setting is optional. Use it when SNAT is needed.

IPv4 and IPv6 multicast policies can be configured in the GUI. Go to *System > Feature Visibility*, and enable *Multicast Policy* and *IPv6*.

Sample basic policy

In this basic policy, multicast packets received on an interface are flooded unconditionally to all interfaces on the forwarding domain, except the incoming interface.

```
config firewall multicast-policy
    edit 1
        set srcintf "any"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
    next
end
```

The destination address (`dstaddr`) is a multicast address object. The `all` option corresponds to all multicast addresses in the range 224.0.0.0-239.255.255.255.

Sample policy with specific source and destination interfaces

This multicast policy only applies to the source port `wan1` and the destination port `internal`.

```
config firewall multicast-policy
  edit 1
    set srcintf "wan1"
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "all"
  next
end
```

Sample policy with specific source address object

In this policy, packets are allowed to flow from `wan1` to `internal`, and sourced by the address 172.20.120.129, which is represented by the `example_addr-1` address object.

```
config firewall multicast-policy
  edit 1
    set srcintf "wan1"
    set dstintf "internal"
    set srcaddr "example_addr-1"
    set dstaddr "all"
  next
end
```

Sample detailed policy

This policy accepts multicast packets that are sent from a PC with IP address 192.168.5.18 to destination address range 239.168.4.0-255. The policy allows the multicast packets to enter the `internal` interface and then exit the `external` interface. When the packets leave the external interface, their source address is translated to 192.168.18.10.

```
config firewall address
  edit "192.168.5.18"
    set subnet 192.168.5.18 255.255.255.255
  next
end

config firewall multicast-address
  edit "239.168.4.0"
    set start-ip 239.168.4.0
    set end-ip 239.168.4.255
  next
end

config firewall multicast-policy
  edit 1
    set srcintf "internal"
    set dstintf "external"
    set srcaddr "192.168.5.18"
    set dstaddr "239.168.4.0"
    set snat enable
```

```

    set snat-ip 192.168.18.10
  next
end

```

To configure multicast policies in the GUI, enable *Multicast Policy* in *System > Feature Visibility*.

Using multi VDOM mode

When using multi VDOM mode, it is important to avoid causing a multicast network loop by creating an all-to-all multicast policy. By default, on models that support NPU virtual links, changing the `vdom-mode` to `multi-vdom` will create a pair of `npu0_vlink0` and `npu0_vlink1` interfaces in the same root VDOM. By virtue of the all-to-all multicast policy and the fact the `npu0_vlink` interfaces are virtually connected, it forms a multicast network loop.

Therefore, when using multi VDOM mode:

1. Ensure there is no existing all-to-all multicast policy before changing to multi VDOM mode.
2. If an all-to-all multicast policy must be defined, ensure that no two connected interfaces (such as `npu0_vlink0` and `npu0_vlink1`) belong in the same VDOM.

This configuration will result in a multicast loop:

```

config system global
    set vdom-mode multi-vdom
end
config firewall multicast-policy
    edit 1
        set logtraffic enable
        set srcintf "any"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
    next
end
show system interface
config system interface
    edit "npu0_vlink0"
        set vdom "root"
        set type physical
    next
    edit "npu0_vlink1"
        set vdom "root"
        set type physical
    next
end

```

FortiExtender

There are two configuration modes available on the FortiGate for FortiExtender integration: WAN extension mode and LAN extension mode.

For information about configuring FortiExtender, see the FortiExtender [Admin Guide \(FGT-Managed\)](#) and [Admin Guide \(Standalone\)](#).

WAN extension mode

In WAN extension mode, the FortiExtender works as an extended WAN interface in IP pass-through mode. The FortiGate manages FortiExtender over the CAPWAP protocol in IP pass-through mode, and is integrated into FortiOS as a manageable interface.

Sample configurations in WAN extension mode could include connecting a FortiExtender to two FortiGates in HA active-passive mode, or connecting two FortiExtenders to two FortiGates in HA active-active mode to provide dual active redundancy for wireless WAN access.

For more information, see [FortiExtender and FortiGate integration](#) in the FortiExtender (Managed) Administration Guide.

LAN extension mode

The LAN extension configuration mode allows FortiExtender to provide remote thin edge connectivity back to the FortiGate over a backhaul connection. A FortiExtender deployed at a remote location will discover the FortiGate access controller (AC) and form an IPsec tunnel (or multiple tunnels when multiple links exist on the FortiExtender) back to the FortiGate. A VXLAN is established over the IPsec tunnels to create an L2 network between the FortiGate and the network behind the remote FortiExtender.

For more information, see [FortiExtender as FortiGate LAN extension](#) in the FortiExtender (Managed) Administration Guide.

Adding a FortiExtender

To add a FortiExtender to the FortiGate, create a virtual FortiExtender interface, then add a FortiExtender and assign the interface to the modem. Like other interface types, the FortiExtender interface can be used in static routes, SD-WAN (see [Manage dual FortiExtender devices](#)), policies, and other functions.

To create a virtual FortiExtender interface in the GUI:

1. Go to *Network > Interfaces* and click *Create New > FortiExtender*.
2. Enter a name for the interface.
3. Configure the remaining settings as needed. See [Interface settings on page 143](#) for more details.

The screenshot shows the 'New Interface' configuration window. The 'Name' field is 'fext'. The 'Type' is 'FortiExtender'. The 'Estimated bandwidth' is set to 1000 kbps Upstream and 500 kbps Downstream. The 'Address' section has 'Retrieve default gateway from server' disabled, 'Distance' set to 5, and 'Override internal DNS' enabled. The 'Administrative Access' section includes checkboxes for IPv4: Speed Test (checked), PING (checked), SNMP (unchecked), Security Fabric (unchecked), HTTPS (checked), FMG-Access (unchecked), FTM (unchecked), HTTP (unchecked), SSH (unchecked), and RADIUS Accounting (unchecked). The 'OK' button is highlighted in green.

4. Click **OK**.

To add a FortiExtender in the GUI:

1. Go to *Network > FortiExtender* and click *Create New > Extenders*.
2. Enter your FortiExtender's serial number in the *Serial number* field.
3. Optionally, set an *Alias* for the FortiExtender.
4. In the *State* section, enable *Authorized*.
5. Set *Interface* to the FortiExtender interface.
6. Configure the remaining setting as required. See the [FortiExtender Administration Guide \(FGT-Managed\)](#) for more information.

The screenshot shows the 'Create New FortiExtender' configuration window. The 'Serial number' is 'FX211E0000000000'. The 'State' section has 'Authorized' checked. The 'Modem 1' section has 'Interface' set to 'fext', 'Default SIM' set to 'SIM1', 'SIM1 PIN' disabled, 'SIM2 PIN' disabled, 'GPS' enabled, and 'Auto SIM switch' enabled. The 'OK' button is highlighted in green.

7. Click **OK**.

8. In the extenders list, right-click on the FortiExtender and select *Diagnostics and Tools* to review the modem and SIM status, and other details about the FortiExtender.

To create a virtual FortiExtender interface in the CLI:

```
config system interface
  edit "fext"
    set vdom "root"
    set mode dhcp
    set allowaccess ping https speed-test
    set type fext-wan
    set estimated-upstream-bandwidth 1000
    set estimated-downstream-bandwidth 500
  next
end
```

To configure the FortiExtender in the CLI:

```
config extender-controller extender
  edit "FX211E0000000000"
    set id "FX211E0000000000"
    set authorized enable
    config modem1
      set ifname "fext"
    end
  next
end
```

To verify the modem settings in the CLI:

```
get extender modem-status FX211E0000000000 1
Modem 0:
  physical_port:      2-1.2
  manufacture:       Sierra Wireless, Incorporated
  product:            Sierra Wireless, Incorporated
  ....
```

For information about configuring FortiExtender, see the FortiExtender [Admin Guide \(FGT-Managed\)](#) and [Admin Guide \(Standalone\)](#).

Direct IP support for LTE/4G

Direct IP is a public IP address that is assigned to a computing device, which allows the device to directly access the internet.

When an LTE modem is enabled in FortiOS, a DHCP interface is created. As a result, the FortiGate can acquire direct IP (which includes IP, DNS, and gateway) from the LTE network carrier.

Since some LTE modems require users to input the access point name (APN) for the LTE network, the LTE modem configuration allows you to set the APN.

LTE modems can only be enabled by using the CLI.

To enable direct IP support using the CLI:

1. Enable the LTE modem:

```
config system lte-modem
  set status enable
end
```

2. Check that the LTE interface was created:

```
config system interface
  edit "wwan"
    set vdom "root"
    set mode dhcp
    set status down
    set distance 1
    set type physical
    set snmp-index 23
  next
end
```

Shortly after the LTE modem joins its carrier network, `wwan` is enabled and granted direct IP:

```
config system interface
  edit wwan
    get

name                : wwan
....
ip                  : 100.112.75.43 255.255.255.248
....
status              : up
....
defaultgw           : enable
DHCP Gateway        : 100.112.75.41
Lease Expires       : Thu Feb 21 19:33:27 2019
dns-server-override : enable
Acquired DNS1       : 184.151.118.254
Acquired DNS2       : 70.28.245.227
....
```

PCs can reach the internet via the following firewall policy:

```
config firewall policy
  edit 5
    set name "LTE"
    set srcintf "port9"
    set dstintf "wwan"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
```

```

set utm-status enable
set fssso disable
set nat enable
next
end

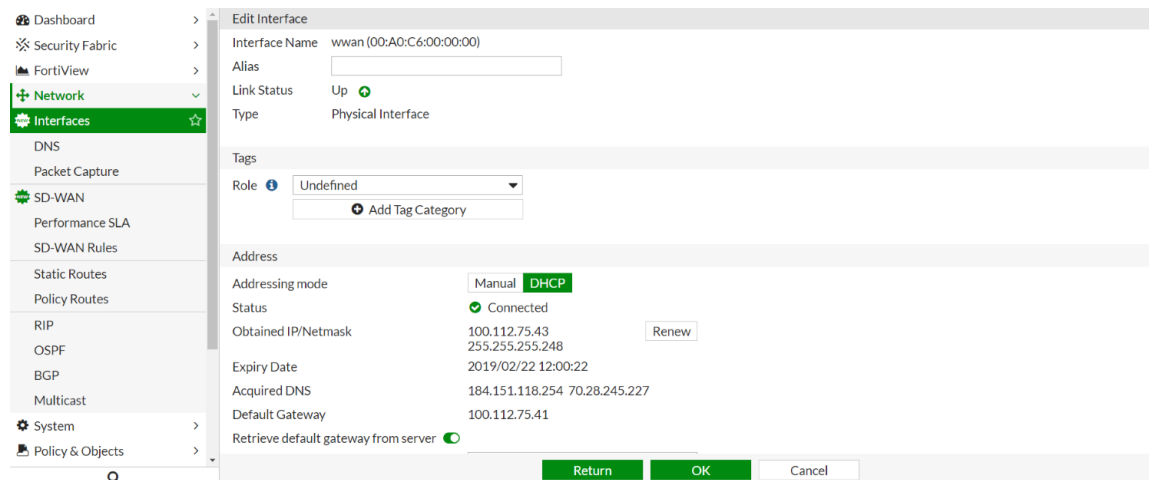

```

Sample LTE interface

When an LTE modem is enabled, you can view the LTE interface in the GUI and check the acquired IP, DNS, and gateway.

To view the LTE interface in the GUI:

1. Go to *Network > Interfaces*.
2. Double-click the LTE interface to view the properties.
3. Look in the *Address* section to see the *Obtained IP/Netmask*, *Acquired DNS*, and *Default Gateway*.

4. Click *Return*.

To configure the firewall policy that uses the LTE interface:

1. Go to *Policy & Objects > Firewall Policy*.
2. Edit the LTE policy.
3. In the *Outgoing Interface* field, select the interface (*wwan* in this example).
4. Configure the rest of the policy as needed.
5. Click *OK*.

Limitations

- Most LTE modems have a preset APN in their SIM card. Therefore, the APN does not need to be set in the FortiOS configuration. In cases where the internet cannot be accessed, consult with your carrier and set the APN in the LTE modem configuration (for example, inet.bell.ca):

```
config system lte-modem
  set status enable
  set apn "inet.bell.ca"
end
```

- Some models, such as the FortiGate 30E-3G4G, have built-in LTE modems. In this scenario, the LTE modem is enabled by default. The firewall policy via the LTE interface is also created by default. Once you plug in a SIM card, your network devices can connect to the internet.

Sample FortiGate 30E-3G4G default configuration:

```
config system lte-modem
  set status enable
  set extra-init ''
  set manual-handover disable
  set force-wireless-profile 0
  set authtype none
  set apn ''
  set modem-port 255
  set network-type auto
  set auto-connect disable
  set gpsd-enabled disable
  set data-usage-tracking disable
  set gps-port 255
end

config firewall policy
....
edit 3
  set srcintf "internal"
  set dstintf "wwan"
  set srcaddr "all"
  set dstaddr "all"
  set action accept
  set schedule "always"
  set service "ALL"
  set nat enable
next
end
```

LLDP reception

Device detection can scan LLDP as a source for device identification, but the FortiGate does not read or store the full information. Enabling LLDP reception allows the FortiGate to receive and store LLDP messages, learn about active neighbors, and makes the LLDP information available via the CLI, REST API, and SNMP.

You need to enable `device-identification` at the interface level, and then `lldp-reception` can be enabled on three levels: globally, per VDOM, or per interface.

To configure device identification on an interface:

```
config system interface
  edit <port>
```

```

    set device-identification enable
  next
end

```

To configure LLDP reception globally:

```

config system global
  set lldp-reception enable
end

```

To configure LLDP reception per VDOM:

```

config system setting
  set lldp-reception enable
end

```

To configure LLDP reception per interface:

```

config system interface
  edit <port>
    set lldp-reception enable
  next
end

```

To view the LLDP information in the GUI:

1. Go to *Dashboard > Users & Devices*.
2. Expand the *Device Inventory* widget to full screen.

Status	Device	User	Address	Interfaces	OS
Online	Other Identified device	artist	172.22.22.22	port3	Artist EOS / 4.20.4

To view the received LLDP information in the CLI:

```

# diagnose user device list
hosts
  vd root/0 44:0a:a0:0a:0a:0a gen 3 req S/2
  created 10290s gen 1 seen 0s port3 gen 1
  ip 172.22.22.22 src lldp
  type 20 'Other Network Device' src lldp id 155 gen 2
  os 'Artist EOS ' version '4.20.4' src lldp id 155
  host 'artist' src lldp

```

To view additional information about LLDP neighbors and ports:

```

# diagnose lldprx neighbor {summary | details | clear}
# diagnose lldprx port {details | summary | neighbor | filter}
# diagnose lldprx port neighbor {summary | details}

```

Note that the port index in the output corresponds to the port index from the following command:

```
# diagnose netlink interface list port2 port3 | grep index
   if=port2 family=00 type=1 index=4 mtu=1500 link=0 master=0
   if=port3 family=00 type=1 index=5 mtu=1500 link=0 master=0
```

To view the received LLDP information in the REST API:

```
{
  "http_method": "GET",
  "results": [
    {
      "mac": "90:9c:9c:c9:c9:90",

}
```

Virtual routing and forwarding

Virtual Routing and Forwarding (VRF) is used to divide the FortiGate's routing functionality (layer 3), including interfaces, routes, and forwarding tables, into separate units. Packets are only forwarded between interfaces that have the same VRF.

VDOMs divide the FortiGate into two or more complete and independent virtual units that include all FortiGate functions. VDOMs can be used for routing segmentation, but that should not be the only reason to implement them when a less complex solution (VRFs) can be used. VDOMs also support administration boundaries, but VRFs do not.

Up to 32 VRFs can be configured in each VDOM for any device, but only ten VDOMs can be configured by default on a FortiGate (more VDOMs can be configured on larger devices with additional licenses).

- [Implementing VRF on page 463](#)
- [VRF routing support on page 464](#)
- [Route leaking between VRFs with BGP on page 469](#)

- [Support cross-VRF local-in and local-out traffic for local services on page 488](#)

Implementing VRF

VRFs are always enabled and, by default, all routing is done in VRF 0. To use additional VRFs, assign a VRF ID to an interface. All routes relating to that interface are isolated to that VRF specific routing table. Interfaces in one VRF cannot reach interfaces in a different VRF.

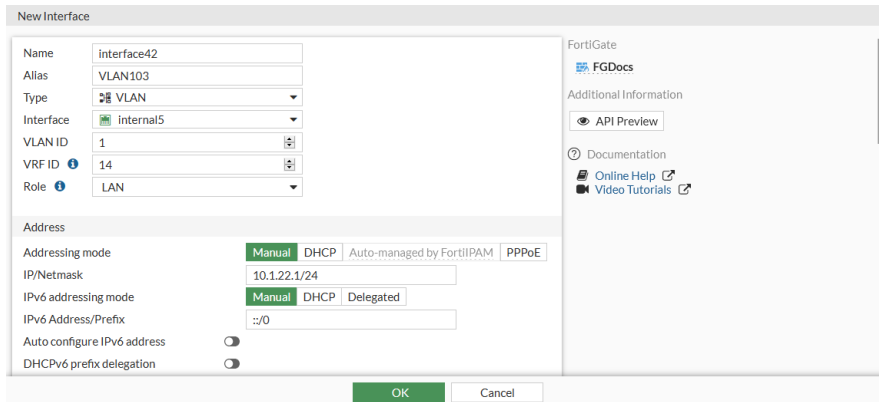

If some traffic does have to pass between VRFs, route leaking can be used. See [Route leaking between VRFs with BGP on page 469](#).

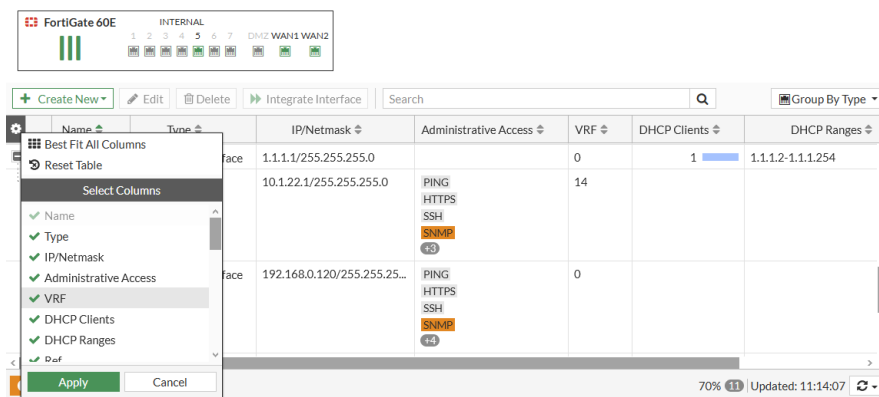

Enable *Advanced Routing* in *System > Feature Visibility* to configure VRFs.

To configure a VRF ID on an interface in the GUI:

1. Go to *Network > Interfaces* and click *Create New > Interface*.
2. Enter a value in the VRF ID field.
3. Configure the other settings as needed.

4. Click **OK**.
5. To add the VRF column in the interface table, click the gear icon, select **VRF**, and click **Apply**.

To configure a VRF ID on an interface in the CLI:

```
config system interface
  edit interface42
    . . .
    set vrf 14
  next
end
```

VRF routing support

VRF supports static routing, OSPF, and BGP. Other routing protocols require using VDOMs.

BGP

In this example, BGP is used to update the VRF that it is neighbors with.

The hub is configured with two neighbors connected to two interfaces. The branches are configured to match the hub, with branch networks configured to redistribute into BGP.

Policies must be created on the hub and branches to allow traffic between them.

To configure the hub:

```
config router bgp
  set as 65000
  config neighbor
    edit "10.101.101.2"
      set soft-reconfiguration enable
      set interface "port2"
      set remote-as 65101
      set update-source "port2"
    next
    edit "10.102.102.2"
      set soft-reconfiguration enable
      set interface "port3"
      set remote-as 65102
      set update-source "port3"
    next
  end
end
```

To configure branch 101:

```
config router bgp
  set as 65101
  config neighbor
    edit "10.101.101.1"
      set soft-reconfiguration enable
      set interface "port2"
      set remote-as 65000
      set update-source "port2"
    next
  end
  config redistribute connected
    set status enable
  end
end
```

To configure branch 102:

```
config router bgp
  set as 65102
  config neighbor
    edit "10.102.102.1"
      set soft-reconfiguration enable
      set interface "port2"
      set remote-as 65000
```

```

        set update-source "port2"
    next
end
config redistribute connected
    set status enable
end
end

```

To verify the BGP neighbors and check the routing table on the hub:

```

# get router info bgp summary
BGP router identifier 192.168.0.1, local AS number 65000
BGP table version is 2
2 BGP AS-PATH entries
0 BGP community entries

```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/Pf
10.101.101.2	4	65101	4	4		2		0	0
10.102.102.2	4	65102	3	3		1		0	0

```
Total number of neighbors 2
```

```

# get router info routing-table all
Routing table for VRF=0
Codes (...)
S* 0.0.0.0/0 [10/0] via 192.168.0.254, port1
C 10.101.101.0/24 is directly connected, port2
C 10.102.102.0/24 is directly connected, port3
C 192.168.0.0/24 is directly connected, port1
B 192.168.101.0/24 [20/0] via 10.101.101.2, port2, 00:01:25
B 192.168.102.0/24 [20/0] via 10.102.102.2, port3, 00:00:50

```

To configure VRF on the hub:

1. Put the interfaces into VRF:

```

config system interface
    edit port2
        set vrf 10
    next
    edit port3
        set vrf 20
    next
end

```

2. Restart the router to reconstruct the routing tables:

```
# execute router restart
```

3. Check the routing tables:

```

# get router info routing-table all
Routing table for VRF=0
Codes (...)
S* 0.0.0.0/0 [10/0] via 192.168.0.254, port1
C 192.168.0.0/24 is directly connected, port1

Routing table for VRF=10

```

```
C    10.101.101.0/24 is directly connected, port2
B    192.168.101.0/24 [20/0] via 10.101.101.2, port2, 00:02:25
```

Routing table for **VRF=20**

```
C    10.102.102.0/24 is directly connected, port3
B    192.168.102.0/24 [20/0] via 10.102.102.2, port2, 00:01:50
```

4. Check the BGP summary:

```
# get router info bgp summary
```

```
VRF 10 BGP router identifier 10.101.101.1, local AS number 65000
BGP table version is 1
2 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State
10.101.101.2	4	65101	4	4		2		0	0

```
Total number of neighbors 1
```

```
VRF 10 BGP router identifier 10.101.101.1, local AS number 65000
BGP table version is 1
2 BGP AS-PATH entries
0 BGP community entries
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State
10.102.102.2	4	65102	3	3		1		0	0

```
Total number of neighbors 1
```

OSPF

OSPF routes in VRFs work the same as BGP: the interface that OSPF is using is added to the VRF.

To configure the hub:

1. Configure OSPF:

```
config router ospf
  set router-id 1.1.1.1
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit Branch101
      set interface "port2"
      set dead-interval 40
      set hello-interval 10
    next
    edit Branch102
      set dead-interval 40
      set hello-interval 10
    next
  end
```

```
config network
  edit 0
    set prefix 10.101.101.0 255.255.255.0
  next
  edit 0
    set prefix 10.102.102.0 255.255.255.0
  next
  edit 0
    set prefix 192.168.1.0 255.255.255.0
  next
end
end
```

2. Put the interfaces into VRF:

```
config system interface
  edit port2
    set vrf 10
  next
  edit port3
    set vrf 20
  next
end
```

To configure branch 101:

```
config router ospf
  set router-id 101.101.101.101
  config area
    edit 0.0.0.0
    next
  end
  config ospf-interface
    edit HUB
      set interface port2
      set dead-interval 40
      set hello-interval 10
    next
  end
  config network
    edit 0
      set prefix 10.101.101.0 255.255.255.0
    next
    edit 0
      set prefix 192.168.101.0 255.255.255.0
    next
  end
end
```

To check the routing table and OSPF summary:

```
# get router info routing-table ospf
# get router info ospf interface
```

Static route

Static routes in VRFs work the same as BGP and OSPF because the interface that the static route is using is added to the VRF.

To add a VRF ID in a static route in the GUI:

1. Configure the interface:
 - a. Go to *Network > Interfaces*.
 - b. Click *Create New > Interface* or *Edit* an existing interface.
 - c. Enter a value in the *VRF ID* field.
 - d. Configure the other settings as needed.
 - e. Click *OK*.
2. Add a static route to the VRF using blackhole:
 - a. Go to *Network > Static Routes*.
 - b. Click *Create New* and select the type of static route.
 - c. Enter the *Subnet*.
 - d. In the *Interface* field, select *Blackhole*.
 - e. In the *VRF ID* field, enter the ID created in the step one.
 - f. Click *OK*.

To add a VRF ID in a static route in the CLI:

1. Configure the interface:

```
config system interface
  edit port2
    set vrf 10
  next
end
```

2. Add a static route to the VRF using blackhole:

```
config router static
  edit 3
    set dst 0.0.0.0/0
    set blackhole enable
    set vrf 10
  next
end
```

To check the routing table:

```
# get router info routing-table static
```

Route leaking between VRFs with BGP

Route leaking allows you to configure communication between VRFs. If route leaking is not configured, then the VRFs are isolated. This example shows route leaking with BGP using virtual inter-VDOM links.

In this example, a hub FortiGate forms BGP neighbors with two branches. It learns the networks 192.168.101.0/24 and 192.168.102.0/24 from the neighbors and separates them into VRF 10 and VRF 20.

To leak the learned routes to each other, an inter-VDOM link (IVL) is formed. An IVL normally bridges two VDOMs, but in this case the links reside on the same VDOM and are used to bridge the two VRFs. NPU links could also be used on models that support it to deliver better performance.

VRF 10 has a leaked route to 192.168.102.0/24 on IVL *link-10-20-0*, and VRF 20 has a leaked route to 192.168.101.0/24 on IVL *link-10-20-1*,

To configure route leaking:

1. Allow interface subnets to use overlapping IP addresses:

```
config system settings
  set allow-subnet-overlap enable
end
```

2. Configure the inter-VDOM links:

```
config system vdom-link
  edit link-10-20-
  next
end
```

3. Configure the interface settings:

```
config system interface
  edit link-10-20-0
    set vdom "root"
    set vrf 10
    set ip 10.1.1.1/30
  next
  edit link-10-20-1
    set vdom "root"
    set vrf 20
    set ip 10.1.1.2/30
  next
end
```

4. Create the prefix lists:

These objects define the subnet and mask that are leaked.

```
config router prefix-list
  edit VRF10_Route
    config rule
      edit 1
        set prefix 192.168.101.0 255.255.255.0
```

```

        next
    end
next
edit VRF20_Route
    config rule
        edit 1
            set prefix 192.168.102.0 255.255.255.0
        next
    end
next
end

```

5. Create the route map:

The route map can be used to group one or more prefix lists.

```

config router route-map
    edit "Leak_from_VRF10_to_VRF20"
        config rule
            edit 1
                set match-ip-address "VRF10_Route"
            next
        end
    next
    edit "Leak_from_VRF20_to_VRF10"
        config rule
            edit 1
                set match-ip-address "VRF20_Route"
            next
        end
    next
end

```

6. Configure the VRF leak in BGP, specifying a source VRF, destination VRF, an the route map to use:

```

config router bgp
    config vrf-leak
        edit "10"
            config target
                edit "20"
                    set route-map "Leak_from_VRF10_to_VRF20"
                    set interface "link-10-20-0"
                next
            end
        next
        edit "20"
            config target
                edit "10"
                    set route-map "Leak_from_VRF20_to_VRF10"
                    set interface "link-10-20-1"
                next
            end
        next
    end
end

```

7. Create policies to allow traffic between the VRFs.

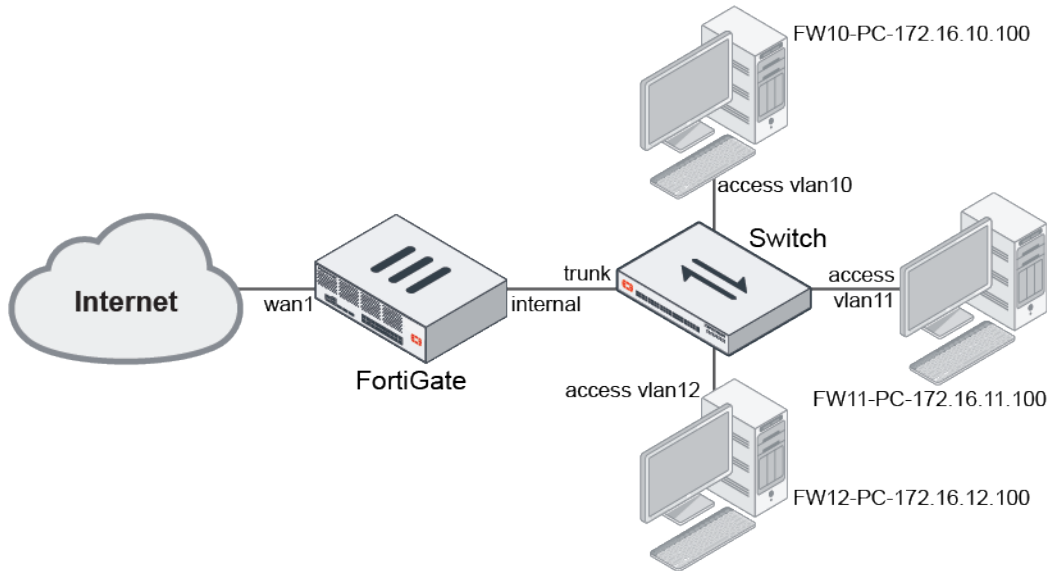

Without a policy permitting traffic on the route between the VRFs, the VRFs are still isolated.

Route leaking between multiple VRFs

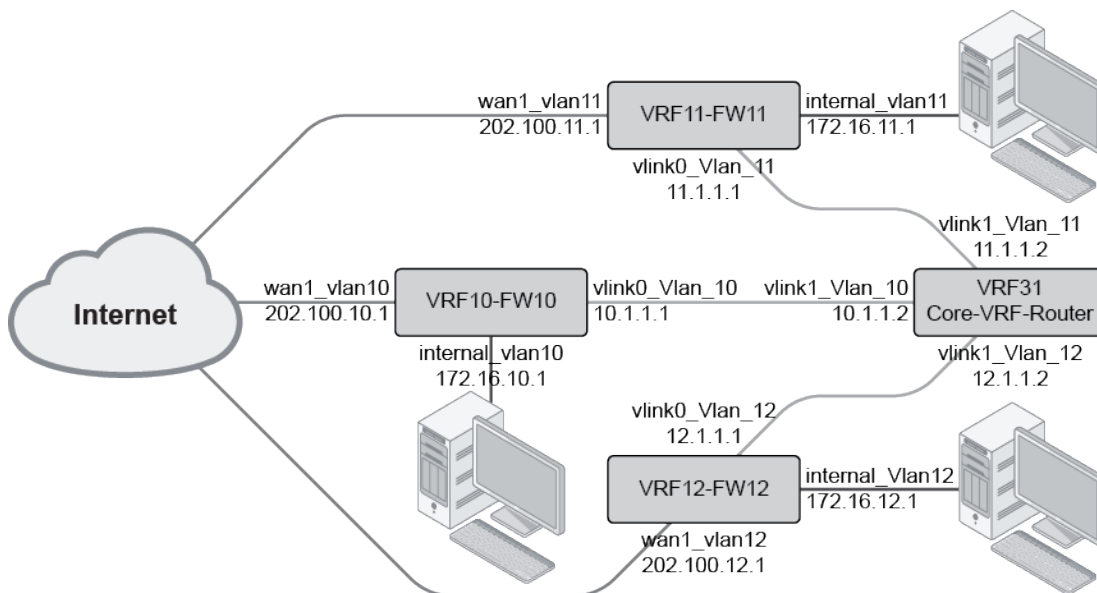

In this example, routing leaking between three VRFs in a star topology is configured. This allows the solution to be scaled to more VRFs without building full mesh, one-to-one connections between each pair of VRFs. VLAN subinterfaces are created on VDOM links to connect each VRF to the central VRF, allowing routes to be leaked from a VRF to the central VRF, and then to the other VRFs. Static routes are used for route leaking in this example.

For instructions on creating route leaking between two VRFs, see [Route leaking between VRFs with BGP on page 469](#).

Physical topology:

Logical topology:

In this example, a specific route is leaked from each of the VRFs to each of the other VRFs. VLAN subinterfaces are created based on VDOM links to connect each VRF to the core VRF router.

Multi VDOM mode is enabled so that NP VDOM links can be used. The setup could be configured without enabling multi VDOM mode by manually creating non-NP VDOM links, but this is not recommended as the links are not offloaded to the NPU.

After VDOMs are enabled, all of the configuration is done in the *root* VDOM.

To configure the FortiGate:

1. Enable multi VDOM mode:

```
config system global
    set vdom-mode multi-vdom
end
```

If the FortiGate has an NP, the VDOM links will be created:

```
# show system interface
config system interface
    ...
    edit "npu0_vlink0"
        set vdom "root"
        set type physical
    next
    edit "npu0_vlink1"
        set vdom "root"
        set type physical
    next
    ...
end
```

If multi VDOM mode is not used, the VDOM links can be manually created:

```
config system vdom-link
    edit <name of vmlink>
    next
end
```

2. Allow interface subnets to use overlapping IP addresses:

```
config vdom
    edit root
        config system settings
            set allow-subnet-overlap enable
        end
end
```

3. Configure the inter-connecting VLAN subinterfaces between VRF based on VDOM-LINK:

```
config system interface
    edit "vlink0_vlan_10"
        set vdom "root"
        set vrf 10
        set ip 10.1.1.1 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink0_vlan_10"
        set role lan
        set interface "npu0_vlink0"
```

```
        set vlanid 10
    next
    edit "vlink1_Vlan_10"
        set vdom "root"
        set vrf 31
        set ip 10.1.1.2 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink1_Vlan_10"
        set role lan
        set interface "np0_vlink1"
        set vlanid 10
    next
    edit "vlink0_Vlan_11"
        set vdom "root"
        set vrf 11
        set ip 11.1.1.1 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink0_Vlan_11"
        set role lan
        set interface "np0_vlink0"
        set vlanid 11
    next
    edit "vlink1_Vlan_11"
        set vdom "root"
        set vrf 31
        set ip 11.1.1.2 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink1_Vlan_11"
        set role lan
        set interface "np0_vlink1"
        set vlanid 11
    next
    edit "vlink0_Vlan_12"
        set vdom "root"
        set vrf 12
        set ip 12.1.1.1 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink0_Vlan_12"
        set role lan
        set interface "np0_vlink0"
        set vlanid 12
    next
    edit "vlink1_Vlan_12"
        set vdom "root"
        set vrf 31
        set ip 12.1.1.2 255.255.255.252
        set allowaccess ping https ssh http
        set alias "vlink1_Vlan_12"
        set role lan
        set interface "np0_vlink1"
        set vlanid 12
    next
end
```

4. Configure a zone to allow intrazone traffic between VLANs in the central VRF:

```
config system zone
  edit "Core-VRF-Router"
    set intrazone allow
    set interface "vlink1_Vlan_10" "vlink1_Vlan_11" "vlink1_Vlan_12"
  next
end
```

5. Add allow policies for the VRF31 core router:

```
config firewall policy
  edit 0
    set name "any_to_core_vrf31"
    set srcintf "any"
    set dstintf "Core-VRF-Router"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
  next
  edit 0
    set name "core_vrf31_to_any"
    set srcintf "Core-VRF-Router"
    set dstintf "any"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
  next
end
```

6. Configure VRF10, VRF11, and VRF12 on the Internal and WAN VLAN sub-interfaces:

```
config system interface
  edit "Internal_VRF10"
    set vdom "root"
    set vrf 10
    set ip 172.16.10.1 255.255.255.0
    set allowaccess ping https ssh http
    set alias "Internal_VRF10"
    set role lan
    set interface "internal"
    set vlanid 10
  next
  edit "Internal_VRF11"
    set vdom "root"
    set vrf 11
    set ip 172.16.11.1 255.255.255.0
    set allowaccess ping https ssh http
    set alias "Internal_VRF11"
    set role lan
    set interface "internal"
    set vlanid 11
  next
end
```

```
edit "Internal_VRF12"
    set vdom "root"
    set vrf 12
    set ip 172.16.12.1 255.255.255.0
    set allowaccess ping https ssh http
    set alias "Internal_VRF12"
    set role lan
    set interface "internal"
    set vlanid 12
next
edit "wan1_VRF10"
    set vdom "root"
    set vrf 10
    set ip 202.100.10.1 255.255.255.0
    set allowaccess ping
    set alias "wan1_VRF10"
    set role wan
    set interface "wan1"
    set vlanid 10
next
edit "wan1_VRF11"
    set vdom "root"
    set vrf 11
    set ip 202.100.11.1 255.255.255.0
    set allowaccess ping
    set alias "wan1_VRF11"
    set role wan
    set interface "wan1"
    set vlanid 11
next
edit "wan1_VRF12"
    set vdom "root"
    set vrf 12
    set ip 202.100.12.1 255.255.255.0
    set allowaccess ping
    set alias "wan1_VRF12"
    set role wan
    set interface "wan1"
    set vlanid 12
next
end
```

7. Configure static routing and route leaking between each VRF and Core-VRF-Router:

```
config router static
    edit 1
        set dst 172.16.10.0 255.255.255.0
        set gateway 10.1.1.1
        set device "vlink1_Vlan_10"
        set comment "VRF31_Core_Router"
    next
    edit 2
        set dst 172.16.11.0 255.255.255.0
        set gateway 11.1.1.1
        set device "vlink1_Vlan_11"
        set comment "VRF31_Core_Router"
```

```
next
edit 3
    set dst 172.16.12.0 255.255.255.0
    set gateway 12.1.1.1
    set device "vlink1_Vlan_12"
    set comment "VRF31_Core_Router"
next
edit 4
    set dst 172.16.11.0 255.255.255.0
    set gateway 10.1.1.2
    set device "vlink0_Vlan_10"
    set comment "VRF10_Route_Leaking"
next
edit 5
    set dst 172.16.12.0 255.255.255.0
    set gateway 10.1.1.2
    set device "vlink0_Vlan_10"

0 packets dropped by kernel

```

VRF with IPv6

IPv6 routes support VRF. Static, connected, OSPF, and BGP routes can be isolated in different VRFs. BGP IPv6 routes can be leaked from one VRF to another.

```

config router bgp
  config vrf-leak6
    edit <origin vrf-id>
      config target
        edit <target vrf-id>
          set route-map <route-map>
          set interface <interface>
        next
      end
    next
  next

```

```
end
end
```

The origin or target VRF ID is an integer value from 0 - 31.

```
config router static6
  edit <id>
    set vrf <vrf-id>
  next
end
```

Using a VRF leak on BGP

In this example, the route 2000:5:5:5::/64 learned from Router 1 is leaked to VRF 20 through the interface vlan552. Conversely, the route 2009:3:3:3::/64 learned from Router 2 is leaked to VRF 10 through interface vlan55.

To configure VRF leaking in BGP:

1. Configure the BGP neighbors:

```
config router bgp
  set as 65412
  config neighbor
    edit "2000:10:100:1::1"
      set activate disable
      set remote-as 20
      set update-source "R150"
    next
    edit "2000:10:100:1::5"
      set activate disable
      set soft-reconfiguration enable
      set interface "R160"
      set remote-as 20
    next
  end
end
```

2. Configure the VLAN interfaces:

```
config system interface
  edit "vlan55"
    set vdom "root"
    set vrf 10
    set ip 55.1.1.1 255.255.255.0
```

```
        set device-identification enable
        set role lan
        set snmp-index 51
        config ipv6
            set ip6-address 2000:55::1/64
        end
        set interface "npu0_vlink0"
        set vlanid 55
    next
edit "vlan552"
    set vdom "root"
    set vrf 20
    set ip 55.1.1.2 255.255.255.0
    set device-identification enable
    set role lan
    set snmp-index 53
    config ipv6
        set ip6-address 2000:55::2/64
    end
    set interface "npu0_vlink1"
    set vlanid 55
next
end
```

3. Configure the IPv6 prefixes:

```
config router prefix-list6
    edit "1"
        config rule
            edit 1
                set prefix6 2000:5:5:5::/64
                unset ge
                unset le
            next
        end
    next
    edit "2"
        config rule
            edit 1
                set prefix6 2009:3:3:3::/64
                unset ge
                unset le
            next
        end
    next
end
```

4. Configure the route maps:

```
config router route-map
    edit "from106"
        config rule
            edit 1
                set match-ip6-address "1"
            next
        end
    next
end
```

```

edit "from206"
  config rule
    edit 1
      set match-ip6-address "2"
    next
  end
next
end

```

5. Configure the IPv6 route leaking (leak route 2000:5:5:5::/64 learned from Router 1 to VRF 20, then leak route 2009:3:3:3::/64 learned from Router 2 to VRF 10):

```

config router bgp
  config vrf-leak6
    edit "10"
      config target
        edit "20"
          set route-map "from106"
          set interface "vlan55"
        next
      end
    next
  edit "20"
    config target
      edit "10"
        set route-map "from206"
        set interface "vlan552"
      next
    end
  next
end

```

To verify the VRF leaking:

1. Check the routing table before the leak:

```

# get router info6 routing-table bgp
Routing table for VRF=10
B      2000:5:5:5::/64 [20/0] via fe00::2000:0000:0000:00, R150, 00:19:45

Routing table for VRF=20
B      2008:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:18:49
B      2009:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:18:49

```

2. Check the routing table after the leak:

```

# get router info6 routing-table bgp
Routing table for VRF=10
B      2000:5:5:5::/64 [20/0] via fe00::2000:0000:0000:0, R150, 00:25:45
B      2009:3:3:3::/64 [20/0] via fe80::10:0000:0000:4245, vlan55, 00:00:17

Routing table for VRF=20
B      2000:5:5:5::/64 [20/0] via fe80::10:0000:0000:4244, vlan552, 00:00:16
B      2008:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:24:49
B      2009:3:3:3::/64 [20/0] via fe00::3000:0000:0000:00, R160, 00:24:49

```

Using VRF on a static route

In this example, a VRF is defined on static route 22 so that it will only appear in the VRF 20 routing table.

To configure the VRF on the static route:

```
config router static6
  edit 22
    set dst 2010:2:2:2::/64
    set blackhole enable
    set vrf 20
  next
end
```

IBGP and EBGp support in VRF

Support is included for internal and external border gateway protocols (IBGP and EBGp) in virtual routing and forwarding (VRF).

FortiGate can establish neighbor connections with other FortiGates or routers, and the learned routes are put into different VRF tables according to the neighbor's settings.

This example uses the following topology:

- BGP routes learned from the Router1 neighbor are put into vrf10.
- BGP routes learned from the Router2 neighbor are put into vrf20.

To configure this example:

```
config system interface
  edit port1
    set vrf 10
  next
  edit port2
    set vrf 20
  next
end

config router bgp
  config neighbor
    edit "192.168.1.1"
```

```

        set update-source port1
    next
    edit "192.168.2.1"
        set interface port2
    next
end
end

```

Results

Using the above topology:

- Both Router1 and Router2 establish OSPF and BGP neighbor with the FortiGate.
- Router1 advertises 10.10.1.0/24 into OSPF and 10.10.2.0/24 into BGP.
- Router2 advertises 20.20.1.0/24 into OSPF and 20.20.2.0/24 into BGP.

When port1 and port2 have not set VRF, all of the routing is in VRF=0:

```

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

```

```

Routing table for VRF=0
S*    0.0.0.0/0 [5/0] via 10.0.1.254, port9
C     10.0.1.0/24 is directly connected, port9
O     10.10.1.0/24 [110/10] via 192.168.1.1, port1, 00:18:31
B     10.10.2.0/24 [20/200] via 192.168.1.1, port1, 00:01:31
O     20.20.1.0/22 [110/10] via 192.168.2.1, port2, 00:19:05
B     20.20.2.0/24 [20/200] via 192.168.2.1, port2, 00:01:31
C     192.168.1.0/24 is directly connected, port1
C     192.168.2.0/24 is directly connected, port2

```

After VRF is set for BGP, BGP routes are added to the VRF tables along with OSPF and connected routes:

```

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

```

```

Routing table for VRF=0
S*    0.0.0.0/0 [5/0] via 10.0.1.254, port9
C     10.0.1.0/24 is directly connected, port9

```

```

Routing table for VRF=10
O     10.10.1.0/24 [110/10] via 192.168.1.1, port1, 00:18:31
B     10.10.2.0/24 [20/200] via 192.168.1.1, port1, 00:01:31
C     192.168.1.0/24 is directly connected, port1

```

```

Routing table for VRF=20
O     20.20.1.0/22 [110/10] via 192.168.2.1, port2, 00:19:05

```

```

B      20.20.2.0/24 [20/200] via 192.168.2.1, port2, 00:01:31
C      192.168.2.0/24 is directly connected, port2

```

BGP neighbor groups

This feature is also supported in the BGP neighbor groups. For example:

```

config router bgp
  config neighbor-group
    edit "FGT"
      set update-source "port1"
    next
  end
  config neighbor-range
    edit 1
      set prefix 172.16.201.0 255.255.255.0
      set neighbor-group "FGT"
    next
  end
end

```

Note that the `set interface` command is not supported.

Support cross-VRF local-in and local-out traffic for local services

When local-out traffic such as SD-WAN health checks, SNMP, syslog, and so on are initiated from an interface on one VRF and then pass through interfaces on another VRF, the reply traffic will be successfully forwarded back to the original VRF.

VRF 0 is a special VRF. By default, all routing is done in VRF 0. So all routes in different VRFs, such as VRF 10 or VRF 20, will all be included in VRF 0. VRF 0 cannot be used in the cross-VRF case.

For local-in and local-out traffic, all routes relating to one VRF are isolated from other VRFs so interfaces in one VRF cannot reach interfaces in a different VRF, except for VRF 0.

Example

In this example, there is an NPU VDOM link that is configured on the root VDOM. Two VLANs, vrf10 and vrf20, are created on either ends of the NPU VDOM link, each belonging to a different VRF.

When pinging from the vrf10 interface in VRF 10 to the destination server 172.16.202.2, since there is a single static route for VRF 10 with a gateway of vrf20/10.32.70.2, traffic is sent to the next hop and subsequently routed through port12 to the server.

As seen in the sniffer trace, the ICMP replies are received on port12 in VRF 20, then pass through vrf20, and are ultimately forwarded back to vrf10 in VRF 10. The traffic flow demonstrates that local-out traffic sourced from one VRF passing through another VRF can return back to the original VRF.

To configure cross-VRF local-out traffic for local services:

1. Configure the interfaces:

```
config system interface
  edit "vrf10"
    set vdom "root"
    set vrf 10
    set ip 10.32.70.1 255.255.255.0
    set allowaccess ping
    set device-identification enable
    set role lan
    set snmp-index 35
    set interface "npu0_vlink0"
    set vlanid 22
  next
  edit "vrf20"
    set vdom "root"
    set vrf 20
    set ip 10.32.70.2 255.255.255.0
    set allowaccess ping
    set device-identification enable
    set role lan
    set snmp-index 36
    set interface "npu0_vlink1"
    set vlanid 22
  next
  edit "port12"
    set vdom "root"
    set vrf 20
    set ip 172.16.202.1 255.255.255.0
    set allowaccess ping https ssh snmp http telnet fgfm radius-acct probe-response
fabric ftm speed-test
  set type physical
  set alias "TO_FGT_D_port22"
  set snmp-index 14
  config ipv6
    set ip6-address 2003:172:16:202::1/64
    set ip6-allowaccess ping
  end
next
end
```

2. Configure the firewall policy:

```
config firewall policy
  edit 1
    set srcintf "vrf20"
    set dstintf "port12"
```

```
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
    next
end
```

3. Configure the static route:

```
config router static
    edit 2
        set gateway 10.32.70.2
        set distance 3
        set device "vrf10"
    next
end
```

To test the configuration:

1. Execute a ping from the vrf10 interface in VRF 10 to the destination server (172.16.202.2):

```
# execute ping-options interface vrf10
# execute ping 172.16.202.2
PING 172.16.202.2 (172.16.202.2): 56 data bytes
64 bytes from 172.16.202.2: icmp_seq=0 ttl=254 time=0.1 ms
64 bytes from 172.16.202.2: icmp_seq=1 ttl=254 time=0.0 ms

--- 172.16.202.2 ping statistics ---
2 packets transmitted, 2 packets received, 0% packet loss
round-trip min/avg/max = 0.0/0.0/0.1 ms
```

2. Run a sniffer trace on 172.16.202.2 for ICMP:

```
# diagnose sniffer packet any "host 172.16.202.2 and icmp" 4
interfaces=[any]
filters=[host 172.16.202.2 and icmp]
3.393920 vrf10 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393922 npu0_vlink0 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393927 vrf20 in 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393943 port12 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
3.393977 port12 in 172.16.202.2 -> 10.32.70.1: icmp: echo reply
3.393987 vrf20 out 172.16.202.2 -> 10.32.70.1: icmp: echo reply
3.393988 npu0_vlink1 out 172.16.202.2 -> 10.32.70.1: icmp: echo reply
3.393993 vrf10 in 172.16.202.2 -> 10.32.70.1: icmp: echo reply
4.393941 vrf10 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
4.393942 npu0_vlink0 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
4.393948 vrf20 in 10.32.70.1 -> 172.16.202.2: icmp: echo request
4.393957 port12 out 10.32.70.1 -> 172.16.202.2: icmp: echo request
4.393980 port12 in 172.16.202.2 -> 10.32.70.1: icmp: echo reply
4.393987 vrf20 out 172.16.202.2 -> 10.32.70.1: icmp: echo reply
4.393987 npu0_vlink1 out 172.16.202.2 -> 10.32.70.1: icmp: echo reply
4.393994 vrf10 in 172.16.202.2 -> 10.32.70.1: icmp: echo reply
```

NetFlow

NetFlow allows you to collect IP network traffic statistics for an interface, and then export those statistics for analysis. NetFlow samplers, that sample every packet, are configured per interface. Full NetFlow is supported through the information maintained in the firewall session.

To configure NetFlow:

```
config system netflow
  set collector-ip <ip>
  set collector-port <port>
  set source-ip <ip>
  set active-flow-timeout <integer>
  set inactive-flow-timeout <integer>
  set template-tx-timeout <integer>
  set template-tx-counter <integer>
end
```

collector-ip <ip>	Collector IP address.
collector-port <port>	NetFlow collector port number (0 - 65535).
source-ip <ip>	Source IP address, for communication with the NetFlow agent.
active-flow-timeout <integer>	Timeout to report active flows, in seconds (60 - 3600, default = 1800).
inactive-flow-timeout <integer>	Timeout for periodic report of finished flows, in seconds (10 - 600, default = 15).
template-tx-timeout <integer>	Timeout for periodic template flowset transmission, in seconds (60 - 86400, default = 1800).
template-tx-counter <integer>	Counter of flowset records, before resending a template flowset record (10 - 6000, default = 20).

To configure NetFlow in a specific VDOM:

```
config vdom
  edit <vdom>
    config system vdom-netflow
      set vdom-netflow enable
      set collector-ip <ip>
      set collector-port <port>
      set source-ip <ip>
    end
  next
end
```

To configure a NetFlow sampler on an interface:

```
config system interface
  edit <interface>
    set netflow-sampler {disable | tx | rx | both}
```

```

    next
end

```

disable	Disable the NetFlow protocol on this interface (default).
tx	Monitor transmitted traffic on this interface.
rx	Monitor received traffic on this interface.
both	Monitor transmitted/received traffic on this interface.

Verification and troubleshooting

If data are not seen on the NetFlow collector after it has been configured, use the following sniffer commands to verify if the FortiGate and the collector are communicating:

- By collector port:

```
# diagnose sniffer packet 'port <collector-port>' 6 0 a
```

- By collector IP address:

```
# diagnose sniffer packet 'host <collector-ip>' 6 0 a
```

NetFlow uses the sflow daemon. The current NetFlow configuration can be viewed using test level 3 or 4:

```
# diagnose test application sflowd 3
```

```
# diagnose test application sflowd 4
```

Netflow Cache Stats:

```
vdoms=1 Collectors=1 Cached_intf=2 Netflow_enabled_intf=1 Live_sessions=0 Session cache max
count:71950
```

NetFlow templates

NetFlow uses templates to capture and categorize the data that it collects. FortiOS supports the following NetFlow templates:

Name	Template ID	Description
STAT_OPTIONS	256	Statistics information about exporter
APP_ID_OPTIONS	257	Application information
IPV4	258	No NAT IPv4 traffic
IPV6	259	No NAT IPv6 traffic
ICMP4	260	No NAT ICMPv4 traffic
ICMP6	261	No NAT ICMPv6 traffic
IPV4_NAT	262	Source/Destination NAT IPv4 traffic
IPV4_AF_NAT	263	AF NAT IPv4 traffic (4->6)

Name	Template ID	Description
IPV6_NAT	264	Source/Destination NAT IPv6 traffic
IPV6_AF_NAT	265	AF NAT IPv6 traffic (6->4)
ICMP4_NAT	266	Source/Destination NAT ICMPv4 traffic
ICMP4_AF_NAT	267	AF NAT ICMPv4 traffic (4->6)
ICMP6_NAT	268	Source/Destination NAT ICMPv6 traffic
ICMPv6_AF_NAT	269	AF NAT ICMPv6 traffic (6->4)

NetFlow on FortiExtender and tunnel interfaces

NetFlow sampling is supported on FortiExtender and VPN tunnel interfaces.

VPN tunnel interfaces can be IPsec, IP in IP, or GRE tunnels. NetFlow sampling is supported on both NPU and non-NPU offloaded tunnels.

Examples

In the following examples, a FortiExtender and a VPN tunnel interface are configured with NetFlow sampling.

To configure a FortiExtender interface with NetFlow sampling:

1. Configure a FortiExtender interface with NetFlow sampling enabled for both transmitted and received traffic:

```
config system interface
  edit "fext-211"
    set vdom "root"
    set mode dhcp
    set type fext-wan
    set netflow-sampler both
    set role wan
    set snmp-index 8
    set macaddr 2a:4e:68:a3:f4:6a
  next
end
```

2. Check the NetFlow status and configuration:

Device index 26 is the FortiExtender interface `fext-211`.

```
# diagnose test application sflowd 3
===== Netflow Vdom Configuration =====
Global collector:172.18.60.80:[2055] source ip: 0.0.0.0 active-timeout(seconds):60
inactive-timeout(seconds):600
___ vdom: root, index=0, is master, collector: disabled (use global config) (mgmt vdom)
  |_ coll_ip:172.18.60.80[2055],src_ip:10.6.30.105,seq_num:300,pkts/time to next
  template: 18/29
  |_ exported: Bytes:3026268, Packets:11192, Sessions:290 Flows:482
  |___ interface:fext-211 sample_direction:both device_index:26 snmp_index:8
```

3. Check the network interface list:

```
# diagnose netlink interface list
...
if=fext-211 family=00 type=1 index=26 mtu=1500 link=0 master=0
ref=27 state=start present fw_flags=60000 flags=up broadcast run multicast
...
```

4. Check the session list for the FortiExtender interface and NetFlow flowset packet:

```
# diagnose sys session list
session info: proto=1 proto_state=00 duration=1732 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty netflow-origin netflow-reply
statistic(bytes/packets/allow_err): org=145572/1733/1 reply=145572/1733/1 tuples=2
tx speed(Bps/kbps): 83/0 rx speed(Bps/kbps): 83/0
orgin->sink: org pre->post, reply pre->post dev=5->26/26->5
gwy=10.39.252.244/172.16.200.55
hook=post dir=org act=snat 172.16.200.55:61290->8.8.8.8:8(10.39.252.243:61290)
hook=pre dir=reply act=dnat 8.8.8.8:61290->10.39.252.243:0(172.16.200.55:61290)
misc=0 policy_id=1 auth_info=0 chk_client_info=0 vd=0
serial=00001298 tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x040000
no_ofld_reason: non-npu-intf
total session 1
```

5. The flowset packet can be captured on UDP port 2055 by a packet analyzer, such as Wireshark:

The screenshot displays a Wireshark capture of a flowset packet. The packet list pane shows a single packet of type 'Flowset' with length 718. The packet details pane shows the flowset structure, including source and destination IP addresses, ports, and various flags. The packet bytes pane shows the raw hex and ASCII data of the flowset packet.

To configure a VPN tunnel interface with NetFlow sampling:

1. Configure a VPN interface with NetFlow sampling enabled for both transmitted and received traffic:

```
config system interface
edit "A-to-B_vpn"
set vdom "vdom1"
set type tunnel
set netflow-sampler both
set snmp-index 42
set interface "port3"
next
end
```

2. Configure the VPN tunnel:

```

config vpn ipsec phase1-interface
  edit "A-to-B_vpn"
    set interface "port3"
    set peertype any
    set net-device disable
    set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
    set comments "VPN: A-to-B_vpn [Created by VPN wizard]"
    set wizard-type static-fortigate
    set remote-gw 10.2.2.2
    set psksecret ENC
  next
end

config vpn ipsec phase2-interface
  edit "A-to-B_vpn"
    set phase1name "A-to-B_vpn"
    set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
    set comments "VPN: A-to-B_vpn [Created by VPN wizard]"
    set src-addr-type name
    set dst-addr-type name
    set src-name "A-to-B_vpn_local"
    set dst-name "A-to-B_vpn_remote"
  next
end

```

3. Check the NetFlow status and configuration:

Device index 52 is the VPN interface A-to-B_vpn.

```

# diagnose test application sflowd 3
===== Netflow Vdom Configuration =====
Global collector:172.18.60.80:[2055] source ip: 0.0.0.0 active-timeout(seconds):60
inactive-timeout(seconds):15
___ vdom: vdom1, index=1, is master, collector: disabled (use global config) (mgmt
vdom)
  |_ coll_ip:172.18.60.80[2055],src_ip:10.1.100.1,seq_num:60,pkts/time to next
template: 15/6
  |_ exported: Bytes:11795591, Packets:48160, Sessions:10 Flows:34
  |___ interface:A-to-B_vpn sample_direction:both device_index:52 snmp_index:42

```

4. Check the session list for the VPN interface and NetFlow flowset packet (unencapsulated traffic going through the VPN tunnel):

```

# diagnose sys session list
session info: proto=6 proto_state=01 duration=6 expire=3599 timeout=3600 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty npu netflow-origin netflow-reply
statistic(bytes/packets/allow_err): org=6433/120/1 reply=884384/713/1 tuples=2
tx speed(Bps/kbps): 992/7 rx speed(Bps/kbps): 136479/1091
origin->sink: org pre->post, reply pre->post dev=10->52/52->10 gwy=10.2.2.2/10.1.100.22
hook=pre dir=org act=noop 10.1.100.22:43714->172.16.200.55:80(0.0.0.0:0)
hook=post dir=reply act=noop 172.16.200.55:80->10.1.100.22:43714(0.0.0.0:0)
pos/(before,after) 0/(0,0), 0/(0,0)

```

```

src_mac=00:0c:29:ac:ae:4f
misc=0 policy_id=5 auth_info=0 chk_client_info=0 vd=1
serial=00003b6c tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpd_b_link_id=00000000 rpd_b_svc_id=0 ngfwid=n/a
npu_state=0x000001 no_offload
npu_info: flag=0x82/0x00, offload=0/0, ips_offload=0/0, epid=0/0, ipid=0/0,
vlan=0x0000/0x0000
vlifid=0/0, vtag_in=0x0000/0x0000 in_npu=0/0, out_npu=0/0, fwd_en=0/0, qid=0/0
no_ofld_reason: disabled-by-policy
total session 1

```

5. The flowset packet can be captured on UDP port 2055 by a packet analyzer, such as Wireshark:

The screenshot displays a Wireshark capture of network traffic. The top pane shows a list of packets, with several selected. The bottom pane provides a detailed view of a selected packet, identified as a flowset packet. The details include:

- Destination:** 192.168.201.22

sFlow

sFlow is a method of monitoring the traffic on your network to identify areas on the network that may impact performance and throughput. FortiGate supports sFlow v5. sFlow collector software is available from a number of third-party software vendors. For more information about sFlow, see www.sflow.org.

The packet information that the FortiGate's sFlow agent collects depends on the interface type:

- On an internal interface, when the interface receives packets from devices with private IP addresses, the collected information includes the private IP addresses.
- On an external, or WAN, interface, when the interface receives to route to or from the internet, the collected information includes the IP address of the WAN interface as the source or destination interface, depending on the direction of the traffic. It does not include IP addresses that are NATed on another interface.

sFlow datagrams contain the following information:

- Packet headers, such as MAC, IPv4, and TCP
- Sample process parameters, such as rate and pool
- Input and output ports
- Priority (802.1p and ToS)
- VLAN (802.1Q)

- Source prefixes, destination prefixes, and next hop addresses
- BGP source AS, source peer AS, destination peer AS, communities, and local preference
- User IDs (TACACS, RADIUS) for source and destination
- Interface statistics (RFC 1573, RFC 2233, and RFC 2358)

Configuring sFlow

sFlow can be configured globally, then on traffic VDOMs and individual interfaces.

When configuring sFlow on a VDOM, the collector can be specified, or the collector that is configured globally can be used.

sFlow is supported on some interface types, such as physical, VLAN, and aggregate. It is not supported on virtual interfaces, such as VDOM link, IPsec, GRE, or SSL. When configuring sFlow on an interface, the rate that the agent samples traffic, the direction of that traffic, and the frequency that the agent sends sFlow datagrams to the sFlow collector can be specified. If sFlow is configured on the VDOM that the interface belongs to, the agent sends datagrams to the collector configured for the VDOM. Otherwise, the datagrams are sent to the collector that is configured globally.

Configuring sFlow for an interface disables NP offloading for all traffic on that interface.

To configure sFlow globally:

```
config system sflow
    set collector-ip <ipv4_address>
    set collector-port <port>
    set source-ip <ipv4_address>
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

<code>collector-ip <ipv4_address></code>	The IPv4 address of the sFlow collector that sFlow agents added to interface (default = 0.0.0.0).
<code>collector-port <port></code>	The UDP port number used for sending sFlow datagrams (0 - 65535, default = 6343). Only configured this option if required by the sFlow collector or your network configuration.
<code>source-ip <ipv4_address></code>	The source IPv4 address that the sFlow agent used to send datagrams to the collector (default = 0.0.0.0). If this option is not configured, the FortiGate uses the IP address of the interface that it sends the datagram through.
<code>interface-select-method {auto sdwan specify}</code>	How the outgoing interface to reach the server is selected (default = auto).
<code>interface <interface></code>	The outgoing interface used to reach the server. This option is only available when <code>interface-select-method</code> is <code>specify</code> .

To configure sFlow for a VDOM:

```

config vdom
  edit <vdom>
    config system vdom-sflow
      set vdom-sflow {enable | disable}
      set collector-ip <ipv4_address>
      set collector-port <port>
      set source-ip <ipv4_address>
      set interface-select-method {auto | sdwan | specify}
      set interface <interface>
    end
  next
end

```

vdom-sflow {enable disable}	Enable/disable the sFlow configuration for the current VDOM (default = disable).
collector-ip <ipv4_address>	The IPv4 address of the sFlow collector that sFlow agents added to interface (default = 0.0.0.0). If this option is not configured, the global setting will be used.
collector-port <port>	The UDP port number used for sending sFlow datagrams (0 - 65535, default = 6343). Only configured this option if required by the sFlow collector or your network configuration. If this option is not configured, the global setting will be used.
source-ip <ipv4_address>	The source IPv4 address that the sFlow agent used to send datagrams to the collector (default = 0.0.0.0). If this option is not configured, the FortiGate uses the IP address of the interface that it sends the datagram through.
interface-select-method {auto sdwan specify}	How the outgoing interface to reach the server is selected (default = auto).
interface <interfae>	The outgoing interface used to reach the server. This option is only available when interface-select-method is specify.

To configure sFlow on an interface:

```

config system interface
  edit <interface>
    set sflow-sampler {enable | disable}
    set sample-rate <integer>
    set polling-interval <integer>
    set sample-direction {tx | rx | both}
  next
end

```

sflow-sampler {enable disable}	Enable/disable sFlow on this interface (default = disable).
----------------------------------	---

<code>sample-rate <integer></code>	The average number of packets that the agent lets pass before taking a sample (10 - 99999, default = 2000). Setting a lower rate will sample a higher number of packets, increasing the accuracy or the sampling data, but also increasing the CPU and network bandwidth usage. The default value is recommended.
<code>polling-interval <integer></code>	The amount of time that the agent waits between sending datagrams to the collector, in seconds (1 - 255, default = 20). Setting a higher value lowers the amount of data that the agent sends across the network, but makes the collector's view of the network less current.
<code>sample-direction {tx rx both}</code>	The direction of the traffic that the agent collects (default = both).

Link monitor

The link monitor is a mechanism that allows the FortiGate to probe the status of a detect server in order to determine the health of the link, next hop, or the path to the server. Ping, TCP echo, UDP echo, HTTP, and TWAMP protocols can be used for the probes. Typically, the detect server is set to a stable server several hops away. Multiple servers can also be configured with options to define the protocol and weights for each server.

The link monitor serves several purposes. In the most basic configuration, it can be used to detect failures and remove routes associated with the interface and gateway to prevent traffic from routing out the failed link. More granularity is added in 7.0 that allows only the routes specified in the link monitor to be removed from the routing table. With this benefit, only traffic to specific routing destinations are removed, rather than all routing destinations.

Another enhancement starting in 7.0.1 is an option to toggle between enabling or disabling policy route updates when a link health monitor fails.

The link monitor can also monitor remote servers for HA failover. Using the HA built-in link monitor, it is only able to detect physical link failovers to trigger HA link failover. With the link monitor, remote servers can be used to monitor the health of the path to the server in order to trigger HA failover.

Finally, the link monitor can cascade the failure to other interfaces. When the `update-cascade-interface` option is enabled, the interface can be configured in conjunction with `fail-detect` enabled to trigger a link down event on other interfaces.

The following topics provide more information about the link monitor:

- [Link monitor with route updates on page 511](#)
- [Enable or disable updating policy routes when link health monitor fails on page 513](#)
- [Add weight setting on each link health monitor server on page 515](#)
- [Dual internet connections on page 357](#)

Link monitor with route updates

When a link monitor fails, only the routes that are specified in the link monitor are removed from the routing table, instead of all the routes with the same interface and gateway. If no routes are specified, then all of the routes are removed. Only IPv4 routes are supported.

Example

In this example, the FortiGate has several routes to 23.2.2.2/32 and 172.16.202.2/24, and is monitoring the link *agg1* by pinging the server at 10.1.100.22. The link monitor uses the gateway 172.16.203.2.

When the link monitor fails, only the routes to the specified subnet using interface *agg1* and gateway 172.16.203.2 are removed.

To configure the link monitor:

```

config system link-monitor
  edit "22"
    set srcintf "agg1"
    set server "10.1.100.22"
    set gateway-ip 172.16.203.2
    set route "23.2.2.2/32" "172.16.202.0/24"
  next
end
  
```

To check the results:

1. When the link monitor is alive:

```

# get router info routing-table static
Routing table for VRF=0
S*  0.0.0.0/0 [5/0] via 10.100.1.249, port12
S   10.1.100.0/24 [10/0] via 172.16.203.2, agg1
S   23.2.2.2/32 [10/0] via 172.16.203.2, agg1
S   23.2.3.2/32 [10/0] via 172.16.203.2, agg1
S   172.16.201.0/24 [10/0] via 172.16.200.4, port9
S   172.16.202.0/24 [10/0] via 172.16.203.2, agg1
S   172.16.204.0/24 [10/0] via 172.16.200.4, port9
                               [10/0] via 172.16.203.2, agg1
                               [10/0] via 172.16.206.2, vlan100, [100/0]
  
```

2. When the link monitor is dead:

```

# get router info routing-table static
Routing table for VRF=0
S*  0.0.0.0/0 [5/0] via 10.100.1.249, port12
S   10.1.100.0/24 [10/0] via 172.16.203.2, agg1
  
```

```

S      23.2.3.2/32 [10/0] via 172.16.203.2, agg1
S      172.16.201.0/24 [10/0] via 172.16.200.4, port9
S      172.16.204.0/24 [10/0] via 172.16.200.4, port9
      [10/0] via 172.16.203.2, agg1
      [10/0] via 172.16.206.2, vlan100, [100/0]

```

Enable or disable updating policy routes when link health monitor fails

An option has been added to toggle between enabling or disabling policy route updates when a link health monitor fails. By disabling policy route updates, a link health monitor failure will not cause corresponding policy-based routes to be removed.

```

config system link-monitor
  edit <name>
    set update-policy-route {enable | disable}
  next
end

```

Example

In the following topology, the FortiGate is monitoring the detect server, 10.1.100.22. The FortiGate has a policy-based route to destination 172.16.205.10 using the same gateway (172.16.202.1) and interface (port22). By configuring `update-policy-route disable`, the policy-based route is not removed when the link health monitor detects a failure.

To disable updating policy routes when the link health monitor fails:

1. Configure the link health monitor:

```

config system link-monitor
  edit "test-1"
    set srcintf "port22"
    set server "10.1.100.22"
    set gateway-ip 172.16.202.1
    set failtime 3
    set update-policy-route disable
  next
end

```

2. Configure the policy route:

```

config router policy
  edit 1
    set input-device "port16"
    set dst "172.16.205.10/255.255.255.255"
    set gateway 172.16.202.1
    set output-device "port22"
    set tos 0x14
    set tos-mask 0xff
  next
end

```

3. When the health link monitor status is up, verify that the policy route is active.**a. Verify the link health monitor status:**

```

# diagnose sys link-monitor status
Link Monitor: test-1, Status: alive, Server num(1), HA state: local(alive), shared
(alive)
Flags=0x1 init, Create time: Fri May 28 15:20:15 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
  Peer: 10.1.100.22(10.1.100.22)
    Source IP(172.16.202.2)
    Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
      protocol: ping, state: alive
        Latency(Min/Max/Avg): 0.374/0.625/0.510 ms
        Jitter(Min/Max/Avg): 0.008/0.182/0.074
        Packet lost: 0.000%
        Number of out-of-sequence packets: 0
        Fail Times(0/3)
        Packet sent: 7209, received: 3400, Sequence(sent/rcvd/exp):
7210/7210/7211

```

b. Verify the policy route list:

```

# diagnose firewall proute list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x0 tos=0x14 tos_mask=0xff protocol=0 sport=0-0 iif=41
dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33

```

4. When the health link monitor status is down, verify that the policy route is active:**a. Verify the link health monitor status:**

```

# diagnose sys link-monitor status
Link Monitor: test-1, Status: die, Server num(1), HA state: local(die), shared(die)
Flags=0x9 init log_downgateway, Create time: Fri May 28 15:20:15 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable

```

```

Diffservcode: 000000
Class-ID: 0
  Peer: 10.1.100.22(10.1.100.22)
    Source IP(172.16.202.2)
    Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
    protocol: ping, state: die
      Packet lost: 11.000%
      Number of out-of-sequence packets: 0
      Recovery times(0/5) Fail Times(0/3)
      Packet sent: 7293, received: 3471, Sequence(sent/rcvd/exp):
7294/7281/7282

```

b. Verify the policy route list:

```

# diagnose firewall proute list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x0 tos=0x14 tos_mask=0xff protocol=0 sport=0-0 iif=41
dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33

```

If the `update-policy-route` setting is enabled, the link health monitor would be down and the policy-based route would be disabled:

```

# diagnose firewall proute list
list route policy info(vf=root):
id=1 dscp_tag=0xff 0xff flags=0x8 disable tos=0x14 tos_mask=0xff protocol=0 sport=0-0
iif=41 dport=0-65535 oif=14(port22) gwy=172.16.202.1
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 172.16.205.10/255.255.255.255
hit_count=1 last_used=2021-05-27 23:04:33

```

Add weight setting on each link health monitor server

Prior to FortiOS 7.0.1, the link health monitor is determined to be dead when all servers are unreachable. Starting in 7.0.1, the link health monitor can configure multiple servers and allow each server to have its own weight setting. When the link health monitor is down, it will trigger static route updates and cascade interface updates if the weight of all dead servers exceeds the monitor's fail weight threshold.

```

config system link-monitor
  edit <name>
    set srcintf <interface>
    set server-config {default | individual}
    set fail-weight <integer>
    config server-list
      edit <id>
        set dst <address>
        set weight <integer>
      next
    end
  next
end

```

server-config

Set the server configuration mode:

	<ul style="list-style-type: none"> • default: all servers share the same attributes. • individual: some attributes can be specified for individual servers.
<code>fail-weight <integer></code>	Threshold weight to trigger link failure alert (0 - 255, default = 0).
<code>server-list</code>	Configure the servers to be monitored by the link monitor.
<code>dst <address></code>	Enter the IP address of the server to be monitored.
<code>weight <integer></code>	Weight of the monitor to this destination (0 - 255, default = 0).

Examples

In the following topology, there are two detect servers that connect to the FortiGate through a router: server 1 (10.1.100.22) and server 2 (10.1.100.55).

Alive link health monitor

In this configuration, one server is dead and one server alive. The failed server weight is not over the threshold, so the link health monitor status is alive.

To configure the weight settings on the link health monitor:

1. Configure the link health monitor:

```

config system link-monitor
  edit "test-1"
    set srcintf "port22"
    set server-config individual
    set gateway-ip 172.16.202.1
    set failtime 3
    set fail-weight 40
  config server-list
    edit 1
      set dst "10.1.100.22"
  
```

```

        set weight 60
    next
    edit 2
        set dst "10.1.100.55"
        set weight 30
    next
end
next
end

```

2. Trigger server 2 to go down. The link monitor is still alive because the fail weight threshold has not been reached.
3. Verify the link health monitor status:

```

# diagnose sys link-monitor status test-1
Link Monitor: test-1, Status: alive, Server num(2), HA state: local(alive), shared
(alive)
Flags=0x1 init, Create time: Fri Jun  4 17:23:29 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
Fail-weight (40): not activated
Peer: 10.1.100.22(10.1.100.22)
Source IP(172.16.202.2)
Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
protocol: ping, state: alive
    Latency(Min/Max/Avg): 0.417/0.585/0.530 ms
    Jitter(Min/Max/Avg): 0.007/0.159/0.057
    Packet lost: 0.000%
    Number of out-of-sequence packets: 0
    Fail Times(0/3)
    Packet sent: 239, received: 236, Sequence(sent/rcvd/exp): 240/240/241
Peer: 10.1.100.55(10.1.100.55)
Source IP(172.16.202.2)
Route: 172.16.202.2->10.1.100.55/32, gwy(172.16.202.1)
Fail weight 30 applied
protocol: ping, state: dead
    Packet lost: 100.000%
    Number of out-of-sequence packets: 0
    Recovery times(0/5) Fail Times(1/3)
    Packet sent: 239, received: 3, Sequence(sent/rcvd/exp): 240/4/5

```

Dead link health monitor

In this configuration, one server is dead and one server alive. The failed server weight is over the threshold, so the link health monitor status is dead.

To configure the weight settings on the link health monitor:

1. Configure the link health monitor:

```

config system link-monitor
    edit "test-1"
        set srcintf "port22"

```

```

set server-config individual
set gateway-ip 172.16.202.1
set failtime 3
set fail-weight 40
config server-list
  edit 1
    set dst "10.1.100.22"
    set weight 30
  next
  edit 2
    set dst "10.1.100.55"
    set weight 50
  next
end
next
end

```

2. Trigger server 2 to go down. The link monitor is dead because the fail weight threshold has been reached.
3. Verify the link health monitor status:

```

# diagnose sys link-monitor status test-1
Link Monitor: test-1, Status: dead, Server num(2), HA state: local(dead), shared(dead)
Flags=0x9 init log_downgateway, Create time: Fri Jun  4 17:23:29 2021
Source interface: port22 (14)
Gateway: 172.16.202.1
Interval: 500 ms
Service-detect: disable
Diffservcode: 000000
Class-ID: 0
Fail-weight (40): activated
Peer: 10.1.100.22(10.1.100.22)
Source IP(172.16.202.2)
Route: 172.16.202.2->10.1.100.22/32, gwy(172.16.202.1)
protocol: ping, state: alive
  Latency(Min/Max/Avg): 0.393/0.610/0.520 ms
  Jitter(Min/Max/Avg): 0.009/0.200/0.095
  Packet lost: 0.000%
  Number of out-of-sequence packets: 0
  Fail Times(0/3)
  Packet sent: 680, received: 677, Sequence(sent/rcvd/exp): 681/681/682
Peer: 10.1.100.55(10.1.100.55)
Source IP(172.16.202.2)
Route: 172.16.202.2->10.1.100.55/32, gwy(172.16.202.1)
Fail weight 50 applied
protocol: ping, state: dead
  Packet lost: 100.000%
  Number of out-of-sequence packets: 0
  Recovery times(0/5) Fail Times(1/3)
  Packet sent: 680, received: 3, Sequence(sent/rcvd/exp): 681/4/5

```

IPv6

From an administrative point of view IPv6 works almost the same as IPv4 in FortiOS. The primary difference is the use of IPv6 format for addresses. See [IPv6 overview on page 519](#) for more information.

By default, the IPv6 settings are not displayed in the GUI.

To enable IPv6 in the GUI:

1. Go to *System > Feature Visibility*.
2. Under *Core Features*, enable *IPv6*.
3. Click *Apply*.

Once enabled, you will be able to use IPv6 addresses as well as the IPv4 addressing for the following FortiGate firewall features which are not limited to:

- [Interfaces](#)
- [DHCP Server](#)
- [DHCP Relay](#)
- [DNS](#)
- [Static Routes](#)
- [Firewall Policy](#)
- [NAT](#)
- [Addresses](#)
- [Virtual IPs](#)
- [IP Pools](#)
- [IPsec VPN](#)
- [GRE over IPsec](#)

This section also contains the following topics:

- [IPv6 overview on page 519](#)
- [IPv6 quick start on page 520](#)
- [Neighbor discovery proxy on page 524](#)
- [IPv6 address assignment on page 525](#)
- [NAT66, NAT46, NAT64, and DNS64 on page 537](#)
- [DHCPv6 relay on page 548](#)
- [IPv6 tunneling on page 549](#)
- [IPv6 Simple Network Management Protocol on page 555](#)
- [Dynamic routing in IPv6 on page 558](#)
- [IPv6 configuration examples on page 560](#)

IPv6 overview

Internet Protocol version 6 (IPv6) is the latest version of the Internet Protocol (IP) and was developed to address the limitations of its predecessor, IPv4. The primary issue with IPv4 is its limited number of addresses, which are based on a 32-bit scheme and have a theoretical limit of 2 to the power of 32. In contrast, IPv6 uses a 128-bit address scheme, allowing for a much larger theoretical limit of 2 to the power of 128 addresses.

In simpler terms:

- IPv4 can support 4 294 967 296 addresses.
- IPv6 can support 340 282 366 920 938 463 463 374 607 431 768 211 456 addresses.

In addition to the expanded number of addresses, some of the other benefits of IPv6 include:

- More efficient routing due to reduction in the size of routing tables. This is achieved through hierarchical address allocation, which allows for more efficient routing of data packets.
- Reduced management requirements by supporting stateless auto-reconfiguration of hosts. This means that devices can automatically configure their network settings without the need for manual intervention.
- Improved methods to change Internet Service Providers. With IPv6, it is easier for users to switch between different ISPs without experiencing any service disruption.
- Better mobility support by providing seamless connection. This means that devices can move between different networks without losing their connection.
- Multi-homing. This allows a device to have multiple network connections, providing increased reliability and redundancy.
- Improved security with built-in support for IPsec. IPsec is a security protocol that provides authentication and encryption for data transmitted over a network.
- IPv6 offers scoped addresses with link-local, unique local, and global address spaces. This allows for more flexible addressing and improved network organization.

Address Type	Notation	Description	Example
Link-local Unicast	FE80::/10	Designed for use on a local link and are automatically configured on all interfaces. These addresses are not routable.	FE80::1
Unique Local Unicast	FC00::/7	Similar to IPv4 private addresses and can be used on your own network. They are not routable globally.	FC00::1 FD00::1
Global Unicast	2001::/3	Similar to IPv4 public addresses and can be used on the Internet. They are routable globally.	2001::1 3000::1

See [Internet Protocol Version 6 Address Space](#) for more information.

IPv6 quick start

This section provides an introduction to setting up a few basic IPv6 settings on the FortiGate. See [Summary of steps on page 23](#) for more information about basic FortiGate administration.

This chapter provides instructions for basic IPv6 configuration that should work in most cases, regardless of whether the device has an existing IPv4 configuration or is a new FortiGate device.

The topics covered in this section include:

- [Configuring an interface on page 521](#)
- [Configuring the default route on page 521](#)
- [Configuring the DNS on page 522](#)
- [Configuring the address object on page 522](#)
- [Configuring the address group on page 522](#)
- [Configuring the firewall policy on page 523](#)

Before starting, make sure to enable the IPv6 feature.

To enable IPv6 in the GUI:

1. Go to *System > Feature Visibility*.
2. Under *Core Features*, enable *IPv6*.
3. Click *Apply*. See [IPv6 quick start example on page 561](#) for a sample configuration.

Configuring an interface

To configure an interface in the GUI:

1. Go to *Network > Interfaces*.
2. Select an interface and click *Edit*.
3. In the *Address* section, enter the *IPv6 Address/Prefix*.
4. In the *Administrative Access* section, select the IPv6 access options as needed (such as *PING*, *HTTPS*, and *SSH*).
5. Click *OK*.

To configure an interface in the CLI:

```
config system interface
  edit <interface name>
    config ipv6
      set ip6-address <IPv6 prefix>
      set ip6-allowaccess{ping | https | ssh | snmp | http | telnet | fgfm | fabric}
    end
  next
end
```

Configuring the default route

Setting the default route enables basic routing to allow the FortiGate to return traffic to sources that are not directly connected. The gateway address should be your existing router or L3 switch that the FortiGate is connected to. Set the interface to be the interface the gateway is connected to.

To configure the default route in the GUI:

1. Go to *Network > Static Routes*.
2. Click *Create New > IPv6 Static Route*.
3. Leave the *Destination* prefix as *::/0*. This is known as a default route, since it would match any IPv6 address.
4. Enter the *Gateway Address*.
5. Select an *Interface*.
6. Click *OK*.

To configure the default route in the CLI:

```
config router static6
  edit 0
    set gateway <IPv6 address>
    set device <interface name>
```

```
    next
end
```

Configuring the DNS

To configure a DNS domain list in the GUI:

1. Go to *Network > DNS*.
2. Under *IPv6 DNS Settings*, configure the primary and secondary DNS servers as needed.
3. Click *Apply*.

To configure a DNS domain list in the CLI:

```
config system dns
    set ip6-primary <IPv6 address>
    set ip6-secondary <IPv6 address>
end
```

Configuring the address object

Addresses define sources and destinations of network traffic and can be used in many functions such as firewall policies, ZTNA, and so on. When creating an IPv6 address object, several different types of addresses can be specified similar to IPv4 addresses. See [Address Types on page 949](#) for more information.

To configure an IPv6 address in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Select *Create New > Address*.
3. In the *Category* field, select *IPv6 Address*.
4. Enter a *Name* for the address object.
5. In the *Type* field, select one of the types from the dropdown menu.
6. Configure the rest of the settings as required.
7. Click *OK*.

To configure an IPv6 address in the CLI:

```
config firewall address6
    edit <name>
        set type {ipprefix | iprange | fqdn | geography | dynamic | template | mac}
    next
end
```

Configuring the address group

Address groups are designed for ease of use in the administration of the device. See [Address group on page 964](#) for more information.

To create an address group:

1. Go to *Policy & Objects > Addresses*.
2. Go to *Create New > Address Group*.
3. In the *Category* field, select *IPv6 Group*.
4. Enter a *Group name* for the address object.
5. Select the + in the *Members* field. The *Select Entries* pane opens.
6. Select members of the group. It is possible to select more than one entry. Select the x icon in the field to remove an entry.
7. Enter any additional information in the *Comments* field.
8. Click *OK*.

To configure an address group in the CLI:

```
config firewall addrgrp6
  edit <name>
    set member <name>
  next
end
```

Configuring the firewall policy

A firewall policy must be in place for any traffic that passes through a FortiGate. See [Firewall policy parameters on page 849](#) for more information.

To create a firewall policy in the GUI:

1. Go to *Policy & Objects > Firewall Policy*.
2. Enter a *Name* and configure the following necessary settings:

Incoming Interface	Incoming (ingress) interface
Outgoing Interface	Outgoing (egress) interface
Source	Source IPv6 address name and address group names
Destination	Destination IPv6 address name and address group names
Schedule	Schedule name
Service	Service and service group names
Action	Policy action

To configure a firewall policy in the CLI:

```
config firewall policy
  edit <policyid>
    set srcintf <name>
    set dstintf <name>
    set action {accept | deny}
    set srcaddr6 <name>
```

```

    set dstaddr6 <name>
    set schedule <name>
    set service <name>
next
end

```

See [IPv6 quick start example on page 561](#) for a sample configuration.

Neighbor discovery proxy

This feature provides support for proxying the IPv6 Neighbor Discovery Protocol (NDP) to allow the following ICMP messages to be forwarded between upstream and downstream interfaces.

Message type	Function
Router Solicitation (RS)	Used by hosts to find any routers in a local segment and to request that they advertise their presence on the network.
Router Advertisement (RA)	Used by an IPv6 router to advertise its presence on the network.
Neighbor Solicitation (NS)	Sent by a host to determine a remote host's link layer IPv6 address. Verifies the reachability of the neighbor or remote host in the Neighbor Discovery (ND) table
Neighbor Advertisement (NA)	Message used by the host to respond to an NS message. If an NS message is received by a remote host, it reciprocates with an NA message to the originating host. Additionally, this message is used by a host to announce a link layer address change.
Network Redirect	Message used by IPv6 routers to notify an originating host of a more optimal next-hop address for a specific destination. Only routers can send redirect messages. Redirect messages are exclusively processed by hosts.

Typically only one interface receives RA traffic, and the interface is automatically considered the upstream interface.

The Neighbor Discovery Protocol (NDP) is a layer 2 protocol that performs several tasks to improve the efficiency and consistency of data transmission across multiple networks and processes. NDP uses ICMPv6 messages to perform the following tasks:

- **Stateless auto-configuration:** This enables the auto-configuration of IPv6 addresses without the need for a DHCP server. This means that each host on the network can automatically configure its unique IPv6 link-local address and global unicast address.
- **Address Resolution:** NDP performs a function similar to IPv4's Address Resolution Protocol (ARP), but instead of using ARP, it uses NDP to dynamically resolve IPv6 addresses to their corresponding MAC addresses.
- **Neighbor Unreachability Detection (NUD):** This function detects when a host is no longer reachable, allowing for more efficient routing and data transmission.
- **Duplicate Address Detection (DAD):** This function verifies that there is no duplication of unicast IPv6 addresses in the network, ensuring that each host has a unique address.

Configure ND proxy in the CLI using the following syntax:

```

config system nd-proxy
  set status {enable|disable}
  set member <interface> <interface> [<interface>...]
end

```

Option	Description
status	Enable/disable the use of neighbor discovery proxy.
member	List of interfaces using the neighbor discovery proxy.

In this example, the client is connected to a FortiGate device that is configured as an ND (Neighbor Discovery) proxy. Port1 is the upstream interface that receives Router Advertisement (RA) traffic, and port5 is the downstream interface that connects to the client. This setup allows the FortiGate device to facilitate communication between the client and the IPv6 router.

To configure ND Proxy on FortiGate:

1. Enable address auto-configuration on the upstream interface:

```

config system interface
  edit "port1"
    config ipv6
      set autoconf enable
    end
  next
end

```

2. Enable ND proxy on the interfaces:

```

config system nd-proxy
  set status enable
  set member "port1" "port5"
end

```

See [RFC 4389](#) for more information on Neighbor Discovery Proxies (ND Proxy).

IPv6 address assignment

On the FortiGate, an interface can use the following methods to obtain an IPv6 address:

Method	Overview
IPv6 stateless address auto-configuration (SLAAC) on page 526	<ul style="list-style-type: none"> Enables each network host to auto-configure a unique IPv6 address. The lack of a state eliminates the need for a centralized server, thereby simplifying network management. SLAAC does not provide DNS server addresses to hosts.
DHCPv6 stateful server on page 528	<ul style="list-style-type: none"> Provides IPv6 addresses and additional information to hosts, such as a DNS server list and a domain name. Offers more control to the administrator in assigning addresses, but requires extra configuration.
SLAAC with DHCPv6 stateless server on page 529	<ul style="list-style-type: none"> Combines the benefits of SLAAC and DHCPv6. Enables each host on the network to auto-configure a unique IPv6 address and allows them to obtain additional information, such as a DNS server list and a domain name.
IPv6 prefix delegation on page 532	<ul style="list-style-type: none"> Enables internet service providers (ISPs) to provide organizations with a block of addresses that can be distributed throughout their network.

Deciding which method to employ should be based on the requirements of your system and your overall IT practice.

You can configure IPv6 using the CLI. To configure IPv6 using the GUI, ensure IPv6 is enabled by going to *System > Feature Visibility* and enabling *IPv6*.

IPv6 stateless address auto-configuration (SLAAC)

FortiGate can easily obtain an IPv6 address on any given interface using SLAAC (stateless address auto-configuration). SLAAC is designed only for IP assignments and does not provide DNS server addresses to hosts. See [RFC 4862](#) for more information.

Use one of the following options to obtain a DNS server address:

- [DHCPv6 stateful server on page 528](#)
- [SLAAC with DHCPv6 stateless server on page 529](#)

In this example, the Enterprise Core FortiGate is connected to the First Floor FortiGate. The Enterprise Core FortiGate has SLAAC enabled, which allows the First Floor FortiGate to automatically obtain an IPv6 address using the auto-configuration IPv6 address option.

To enable IPv6 auto-configuration in the GUI:

- Configure SLAAC on the Enterprise Core FortiGate:
 - Go to *Network > Interfaces* and edit port5.
 - Configure the following settings:

IPv6 addressing mode	Manual
IPv6 Address/Prefix	2001:db8:d0c:1::1/64
Stateless Address Auto-configuration (SLAAC)	Enable
IPv6 prefix list	Enable
IPv6 prefix	2001:db8:d0c:1::/64

- c. Click OK.
2. Configure the First Floor FortiGate to automatically obtain an IPv6 address:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Enable *Auto configure IPv6 address*. The First Floor FortiGate uses the prefix that it obtains from the Enterprise Core FortiGate interface, and automatically generates an IPv6 address.
3. Verify that the First Floor FortiGate automatically generated an IPv6 address:
 - a. Go to *Network > Interfaces* and edit port5. The *IPv6 Address/Prefix* field is prepopulated with an IPv6 address.

To enable IPv6 auto-configuration in the CLI:

1. Configure SLAAC on the Enterprise Core FortiGate:

```
config system interface
  edit "port5"
    config ipv6
      set ip6-address 2001:db8:d0c:1::1/64
      set ip6-send-adv enable
      config ip6-prefix-list
        edit 2001:db8:d0c:1::/64
        next
      end
    end
  end
next
end
```

2. Configure the First Floor FortiGate to automatically obtain an IPv6 address:

```
config system interface
  edit "port5"
    config ipv6
      set autoconf enable
    end
  next
end
```

3. Verify that the First Floor FortiGate automatically generated an IPv6 address:

```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2001:db8:d0c:1:20c:29ff:fe4d:f83d
preferred=604419 valid=2591619 cstamp=976270 tstamp=979470
```

DHCPv6 stateful server

Similar to a DHCPv4 server, a DHCPv6 server is stateful. It can track client/server states, assign IP addresses to clients, and maintain full control over the process. In addition to assigning IP addresses, a DHCP server can also provide DNS server addresses. However, this IP address assignment method does not support failover protection. If the DHCPv6 server fails, hosts are unable to obtain an IPv6 address, and the network ceases to function. Furthermore, DHCPv6 does not provide gateway information. See [RFC 3315](#) for more information.

In this example, the Enterprise Core FortiGate is connected to the First Floor FortiGate. The Enterprise Core FortiGate has a stateful DHCPv6 server configured that allows the First Floor FortiGate to automatically obtain an IPv6 address and DNS server address using the DHCP option.

To configure a DHCPv6 stateful server in the GUI:

1. Configure the Enterprise Core FortiGate with DHCPv6 stateful server:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Configure the following settings:

DHCPv6 Server	Enable
IPv6 subnet	2001:db8:d0c:1::/64
DNS service	Same as System DNS
Stateful server.	Enable
IP mode	IP range
Address range	2001:db8:d0c:1::a to 2001:db8:d0c:1::f

- c. Click OK.
2. Configure the First Floor FortiGate to obtain an IPv6 address using DHCP:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Set *IPv6 addressing mode* to *DHCP*.
 - c. Click OK.
3. Verify that the First Floor FortiGate obtained an IPv6 address and DNS server address from the DHCPv6 server:
 - a. Go to *Network > Interfaces* and edit port5. The *Obtained IP/Netmask* and *Acquired DNS* fields are populated with an IPv6 address.

To configure a DHCPv6 stateful server in the CLI:

1. Configure the Enterprise Core FortiGate with DHCPv6 stateful server:

```
config system dhcp6 server
  edit 1
    set dns-service default
    set subnet 2001:db8:d0c:1::/64
    set interface "port5"
    config ip-range
```

```

        edit 1
            set start-ip 2001:db8:d0c:1::a
            set end-ip 2001:db8:d0c:1::f
        next
    end
next
end

```

2. Configure the First Floor FortiGate to obtain an IPv6 address using DHCP:

```

config system interface
    edit "port5"
        config ipv6
            set ip6-mode dhcp
        end
    next
end

```

3. Verify that the First Floor FortiGate obtained an IPv6 address and DNS server address from the DHCPv6 server:

```

# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag=P scope=0 prefix=128 addr=2001:db8:d0c:1::a
preferred=4294967295 valid=4294967295 cstamp=1298969 tstamp=1298969ip6-address
# dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::ff:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0
probe=0 failure=1 last_failed=19812

```

SLAAC with DHCPv6 stateless server

Using Stateless Address Auto Configuration (SLAAC) with a stateless DHCPv6 server provides a solution for obtaining other host configurations, such as DNS server addresses, while retaining the auto-configuration aspect of SLAAC. This approach also provides failover protection in the event that the DHCPv6 server fails. In addition to obtaining host configurations through the stateless DHCPv6 server, interfaces can also obtain gateway information through Router Advertisements (RAs). This allows for a robust and flexible IPv6 network configuration.

In this example, the Enterprise Core FortiGate is connected to the First Floor FortiGate. The Enterprise Core FortiGate has both SLAAC and stateless DHCPv6 server enabled. This allows the First Floor FortiGate to automatically obtain an IPv6 address using the *Auto configure IPv6 address* option and to acquire a DNS server address using the `dhcp6-information-request` option.

To enable IPv6 auto-configuration with DHCPv6 stateless server in the GUI:

1. Configure SLAAC on the Enterprise Core FortiGate:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Configure the following settings:

IPv6 addressing mode	Manual
IPv6 Address/Prefix	2001:db8:d0c:1::1/64
Stateless Address Auto-configuration (SLAAC)	Enable
IPv6 prefix list	Enable
IPv6 prefix	2001:db8:d0c:1::/64

- c. Click *OK*.
- d. Input the following commands from the CLI:

```
config system interface
  edit "port5"
    config ipv6
      set ip6-other-flag enable
    end
  next
end
```

2. Configure DHCPv6 stateless server on the Enterprise Core FortiGate:

- a. Go to *Network > Interfaces* and edit port5.
- b. Configure the following settings:

DHCPv6 Server	Enable
DNS service	Same as System DNS
Stateful server	Disable

- c. Click *OK*.
3. Configure the First Floor FortiGate to automatically obtain an IPv6 address and DNS server address from the DHCPv6 server:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Enable *Auto configure IPv6 address*. The First Floor FortiGate uses the prefix obtained from the Enterprise Core FortiGate interface to automatically generate an IPv6 address.
 - c. Input the following commands from the CLI:

```
config system interface
  edit "port5"
    config ipv6
      set dhcp6-information-request enable
    end
  next
end
```

- d. Click *OK*.
4. Verify that the First Floor FortiGate automatically generated an IPv6 address and obtained the DNS server address from the DHCPv6 server:
 - a. Go to *Network > Interfaces* and edit port5. The IPv6 Address/Prefix field is populated with an IPv6 address
 - b. Use the below CLI command to verify the DNS server address:

```
#dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8:d0c:1::1:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0
probe=0 failure=1 last_failed=46738
...
```

To enable IPv6 auto-configuration with DHCPv6 stateless server in the CLI:

1. Configure SLAAC on the Enterprise Core FortiGate:

```
config system interface
  edit "port5"
    config ipv6
      set ip6-address 2001:db8:d0c:1::1/64
      set ip6-send-adv enable
      set ip6-other-flag enable
      config ip6-prefix-list
        edit 2001:db8:d0c:1::/64
      next
    end
  next
end
```

2. Configure DHCPv6 stateless server on the Enterprise Core FortiGate:

```
config system dhcp6 server
  edit 1
    set dns-service default
    set interface "port5"
  next
end
```

3. Configure the First Floor FortiGate to obtain an IPv6 address automatically:

```
config system interface
  edit "port5"
    config ipv6
      set autoconf enable
      set dhcp6-information-request enable
    end
  next
end
```

4. Verify that the First Floor FortiGate automatically generated an IPv6 address and obtained the DNS server address from the DHCPv6 server:

```
# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2001:db8:d0c:1:20c:29ff:fe4d:f83d
preferred=604681 valid=2591881 cstamp=1675487 tstamp=1772919
# dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
```

```
DNS servers:
2001:db8:d0c:1::1:53 vrf=0 tz=0 encrypt=none req=1 to=1 res=0 rt=0 ready=1 timer=0
probe=0 failure=1 last_failed=46738
...
```

IPv6 prefix delegation

IPv6 prefix delegation allows the dynamic assignment of an address prefix and DNS server address to an upstream interface. An upstream interface is typically the interface that is connected to an Internet Service Provider (ISP). This process also automates the assignment of prefixes to downstream interfaces. A downstream interface is any interface that is not an upstream interface and uses delegated addressing mode. Downstream interfaces can be configured to request specific IPv6 subnets from the upstream interface. Once a downstream interface receives the IPv6 address, other devices connected to the downstream interface can obtain an IPv6 address by using DHCPv6 or by configuring their own IP address using auto-configuration.

In this example, the Enterprise Core FortiGate is connected to a DHCPv6 server provided by the ISP through an upstream interface (port1). The Enterprise Core FortiGate is configured with a delegate interface (port5) to receive the IPv6 prefix and DNS server address from the upstream interface.

A downstream interface (port5) connects the First Floor FortiGate to the Enterprise Core FortiGate. The First Floor FortiGate interface (port5) is configured to receive the IPv6 address and DNS server address from the Enterprise Core FortiGate using DHCP addressing mode or auto-configuration.

Using the GUI or CLI to configure a downstream FortiGate to obtain the IPv6 and DNS server address from delegated interface using DHCP mode requires the following steps:

1. Configure the following items on the Enterprise Core FortiGate:
 - Upstream interface
 - Downstream interface
 - DHCPv6 server on the downstream interface.
2. Configure First Floor FortiGate to receive IPv6 prefix and DNS from the delegated interface.

Instead of configuring a DHCPv6 server on the downstream interface of the Enterprise Core FortiGate, you can configure SLAAC. See [IPv6 prefix delegation with SLAAC on page 536](#).

GUI configuration

To configure the Enterprise Core FortiGate:

1. Configure the upstream interface on Enterprise Core FortiGate:
 - a. Go to *Network > Interfaces* and edit port1.
 - b. Enable *DHCPv6 prefix delegation*.
 - c. Select the + in the IAPD prefix hint to open the ID and prefix field.
 - d. Enter 1 for *ID* and *::/48* for *prefix* field. You can add two or more entries. Select the x icon in the field to remove an entry.

The screenshot shows the 'Edit Interface' configuration page. At the top, there is a header 'Edit Interface'. Below it, the 'DHCPv6 prefix delegation' option is enabled with a green toggle. Underneath, the 'IAPD 1 prefix hint' is set to '1'. To the right, there is a field for the prefix, which contains '::/48'. Below the prefix field is a plus sign icon, and to the right of the plus sign is a close button (an 'x' in a square).

- e. Click OK.
2. Verify that the upstream interface obtained the prefix delegation, see [Verify upstream interface obtained prefix delegation and DNS server address](#).
3. Configure the downstream interface on Enterprise Core FortiGate:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Set *IPv6 addressing mode* to *Delegated*.
 - c. Enter 1 for *Identity association identifier* field.
 - d. Set *IPv6 upstream* interface to *port1*.
 - e. Click OK.
4. Verify that the downstream interface obtained an IPv6 address/prefix:
 - a. Go to *Network > Interfaces* and edit port5. The *IPv6 Address/Prefix* field is prepopulated.
5. Configure the DHCPv6 server on the downstream interface:
 - a. Go to *Network > Interfaces* and edit port5
 - b. Enable *DHCPv6 Server*.
 - c. Set *DNS service* to *Delegated*.
 - d. From the *Upstream interface* dropdown list, select *port1*.
 - e. Input the following commands from the CLI:

```
config system dhcp6 server
  edit 1
    set delegated-prefix-iaid 1
  next
end
```
 - f. Enable *Stateful server*.
 - g. Set *IP mode* to *Delegated*.
 - h. Click OK.

To configure the First Floor FortiGate:

1. Configure the First Floor FortiGate interface using DHCP mode:
 - a. Go to *Network > Interfaces* and edit the port5.
 - b. Set *IPv6 addressing mode* to *DHCP*. This allows the First Floor FortiGate to obtain the IPv6 prefix and DNS from the delegated interface.
 - c. Click OK.
2. Verify that the First Floor FortiGate obtained an IPv6 address and the DNS server address from the delegated interface:
 - a. Go to *Network > Interfaces* and edit port5. The *Obtained IP/Netmask* and *Acquired DNS* fields are prepopulated with an IPv6 address.

CLI configuration

Using the CLI to configure a downstream FortiGate to obtain the IPv6 and DNS server address from delegated interface using DHCP mode requires the following steps:

To configure the Enterprise Core FortiGate:

1. Configure the upstream interface on the Enterprise Core FortiGate:

```
config system interface
  edit "port1"
    config ipv6
      set dhcp6-prefix-delegation enable
      config dhcp6-iapd-list
        edit 1
          set prefix-hint ::/48
        next
      end
    end
  next
end
```

2. Verify that the upstream interface obtained a prefix delegation and DNS server address:

```
config system interface
  edit port1
    config ipv6
Enterprise Core FortiGate # get
ip6-mode          : static
...
dhcp6-prefix-delegation: enable
delegated-prefix iaid 1      : 2001:db8:d0c::/48
preferred-life-time      : 4294967295
valid-life-time         : 4294967295
delegated-DNS1      : 2001:db8::35
delegated-DNS2         : ::
...
dhcp6-iapd-list:
  == [ 1 ]
  iaid:      1      prefix-hint: ::/48      prefix-hint-plt: 604800
  prefix-hint-vlt: 2592001
```

3. Configure the downstream interface on the Enterprise Core FortiGate:

```
config system interface
  edit "port5"
    config ipv6
      set ip6-mode delegated
      set ip6-delegated-prefix-iaid 1
      set ip6-upstream-interface "port1"
    end
  next
```

```
end
```

4. Verify that the downstream interface obtained an IPv6 address/prefix:

```
config system interface
  edit "port5"
    config ipv6
Enterprise Core FortiGate # get
ip6-mode          : delegated
nd-mode           : basic
ip6-address      : 2001:db8:d0c::/48
...
ip6-delegated-prefix-iaid: 1
ip6-upstream-interface: port1
ip6-subnet        : ::/0
```

5. Configure the DHCPv6 server on the downstream interface:

```
config system dhcp6 server
  edit 1
    set dns-service delegated
    set interface "port5"
    set upstream-interface "port1"
    set delegated-prefix-iaid 1
    set ip-mode delegated
  next
end
```

To configure the First Floor FortiGate:

1. Configure the First Floor FortiGate interface to use DHCP mode:

```
config system interface
  edit "port5"
    config ipv6
      set ip6-mode dhcp
    end
  next
end
```

2. Verify that the First Floor FortiGate obtained an IPv6 address and DNS server address from the delegated interface:

```
# diagnose ipv6 address list | grep port5
dev=7 devname=port5 flag=P scope=0 prefix=128 addr=2001:db8:d0c::1
preferred=4294967295 valid=4294967295 cstamp=43208325 tstamp=43208325
# dia test application dnsproxy 3
worker idx: 0
VDOM: root, index=0, is primary, vdom dns is enabled, pip-0.0.0.0 dns_log=1
dns64 is disabled
DNS servers:
2001:db8::35:53 vrf=0 tz=0 encrypt=none req=3 to=2 res=0 rt=1046 ready=1 timer=0
probe=0 failure=2 last_failed=65131
```

IPv6 prefix delegation with SLAAC

A downstream FortiGate can be configured to obtain the IPv6 address and DNS server address from a delegated interface using SLAAC instead of DHCPv6. Following is a summary of the configuration steps:

1. Configure the following items on the Enterprise Core FortiGate:
 - Upstream interface
 - Downstream interface
 - SLAAC on the downstream interface
2. Configure the First Floor FortiGate to receive an IPv6 prefix and DNS server address from the delegated interface.

To configure the Enterprise Core FortiGate:

1. Configure the upstream interface on Enterprise Core FortiGate:
 - a. Go to *Network > Interfaces* and edit port1.
 - b. Enable *DHCPv6 prefix delegation*.
 - c. Select the + in the IAPD prefix hint to open the ID and prefix field.
 - d. Enter 1 for *ID* and *::/48* for *prefix* field. You can add two or more entries. Select the x icon in the field to remove an entry.

- e. Click OK.
2. Verify that the upstream interface obtained the prefix delegation, see [Verify upstream interface obtained prefix delegation and DNS server address](#).
 3. Configure the downstream interface on Enterprise Core FortiGate:
 - a. Go to *Network > Interfaces* and edit port5.
 - b. Set *IPv6 addressing mode* to *Delegated*.
 - c. Enter 1 for *Identity association identifier* field.
 - d. Set *IPv6 upstream* interface to *port1*.
 - e. Click OK.
 4. Verify that the downstream interface obtained an IPv6 address/prefix:
 - a. Go to *Network > Interfaces* and edit port5. The *IPv6 Address/Prefix* field is prepopulated.
 5. Configure SLAAC on the downstream interface:

```
config system interface
  edit "port5"
    config ipv6
      set ip6-mode delegated
      set ip6-send-adv enable
      set ip6-delegated-prefix-iaid 1
      set ip6-upstream-interface "port1"
      config ip6-delegated-prefix-list
        edit 1
          set upstream-interface "port1"
```

```

        set delegated-prefix-iaid 1
        set subnet 0:0:0:1::/64
        set rdns-service delegated
    next
end
end
next
end

```

To configure the First Floor FortiGate:

1. Configure the First Floor FortiGate interface using auto-configure:

```

config system interface
  edit "port5"
    config ipv6
      set autoconf enable
    end
  next
end

```

2. Verify that the First Floor FortiGate automatically generated an IPv6 address and obtained the DNS server address from the delegated interface:

```

# diagnose ipv6 address list | grep port5
dev=4 devname=port5 flag= scope=0 prefix=64 addr=2000:db8:d0c:1:20c:29ff:fe4d:f847
preferred=4294967295 valid=4294967295 cstamp=17203697 tstamp=17225377

```

FortiGate can send DNS server addresses using Router Advertisement (RA), which allows any device that is capable of receiving DNS server addresses by using RA to obtain DNS server addresses.

Additionally, FortiGate can receive DNS server addresses through the use of SLAAC with a DHCPv6 stateless server, even though it is currently unable to receive DNS server addresses using RA due to [RFC 4862](#) implementation. See [SLAAC with DHCPv6 stateless server on page 529](#) for more information.

NAT66, NAT46, NAT64, and DNS64

NAT66, NAT46, NAT64, and DNS64 each offer their own distinct strategies and solutions to tackle the obstacles encountered during the transition from IPv4 to IPv6. This section provides a concise overview of these methods.

Method	Overview
NAT66	<ul style="list-style-type: none"> • NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. • Not a common method, since most IPv6 networks do not require NAT66.
NAT46	<ul style="list-style-type: none"> • NAT46 is used to translate IPv4 addresses to IPv6 addresses. • Enable a client on an IPv4 network to communicate transparently with a server on an IPv6 network.

Method	Overview
NAT64 and DNS64	<ul style="list-style-type: none"> NAT64 is used to translate IPv6 addresses to IPv4 addresses. Enable a client on an IPv6 network to communicate transparently with a server on an IPv4 network. Typically used when networks are being transitioned from IPv4 to IPv6. NAT64 is typically employed in tandem with DNS64. DNS64 is responsible for synthesizing AAAA records from A records.

Note that these are broad use cases and the specific use of each type of NAT can vary depending on the network configuration and requirement.

Multiple NAT46 and NAT64 related objects are consolidated into regular objects. A per-VDOM virtual interface, `naf.<vdom>`, is automatically added to process NAT46 and NAT64 traffic. The features include:

- `vip46` and `vip64` settings are consolidated in `vip` and `vip6` configurations.
- `policy46` and `policy64` settings are consolidated in `firewall policy` settings.
- `nat46` and `nat64` are included in `firewall policy` settings.
- `ippool` and `ippool6` support NAT46 and NAT64 (when enabled, the IP pool should match a subnet).
- Central SNAT supports NAT46 and NAT64.
- `add-nat46-route` in `ippool6` and `add-nat64-route` in `ippool` are enabled by default. The FortiGate generates a static route that matches the IP range in `ippool6` or `ippool` for the `naf` tunnel interface.

Automatic processing of the `naf` tunnel interface is not supported in security policies.

To configure NAT46 or NAT64 translation, use the standard `vip` or `vip6` setting, apply it in a firewall policy, enable NAT46 or NAT64, and enter the IP pool to complete the configuration.

The external IP address cannot be the same as the external interface IP address.

NAT66 policy

NAT66 is used for translating an IPv6 source or destination address to a different IPv6 source or destination address. NAT66 is not as common or as important as IPv4 NAT, as many IPv6 addresses do not need NAT66 as much as IPv4 NAT. However, NAT66 can be useful for a number of reasons. For example, you may have changed the IP addresses of some devices on your network but want traffic to still appear to be coming from their old addresses. You can use NAT66 to translate the source addresses of packets from the devices to their old source addresses.

In FortiOS, NAT66 options can be added to an IPv6 security policy. Configuring NAT66 is very similar to configuring NAT in an IPv4 security policy.

To configure NAT66:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New*.
3. Configure the required policy parameters.
4. Enable *NAT* and select *Use Outgoing Interface Address*. For packets that match this policy, its source IP address is translated to the IP address of the outgoing interface.
5. Click *OK*.

Nat66 can also translate one IPv6 source address to another address that is not the same as the address of the existing interface. You can do this using IP pools.

To configure the IPv6 pool:

1. Go to *Policy & Objects > IP Pools*.
2. Click *Create New*.
3. Enter the following:

IP Pool Type	IPv6 Pool
Name	test-ippool6-1
External IP address/range	2000:172:16:101::1-2000:172:16:101::1

4. Click *OK*.

To use the IPv6 pool in the firewall policy:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New* or edit an existing policy.
3. Configure the required policy parameters.
4. Enable *NAT* and select *Use Dynamic IP Pool*.
5. Click *OK*.

NAT66 destination address translation

NAT66 can also be used to translate destination addresses. This is done in an IPv6 policy by using IPv6 virtual IPs. For example, the destination address 2001:db8::dd can be mapped to 2001:db8::ee.

To configure the IPv6 VIP:

1. Go to *Policy & Objects > Virtual IPs*.
2. Click *Create New > Virtual IP*.

3. Enter the following:

VIP type	IPv6
Name	example-vip6
External IP address/range	2001:db8::dd
Map to IPv6 address/range	2001:db8::ee

4. Click *OK*.

To use the IPv6 VIP in the firewall policy:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New* or edit an existing policy.
3. Configure the required policy parameters.
4. In the *Destination* field, select *example-vip6* from the dropdown menu.
5. Click *OK*.

NAT46 policy

NAT46 refers to the mechanism that allows IPv4 addressed hosts to communicate with IPv6 hosts. Without such a mechanism, IPv4 environments cannot connect to IPv6 networks.

Sample topology

In this example, an IPv4 client tries to connect to an IPv6 server. A VIP is configured on FortiGate to map the server IPv6 IP address `2000:172:16:200:55` to an IPv4 address `10.1.100.55`. On the other side, an IPv6 IP pool is configured and the source address of packets from client are changed to the defined IPv6 address. In this setup, the client PC can access the server by using IP address `10.1.100.55`.

Sample configuration

To configure NAT46 in the GUI:

1. Enable IPv6:
 - a. Go to *System > Feature Visibility*.
 - b. In the *Core Features* section, enable *IPv6*.
 - c. Click *Apply*.
2. Configure the VIP:

- a. Go to *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP*.
- b. Enter the following:

VIP type	IPv4
Name	vip46_server
Interface	port2
Type	Static NAT
External IP address/range	10.1.100.55
Map to IPv6 address/range	2000:172:16:200::55

- c. Click *OK*.

3. Configure the IPv6 IP pool:

- a. Go to *Policy & Objects > IP Pools* and click *Create New*.
- b. Enter the following:

IP Pool Type	IPv6 Pool
Name	client_external
External IP address/range	2000:172:16:201::-2000:172:16:201::7
NAT46	Enable

- c. Click *OK*.

4. Configure the firewall policy:

- a. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
- b. Enter the following:

Name	policy46-1
Incoming Interface	port10
Outgoing Interface	port9
Source	all
Destination	vip46_server
Schedule	always
Service	ALL
Action	ACCEPT
NAT	NAT46
IP Pool Configuration	client_external

- c. Configure the other settings as needed.
- d. Click *OK*.

To configure NAT46 in the CLI:**1. Enable IPv6:**

```
config system global
    set gui-ipv6 enable
end
```

2. Configure the VIP:

```
config firewall vip
    edit "vip46_server"
        set extip 10.1.100.55
        set nat44 disable
        set nat46 enable
        set extintf "port2"
        set ipv6-mappedip 2000:172:16:200::55
    next
end
```

3. Configure the IPv6 IP pool:

```
config firewall ippool6
    edit "client_external"
        set startip 2000:172:16:201::
        set endip 2000:172:16:201::7
        set nat46 enable
    next
end
```

4. Configure the firewall policy:

```
config firewall policy
    edit 2
        set name "policy46-1"
        set srcintf "port10"
        set dstintf "port9"
        set action accept
        set nat46 enable
        set srcaddr "all"
        set dstaddr "vip46_server"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set ippool enable
        set poolname6 "client_external"
    next
end
```

Sample troubleshooting

To trace the flow and troubleshoot:

```
# diagnose debug flow filter saddr 10.1.100.11
# diagnose debug flow show function-name enable
show function name
# diagnose debug flow show iprope enable
show trace messages about iprope
# diagnose debug flow trace start 5

NAT64 policy and DNS64 (DNS proxy)

NAT64 policy translates IPv6 addresses to IPv4 addresses so that a client on an IPv6 network can communicate transparently with a server on an IPv4 network.

NAT64 policy is usually implemented in combination with the DNS proxy called DNS64. DNS64 synthesizes AAAA records from A records and is used to synthesize IPv6 addresses for hosts that only have IPv4 addresses. DNS proxy and DNS64 are interchangeable terms.

Sample topology

In this example, a host on the internal IPv6 network communicates with `ControlPC.qa.fortinet.com` that only has IPv4 address on the Internet. Central NAT is disabled.

1. The host on the internal network does a DNS lookup for `ControlPC.qa.fortinet.com` by sending a DNS query for an AAAA record for `ControlPC.qa.fortinet.com`.
2. The DNS query is intercepted by the FortiGate DNS proxy. The DNS proxy performs an A-record query for `ControlPC.qa.fortinet.com` and gets back an RRSet containing a single A record with the IPv4 address `172.16.200.55`.
3. The DNS proxy then synthesizes an AAAA record. The IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits and the received IPv4 address in the lower 32 bits. By default, the resulting IPv6 address is `64:ff9b::172.16.200.55`.
4. The host on the internal network receives the synthetic AAAA record and sends a packet to the destination address `64:ff9b::172.16.200.55`.
5. The packet is routed to the FortiGate internal interface (port10) where it is accepted by the NAT64 security policy.
6. The FortiGate translates the destination address of the packets from IPv6 address `64:ff9b::172.16.200.55` to IPv4 address `172.16.200.55` and translates the source address of the packets to `172.16.200.200` (or another address in the IP pool range) and forwards the packets out the port9 interface to the Internet.

Sample configuration

To configure a NAT64 policy with DNS64 in the GUI:

1. Enable IPv6 and DNS database:
 - a. Go to *System > Feature Visibility*.
 - b. In the *Core Features* section, enable *IPv6*.
 - c. In the *Additional Features* section, enable *DNS Database*.
 - d. Click *Apply*.
2. Enable DNS proxy on the IPv6 interface:
 - a. Go to *Network > DNS Servers*.
 - b. In the *DNS Service on Interface* table, click *Create New*.
 - c. For *Interface*, select *port10*.
 - d. For *Mode*, select *Forward to System DNS*.
 - e. Click *OK*.
3. Configure the IPv6 DHCP server:

- a. Go to *Network > Interfaces* and edit port10.
- b. Enable *DHCPv6 Server* and enter the following:

IPv6 subnet	2001:db8:1::/64
DNS service	Specify
DNS server 1	2001:db8:1::10

- c. Click *OK*.

4. Configure the IPv6 VIP for the destination IPv6 addresses:

These are all of the IPv6 addresses that the FortiGate DNS proxy synthesizes when an IPv6 device performs a DNS query that resolves to an IPv4 Address. In this example, the synthesized IPv6 address in the AAAA record begins with the configured NAT64 prefix in the upper 96 bits, so the VIP is for all the IPv6 addresses that begin with 64:ff9b.

- a. Go to *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP*.
- b. Enter the following:

VIP type	IPv6
Name	vip6
Eternal IP address/range	64:ff9b::-64:ff9b::ffff:ffff
Map to IPv4 address/range	Use Embedded

- c. Click *OK*.

5. Configure the IPv6 firewall address for the internal network:

- a. Click *Create New > Address*.
- b. Enter the following:

Category	IPv6 Address
Name	internal-net6
Type	IPv6 Subnet
IP/Netmask	2001:db8:1::/48

- c. Click *OK*.

6. Configure the IP pool containing the IPv4 address that is used as the source address of the packets exiting port9:

- a. Go to *Policy & Objects > IP Pools* and click *Create New*.
- b. Enter the following:

IP Pool Type	IPv4 Pool
Name	exit-pool4
Type	Overload
External IP address/range	172.16.200.200-172.16.200.207
NAT64	Enable

External IP address/range must start and end on the boundaries of a valid subnet. For example, 172.16.200.0-172.16.200.7 and 172.16.200.16-172.16.200.31 are a valid subnets (/29 and /28 respectively).

- c. Click OK.
7. Configure the NAT64 policy:
 - a. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
 - b. Enter the following:

Name	policy64-1
Incoming Interface	port10
Outgoing Interface	port9
Source	internal-net6
Destination	vip6
Schedule	always
Service	ALL
Action	ACCEPT
NAT	NAT64
IP Pool Configuration	exit-pool4

- c. Click OK.

To configure a NAT64 policy with DNS64 in the CLI:

1. Enable IPv6 and DNS database:

```
config system global
  set gui-ipv6 enable
end

config system settings
  set gui-dns-database enable
end
```

2. Enable DNS proxy on the IPv6 interface:

```
config system dns-server
  edit "port10"
    set mode forward-only
  next
end
```

3. Configure the IPv6 DHCP server:

```
config system dhcp6 server
  edit 1
    set subnet 2001:db8:1::/64
    set interface "port10"
    set dns-server1 2001:db8:1::10
```

```
    next
end
```

4. Configure the IPv6 VIP for the destination IPv6 addresses:

```
config firewall vip6
    edit "vip6"
        set extip 64:ff9b::-64:ff9b::ffff:ffff
        set embedded-ipv4-address enable
    next
end
```

5. Configure the IPv6 firewall address for the internal network:

```
config firewall address6
    edit "internal-net6"
        set ip6 2001:db8:1::/48
    next
end
```

6. Configure the IP pool containing the IPv4 address that is used as the source address of the packets exiting port9:

```
config firewall ippool
    edit "exit-pool4"
        set startip 172.16.200.200
        set endip 172.16.200.207
        set nat64 enable
    next
end
```

External IP address/range must start and end on the boundaries of a valid subnet. For example, 172.16.200.0-172.16.200.7 and 172.16.200.16-172.16.200.31 are a valid subnets (/29 and /28 respectively).

7. Configure the NAT64 policy:

```
config firewall policy
    edit 1
        set name "policy64-1"
        set srcintf "port10"
        set dstintf "port9"
        set action accept
        set nat64 enable
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 internal-net6
        set dstaddr6 vip6
        set schedule "always"
        set service "ALL"
        set ippool enable
        set poolname "exit-pool4"
    next
end
```

To enable DNS64 and related settings using the CLI:

Enabling DNS64 means that all IPv6 traffic received by the current VDOM can be subject to NAT64 if the source and destination address matches an NAT64 security policy.

By default, the setting `always-synthesize-aaaa-record` is enabled. If you disable this setting, the DNS proxy (DNS64) will attempt to find an AAAA records for queries to domain names and therefore resolve the host names to IPv6 addresses. If the DNS proxy cannot find an AAAA record, it synthesizes one by adding the NAT64 prefix to the A record.

```
config system dns64
    set status {enable | disable}
    set dns64-prefix <ipv6-prefix>
    set always-synthesize-aaaa-record {enable | disable}
end
```

By default, the `dns64-prefix` is `64:ff9b::/96`.

DHCPv6 relay

Similar to DHCPv4, DHCPv6 facilitates communication between networks by relaying queries and responses between a client and a DHCP server on separate networks. The FortiGate device serves as a DHCPv6 relay agent and forwards DHCPv6 messages between clients and servers. The relay agent receives DHCPv6 messages from clients and forwards them to the appropriate DHCPv6 server. In response, the server sends a message containing configuration information for the client, which the relay agent forwards to the client. This enables seamless information exchange between the two networks.

Configure DHCPv6 relay in the CLI using the following syntax:

```
config system interface
    edit <interface>
        config ipv6
            set dhcp6-relay-service {enable|disable}
            set dhcp6-relay-type regular
            set dhcp6-relay-ip <ip6-address>
        end
    end
next
end
```

In this example, a client connects to a FortiGate device that is configured to function as a DHCPv6 relay. Port1 on the FortiGate device connects to a DHCPv6 server, and port5 is configured as a DHCPv6 relay. The DHCPv6 server has an IP address of `2000:db8:d0c::a`. This configuration enables the FortiGate device to facilitate communication between the client and the DHCPv6 server on separate networks.

To configure DHCPv6 relay on the FortiGate:

```
config system interface
    edit port5
        config ipv6
            set dhcp6-relay-service enable
```

```

        set dhcp6-relay-type regular
        set dhcp6-relay-ip 2000:db8:d0c::a
    end
next
end

```

IPv6 tunneling

IPv6 tunneling involves tunneling IPv6 packets from an IPv6 network through an IPv4 network to another IPv6 network. This is different than NAT because once the packet reaches its final destination, the true originating address of the sender is still readable. The IPv6 packets are encapsulated within packets with IPv4 headers that carry their IPv6 payload through the IPv4 network. IPv6 tunneling is suitable in networks that have completely transitioned over to IPv6 but need an internet connection, which is still mostly IPv4 addresses.

Both IPv6 tunneling devices, whether they are a host or a network device, must be dual stack compatible. The tunneling process is as follows:

1. The tunnel entry node creates an encapsulating IPv4 header and transmits the encapsulated packet.
2. The tunnel exit node receives the encapsulated packet.
3. The IPv4 header is removed.
4. The IPv6 header is updated and the IPv6 packet is processed.

There are two types of tunnels in IPv6 tunneling, automatic and configured. Automatic tunnels are configured by using IPv4 address information embedded in an IPv6 address. The IPv6 address of the destination host includes information about which IPv4 address the packet should be tunneled to. Configured tunnels are manually configured, and they are used for IPv6 addresses that do not have any embedded IPv4 information. The IPv6 and IPv4 addresses of the tunnel endpoints must be specified.

Tunnel configurations

There are four tunneling configurations available depending on which segment of the path between the endpoints of the session the encapsulation takes place.

Type	Description
Network device-to-network device	Dual stack capable devices connected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. The tunnel spans one segment of the path taken by the IPv6 packets.
Host-to-network device	Dual stack capable hosts can tunnel IPv6 packets to an intermediary IPv6 or IPv4 network device that is reachable through an IPv4 infrastructure. The tunnel spans the first segment of the path taken by the IPv6 packets.
Host-to-host	Dual stack capable hosts that are interconnected by an IPv4 infrastructure can tunnel IPv6 packets between themselves. The tunnel spans the entire path taken by the IPv6 packets.
Network device-to-host	Dual stack capable network devices can tunnel IPv6 packets to their final destination IPv6 or IPv4 host. The tunnel spans only the last segment of the path taken by the IPv6 packets.

Regardless of whether the tunnel starts at a host or a network device, the node that does the encapsulation needs to maintain soft state information, such as the maximum transmission unit (MTU), about each tunnel in order to process the IPv6 packets.

6in4 tunnel

The following tunnel configuration tunnels IPv6 traffic over an IPv4 network. An internal IPv6 interface can be configured under `config system` interface.

To configure an IPv6 tunnel over IPv4:

```
config system sit-tunnel
  edit <name>
    set source <src_IPv4_address>
    set destination <dst_IPv4_address>
    set interface <src_interface>
    set ip6 <tunnel_IPv6_address>
  next
end
```

4in6 tunnel

Conversely, the following tunnel configuration tunnels IPv4 traffic over an IPv6 network.

To configure an IPv4 tunnel over IPv6:

```
config system ipv6-tunnel
  edit <name>
    set source <src_IPv6_address>
    set destination <dst_IPv6_address>
    set interface <src_interface>
  next
end
```

The preceding configurations are not available in transparent mode.

- [IPv6 GRE tunnels on page 552](#)
- [IPv6 tunnel inherits MTU based on physical interface on page 552](#)

IPv6 IPsec VPN

This topic describes how to configure the IPv6 IPsec VPN feature on your FortiGate device.

You can configure IPv6 using the CLI. To configure IPv6 using GUI, ensure IPv6 is enabled by going to *System > Feature Visibility* and enabling IPv6.

Overview

FortiOS supports route-based IPv6 IPsec, but not policy-based. This section describes different ways IPv6 IPsec can be used:

IPv4 over IPv6	The VPN gateways have IPv6 addresses. The protected networks have IPv4 addresses. The phase 2 configurations at either end use IPv4 selectors. See Site-to-site IPv4 over IPv6 VPN example on page 576 for sample configuration.
IPv6 over IPv4	The VPN gateways have IPv4 addresses. The protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors. See Site-to-site IPv6 over IPv4 VPN example on page 584 for sample configuration.
IPv6 over IPv6	Both the VPN gateways and the protected networks use IPv6 addresses. The phase 2 configurations at either end use IPv6 selectors. See Site-to-site IPv6 over IPv6 VPN example on page 567 for sample configuration.

Configuring IPv6 IPsec VPNs

Configuration of an IPv6 IPsec VPN follows the same sequence as for an IPv4 route-based VPN:

Phase 1 and Phase 2 settings	The configuration is the same as for an IPv4 route-based VPN, except that <code>ip-version</code> is set to <code>6</code> and the <code>remote-gw6</code> keyword is used to specify an IPv6 remote gateway address. See Phase 1 configuration on page 1438 and Phase 2 configuration on page 1452 for more information.
Security policies	To complete the VPN configuration, you need a security policy in each direction to permit traffic between the protected network's port and the IPsec interface. You need IPv6 policies unless the VPN is IPv4 over IPv6. See VPN security policies on page 1456 for more information.
Routing	Appropriate routing is needed for both the IPsec packets and the encapsulated traffic within them: <ul style="list-style-type: none"> You need a route, which could be the default route, to the remote VPN gateway via the appropriate interface. You need a route to the remote protected network via the IPsec interface. You need a blackhole route to the remote protected network to ensure that IPsec traffic doesn't match the default route when the IPsec tunnel is down. Routing is dependent on the method:

- **IPv4 over IPv6:** The route to the remote VPN gateway is an IPv6 route. The route to the remote protected network is an IPv4 route.
- **IPv6 over IPv4:** The route to the remote VPN gateways is an IPv4 route. The route to the remote protected network is an IPv6 route.
- **IPv6 over IPv6:** Routes to both the remote VPN gateway and the remote protected network are IPv6 routes.

You can create a new IPv6 static route from *Network > Static Routes*.

You can configure Phase 1 and Phase 2 settings from *VPN > IPsec Wizard*.

To configure Phase 1 and phase 2 settings:

1. Go to *VPN > IPsec Wizard*.
2. Enter a name and set *Template type* to *Custom*.
3. Click *Next*.
4. Under *Network*, set *IP Version* to *IPv6*.
5. Configure the rest of phase 1 and phase 2 settings as required and click *OK*.

IPv6 GRE tunnels

IPv6 addresses can be used at both ends of a GRE tunnel in the same way as with IPv4. See [GRE over IPsec on page 1483](#) for more information.

The configuration is similar to a tunnel for IPv4. However, when you configure the specific tunnel, you need to set the `ip-version` option to 6. This will enable IPv6-specific options for the tunnel.

To configure a GRE tunnel:

```
config system gre-tunnel
  edit <name of tunnel>
    set ip-version 6
    set remote-gw6 <IPv6 address of the remote gateway>
    set local-gw6 <IPv6 address of the local gateway>
  next
end
```

IPv6 tunnel inherits MTU based on physical interface

The MTU of an IPv6 tunnel interface is calculated from the MTU of its parent interface minus headers.

Example

In this topology, FortiGate B and FortiGate D are connected over an IPv6 network. An IPv6 tunnel is formed, and IPv4 can be used over the IPv6 tunnel. The tunnel interface MTU is based on the physical interface MTU minus the IP and TCP headers (40 bytes). On FortiGate B's physical interface port5, the MTU is set to 1320. The IPv6 tunnel is based on port5, and its MTU value of 1280 is automatically calculated from the MTU value of its physical interface minus the header. The same is true for port3 on FortiGate D.

To verify the MTU for the IPv6 tunnel on FortiGate B:

1. Configure port5:

```
config system interface
  edit "port5"
    set vdom "root"
    set type physical
    set snmp-index 7
    config ipv6
      set ip6-address 2000:172:16:202::1/64
      set ip6-allowaccess ping
    end
    set mtu-override enable
    set mtu 1320
  next
end
```

2. Configure the IPv6 tunnel:

```
config system ipv6-tunnel
  edit "B_2_D"
    set source 2000:172:16:202::1
    set destination 2000:172:16:202::2
    set interface "port5"
  next
end
```

3. Configure the tunnel interface:

```
config system interface
  edit "B_2_D"
    set vdom "root"
    set ip 172.16.210.1 255.255.255.255
    set allowaccess ping https http
    set type tunnel
    set remote-ip 172.16.210.2 255.255.255.255
    set snmp-index 33
    config ipv6
      set ip6-address 2000:172:16:210::1/64
      set ip6-allowaccess ping
      config ip6-extra-addr
```

```

        edit fe80::2222/10
        next
    end
end
set interface "port5"
next
end

```

4. Verify the interface lists:

```

# diagnose netlink interface list port5
if=port5 family=00 type=1 index=13 mtu=1320 link=0 master=0
ref=68 state=start present fw_flags=0 flags=up broadcast run multicast
Qdisc=mq hw_addr=**:**:**:**:**:** broadcast_addr=**:**:**:**:**
stat: rxp=1577 txp=1744 rxb=188890 txb=203948 rxe=0 txe=0 rxd=0 txd=0 mc=825 collision=0
@ time=1631647112
re: rxl=0 rxo=0 rxc=0 rxf=0 rxfi=0 rxm=0
te: txa=0 txc=0 txfi=0 txh=0 txw=0
misc rxc=0 txc=0
input_type=0 state=3 arp_entry=0 refcnt=68

# diagnose netlink interface list B_2_D
if=B_2_D family=00 type=769 index=41 mtu=1280 link=0 master=0
ref=25 state=start present fw_flags=0 flags=up p2p run noarp multicast
Qdisc=noqueue local=0.0.0.0 remote=0.0.0.0
stat: rxp=407 txp=417 rxb=66348 txb=65864 rxe=0 txe=61 rxd=0 txd=0 mc=0 collision=60 @
time=1631647126
re: rxl=0 rxo=0 rxc=0 rxf=0 rxfi=0 rxm=0
te: txa=0 txc=0 txfi=0 txh=0 txw=0
misc rxc=0 txc=0
input_type=0 state=3 arp_entry=0 refcnt=25

```

To verify the MTU for the IPv6 tunnel on FortiGate D:

1. Configure port3:

```

config system interface
    edit "port3"
        set vdom "root"
        set type physical
        set snmp-index 5
        config ipv6
            set ip6-address 2000:172:16:202::2/64
            set ip6-allowaccess ping
        end
        set mtu-override enable
        set mtu 1320
    next
end

```

2. Configure the IPv6 tunnel:

```

config system ipv6-tunnel
    edit "D_2_B"
        set source 2000:172:16:202::2
        set destination 2000:172:16:202::1
        set interface "port3"
    end
end

```

```
    next
end
```

3. Configure the tunnel interface:

```
config system interface
  edit "D_2_B"
    set vdom "root"
    set ip 172.16.210.2 255.255.255.255
    set allowaccess ping https http
    set type tunnel
    set remote-ip 172.16.210.1 255.255.255.255
    set snmp-index 36
  config ipv6
    set ip6-address 2000:172:16:210::2/64
    set ip6-allowaccess ping
    config ip6-extra-addr
      edit fe80::4424/10
        next
      end
    end
  end
  set interface "port3"
next
end
```

4. Verify the interface lists:

```
# diagnose netlink interface list port3
# diagnose netlink interface list D_2_B
```

IPv6 Simple Network Management Protocol

Simple Network Management Protocol (SNMP) in IPv6 is similar to IPv4, with the main difference being the address format. Despite this, SNMP's principles and functionalities, including network management, device monitoring, and performance information gathering, remain consistent across both versions. See [SNMP on page 2255](#) for more information.

SNMP for monitoring interface status example

In this example, SNMP manager (2001:db8:d0c:2::1) is configured to receive notifications when a FortiGate port either goes down or is brought up. Additionally, the SNMP manager has the capability to query the current status of the FortiGate port.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](#) for more information.

To configure SNMP for monitoring interface status in the GUI:

1. Configure the Interface access:
 - a. Go to *Network > Interfaces* and edit *port1*.
 - b. In the *Administrative Access* options, enable *SNMP* under *IPv6*.
 - c. Click *OK*.
2. Configure the SNMP agent:
 - a. Go to *System > SNMP*.
 - b. Enable *SNMP Agent*.
 - c. Configure the following fields:

Description	Branch
Location	Burnaby
Contact Info	Jane Doe

- d. Click *Apply*.
3. Configure an SNMP v3 user:
 - a. Go to *System > SNMP*.
 - b. In the *SNMP v3* table, click *Create New*.
 - c. Configure the following fields:

User Name	Interface_Status
Security Level	Authentication
Authentication Algorithm	SHA1
Password	*****
IPv6 Hosts > IP Address	2001:db8:d0c:2::1

- d. Click *OK*.
 - e. Click *Apply*.

To configure SNMP for monitoring interface status in the CLI:

1. Configure the Interface access:

```
config system interface
  edit port1
    config ipv6
      append ip6-allowaccess snmp
    end
  next
end
```

2. Configure the SNMP agent:

```
config system snmp sysinfo
  set status enable
  set description Branch
  set contact-info "Jane Doe"
```

```

    set location Burnaby
end

```

3. Configure an SNMP v3 user:

```

config system snmp user
  edit "Interface_Status"
    set notify-hosts6 2001:db8:d0c:2::1
    set security-level auth-no-priv
    set auth-proto sha
    set auth-pwd *****
  next
end

```

Verification

To verify the SNMP configuration:

1. Start the packet capture on interface port1 with the filter set to port 162. See [Performing a sniffer trace or packet capture on page 2872](#).
2. Turn off one of the FortiGate interface statuses to down; in this case, port2.
3. Save the packet capture.

```

> Internet Protocol Version 6, Src: 2001:db8:d0c:2::f, Dst: 2001:db8:d0c:2::1
> User Datagram Protocol, Src Port: 162, Dst Port: 162
< Simple Network Management Protocol
  msgVersion: snmpv3 (3)
  > msgGlobalData
  > msgAuthoritativeEngineID: 80003044058000304404085b0e9f05f0
  msgAuthoritativeEngineBoots: 1695743618
  msgAuthoritativeEngineTime: 189193
  msgUserName: Interface_Status
  msgAuthenticationParameters: 064b1a16a3db6b06f4d66d86
  msgPrivacyParameters: <MISSING>
< msgData: plaintext (0)
  < plaintext
    > contextEngineID: 80003044058000304404085b0e9f05f0
    contextName:
  < data: snmpV2-trap (7)
  < snmpV2-trap
    request-id: 753
    error-status: noError (0)
    error-index: 0
  < variable-bindings: 9 items
    > 1.3.6.1.2.1.1.3.0: 18925675
    > 1.3.6.1.6.3.1.1.4.1.0: 1.3.6.1.6.3.1.1.5.3 (iso.3.6.1.6.3.1.1.5.3)
    > 1.3.6.1.2.1.2.2.1.1.2: 2
    > 1.3.6.1.2.1.2.2.1.7.2: 1
    > 1.3.6.1.2.1.2.2.1.8.2: 2
    > 1.3.6.1.4.1.12356.100.1.1.1.0: "FGVM08TM22004645"
    > 1.3.6.1.2.1.1.5.0: "Root"
    > 1.3.6.1.2.1.31.1.1.1.1.2: "port2"
    > 1.3.6.1.2.1.2.2.1.2.2: <MISSING>

```

The SNMP v3 trap is observed to be transmitted from port1 to the SNMP manager. It's also noteworthy that the *msgAuthenticationParameters* are configured, signifying that authentication is active. However, the absence of *msgPrivacyParameters* suggests that encryption is not in place, a fact further corroborated by the plaintext nature of the *msgData*.

4. Verify that the SNMP manager has received the trap. See [Important SNMP traps on page 2259](#) for an example of a trap.
5. Verify that the SNMP manager can successfully query and receive a response on the current status of the FortiGate ports.

```
# snmpwalk -v3 -u Interface_Status -l authNoPriv -a SHA -A xxxxxxxx
udp6:2001:db8:d0c:2::f 1.3.6.1.2.1.2.2.1.8

iso.3.6.1.2.1.2.2.1.8.4 = INTEGER: 1
iso.3.6.1.2.1.2.2.1.8.5 = INTEGER: 1
iso.3.6.1.2.1.2.2.1.8.6 = INTEGER: 1
iso.3.6.1.2.1.2.2.1.8.7 = INTEGER: 1
iso.3.6.1.2.1.2.2.1.8.8 = INTEGER: 1
iso.3.6.1.2.1.2.2.1.8.9 = INTEGER: 1
iso.3.6.1.2.1.2.2.1.8.10 = INTEGER: 1
```

Dynamic routing in IPv6

The principles that govern dynamic routing in IPv6 are fundamentally the same as those in IPv4. However, it's crucial to understand that while IPv6 operates similarly to IPv4 in terms of routing, it utilizes a distinct routing table and process.

When a router receives a packet, the routing scheme of the packet determines how the traffic will be routed. If the packet is using the IPv4 scheme, the router will refer to the IPv4 routing table to determine the best path for the packet. This table contains all the necessary information about network paths within the IPv4 framework. See [Dynamic routing on page 362](#) for more information.

Conversely, if the router receives a packet with an IPv6 address, it will consult the IPv6 routing table. This separate table contains all the relevant information for routing within the IPv6 framework.

In essence, while both IPv4 and IPv6 use similar methods for routing packets, they each have their own dedicated processes and tables to ensure efficient and accurate routing.

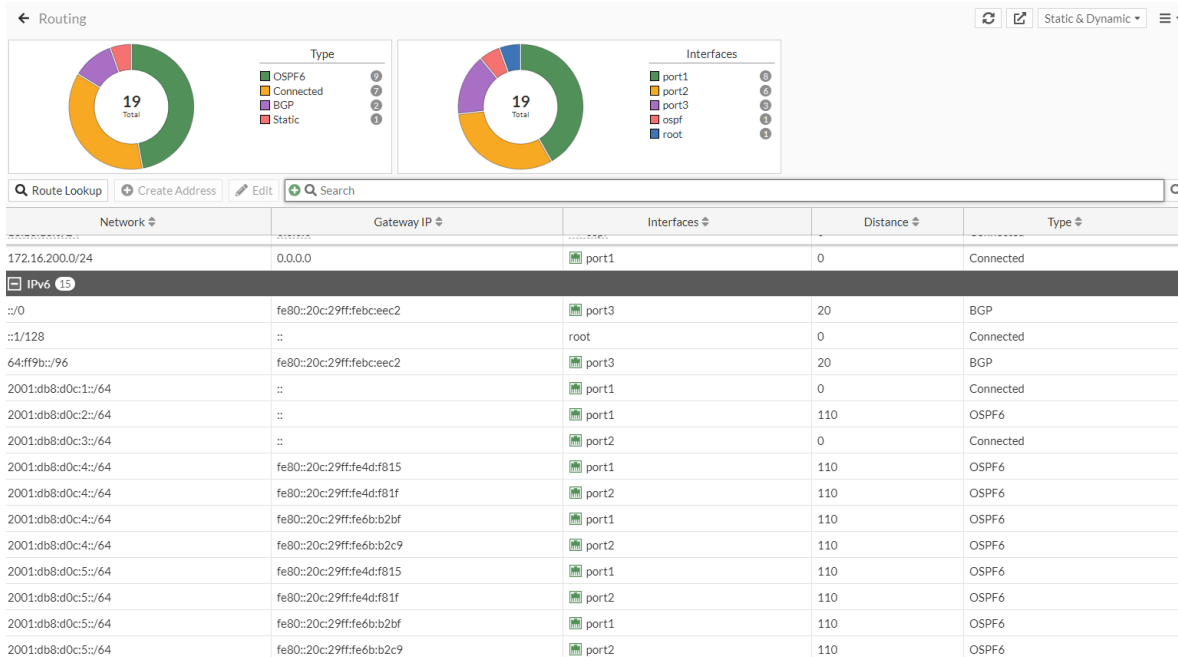

Go to *System > Feature Visibility* and enable *Advanced Routing* to configure dynamic routing options in the GUI. See [Feature visibility on page 2292](#) for more information.

This section includes:

- [OSPFv3 and IPv6 on page 559](#)
- [BGP and IPv6 on page 560](#)

To view the routing table and perform route look-ups in the GUI, go to *Dashboard > Network* and expand the *Routing* widget.

To view the routing table in the CLI:

```
# get router info6 routing-table
IPv6 Routing Table
Codes: K - kernel route, C - connected, S - static, R - RIP, O - OSPF,
IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, B - BGP, V - BGP VPNv6
* - candidate default
```

Timers: Uptime

Routing table for VRF=0

```
B*  ::/0 [20/0] via fe80::20c:29ff:febc:eec2, port3, 02:45:56, [1024/0]

O   2001:db8:d0c:4::/64 [110/2] via fe80::20c:29ff:fe4d:f81f, port1, 00:33:04, [1024/0]
O   2001:db8:d0c:5::/64 [110/2] via fe80::20c:29ff:fe6b:b2c9, port2, 02:51:32, [1024/0]
C   2001:db8:d0c:6::/64 via ::, port3, 03:45:04
```

OSPFv3 and IPv6

OSPF version 3 (OSPFv3) includes support for IPv6 and can only be configured via the CLI. Unlike its predecessor, OSPFv2, which uses IPv4, OSPFv3 utilizes IPv6 addresses. However, the area numbers in OSPFv3 still adhere to the 32-bit numbering system of OSPFv2, as described in [RFC 2740](#). Likewise, the router ID and area ID are in the same format as OSPFv2. See [OSPF on page 383](#) for more information.

For IPv6, the main difference in OSPFv3 is that rather than using a network statement to enable OSPFv3 on an interface, you define OSPF6 (OSPF for IPv6) interfaces, which are bound to the interface and area. This configuration must be done in the CLI, as follows:

```
config router ospf6
  set router-id <id>
  config area
    edit <id>
      next
    end
  config ospf6-interface
    edit <name>
      set interface <string>
      set area-id <id>
    next
  end
end
```

Note that OSPFv3 neighbors use link-local IPv6 addresses, but with broadcast and point-to-point network types, and neighbors are automatically discovered. You only have to manually configure neighbors when using non-broadcast network types.

See [Basic OSPFv3 example on page 593](#) for a sample configuration.

BGP and IPv6

Border Gateway Protocol (BGP) is a standardized routing protocol that is used to route traffic across the internet. See [BGP on page 395](#) for more information.

FortiGate units support IPv6 over BGP using the same `config router bgp` command as IPv4, but different subcommands.

The main CLI keywords have IPv6 equivalents that are identified by the “6” on the end of the keyword, such as with `config network6` or `set allowas-in6`.

See [config router bgp](#) for a comprehensive list of commands.

See [Basic IPv6 BGP example on page 600](#) for a sample configuration.

IPv6 configuration examples

The following topics provide instructions on different IPv6 configuration examples:

- [IPv6 quick start example on page 561](#)
- [Site-to-site IPv6 over IPv6 VPN example on page 567](#)
- [Site-to-site IPv4 over IPv6 VPN example on page 576](#)
- [Site-to-site IPv6 over IPv4 VPN example on page 584](#)
- [Basic OSPFv3 example on page 593](#)
- [Basic IPv6 BGP example on page 600](#)

IPv6 quick start example

In this example, a host belonging to a specific range on the internal IPv6 network can communicate exclusively with the web server and FTP server.

Additionally, all internal clients can access the Internet.

Prerequisites

Before you begin to configure IPv6, go through the following steps:

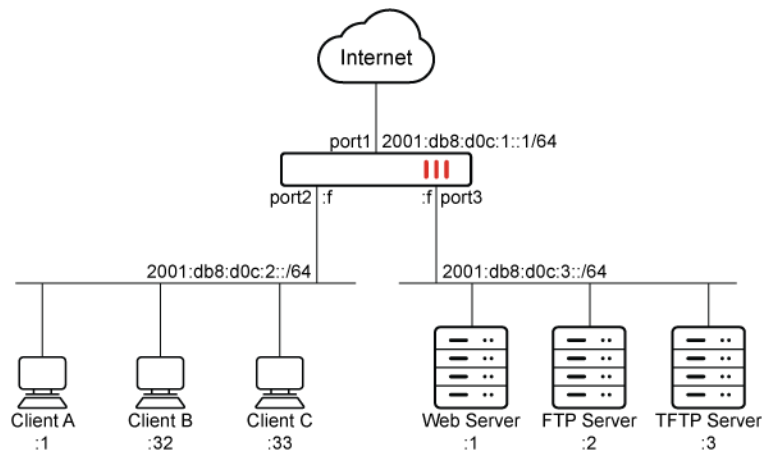

1. Obtain an IPv6 /48 global routing prefix, commonly known as a site prefix. To procure a 48-bit IPv6 site prefix for your organization simply liaise with your ISP.
2. Design a subnetting plan for your organization's IPv6 network using a 16-bit subnet ID, allowing for up to 65 535 subnets. The specific scheme will depend on the network's size, structure, and the organization's needs.

At this stage, the following installation and configuration conditions are assumed:

- You have administrative access to the GUI or CLI.
- The FortiGate unit is incorporated into your WAN or other networks, but for simplicity, only the standalone FortiGate configuration is displayed.

Topology

The following topology is used for this example:

- The company is assigned the site prefix of 2001:db8:d0c::/48 by their ISP.
- The IPv6 address for the Web Server is 2001:db8:d0c:3::1/64.
- The IPv6 address for the FTP Server is 2001:db8:d0c:3::2/64.
- The IPv6 address for the TFTP Server is 2001:db8:d0c:3::3/64.
- The range on the internal IPv6 network that can access both servers is from 2001:db8:d0c:2::1 to 2001:db8:d0c:2::32.
- The IPv6 address of port1 is 2001:db8:d0c:1::1/64.
- The IPv6 address of port2 is 2001:db8:d0c:2::f/64.
- The IPv6 address of port3 is 2001:db8:d0c:3::f/64.
- The IPv6 address of the default gateway is 2001:db8:d0c:1::f/64.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](#) for more information.

To configure the example in the GUI:

1. Configure the IPv6 address on port1, port2 and port3:

- a. Go to *Network > Interfaces* and edit port1.
- b. For *IPv6 addressing Mode*, select manual and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::1/64
----------------------------	----------------------

- c. Click *OK*.
- d. Repeat steps a and b for port2.

IPv6 Address/Prefix	2001:db8:d0c:2::f/64
----------------------------	----------------------

- e. Repeat steps a and b for port3.

IPv6 Address/Prefix	2001:db8:d0c:3::f/64
----------------------------	----------------------

2. Configure the default route:

- a. Go to *Network > Static Routes*.
- b. Click *Create New > IPv6 Static Route*.
- c. Configure the following settings:

Destination	::/0
Gateway Address	2001:db8:d0c:1::f
Interface	port1

- d. Select *OK*.

3. Configure the IPv6 firewall address for the Web Server:

- a. Go to *Policy & Objects > Addresses*.
- b. Select *Create New > Address*.
- c. Select *IPv6 Address* and fill out the fields with the following information:

Name	Web_Server
Type	IPv6 Subnet
IPv6 Address	2001:db8:d0c:3::1/128

- d. Select *OK*.

4. Configure the IPv6 firewall address for the FTP Server:

- a. Go to *Policy & Objects > Addresses*.
- b. Select *Create New > Address*.

- c. Select *IPv6 Address* and fill out the fields with the following information:

Name	FTP_Server
Type	IPv6 Subnet
IPv6 Address	2001:db8:d0c:3::2/128

- d. Select *OK*.

5. Configure the IPv6 address group, which includes both the Web and FTP servers:

- Go to *Policy & Objects > Addresses*.
- Select *Create New > Address Group*.
- Select *IPv6 Group* and fill out the fields with the following information:

Group name	Custom_Server
Members	Web_Server, FTP_Server

- d. Select *OK*.

6. Configure the IPv6 firewall address for the Internal IPv6 network range which can access both the Web and FTP server:

- Go to *Policy & Objects > Addresses*.
- Select *Create New > Address*.
- Select *IPv6 Address* and fill out the fields with the following information:

Name	Internal_Custom_Range
Type	IPv6 Range
IP Range	2001:db8:d0c:2::1 - 2001:db8:d0c:2::32

- d. Select *OK*.

7. Configure the IPv6 firewall policy to allow IPv6 traffic from *Internal_Custom_Range* to *Custom_Server*:

- Go to *Policy & Objects > Firewall Policy*.
- Click *Create New*.
- Name the policy and configure the following parameters:

Incoming Interface	port2
Outgoing Interface	port3
Source	Internal_Custom_Range
Destination	Custom_Server
Schedule	always
Service	FTP, HTTPS
Action	ACCEPT

- d. Click *OK*.

8. Configure the IPv6 firewall policy to allow IPv6 traffic from internal clients to the Internet:

- a. Go to *Policy & Objects > Firewall Policy*.
- b. Click *Create New*.
- c. Name the policy and configure the following parameters:

Incoming Interface	port2
Outgoing Interface	port1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- d. Click *OK*.

To configure the example in the CLI:

1. Configure the IPv6 address on port1, port2, and port3:

```
config system interface
  edit "port1"
    config ipv6
      set ip6-address 2001:db8:d0c:1::1/64
    end
  next
  edit "port2"
    config ipv6
      set ip6-address 2001:db8:d0c:2::f/64
    end
  next
  edit "port3"
    config ipv6
      set ip6-address 2001:db8:d0c:3::f/64
    end
  next
end
```

2. Configure the default route:

```
config router static6
  edit 0
    set gateway 2001:db8:d0c:1::f
    set device "port1"
  next
end
```

3. Configure the IPv6 firewall address for the Web Server:

```
config firewall address6
  edit "Web_Server"
    set ip6 2001:db8:d0c:3::1/128
  next
end
```

4. Configure the IPv6 firewall address for the FTP Server:

```
config firewall address6
  edit "FTP_Server"
    set ip6 2001:db8:d0c:3::2/128
  next
end
```

5. Configure the IPv6 address group, which includes for the Web and FTP Servers:

```
config firewall addrgrp6
  edit "Custom_Server"
    set member "FTP_Server" "Web_Server"
  next
end
```

6. Configure the IPv6 firewall address for the Internal IPv6 network range which can access both the Web and FTP Server:

```
config firewall address6
  edit "Internal_Custom_Range"
    set type iprange
    set start-ip 2001:db8:d0c:2::1
    set end-ip 2001:db8:d0c:2::32
  next
end
```

7. Configure the IPv6 firewall policy to allow IPv6 traffic from *Internal_Custom_Range* to *Custom_Server*:

```
config firewall policy
  edit 1
    set name "IPv6_internal_to_server"
    set srcintf "port2"
    set dstintf "port3"
    set action accept
    set srcaddr6 "Internal_Custom_Range"
    set dstaddr6 "Custom_Server"
    set schedule "always"
    set service "FTP" "HTTPS"
    set utm-status enable
    set logtraffic all
  next
end
```

8. Configure the IPv6 firewall policy to allow IPv6 traffic from Internal clients to the Internet:

```
config firewall policy
  edit 1
    set name "IPv6_internal_to_internet"
    set srcintf "port2"
    set dstintf "port1"
    set action accept
    set srcaddr6 "all"
    set dstaddr6 "all"
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set logtraffic all
```

```

    next
end

```

Verification

The following commands can be used to verify that IPv6 traffic is entering and leaving the FortiGate as expected. See [Debugging the packet flow on page 2876](#) for more information.

```

diagnose debug enable
diagnose debug flow trace start6 200

```

The output below indicates that hosts belonging to the *Internal_Custom_Range* can successfully reach both the *Web_Server* and *FTP_Server* defined in the *Custom_Server* address group.

However, they are unable to reach the TFTP server, as it is not included in the *Custom_Server* group. Furthermore, hosts with IPv6 addresses that do not belong to the *Internal_Custom_Range* are not able to access *Custom_Server*.

Host belonging to *Internal_Custom_Range* accessing *Web_Server*:

```

Site-to-site IPv6 over IPv6 VPN example

In this example, clients on IPv6-addressed networks communicate securely over public IPv6 infrastructure.

The following topology is used for this example:

- Port2 connects to the public network and port3 connects to the local network.
- The IPv6 address for HQ1 port2 and port3 is 2001:db8:d0c:1::e and 2001:db8:d0c:4::e, respectively.
- The IPv6 address for HQ2 port2 and port3 is 2001:db8:d0c:2::e and 2001:db8:d0c:3::e, respectively.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](https://www.rfc-editor.org/rfc/3849) for more information.

To configure the example in the GUI:**1. Configure the HQ1 FortiGate.****a. Configure the IPv6 address on port2 and port3:**

- i. Go to *Network > Interfaces* and edit port2.
- ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::e/64
----------------------------	----------------------

- iii. Click *OK*.
- iv. Repeat these steps for port3.

IPv6 Address/Prefix	2001:db8:d0c:4::e/64
----------------------------	----------------------

b. Configure IPsec settings:

- i. Go to *VPN > IPsec Wizard* and enter a VPN name.
- ii. Set *Template type* to *Custom*.
- iii. Click *Next*.
- iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:2::e
Interface	port2

v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:

- i. Go to *Policy & Objects > Firewall Policy*.
- ii. Click *Create New*.

- iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

- d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:

i. Go to *Policy & Objects > Firewall Policy*.

ii. Click *Create New*.

- iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

- e. Configure the static routes:

i. Go to *Network > Static Routes*.

ii. Click *Create New > IPv6 Static Route*.

- iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	::/0
Gateway Address	2001:db8:d0c:1::f
Interface	port2

- iv. Select *OK*.

- v. Repeat the first two steps and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:3::/64
Interface	to_HQ2

- vi. Select *OK*.

- vii. Repeat the first two steps and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:3::/64
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

2. Configure the HQ2 FortiGate:

- a. Configure the IPv6 address on port2 and port3:

- i. Go to *Network > Interfaces* and edit port2.
- ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:2::e/64
----------------------------	----------------------

- iii. Click *OK*.
- iv. Repeat these steps for port3.

IPv6 Address/Prefix	2001:db8:d0c:3::e/64
----------------------------	----------------------

- b. Configure IPsec settings:

- i. Go to *VPN > IPsec Wizard* and enter a VPN name.
- ii. Set *Template type* to *Custom*.
- iii. Click *Next*.
- iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:1::e
Interface	port2

- v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

- vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

- c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:
- i. Go to *Policy & Objects > Firewall Policy*.
 - ii. Click *Create New*.

- iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

- d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:

- i. Go to *Policy & Objects > Firewall Policy*.

- ii. Click *Create New*.

- iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.

- e. Configure the static routes:

- i. Go to *Network > Static Routes*.

- ii. Click *Create New > IPv6 Static Route*.

- iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	::/0
Gateway Address	2001:db8:d0c:2::f
Interface	port2

- iv. Select *OK*.

- v. Repeat the first two steps and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:4::/64
Interface	to_HQ1

- vi. Select *OK*.

- vii. Repeat the first two steps and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:4::/64
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.

- a. Configure the IPv6 address on port2 and port3:

```
config system interface
  edit port2
    config ipv6
      set ip6-address 2001:db8:d0c:1::e/64
    end
  next
  edit port3
    config ipv6
      set ip6-address 2001:db8:d0c:4::e/64
    end
  next
end
```

- b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
  edit "to_HQ2"
    set interface port2
    set ip-version 6
    set peertype any
    set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
    set remote-gw6 2001:db8:d0c:2::e
    set psksecret sample
  next
end
config vpn ipsec phase2-interface
  edit "to_HQ2"
    set phase1name "to_HQ2"
    set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
    aes256gcm chacha20poly1305
    set src-addr-type subnet6
    set dst-addr-type subnet6
  next
end
```

- c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
  edit 1
    set srcintf "port3"
    set dstintf "to_HQ2"
    set srcaddr6 "all"
```

```
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
        set gateway 2001:db8:d0c:1::f
        set device "port2"
    next
    edit 2
        set dst 2001:db8:d0c:3::/64
        set device "to_HQ2"
    next
    edit 3
        set dst 2001:db8:d0c:3::/64
        set blackhole enable
        set distance 254
    next
end
```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:2::e/64
        end
    next
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:3::e/64
        end
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ1"
        set interface port2
```

```

        set ip-version 6
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:1::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phasename "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end

```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```

config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ1"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ1"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end

```

d. Configure the static routes:

```

config router static6
    edit 1
        set gateway 2001:db8:d0c:2::f
        set device "port2"
    next
    edit 2
        set dst 2001:db8:d0c:4::/64
        set device "to_HQ1"
    next
    edit 3
        set dst 2001:db8:d0c:4::/64
        set blackhole enable
        set distance 254

```

```

    next
end

```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```

vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 2001:db8:d0c:1::e:500 -> 2001:db8:d0c:2::e:500
tun_id: 10.0.0.1/::10.0.0.1
remote_location: 0.0.0.0
network-id: 0
created: 1537s ago
peer-id: 2001:db8:d0c:2::e
peer-id-auth: no
IKE SA: created 1/1 established 1/1 time 0/0/0 ms
IPsec SA: created 1/1 established 1/1 time 0/0/0 ms

id/spi: 160 8d7231820bb5ffd9/6c840a4c11b57927
direction: initiator
status: established 1537-1537s ago = 0ms
proposal: aes128-sha256
key: 32d8521a77d98529-5fe4b67914d30f87
lifetime/rekey: 86400/84562
DPD sent/recv: 00000007/00000003
peer-id: 2001:db8:d0c:2::e

```

2. Run the `diagnose vpn tunnel list` command on HQ1. The system should return the following:

```

list all ipsec tunnel in vd 0
-----

Site-to-site IPv4 over IPv6 VPN example

In this example, two private networks with IPv4 addressing communicate securely over IPv6 infrastructure.

The following topology is used for this example:

- Port2 connects to the IPv6 public network and port3 connects to the IPv4 local network.
- HQ1 port2 IPv6 address is 2001:db8:d0c:1::e and port3 IPv4 address is 192.168.2.1.
- HQ2 port2 IPv6 address is 2001:db8:d0c:2::e and port3 IPv4 address is 192.168.3.1.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](#) for more information.

To configure the example in the GUI:

1. Configure the HQ1 FortiGate.
 - a. Configure the IPv6 address on port2 and IPv4 address on port3:
 - i. Go to *Network > Interfaces* and edit port2.
 - ii. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:1::e/64
----------------------------	----------------------

- iii. Click *OK*.
- iv. Go to *Network > Interfaces* and edit port3.
- v. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	192.168.2.1/24
-------------------	----------------

- b. Configure IPsec settings:
 - i. Go to *VPN > IPsec Wizard* and enter a VPN name.
 - ii. Set *Template type* to *Custom*.
 - iii. Click *Next*.
 - iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:2::e
Interface	port2

- v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

- vi. Configure the following *New Phase 2* settings:

Local Address	addr_subnet
Remote Address	addr_subnet

- c. Configure the IPv4 firewall policy to allow IPv4 traffic from port3 to the IPsec interface:

- i. Go to *Policy & Objects > Firewall Policy*.
- ii. Click *Create New*.
- iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- d. Configure the IPv4 firewall policy to allow IPv4 traffic from the IPsec interface to port3:
- i. Go to *Policy & Objects > Firewall Policy*.
 - ii. Click *Create New*.

- iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- e. Configure the static routes:
- Go to *Network > Static Routes*.
 - Click *Create New > IPv6 Static Route*.
 - Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	2001:db8:d0c:1::f
Interface	port2

- iv. Select *OK*.
- v. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the route to the remote protected network:

Destination	192.168.3.0/24
Interface	to_HQ2

- vi. Select *OK*.
- vii. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the blackhole route:

Destination	192.168.3.0/24
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

2. Configure the HQ2 FortiGate:

- a. Configure the IPv6 address on port2 and IPv4 address on port3:
- Go to *Network > Interfaces* and edit port2.
 - Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:2::e/64
----------------------------	----------------------

- iii. Click *OK*.

- iv. Go to *Network > Interfaces* and edit port3.
- v. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	192.168.3.1/24
-------------------	----------------

- b. Configure IPsec settings:
 - i. Go to *VPN > IPsec Wizard* and enter a VPN name.
 - ii. Set *Template type* to *Custom*.
 - iii. Click *Next*.
 - iv. Configure the following *Network* settings:

IP Version	IPv6
Remote Gateway	Static IP Address
IP Address	2001:db8:d0c:1::e
Interface	port2

- v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

- vi. Configure the following *New Phase 2* settings:

Local Address	addr_subnet
Remote Address	addr_subnet

- c. Configure the IPv4 firewall policy to allow IPv4 traffic from port3 to the IPsec interface:
 - i. Go to *Policy & Objects > Firewall Policy*.
 - ii. Click *Create New*.
 - iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- d. Configure the IPv4 firewall policy to allow IPv4 traffic from the IPsec interface to port3:
 - i. Go to *Policy & Objects > Firewall Policy*.
 - ii. Click *Create New*.

- iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- e. Configure the static routes:
- Go to *Network > Static Routes*.
 - Click *Create New > IPv6 Static Route*.
 - Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	2001:db8:d0c:2::f
Interface	port2

- iv. Select *OK*.
- v. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the route to the remote protected network:

Destination	192.168.2.0/24
Interface	to_HQ1

- vi. Select *OK*.
- vii. Repeat the first two steps for *IPv4 Static Route* and configure the following settings for the blackhole route:

Destination	192.168.2.0/24
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

To configure the example in the CLI:

- Configure the HQ1 FortiGate.
 - Configure the IPv6 address on port2 and IPv4 address on port3:

```
config system interface
  edit port2
    config ipv6
      set ip6-address 2001:db8:d0c:1::e/64
```

```
        end
    next
    edit port3
        set ip 192.168.2.1/24
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ2"
        set interface port2
        set ip-version 6
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:2::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phase1name "to_HQ2"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet
        set dst-addr-type subnet
    next
end
```

c. Configure the IPv4 firewall policy to allow IPv4 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ2"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static6
    edit 1
```

```

        set gateway 2001:db8:d0c:1::f
        set device "port2"
    next
end
config router static
    edit 1
        set dst 192.168.3.0 255.255.255.0
        set device "to_HQ2"
    next
    edit 2
        set dst 192.168.3.0 255.255.255.0
        set device blackhole
        set distance 254
    next
end

```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and IPv4 address on port3:

```

config system interface
    edit port2
        config ipv6
            set ip6-address 2001:db8:d0c:2::e/64
        end
    next
    edit port3
        set ip 192.168.3.1/24
    next
end

```

b. Configure IPsec settings:

```

config vpn ipsec phase1-interface
    edit "to_HQ1"
        set interface port2
        set ip-version 6
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw6 2001:db8:d0c:1::e
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phasename "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
        aes256gcm chacha20poly1305
        set src-addr-type subnet
        set dst-addr-type subnet
    next
end

```

c. Configure the IPv4 firewall policy to allow IPv4 traffic between port3 to the IPsec interface:

```

config firewall policy
    edit 1
        set srcintf "port3"

```

```

        set dstintf "to_HQ1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ1"
        set dstintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end

```

d. Configure the static routes:

```

config router static6
    edit 1
        set gateway 2001:db8:d0c:2::f
        set device "port2"
    next
end
config router static
    edit 1
        set dst 192.168.2.0 255.255.255.0
        set device "to_HQ1"
    next
    edit 2
        set dst 192.168.2.0 255.255.255.0
        set device blackhole
        set distance 254
    next
end

```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```

vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 2001:db8:d0c:1::e:500 -> 2001:db8:d0c:2::e:500
tun_id: 10.0.0.1/::10.0.0.1
remote_location: 0.0.0.0
network-id: 0
created: 7215s ago
peer-id: 2001:db8:d0c:2::e
peer-id-auth: no

```

```

Site-to-site IPv6 over IPv4 VPN example

In this example, IPv6-addressed networks communicate securely over IPv4 public infrastructure.

The following topology is used for this example:

- Port2 connects to the IPv4 public network and port3 connects to the IPv6 local network.
- HQ1 port2 IPv4 address is 10.0.0.1 and port3 IPv6 address is 2001:db8:d0c:4::e.
- HQ2 port2 IPv4 address is 10.0.1.1 and port3 IPv6 address is 2001:db8:d0c:3::e.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](#) for more information.

To configure the example in the GUI:

1. Configure the HQ1 FortiGate.

- Configure the IPv4 address on port2 and IPv6 address on port3:
 - Go to *Network > Interfaces* and edit port2.
 - Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	10.0.0.1/24
-------------------	-------------

- Click *OK*.

- Go to *Network > Interfaces* and edit port3.

- Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:4::e/64
----------------------------	----------------------

- Configure IPsec settings:

- Go to *VPN > IPsec Wizard* and enter a VPN name.
- Set *Template type* to *Custom*.
- Click *Next*.
- Configure the following *Network* settings:

IP Version	IPv4
Remote Gateway	Static IP Address
IP Address	10.0.1.1
Interface	port2

- Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

- Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

- Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:

- i. Go to *Policy & Objects > Firewall Policy*.
- ii. Click *Create New*.
- iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ2
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
 - i. Go to *Policy & Objects > Firewall Policy*.
 - ii. Click *Create New*.
 - iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ2
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- e. Configure the static routes:
 - i. Go to *Network > Static Routes*.
 - ii. Click *Create New > IPv4 Static Route*.
 - iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	10.0.0.2
Interface	port2

- iv. Select *OK*.
- v. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:3::/64
--------------------	---------------------

Interface	to_HQ2
------------------	--------

- vi. Select *OK*.
- vii. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:3::/64
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

2. Configure the HQ2 FortiGate:

- a. Configure the IPv4 address on port2 and IPv6 address on port3:
 - i. Go to *Network > Interfaces* and edit port2.
 - ii. Set *Addressing mode* to *Manual* and enter the *IP/Netmask*.

IP/Netmask	10.0.1.1/24
-------------------	-------------

- iii. Click *OK*.
- iv. Go to *Network > Interfaces* and edit port3.
- v. Set *IPv6 addressing mode* to *Manual* and enter the *IPv6 Address/Prefix*.

IPv6 Address/Prefix	2001:db8:d0c:3::e/64
----------------------------	----------------------

- b. Configure IPsec settings:
 - i. Go to *VPN > IPsec Wizard* and enter a VPN name.
 - ii. Set *Template type* to *Custom*.
 - iii. Click *Next*.
 - iv. Configure the following *Network* settings:

IP Version	IPv4
Remote Gateway	Static IP Address
IP Address	10.0.0.1
Interface	port2

- v. Configure the following *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	sample

- vi. Configure the following *New Phase 2* settings:

Local Address	IPv6 Subnet
Remote Address	IPv6 Subnet

- c. Configure the IPv6 firewall policy to allow IPv6 traffic from port3 to the IPsec interface:

- i. Go to *Policy & Objects > Firewall Policy*.
- ii. Click *Create New*.
- iii. Name the policy and configure the following parameters:

Incoming Interface	port3
Outgoing Interface	to_HQ1
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- d. Configure the IPv6 firewall policy to allow IPv6 traffic from the IPsec interface to port3:
 - i. Go to *Policy & Objects > Firewall Policy*.
 - ii. Click *Create New*.
 - iii. Name the policy and configure the following parameters:

Incoming Interface	to_HQ1
Outgoing Interface	port3
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT

- iv. Click *OK*.
- e. Configure the static routes:
 - i. Go to *Network > Static Routes*.
 - ii. Click *Create New > IPv4 Static Route*.
 - iii. Configure the following settings for the default route to the remote VPN gateway:

Destination	0.0.0.0/0.0.0.0
Gateway Address	10.0.1.2
Interface	port2

- iv. Select *OK*.
- v. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the route to the remote protected network:

Destination	2001:db8:d0c:4::/64
--------------------	---------------------

Interface	to_HQ1
------------------	--------

- vi. Select *OK*.
- vii. Repeat the first two steps for *IPv6 Static Route* and configure the following settings for the blackhole route:

Destination	2001:db8:d0c:4::/64
Interface	Blackhole
Administrative Distance	254

- viii. Select *OK*.

To configure the example in the CLI:

1. Configure the HQ1 FortiGate.

- a. Configure the IPv6 address on port2 and port3:

```
config system interface
  edit port2
    set ip 10.0.0.1/24
  next
  edit port3
    config ipv6
      set ip6-address 2001:db8:d0c:4::e/64
    end
  next
end
```

- b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
  edit "to_HQ2"
    set interface port2
    set ip-version 4
    set peertype any
    set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
    set remote-gw 10.0.1.1
    set psksecret sample
  next
end
config vpn ipsec phase2-interface
  edit "to_HQ2"
    set phase1name "to_HQ2"
    set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
    aes256gcm chacha20poly1305
    set src-addr-type subnet6
    set dst-addr-type subnet6
  next
end
```

- c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
  edit 1
    set srcintf "port3"
    set dstintf "to_HQ2"
```

```
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ2"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static
    edit 1
        set gateway 10.0.0.2
        set device "port2"
    next
end
config router static6
    edit 1
        set dst 2001:db8:d0c:3::/64
        set device "to_HQ2"
    next
    edit 2
        set dst 2001:db8:d0c:3::/64
        set device blackhole
        set distance 254
    next
end
```

2. Configure the HQ2 FortiGate.

a. Configure the IPv6 address on port2 and port3:

```
config system interface
    edit port2
        set ip 10.0.1.1/24
    next
    edit port3
        config ipv6
            set ip6-address 2001:db8:d0c:3::e/64
        end
    next
end
```

b. Configure IPsec settings:

```
config vpn ipsec phase1-interface
    edit "to_HQ1"
```

```
        set interface port2
        set ip-version 4
        set peertype any
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set remote-gw 10.0.0.1
        set psksecret sample
    next
end
config vpn ipsec phase2-interface
    edit "to_HQ2"
        set phaselname "to_HQ1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm
aes256gcm chacha20poly1305
        set src-addr-type subnet6
        set dst-addr-type subnet6
    next
end
```

c. Configure the IPv6 firewall policy to allow IPv6 traffic between port3 to the IPsec interface:

```
config firewall policy
    edit 1
        set srcintf "port3"
        set dstintf "to_HQ1"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
    edit 2
        set srcintf "to_HQ1"
        set dstintf "port3"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic "all"
    next
end
```

d. Configure the static routes:

```
config router static
    edit 1
        set gateway 10.0.1.2
        set device "port2"
    next
end
config router static6
    edit 1
        set dst 2001:db8:d0c:4::/64
        set device "to_HQ1"
    next
    edit 2
        set dst 2001:db8:d0c:4::/64
```

```

        set device blackhole
        set distance 254
    next
end

```

Verification

The following commands are useful to check IPsec phase1/phase2 interface status:

1. Run the `diagnose vpn ike gateway list` command on HQ1. The system should return the following:

```

vd: root/0
name: to_HQ2
version: 1
interface: port2 6
addr: 10.0.0.1:500 -> 10.0.0.2:500
tun_id: 10.0.0.2/::10.0.0.2
remote_location: 0.0.0.0
network-id: 0
created: 576319s ago
peer-id: 10.0.0.2
peer-id-auth: no
IKE SA: created 1/8 established 1/8 time 0/1127/9000 ms
IPsec SA: created 1/7 established 1/7 time 0/5/10 ms

```

```

id/spi: 8 c04ab0ead989f579/267813e164d4ec22
direction: initiator
status: established 59710-59710s ago = 0ms
proposal: aes128-sha256
key: 034a0c3bf3deb551-8d647af9b6f76578
lifetime/rekey: 86400/26389
DPD sent/recv: 00000044/00000047
peer-id: 10.0.0.2

```

2. Run the `diagnose vpn tunnel list` command on HQ1. The system should return the following:

```

list all ipsec tunnel in vd 0
-----
name=to_HQ2 ver=1 serial=1 10.0.0.1:0->10.0.0.2:0 tun_id=10.0.0.2 tun_id6=:10.0.0.2

```

Basic OSPFv3 example

In this example, three FortiGate devices are configured in an OSPF network.

- 1st Floor FortiGate is the Designated Router (DR). It has the highest priority and the lowest IP address, to ensure that it becomes the DR.
- 2nd Floor FortiGate is the Backup Designated Router (BDR). It has a high priority to ensure that it becomes the BDR.
- Enterprise Core FortiGate is the Autonomous System Border Router (ASBR). It routes all traffic to the ISP BGP router for internet access. It redistributes routes from BGP and advertises a default route to its neighbors. It can allow different types of routes, learned outside of OSPF, to be used in OSPF. Different metrics can be assigned to these routes to make them more or less preferred than regular OSPF routes. Route maps could be used to further control what prefixes are advertised or received from the ISP.

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](#) for more information.

FortiGate	Interface	IP address
1st Floor FortiGate (DR)	loopback	1.1.1.1
	port1	2001:db8:d0c:2::1/64
	port2	2001:db8:d0c:1::2/64
	port3	2001:db8:d0c:4::1/64
2nd Floor FortiGate (BDR)	loopback	2.2.2.2
	port1	2001:db8:d0c:2::2/64
	port2	2001:db8:d0c:3::2/64
	port3	2001:db8:d0c:5::1/64
Enterprise Core FortiGate (ASBR)	loopback	13.13.13.13
	port1	2001:db8:d0c:1::1/64
	port2	2001:db8:d0c:3::1/64
	port3	2001:db8:d0c:6::1/64

- Firewall policies are already configured to allow unfiltered traffic in both directions between all of the connected interfaces.
- The interfaces are already configured. The cost for all of the interfaces is left at 0.
- The OSPF network belongs to Area 0, and is not connected to any other OSPF networks. All of the routers are part of the backbone 0.0.0.0 area, so no inter-area communications are needed.
- Enterprise Core FortiGate redistributes BGP routes into the OSPF AS and peers with the ISP BGP Router over eBGP. For information about configuring BGP, see [Basic IPv6 BGP example on page 600](#).
- The ISP IPv6 address is 2001:db8:d0c:6::2/64.

1st Floor FortiGate

To configure 1st Floor FortiGate in the CLI:

```

config router ospf6
  set router-id 1.1.1.1
  config area
    edit 0.0.0.0
      next
    end
  config ospf6-interface
    edit "1st-Floor-FortiGate-Internal-DR"
      set interface "port1"
      set priority 255
      set dead-interval 40
      set hello-interval 10
    next
    edit "1st-Floor-FortiGate-External"
      set interface "port2"
      set dead-interval 40
      set hello-interval 10
  
```

```
        next
    end
    edit "1st-Floor-FortiGate-Internal"
        set interface "port3"
        set dead-interval 40
        set hello-interval 10
    next
end
```

2nd Floor FortiGate

To configure 2nd Floor FortiGate in the CLI:

```
config router ospf6
    set router-id 2.2.2.2
    config area
        edit 0.0.0.0
        next
    end
    config ospf6-interface
        edit "2nd-Floor-FortiGate-Internal"
            set interface "port1"
            set priority 250
            set dead-interval 40
            set hello-interval 10
        next
        edit "2nd-Floor-FortiGate-External"
            set interface "port2"
            set dead-interval 40
            set hello-interval 10
        next
    end
    edit "2nd-Floor-FortiGate-Internal1"
        set interface "port3"
        set dead-interval 40
        set hello-interval 10
    next
end
```

Enterprise Core FortiGate

To configure Enterprise Core FortiGate in the CLI:

```
config router ospf6
    set default-information-originate enable
    set router-id 13.13.13.13
    config area
        edit 0.0.0.0
        next
    end
    config ospf6-interface
        edit "Enterprise-Core-FortiGate-Internal"
            set interface "port1"
            set dead-interval 40
            set hello-interval 10
```

```

    next
    edit "Enterprise-Core-FortiGate-Internal2"
        set interface "port2"
        set dead-interval 40
        set hello-interval 10
    next
end
config redistribute "bgp"
    set status enable
end
end

```

Testing and configuration

Both the network connectivity and OSPF routing are tested. When a link goes down, routes should converge as expected.

1. Working state

- Enterprise Core FortiGate:

```

# get router info6 ospf neighbor
OSPFv3 Process (root)
Neighbor ID      Pri   State           Dead Time   Interface
1.1.1.1          1    Full/Backup     00:00:38   port1
2.2.2.2          1    Full/Backup     00:00:32   port2

# get router info6 ospf status
Routing Process "OSPFv3 (root)" with ID 13.13.13.13
Process uptime is 28 minutes
Do not support Restarting
This router is an ASBR (injecting external routing information)
SPF schedule delay 5 secs, Hold time between SPFs 10 secs
Minimum LSA interval 5 secs, Minimum LSA arrival 1 secs
Number of incoming current DD exchange neighbors 0/5
Number of outgoing current DD exchange neighbors 0/5
Number of external LSA 0. Checksum Sum 0x0000
Number of AS-Scoped Unknown LSA 0
Number of LSA originated 14
Number of LSA received 187
Number of areas in this router is 1
    Area BACKBONE(0)
        Number of interfaces in this area is 2(2)
        SPF algorithm executed 36 times
        Number of LSA 9. Checksum Sum 0x2DB91
        Number of Unknown LSA

# get router info6 routing-table
IPv6 Routing Table

C       fe80::/64 via ::, port8, 00:15:47

```

The default route advertised by Enterprise Core FortiGate using `default-information-originate` is considered an OSPF E2 route. Other routes redistributed from BGP are also E2 routes.

- 1st Floor FortiGate:

```

# get router info6 ospf neighbor
OSPFv3 Process (root)
Neighbor ID      Pri   State           Dead Time   Interface
2.2.2.2          250   Full/Backup     00:00:33   port1

Basic IPv6 BGP example

In this example, Enterprise Core FortiGate peers with the ISP BGP Router over eBGP to receive a default route.

Topology

The following topology is used for this example:

Please note that the IPv6 addresses used in this example are for illustrative purposes only and should not be used in your environment.

The 2001:db8::/32 prefix is a special IPv6 prefix designated for use in documentation examples. See [RFC 3849](#) for more information.

Please note that the Autonomous System Numbers (ASN) used in this example are reserved for documentation use only and should not be used in your environment. See [RFC 5398](#) for more information.

To configure BGP on the Enterprise Core FortiGate in the GUI:

1. Go to *Network > BGP*.
2. Set *Local AS* to *64511*.
3. Set *Router ID* to *13.13.13.13*.
4. In the *Neighbors* table, click *Create New* and set the following:

IP	2001:db8:d0c:6::2
Remote AS	64510

5. Click *OK*.
6. Under *IPv6 Networks*, set *IP/Netmask* to *2001:db8:d0c:6::/64*.
7. Click *Apply*.

To configure BGP on the Enterprise Core FortiGate in the CLI:

```
config router bgp
  set as 64511
  set router-id 13.13.13.13
  config neighbor
    edit "2001:db8:d0c:6::2"
      set remote-as 64510
    next
  end
  config network6
    edit 1
      set prefix6 2001:db8:d0c:6::/64
    next
  end
end
```

Testing the configuration**To verify the status of the neighbors:**

```
# get router info6 bgp neighbors
VRF 0 neighbor table:
BGP neighbor is 2001:db8:d0c:6::2, remote AS 64510, local AS 64511, external link
  BGP version 4, remote router ID 1.1.1.2
  BGP state = Established, up for 02:43:35
  Last read 00:00:14, hold time is 180, keepalive interval is 60 seconds
  Configured hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:

SD-WAN

The following topics provide information about SD-WAN:

- [SD-WAN overview on page 604](#)
- [SD-WAN quick start on page 608](#)
- [SD-WAN members and zones on page 618](#)
- [Performance SLA on page 629](#)
- [SD-WAN rules on page 650](#)
- [Advanced routing on page 715](#)
- [VPN overlay on page 739](#)
- [Advanced configuration on page 782](#)
- [SD-WAN cloud on-ramp on page 799](#)
- [Hub and spoke SD-WAN deployment example on page 822](#)
- [Troubleshooting SD-WAN on page 834](#)

SD-WAN overview

SD-WAN is a software-defined approach to managing Wide-Area Networks (WAN). It consolidates the physical transport connections, or underlays, and monitors and load-balances traffic across the links. VPN overlay networks can be built on top of the underlays to control traffic across different sites.

Health checks and SD-WAN rules define the expected performance and business priorities, allowing the FortiGate to automatically and intelligently route traffic based on the application, internet service, or health of a particular connection.

WAN security and intelligence can be extended into the LAN by incorporating wired and wireless networks under the same domain. FortiSwitch and FortiAP devices integrate seamlessly with the FortiGate to form the foundation of an SD-Branch.

Some of the key benefits of SD-WAN include:

- Reduced cost with transport independence across MPLS, 4G/5G LTE, and others.
- Reduced complexity with a single vendor and single-pane-of-glass management.
- Improve business application performance thanks to increased availability and agility.
- Optimized user experience and efficiency with SaaS and public cloud applications.

SD-WAN components and design principles

SD-WAN can be broken down into three layers:

- Management and orchestration
- Control, data plane, and security
- Network access

The control, data plane, and security layer can only be deployed on a FortiGate. The other two layers can help to scale and enhance the solution. For large deployments, FortiManager and FortiAnalyzer provide the management and orchestration capabilities FortiSwitch and FortiAP provide the components to deploy an SD-Branch.

Layer	Functions	Devices	
Management and orchestration	<ul style="list-style-type: none"> Unified management Template based solution Zero touch provisioning Logging, monitoring, and analysis Automated orchestration using the REST API 	FortiManager 	FortiAnalyzer 
Control, data plane, and security	<ul style="list-style-type: none"> Consolidation of underlays and overlays into SD-WAN zones <ul style="list-style-type: none"> Underlay and Overlay Scalable VPN solutions using ADVPN <ul style="list-style-type: none"> Overlay Static and dynamic routing definition <ul style="list-style-type: none"> Routing NGFW firewalling <ul style="list-style-type: none"> Security SD-WAN health-checks and monitoring <ul style="list-style-type: none"> SD-WAN Application-aware steering and intelligence <ul style="list-style-type: none"> SD-WAN 	FortiGate 	
Network access	<ul style="list-style-type: none"> Wired and wireless network segmentation Built-in network access control 	FortiSwitch 	FortiAP 

Design principles

The [Five-pillar approach](#), described in the SD-WAN / SD-Branch Architecture for MSSPs guide, is recommended when designing a secure SD-WAN solution.

Underlay

Determine the WAN links that will be used for the underlay network, such as your broadband link, MPLS, 4G/5G LTE connection, and others.

For each link, determine the bandwidth, quality and reliability (packet loss, latency, and jitter), and cost. Use this information to determine which link to prefer, what type of traffic to send across the each link, and to help you the baselines for health-checks.

Overlay

VPN overlays are needed when traffic must travel across multiple sites. These are usually site-to-site IPsec tunnels that interconnect branches, datacenters, and the cloud, forming a hub-and-spoke topology.

The management and maintenance of the tunnels should be considered when determining the overlay network requirements. Manual tunnel configuration might be sufficient in a small environment, but could become unmanageable as the environment size increases. ADVPN can be used to help scale the solution; see [ADVPN on page 1639](#) for more information.

Routing

Traditional routing designs manipulate routes to steer traffic to different links. SD-WAN uses traditional routing to build the basic routing table to reach different destinations, but uses SD-WAN rules to steer traffic. This allows the steering to be based on criteria such as destination, internet service, application, route tag, and the health of the link. Routing in an SD-WAN solution is used to identify all possible routes across the underlays and overlays, which the FortiGate balances using ECMP.

In the most basic configuration, static gateways that are configured on an SD-WAN member interface automatically provide the basic routing needed for the FortiGate to balance traffic across the links. As the number of sites and destinations increases, manually maintaining routes to each destination becomes difficult. Using dynamic routing to advertise routes across overlay tunnels should be considered when you have many sites to interconnect.

Security

Security involves defining policies for access control and applying the appropriate protection using the FortiGate's NGFW features. Efficiently grouping SD-WAN members into SD-WAN zones must also be considered. Typically, underlays provide direct internet access and overlays provide remote internet or network access. Grouping the underlays together into one zone, and the overlays into one or more zones could be an effective method.

SD-WAN

The SD-WAN pillar is the intelligence that is applied to traffic steering decisions. It is comprised of four primary elements:

- **SD-WAN zones**

SD-WAN is divided into zones. SD-WAN member interfaces are assigned to zones, and zones are used in policies as source and destination interfaces. You can define multiple zones to group SD-WAN interfaces together, allowing logical groupings for overlay and underlay interfaces. Routing can be configured per zone.

See [SD-WAN members and zones on page 618](#).

- **SD-WAN members**

Also called interfaces, SD-WAN members are the ports and interfaces that are used to run traffic. At least one interface must be configured for SD-WAN to function.

See [Configuring the SD-WAN interface on page 609](#).

- **Performance SLAs**

Also called health-checks, performance SLAs are used to monitor member interface link quality, and to detect link failures. When the SLA falls below a configured threshold, the route can be removed, and traffic can be steered to different links in the SD-WAN rule.

SLA health-checks use active or passive probing:

- Active probing requires manually defining the server to be probed, and generates consistent probing traffic.
- Passive probing uses active sessions that are passing through firewall policies used by the related SD-WAN interfaces to derive health measurements. It reduces the amount of configuration, and eliminates probing traffic. See [Passive WAN health measurement on page 640](#) for details.

See [Performance SLA on page 629](#).

- **SD-WAN rules**

Also called services, SD-WAN rules control path selection. Specific traffic can be dynamically sent to the best link, or use a specific route.

Rules control the strategy that the FortiGate uses when selecting the outbound traffic interface, the SLAs that are monitored when selecting the outgoing interface, and the criteria for selecting the traffic that adheres to the rule. When no SD-WAN rules match the traffic, the implicit rule applies.

See [SD-WAN rules on page 650](#).

SD-WAN designs and architectures

The core functionalities of Fortinet's SD-WAN solution are built into the FortiGate. Whether the environment contains one FortiGate, or one hundred, you can use SD-WAN by enabling it on the individual FortiGates.

At a basic level, SD-WAN can be deployed on a single device in a single site environment:

At a more advanced level, SD-WAN can be deployed in a multi-site, hub and spoke environment:

At an enterprise or MSSP level, the network can include multiple hubs, possibly across multiple regions:

For more details, see the [SD-WAN / SD-Branch Architecture for MSSPs](#) guide.

SD-WAN quick start

This section provides an example of how to start using SD-WAN for load balancing and redundancy.

In this example, two ISP internet connections, wan1 (DHCP) and wan2 (static), use SD-WAN to balance traffic between them at 50% each.

1. [Configuring the SD-WAN interface on page 609](#)
2. [Adding a static route on page 610](#)
3. [Selecting the implicit SD-WAN algorithm on page 610](#)
4. [Configuring firewall policies for SD-WAN on page 611](#)
5. [Link monitoring and failover on page 611](#)
6. [Results on page 613](#)
7. [Configuring SD-WAN in the CLI on page 616](#)

Configuring the SD-WAN interface

First, SD-WAN must be enabled and member interfaces must be selected and added to a zone. The selected FortiGate interfaces can be of any type (physical, aggregate, VLAN, IPsec, and others), but must be removed from any other configurations on the FortiGate.

In this step, two interfaces are configured and added to the default SD-WAN zone (virtual-wan-link) as SD-WAN member interfaces. This example uses a mix of static and dynamic IP addresses; your deployment could also use only one or the other.

Once the SD-WAN members are created and added to a zone, the zone can be used in firewall policies, and the whole SD-WAN can be used in static routes.

To configure SD-WAN members:

1. Configure the wan1 and wan2 interfaces. See [Interface settings on page 143](#) for details.
 - a. Set the wan1 interface *Addressing mode* to *DHCP* and *Distance* to *10*.

By default, a DHCP interface has a distance of 5, and a static route has a distance of 10. It is important to account for this when configuring your SD-WAN for 50/50 load balancing by setting the DHCP interface's distance to 10.

- b. Set the wan2 interface *IP/Netmask* to *10.100.20.1 255.255.255.0*.
2. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
3. Set the *Interface* to *wan1*.
4. Leave *SD-WAN Zone* as *virtual-wan-link*.
5. As wan1 uses DHCP, leave *Gateway* set to *0.0.0.0*.

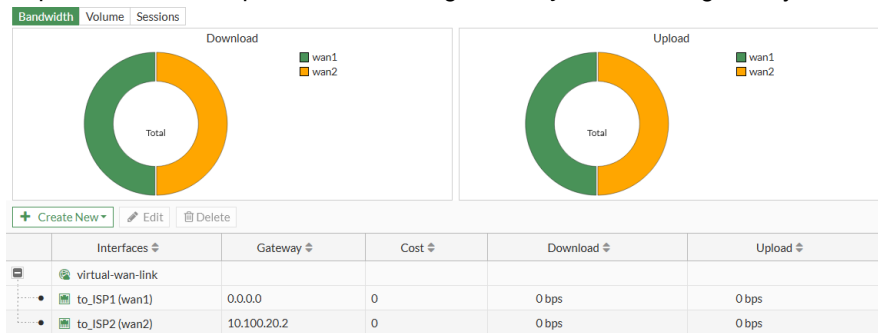

If IPv6 visibility is enabled in the GUI, an IPv6 gateway can also be added for each member. See [Feature visibility on page 2292](#) for details.

6. Leave *Cost* as *0*.

The *Cost* field is used by the Lowest Cost (SLA) strategy. The link with the lowest cost is chosen to pass traffic. The lowest possible *Cost* is *0*.

7. Set *Status* to *Enable*, and click *OK*.

8. Repeat the above steps for wan2, setting *Gateway* to the ISP's gateway: *10.100.20.2*.

Adding a static route

You must configure a default route for the SD-WAN. The default gateways for each SD-WAN member interface do not need to be defined in the static routes table. FortiGate will decide what route or routes are preferred using Equal Cost Multi-Path (ECMP) based on distance and priority.

To create a static route for SD-WAN:

1. Go to *Network > Static Routes*.
2. Click *Create New*. The *New Static Route* page opens.
3. Set *Destination* to *Subnet*, and leave the IP address and subnet mask as *0.0.0.0/0.0.0.0*.
4. In the *Interface* field select an SD-WAN zone.

New Static Route

Automatic gateway retrieval

Destination Internet Service
0.0.0.0/0.0.0.0

Interface

Comments 0/255

Status Enabled Disabled

Additional Information

5. Ensure that *Status* is *Enabled*.
6. Click *OK*.

Selecting the implicit SD-WAN algorithm

SD-WAN rules define specific routing options to route traffic to an SD-WAN member.

If no routing rules are defined, the default *Implicit* rule is used. It can be configured to use one of five different load balancing algorithms. See [Implicit rule on page 658](#) for more details and examples.

This example shows four methods to equally balance traffic between the two WAN connections. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and edit the *sd-wan* rule to select the method that is appropriate for your requirements.

- *Source IP* (CLI command: `source-ip-based`):
Select this option to balance traffic equally between the SD-WAN members according to a hash algorithm based on the source IP addresses.

- **Session** (*weight-based*):
Select this option to balance traffic equally between the SD-WAN members by the session numbers ratio among its members. Use weight 50 for each of the 2 members.
- **Source-Destination IP** (*source-dest-ip-based*):
Select this option to balance traffic equally between the SD-WAN members according to a hash algorithm based on the source and destination IP addresses.
- **Volume** (*measured-volume-based*):
Select this option to balance traffic equally between the SD-WAN members according to the bandwidth ratio among its members.

Configuring firewall policies for SD-WAN

SD-WAN zones can be used in policies as source and destination interfaces. Individual SD-WAN members cannot be used in policies.

You must configure a policy that allows traffic from your organization's internal network to the SD-WAN zone. Policies configured with the SD-WAN zone apply to all SD-WAN interface members in that zone.

To create a firewall policy for SD-WAN:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New*. The *New Policy* page opens.
3. Configure the following:

Name	Enter a name for the policy.
Incoming Interface	<i>internal</i>
Outgoing Interface	<i>virtual-wan-link</i>
Source	<i>all</i>
Destination	<i>all</i>
Schedule	<i>always</i>
Service	<i>ALL</i>
Action	<i>ACCEPT</i>
Firewall / Network Options	Enable <i>NAT</i> and set <i>IP Pool Configuration</i> to <i>Use Outgoing Interface Address</i> .
Security Profiles	Apply profiles as required.
Logging Options	Enable <i>Log Allowed Traffic</i> and select <i>All Sessions</i> . This allows you to verify results later.

4. Enable the policy, then click *OK*.

Link monitoring and failover

Performance SLA link monitoring measures the health of links that are connected to SD-WAN member interfaces by sending probing signals through each link to a server, and then measuring the link quality based on latency, jitter, and

packet loss. If a link is broken, the routes on that link are removed and traffic is routed through other links. When the link is working again, the routes are re-enabled. This prevents traffic being sent to a broken link and lost.

In this example, the detection server IP address is 208.91.112.53. A performance SLA is created so that, if ping fails per the metrics defined, the routes to that interface are removed and traffic is detoured to the other interface. The ping protocol is used, but other protocols could also be selected as required.

To configure a performance SLA:

1. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Enter a name for the SLA and set *Protocol* to *Ping*.
3. In the *Server* field, enter the detection server IP address (208.91.112.53 in this example).
4. In the *Participants* field, select *Specify* and add wan1 and wan2.

The screenshot shows the 'New Performance SLA' configuration window. The 'Name' field is set to 'server'. The 'Detection Mode' is set to 'Active'. The 'Protocol' is set to 'Ping'. The 'Server' field contains the IP address '208.91.112.53'. Under 'Participants', 'All SD-WAN Members' is selected, and 'Specify' is chosen, with two entries: 'to_ISP1 (wan1)' and 'to_ISP2 (wan2)'. The 'Enable probe packets' checkbox is checked. The 'SLA Target' checkbox is unchecked. Under 'Link Status', 'Check interval' is 500 ms, 'Failures before inactive' is 5, and 'Restore link after' is 5 check(s). Under 'Actions when Inactive', 'Update static route' is checked. The 'Additional Information' section on the right includes links for 'API Preview', 'Edit in CLI', 'Performance SLA Setup Guides', 'Link Monitoring', 'SLA Targets', 'Documentation', 'Online Help', and 'Video Tutorials'. 'OK' and 'Cancel' buttons are at the bottom.

SLA targets are not required for link monitoring.

5. Configure the required metrics in *Link Status*.
6. Ensure that *Update static route* is enabled. This disables static routes for the inactive interface and restores routes on recovery.
7. Click *OK*.

Results

The following GUI pages show the function of the SD-WAN and can be used to confirm that it is setup and running correctly:

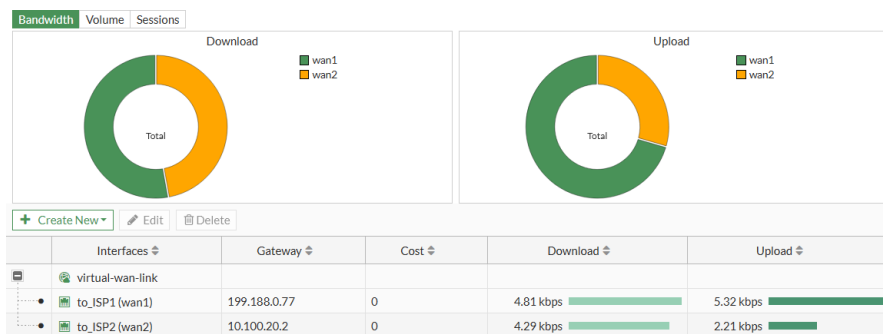

- [Interface usage on page 613](#)
- [Performance SLA on page 614](#)
- [Routing table on page 615](#)
- [Firewall policy on page 616](#)

Interface usage

Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab to review the SD-WAN interfaces' usage.

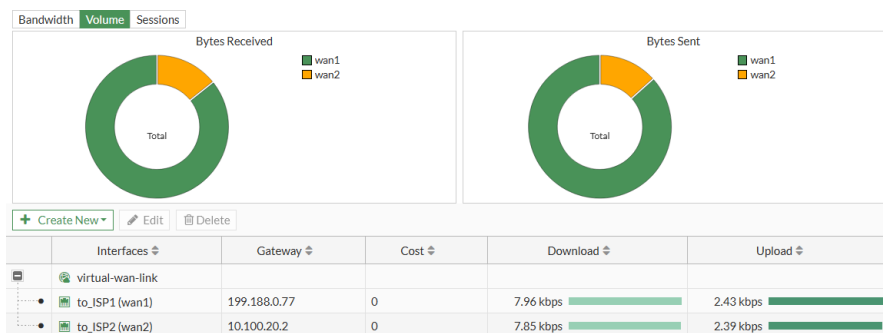

Bandwidth

Select *Bandwidth* to view the amount of downloaded and uploaded data for each interface.

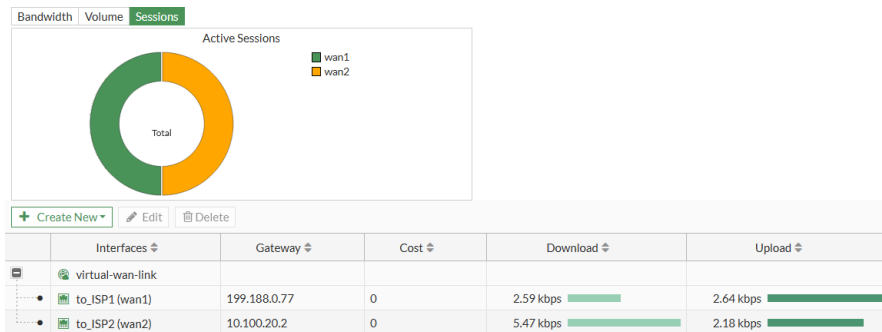

Volume

Select *Volume* to see donut charts of the received and sent bytes on the interfaces.

Sessions

Select **Sessions** to see a donut chart of the number of active sessions on each interface.

Performance SLA

Go to **Network > SD-WAN**, select the **Performance SLAs** tab, and select the SLA from the table (*server* in this example) to view the packet loss, latency, and jitter on each SD-WAN member in the health check server.

Packet loss

Select **Packet Loss** to see the percentage of packets lost for each member.

Latency

Select *Latency* to see the current latency, in milliseconds, for each member.

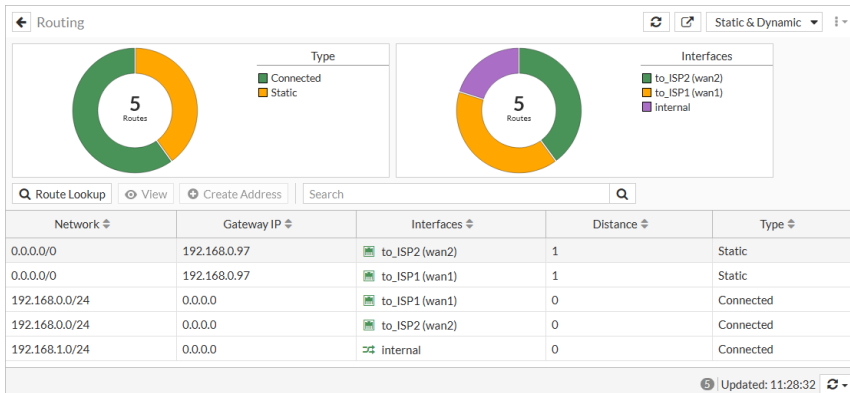

Jitter

Select *Jitter* to see the jitter, in milliseconds, for each member.

Routing table

Go to *Dashboard > Network*, expand the *Routing* widget, and select *Static & Dynamic* to review all static and dynamic routes. For more information about the widget, see [Static & Dynamic Routing monitor on page 96](#).

Firewall policy

Go to *Policy & Objects > Firewall Policy* to review the SD-WAN policy.

Name	Source	Destination	Schedule	Service	Action	NAT	Security Profiles	Log	Bytes
sd-wan	all	all	always	ALL	ACCEPT	Enabled	no-inspection	All	59.19 MB
Implicit Deny	all	all	always	ALL	DENY	Disabled			1.27 kB

Configuring SD-WAN in the CLI

This example can be entirely configured using the CLI.

To configure SD-WAN in the CLI:

1. Configure the wan1 and wan2 interfaces:

```
config system interface
  edit "wan1"
    set alias to_ISP1
    set mode dhcp
    set distance 10
  next
  edit "wan2"
    set alias to_ISP2
    set ip 10.100.20.1 255.255.255.0
  next
end
```

2. Enable SD-WAN and add the interfaces as members:

```
config system sdwan
  set status enable
  config members
    edit 1
      set interface "wan1"
    next
    edit 2
      set interface "wan2"
      set gateway 10.100.20.2
    next
  end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

3. Create a static route for SD-WAN:

```
config router static
  edit 1
    set sdwan-zone "virtual-wan-link"
  next
end
```

4. Select the implicit SD-WAN algorithm:

```
config system sdwan
  set load-balance-mode {source-ip-based | weight-based | source-dest-ip-based |
measured-volume-based}
end
```

5. Create a firewall policy for SD-WAN:

```
config firewall policy
  edit <policy_id>
    set name <policy_name>
    set srcintf "internal"
    set dstintf "virtual-wan-link"
    set srcaddr all
    set dstaddr all
    set action accept
    set schedule always
    set service ALL
    set utm-status enable
    set ssl-ssh-profile <profile_name>
    set av-profile <profile_name>
    set webfilter-profile <profile_name>
    set dnsfilter-profile <profile_name>
    set emailfilter-profile <profile_name>
    set ips_sensor <sensor_name>
    set application-list <app_list>
    set voip-profile <profile_name>
    set logtraffic all
    set nat enable
    set status enable
  next
end
```

6. Configure a performance SLA:

```
config system sdwan
  config health-check
    edit "server"
      set server "208.91.112.53"
      set update-static-route enable
      set members 1 2
    next
  end
end
```

Results

To view the routing table:

```
# get router info routing-table all

Routing table for VRF=0
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

S*      0.0.0.0/0 [1/0] via 172.16.20.2, wan1
         [1/0] via 10.100.20.2, wan2
C       10.100.20.0/24 is directly connected, wan2
C       172.16.20.2/24 is directly connected, wan1
C       192.168.0.0/24 is directly connected, internal
```

To diagnose the Performance SLA status:

```
FGT # diagnose sys sdwan health-check
Health Check(server):
Seq(1): state(alive), packet-loss(0.000%) latency(15.247), jitter(5.231) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(13.621), jitter(6.905) sla_map=0x0
```

SD-WAN members and zones

SD-WAN bundles interfaces together into zones. Interfaces are first configured as SD-WAN members. This does not change the interface, it just allows SD-WAN to reference the interface as a member. SD-WAN member interfaces can be any interface supported by FortiGates, such as physical ports, VLAN interfaces, LAGs, IPsec tunnels, GRE tunnels, IPsec tunnels, and FortiExtender interfaces. Once SD-WAN members are configured, they can be assigned to a zone. Zones are used in policies as source and destination interfaces, in static routes, and in SD-WAN rules.

Multiple zones can be used to group SD-WAN interfaces for logical scenarios, such as overlay and underlay interfaces. Using multiple zones in policies allows for more granular control over functions like resource access and UTM access. Individual SD-WAN member interfaces cannot be used directly in policies, but they can be moved between SD-WAN zones at any time. If a member interface requires a special SD-WAN consideration, it can be put into an SD-WAN zone by itself.

SD-WAN zones and members can be used in IPv4 and IPv6 static routes to make route configurations more flexible. SD-WAN zones and members can be used in SD-WAN rules to simplify the rule configuration. See [Specify an SD-WAN zone in static routes and SD-WAN rules on page 624](#) for more information.

When the Security Fabric is configured, SD-WAN zones are included in the Security Fabric topology views.

Topology

This topology is used in the following procedures:

- [Configuring SD-WAN member interfaces](#)
- [Configuring SD-WAN zones](#)
- [Using SD-WAN zones](#)

Configuring SD-WAN member interfaces

When configuring SD-WAN zones and members, it does not matter what order they are defined. In this example, the members are defined first, and they will be placed temporarily in the default zone called virtual-wan-link. A zone must be defined when creating a member, and the overlay and underlay zones will be created in the next procedure. It is standard practice to create SD-WAN members for each underlay and overlay interface, as most SD-WAN implementations apply SD-WAN intelligence to both underlay and overlay networks.

The following options can be configured for SD-WAN members:

GUI option	CLI option	Description
<i>Interface</i>	<code>interface</code>	Select the interface to use as an SD-WAN member. Optionally, select <i>None</i> in the GUI to not use an interface yet.
<i>SD-WAN Zone</i>	<code>zone</code>	Select the destination zone if it exists at the time of member creation. Otherwise, the default virtual-wan-link zone is applied. A new zone can be created within the GUI dropdown field.

GUI option	CLI option	Description
Gateway/IPv6 Gateway	gateway/gateway6	Enter the default gateway for the interface. For interfaces that already have a default gateway, such as those configured using DHCP, this field is pre-populated in the GUI.
Cost	cost	Enter the cost of the interface for services in SLA mode (0 - 4294967295, default = 0). A lower cost has a higher preference.
Priority	priority	Enter the priority of the interface for IPv4 (1 - 65535, default = 1). The priority is used in the static route created for the SD-WAN member interface and in SD-WAN rules (including the implicit rule). When priority is used to determine the best route, the lower value takes precedence.
Status	status	Enable or disable the interface in SD-WAN.
n/a	source/source6	Set the source IP address used in the health check packet to the server.

To configure the SD-WAN members and add them to the default zone in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
2. Set the *Interface* to *WAN1*.
3. Leave the *SD-WAN Zone* as *virtual-wan-link*.

4. Click *OK*.
5. Repeat these steps to create SD-WAN members for the *WAN2*, *VPN1*, and *VPN2* interfaces.

To configure the SD-WAN members and add them to the default zone in the CLI:

```
config system sdwan
  config members
    edit 1
      set interface "WAN1"
      set zone "virtual-wan-link"
    next
    edit 2
      set interface "WAN2"
```

```

        set zone "virtual-wan-link"
    next
    edit 3
        set interface "VPN1"
        set zone "virtual-wan-link"
    next
    edit 4
        set interface "VPN2"
        set zone "virtual-wan-link"
    next
end
end

```

In the `config zone` settings, there is a `service-sla-tie-break` parameter that includes two options for the tie-break method used when multiple interfaces in a zone are eligible for traffic:

- `cfg-order`: members that meet the SLA are selected in the order they are configured (default).
- `fib-best-match`: members that meet the SLA are selected that match the longest prefix in the routing table.

Configuring SD-WAN zones

While SD-WAN zones are primarily used to logically group interfaces that are often used for the same purpose (such as WAN1 and WAN2), sometimes an SD-WAN zone can have a single member. This is due to the constraint that SD-WAN members may not be referenced directly in policies; however, SD-WAN members can be referenced directly in SD-WAN rules.

In this example, two zones named *Overlay* and *Underlay* are configured, and the member interfaces are added to their respective zones.

To configure the SD-WAN zones in the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab.
2. Click *Create New > SD-WAN Zone*.
3. Enter the *Name*, *Underlay*.
4. Set the *Interface members* to *WAN1* and *WAN2*.

5. Click *OK*.
6. Repeat these steps to configure the *Overlay* zone with members *VPN1* and *VPN2*.

To configure the SD-WAN zones in the CLI:

1. Configure the SD-WAN zones:

```
config system sdwan
  config zone
    edit "Overlay"
    next
    edit "Underlay"
    next
  end
end
```

2. Add the member interfaces to their respective zones:

```
config system sdwan
  config members
    edit 1
      set interface WAN1
      set zone "Underlay"
    next
    edit 2
      set interface WAN2
      set zone "Underlay"
    next
    edit 3
      set interface VPN1
      set zone "Overlay"
    next
    edit 4
      set interface VPN2
      set zone "Overlay"
    next
  end
end
```

Using SD-WAN zones

Once SD-WAN zones are defined, they can be used in firewall policies. This section covers three policy scenarios:

- [Datacenter resource access](#)
- [Direct internet access](#)
- [Remote internet access](#)

SD-WAN zones are a critical component of SD-WAN rules. See [Fields for configuring WAN intelligence on page 655](#) for more information.

Datacenter resource access

Datacenter resources are made available through the VPN branches or overlay. In this example, there are two SD-WAN members in the overlay zone that the branch FortiGate can use to route traffic to and from the datacenter resource. The

overlay zone is used as the destination in the firewall policy.

To configure the firewall policy:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	<i>DC_Access</i>
Incoming Interface	<i>LAN</i>
Outgoing Interface	<i>Overlay</i>
Source	<i>Branch_LAN</i>
Destination	<i>DC_LAN</i>
Action	<i>ACCEPT</i>

3. Configure the other settings as needed.
4. Click *OK*.

This firewall policy allows traffic to any interfaces included in the zone. The SD-WAN rules contain the intelligence used to select which members in the zone to use.

Direct internet access

Direct internet access (DIA) is how a branch may access resources contained on the public internet. This can be non-business resources (such as video streaming sites), or publically available business resources (such as vendor portals).

To configure the firewall policy:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	<i>DIA</i>
Incoming Interface	<i>LAN</i>
Outgoing Interface	<i>Underlay</i>
Source	<i>Branch_LAN</i>
Destination	<i>all</i>
Action	<i>ACCEPT</i>

3. Configure the other settings as needed.
4. Click *OK*.

Remote internet access

Remote internet access (RIA) is the ability for a branch location to route public internet access requests across the overlay and out one of the hub's (or datacenter's) WAN interfaces. This option is effective when a branch has a WAN circuit with a local ISP and a second circuit that is private, such as MPLS. When the WAN circuit goes down, it is possible to send traffic through the hub using the MPLS overlay.

To configure the firewall policy:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	<i>RIA</i>
Incoming Interface	<i>LAN</i>
Outgoing Interface	<i>Overlay</i>
Source	<i>Branch_LAN</i>
Destination	<i>all</i>
Action	<i>ACCEPT</i>

3. Configure the other settings as needed.
4. Click *OK*.

Specify an SD-WAN zone in static routes and SD-WAN rules

SD-WAN zones can be used in IPv4 and IPv6 static routes, and in SD-WAN service rules. This makes route configuration more flexible, and simplifies SD-WAN rule configuration.

To configure an SD-WAN zone in a static route in the GUI:

1. Go to *Network > Static Routes*
2. Edit an existing static route, or click *Create New* to create a new route.
3. Set *Interface* to one or more SD-WAN zones.

The screenshot shows the 'New Static Route' configuration window in FortiOS. The 'Destination' is set to 'Subnet' with the value '0.0.0.0/0.0.0.0'. The 'Interface' field is populated with 'virtual-wan-link' and 'vpn-zone'. The 'Status' is set to 'Enabled'. A 'Select Entries' dialog is open, showing a list of interfaces including 'virtual-wan-link', 'port1 (wan1)', 'port4 (wan2)', and 'dmz'.

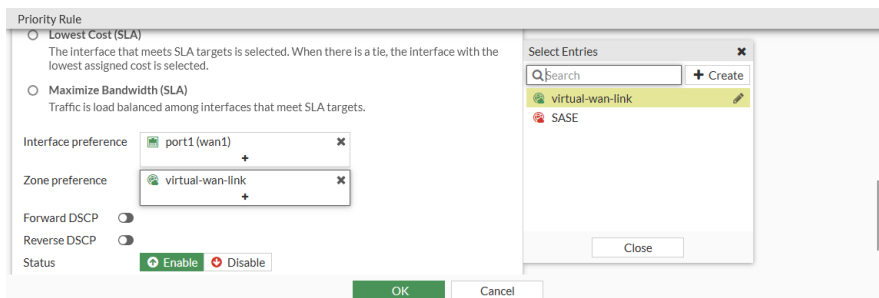

4. Configure the remaining settings are required.
5. Click **OK**.

To configure an SD-WAN zone in a static route in the CLI:

```
config router {static | static6}
  edit 1
    set sdwan-zone <zone> <zone> ...
  next
end
```

To configure an SD-WAN zone in an SD-WAN rule in the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab
2. Edit an existing rule, or click *Create New* to create a new rule.
3. In the *Zone preference* field add one or more SD-WAN zones.

4. Configure the remaining settings are needed.
5. Click **OK**.

To configure an SD-WAN zone in an SD-WAN rule in the CLI:

```
config system sdwan
  config service
    edit 1
      set priority-zone <zone>
    next
  end
end
```

Examples

In these two examples, three SD-WAN members are created. Two members, port13 and port15, are in the default zone (*virtual-wan-link*), and the third member, to_FG_B_root, is in the *SASE* zone.

Example 1

In this example:

- Two service rules are created. Rule 1 uses the *virtual-wan-link* zone, and rule 2 uses the *SASE* zone.
- Two IPv4 static routes are created. The first route uses the *virtual-wan-link* zone, and the second route uses the *SASE* zone.

To configure the SD-WAN:

1. Assign port13 and port15 to the *virtual-wan-link* zone and to *_FG_B_root* to the *SASE* zone:

```
config system sdwan
  set status enable
  config members
    edit 1
      set interface "port13"
      set zone "virtual-wan-link"
      set gateway 10.100.1.1
    next
    edit 2
      set interface "port15"
      set zone "virtual-wan-link"
      set gateway 10.100.1.5
    next
    edit 3
      set interface "to_FG_B_root"
      set zone "SASE"
    next
  end
end
```

2. Create two service rules, one for each SD-WAN zone:

```
config system sdwan
  config service
    edit 1
      set dst "10.100.20.0"
      set priority-zone "virtual-wan-link"
    next
    edit 2
```

```

        set internet-service enable
        set internet-service-name "Fortinet-FortiGuard"
        set priority-zone "SASE"
    next
end
end

```

3. Configure static routes for each of the SD-WAN zones:

```

config router static
  edit 1
    set distance 1
    set sdwan-zone "virtual-wan-link"
  next
  edit 2
    set dst 172.16.109.0 255.255.255.0
    set distance 1
    set sdwan-zone "SASE"
  next
end

```

To verify the results:

1. Check the service rule 1 diagnostics:

```

# diagnose sys sdwan service 1

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members(2):
  1: Seq_num(1 port13), alive, selected
  2: Seq_num(2 port15), alive, selected
Dst address(1):
  10.100.20.0-10.100.20.255

```

Both members of the *virtual-wan-link* zone are selected. In manual mode, the interface members are selected based on the member configuration order. In SLA and priority mode, the order depends on the link status. If all of the link statuses pass, then the members are selected based on the member configuration order.

2. Check the service rule 2 diagnostics:

```

# diagnose sys sdwan service 2

Service(2): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members(1):
  1: Seq_num(3 to_FG_B_root), alive, selected
Internet Service(1): Fortinet-FortiGuard(1245324,0,0,0)

```

The member of the *SASE* zone is selected.

3. Review the routing table:

```

# get router info routing-table static
Routing table for VRF=0
S*   0.0.0.0/0 [1/0] via 10.100.1.1, port13
      [1/0] via 10.100.1.5, port15
S    172.16.109.0/24 [1/0] via 172.16.206.2, to_FG_B_root

```

The default gateway has the members from the *virtual-wan-link* zone, and the route to 172.16.10.9.0/24 has the single member from the *SASE* zone.

Example 2

In this example, two IPv6 static routes are created. The first route uses the *virtual-wan-link* zone, and the second route uses the *SASE* zone.

To configure the SD-WAN:

1. Configure port13 and port15 with IPv6 addresses and assign them to the *virtual-wan-link* zone, and assign to_FG_B_root to the *SASE* zone:

```
config system sdwan
  set status enable
  config members
    edit 1
      set interface "port13"
      set zone "virtual-wan-link"
      set gateway6 2004:10:100:1::1
      set source6 2004:10:100:1::2
    next
    edit 2
      set interface "port15"
      set zone "virtual-wan-link"
      set gateway6 2004:10:100:1::5
      set source6 2004:10:100:1::6
    next
    edit 3
      set interface "to_FG_B_root"
      set zone "SASE"
    next
  end
end
```

2. Configure IPv6 static routes for each of the SD-WAN zones:

```
config router static6
  edit 1
    set distance 1
    set sdwan-zone "virtual-wan-link"
  next
  edit 2
    set dst 2003:172:16:109::/64
    set distance 1
    set sdwan-zone "SASE"
  next
end
```

To verify the results:

1. Review the routing table:

```
# get router info6 routing-table static
Routing table for VRF=0
S*      ::/0 [1/0] via 2004:10:100:1::1, port13, 00:20:51, [1024/0]
```

```
[1/0] via 2004:10:100:1::5, port15, 00:20:51, [1024/0]
S    2003:172:16:109::/64 [1/0] via ::ac10:ce02, to_FG_B_root, 00:20:51, [1024/0]
S    2003:172:16:209::/64 [5/0] via ::ac10:ce02, to_FG_B_root, 14:40:14, [1024/0]
```

The IPv6 default route includes the members from the *virtual-wan-link* zone, and the route to 2003:172:16:109::/64 has the single member from the *SASE* zone.

Performance SLA

Performance SLAs are used to measure the health of links that are connected to SD-WAN member interfaces by either sending probing signals through each link to a server, or using session information that is captured by firewall policies (see [Passive WAN health measurement on page 640](#) for information), and measuring the link quality based on latency, jitter, and packet loss. If a link fails all of the health checks, the routes on that link are removed from the SD-WAN link load balancing group, and traffic is routed through other links. When the link passes SLA, the routes are reestablished. This prevents traffic from being sent to a broken link and getting lost.

The following topics provide instructions on configuring performance SLA:

- [Performance SLA overview on page 629](#)
- [Link health monitor on page 634](#)
- [Monitoring performance SLA on page 636](#)
- [Passive WAN health measurement on page 640](#)
- [Passive health-check measurement by internet service and application on page 646](#)

Performance SLA overview

Performance SLAs consist of three parts:

- [Health checks](#)
- [SLA targets](#)
- [Link status](#)

Health checks

A health check is defined by a [probe mode](#), [protocol](#), and [server](#). These three options specify what resource is being evaluated and how the evaluation is done. Each health check should be configured specifically for that resource, so the probe mode, protocol and server should be tailored for the particular service. For example, the health check for a VoIP service will differ than one for a database replication service.

Performance SLA participants are the interfaces that will be evaluated for a given health check. They must be SD-WAN member interfaces, but do not have to belong to the same zone. When selecting participants, only select participants that you expect the service communications to use. For example, a health check for a corporate resource might only use the overlay to access the service. Therefore, you would only add the VPN interfaces as participants.

There are six predefined performance SLA profiles for newly created VDOMs or factory reset FortiGate devices: AWS, DNS, FortiGuard, Gmail, Google Search, and Office 365. These performance SLA profiles provide Fortinet recommended settings for common services. To complete the performance SLA configuration, add the participants for the service. You can adjust the default settings to suit your needs.

Probe mode

The probe mode can be set to active, passive, or prefer passive.

In active mode, the FortiGate sends a packet of the type specified by the protocol setting towards the defined server. This allows you to evaluate the path to the destination server using the protocol that matches the service provided by the server. Active probing does add some overhead in the form of health check probes (and additional configurations to define the probe type and server), but it has the benefit of constantly measuring the performance of the path to the server. This can be beneficial when reviewing historical data.

In passive mode, session information captured by firewall policies is used to determine latency, jitter, and packet loss. This has the added benefit of not generating additional traffic, and does not require the performance SLA to define a specific server for measurement. Instead, the SD-WAN rule must define the traffic to evaluate, and the firewall policy permitting the traffic must have a setting enabled. See [Passive WAN health measurement on page 640](#) and [Passive health-check measurement by internet service and application on page 646](#) for more information.

Prefer passive mode is a combination of active and passive modes. Health is measured using traffic when there is traffic, and using probes when there is no traffic. A protocol and server must be configured.

Protocol

Health checks support a variety of protocols and protocol specific options. The most commonly used protocols (ping, HTTP, and DNS) can be configured in the GUI when creating a new performance SLA on the *Network > SD-WAN > Performance SLAs* page. The following protocols and options can be configured in the CLI using the `set protocol <option>` parameter:

ping	Use PING to test the link with the server.
tcp-echo	Use TCP echo to test the link with the server.
udp-echo	Use UDP echo to test the link with the server.
http	Use HTTP-GET to test the link with the server.
twamp	Use TWAMP to test the link with the server.
dns	Use DNS query to test the link with the server. The FortiGate sends a DNS query for an A Record and the response matches the expected IP address.
tcp-connect	Use a full TCP connection to test the link with the server. The method to measure the quality of the TCP connection can be: <ul style="list-style-type: none"> <code>half-open</code>: FortiGate sends SYN and gets SYN-ACK. The latency is based on the round trip between SYN and SYN-ACK (default). <code>half-close</code>: FortiGate sends FIN and gets FIN-ACK. The latency is based on the round trip between FIN and FIN-ACK.
ftp	Use FTP to test the link with the server. The FTP mode can be: <ul style="list-style-type: none"> <code>passive</code>: The FTP health-check initiates and establishes the data connection (default). <code>port</code>: The FTP server initiates and establishes the data connection.

SD-WAN health checks can generate traffic that becomes quite high as deployments grow. Take this into consideration when setting DoS policy thresholds. For details on setting DoS policy thresholds, refer to [DoS protection on page 900](#).

To use UDP-echo and TCP-echo as health checks:

```
config system sdwan
  set status enable
  config health-check
    edit "h4_udp1"
      set protocol udp-echo
      set port 7
      set server <server>
    next
    edit "h4_tcp1"
      set protocol tcp-echo
      set port 7
      set server <server>
    next
    edit "h6_udp1"
      set addr-mode ipv6
      set server "2032::12"
      set protocol udp-echo
      set port 7
    next
  end
end
```

To use DNS as a health check, and define the IP address that the response must match:

```
config system sdwan
  set status enable
  config health-check
    edit "h4_dns1"
      set protocol dns
      set dns-request-domain "ip41.forti2.com"
      set dns-match-ip 1.1.1.1
    next
    edit "h6_dns1"
      set addr-mode ipv6
      set server "2000::15.1.1.4"
      set protocol dns
      set port 53
      set dns-request-domain "ip61.xxx.com"
    next
  end
end
```

To use TCP Open (SYN/SYN-ACK) and TCP Close (FIN/FIN-ACK) to verify connections:

```
config system sdwan
  set status enable
  config health-check
    edit "h4_tcpconnect1"
```

```

        set protocol tcp-connect
        set port 443
        set quality-measured-method {half-open | half-close}
        set server <server>
    next
    edit "h6_tcpconnect1"
        set addr-mode ipv6
        set server "2032::13"
        set protocol tcp-connect
        set port 444
        set quality-measured-method {half-open | half-close}
    next
end
end

```

To use active or passive mode FTP to verify connections:

```

config system sdwan
    set status enable
    config health-check
        edit "h4_ftpl"
            set protocol ftp
            set port 21
            set user "root"
            set password *****
            set ftp-mode {passive | port}
            set ftp-file "1.txt"
            set server <server>
        next
        edit "h6_ftpl"
            set addr-mode ipv6
            set server "2032::11"
            set protocol ftp
            set port 21
            set user "root"
            set password *****
            set ftp-mode {passive | port}
            set ftp-file "2.txt"
        next
    end
end
end

```

Health check probe packets support DSCP markers for accurate link performance evaluation for high priority applications. This allows the probe packet to match the real traffic it is providing measurements for, including how that traffic is shaped by upstream devices based on the DSCP markers.

To mark health check packets with DSCP:

```

config system sdwan
    config health-check
        edit <name>
            set diffservcode <6-bits_binary, 000000-111111>
            set protocol <option>
        next
    end
end
end

```

Server

An IP address or FQDN can be defined as the server that the probe packets will be sent to. Up to two servers can be defined this way. When two servers are provided, both must fail in order for the health check to fail. This is to avoid a scenario where one remote server is down and causes a false positive that the link is down. The FortiGate can still use the interface associated with this health check to reach the remaining healthy server.

The purpose of the server is not simply to measure the health of the link, but rather the health of the path to a resource. It is highly recommended to use an IP address or FQDN that reflects the resource so the traffic path is considered.

A server can only be used in one performance SLA at any given time.

SLA targets

SLA targets are a set of constraints that are used in SD-WAN rules to control the paths that traffic takes. The constraints are:

- Latency threshold: latency for SLA to make a decision, in milliseconds (0 - 10000000, default = 5).
- Jitter threshold: jitter for SLA to make a decision, in milliseconds (0 - 10000000, default = 5).
- Packet loss threshold: packet loss for SLA to make a decision, in percentage (0 - 100, default = 0).

These settings should be specific to the service whose performance is being considered. You should attempt to configure the constraints to be just under the maximum values for the application or service to function well. For example, if your application requires less than 100 ms latency, then you should configure the SLA target to be 90 ms. Misconfiguring these settings will cause the performance SLA to lose value. If the values are too tight, then you may have traffic flipping between links before necessary. If the values are too loose, then performance may be impacted and the FortiGate will do nothing about it.

In the GUI, one SLA target can be configured, but additional targets can be configured in the CLI. Once a second target is configured in the CLI, additional targets can be configured from the GUI. Multiple SLA targets can be configured where a server provides multiple services that have different values for acceptable performance. For example, Google provides a DNS service and entertainment services (YouTube), so it is necessary to configure multiple SLA targets in this case since you can only configure a server in one performance SLA.

Link status

The *Link Status* section of the performance SLA configuration consists of three settings that determine the frequency that the link is evaluated, and the requirements to be considered valid or invalid:

- *Check interval*: the interval in which the FortiGate checks the interface, in milliseconds (500 - 3600000, default = 500).
- *Failures before inactive*: the number of failed status checks before the interface shows as inactive (1 - 3600, default = 5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links.
- *Restore link after*: the number of successful status checks before the interface shows as active (1 - 3600, default = 5). This setting also helps prevent flapping.

When a participant becomes inactive, the performance SLA causes the FortiGate to withdraw all static routes associated with that interface. If there are multiple static routes using the same interface, they will all be withdrawn when the link monitor is failing.

Link health monitor

Performance SLA link health monitoring measures the health of links that are connected to SD-WAN member interfaces by either sending probing signals through each link to a server, or using session information that is captured on firewall policies (see [Passive WAN health measurement on page 640](#) for information), and measuring the link quality based on latency, jitter, and packet loss. If a link fails all of the health checks, the routes on that link are removed from the SD-WAN link load balancing group, and traffic is routed through other links. When the link is working again the routes are reestablished. This prevents traffic being sent to a broken link and lost.

When an SD-WAN member has multiple health checks configured, all of the checks must fail for the routes on that link to be removed from the SD-WAN link load balancing group.

Two health check servers can be configured to ensure that, if there is a connectivity issue, the interface is at fault and not the server. A server can only be used in one health check.

The FortiGate uses the first server configured in the health check server list to perform the health check. If the first server is unavailable, then the second server is used. The second server continues to be used until it becomes unavailable, and then the FortiGate returns to the first server, if it is available. If both servers are unavailable, then the health check fails.

You can configure the protocol that is used for status checks, including: Ping, HTTP, DNS, TCP echo, UDP echo, two-way active measurement protocol (TWAMP), TCP connect, and FTP. In the GUI, only Ping, HTTP, and DNS are available.

You can view link quality measurements by going to *Network > SD-WAN* and selecting the *Performance SLAs* tab. The table shows the default health checks, the health checks that you configured, and information about each health check. The values shown in the *Packet Loss*, *Latency*, and *Jitter* columns are for the health check server that the FortiGate is currently using. The green up arrows indicate that the server is responding, and does not indicate if the health checks are being met. See [Results on page 613](#) for more information.

To configure a link health monitor in the GUI:

1. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Set a *Name* for the SLA.
3. Set the *Protocol* that you need to use for status checks: *Ping*, *HTTP*, or *DNS*.
4. Set *Server* to the IP addresses of up to two servers that all of the SD-WAN members in the performance SLA can reach.
5. Set *Participants* to *All SD-WAN Members*, or select *Specify* to choose specific SD-WAN members.
6. Set *Enable probe packets* to enable or disable sending probe packets.
7. Configure *SLA Target*:

If the health check is used in an SD-WAN rule that uses *Manual* or *Best Quality* strategies, enabling *SLA Target* is optional. If the health check is used in an SD-WAN rule that uses *Lowest Cost (SLA)* or *Maximum Bandwidth (SLA)* strategies, then *SLA Target* is enabled.

When *SLA Target* is enabled, configure the following:

- *Latency threshold*: Calculated based on last 30 probes (default = 5ms).
- *Jitter threshold*: Calculated based on last 30 probes (default = 5ms).
- *Packet Loss threshold*: Calculated based on last 100 probes (default = 0%).

8. In the *Link Status* section configure the following:

- *Check interval*: The interval in which the FortiGate checks the interface, in milliseconds (500 - 3600000, default = 500).
- *Failures before inactive*: The number of failed status checks before the interface shows as inactive (1 - 3600, default =5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links
- *Restore link after*: The number of successful status checks before the interface shows as active (1 - 3600, default = 5). This setting helps prevent flapping, where the system continuously transfers traffic back and forth between links

9. In the *Actions when Inactive* section, enable *Update static route* to disable static routes for inactive interfaces and restore routes when interfaces recover.

10. Click *OK*.

To configure a link health monitor in the CLI:

```
config system sdwan
  config health-check
    edit "PingSLA"
      set addr-mode {ipv4 | ipv6}
      set server <server1_IP_address> <server2_IP_address>
      set detect-mode {active | passive | prefer-passive}
      set protocol {ping | tcp-echo | udp-echo | http | twamp | dns | tcp-connect |
ftp}

      set ha-priority <integer>
      set probe-timeout <integer>
      set probe-count <integer>
      set probe-packets {enable | disable}
      set interval <integer>
      set failtime <integer>
      set recoverytime <integer>
      set diffservcode <binary>
      set update-static-route {enable | disable}
      set update-cascade-interface {enable | disable}
      set sla-fail-log-period <integer>
      set sla-pass-log-period <integer>
      set threshold-warning-packetloss <integer>
```

```

set threshold-alert-packetloss <integer>
set threshold-warning-latency <integer>
set threshold-alert-latency <integer>
set threshold-warning-jitter <integer>
set threshold-alert-jitter <integer>
set members <member_number> ... <member_number>
config sla
  edit 1
    set link-cost-factor {latency jitter packet-loss}
    set latency-threshold <integer>
    set jitter-threshold <integer>
    set packetloss-threshold <integer>
  next
end
next
end
end

```

Additional settings are available for some of the protocols:

Protocol	Additional options
http	port <port_number> http-get <url> http-match <response_string>
twamp	port <port_number> security mode {none authentication} password <password> packet-size <size>
ftp	ftp {passive port} ftp-file <path>

For more examples see [Protocol](#).

Monitoring performance SLA

SD-WAN diagnostics can be used to help maintain your SD-WAN solution.

Monitoring SD-WAN link quality status

Link quality plays a significant role in link selection for SD-WAN. Investigate any prolonged issues with packet loss, latency, or jitter to ensure that your network does not experience degraded performance or an outage.

You can monitor the link quality status of SD-WAN interface members by going to *Network > SD-WAN* and selecting the *Performance SLAs* tab.

The live charts show the packet loss, latency, or jitter for the selected health check. Hover the cursor over a line in the chart to see the specific value for that interface at that specific time.

The table shows information about each health check, including the configured servers, link quality data, and thresholds. The colored arrow indicates the status of the interface when the last status check was performed: green means that the interface was active, and red means that the interface was inactive. Hover the cursor over the arrow for additional information.

Monitoring system event logs

The features adds an SD-WAN daemon function to keep a short, 10 minute history of SLA that can be viewed in the CLI.

Performance SLA results related to interface selection, session failover, and other information, can be logged. These logs can then be used for long-term monitoring of traffic issues at remote sites, and for reports and views in FortiAnalyzer.

The time intervals that Performance SLA fail and pass logs are generated in can be configured.

To configure the fail and pass logs' generation time interval:

```
config system sdwan
    config health-check
        edit "PingSLA"
            set sla-fail-log-period 30
            set sla-pass-log-period 60
        next
    end
end
```

To view the 10 minute Performance SLA link status history:

```
FGDocs # diagnose sys sdwan sla-log PingSLA 1
Timestamp: Fri Sep  4 10:32:37 2020, vdom root, health-check PingSLA, interface: wan2,
status: up, latency: 4.455, jitter: 0.430, packet loss: 0.000%.
Timestamp: Fri Sep  4 10:32:37 2020, vdom root, health-check PingSLA, interface: wan2,
status: up, latency: 4.461, jitter: 0.436, packet loss: 0.000%.
Timestamp: Fri Sep  4 10:32:38 2020, vdom root, health-check PingSLA, interface: wan2,
status: up, latency: 4.488, jitter: 0.415, packet loss: 0.000%.
...
Timestamp: Fri Sep  4 10:42:36 2020, vdom root, health-check PingSLA, interface: wan2,
status: up, latency: 6.280, jitter: 0.302, packet loss: 0.000%.
```

Timestamp: Fri Sep 4 10:42:37 2020, vdom root, health-check PingSLA, interface: wan2, status: up, latency: 6.261, jitter: 0.257, packet loss: 0.000%.
 Timestamp: Fri Sep 4 10:42:37 2020, vdom root, health-check PingSLA, interface: wan2, status: up, latency: 6.229, jitter: 0.245, packet loss: 0.000%.

SLA pass logs

The FortiGate generates Performance SLA logs at the specified pass log interval (sla-pass-log-period) when SLA passes.

```

Monitoring using the REST API

SLA log and interface information can be monitored using the REST API. This feature is also used by FortiManager as part of its detailed SLA monitoring and drilldown features.

API call	URL
Interface log	https://172.172.172.9/api/v2/monitor/virtual-wan/interface-log
SLA log	https://172.172.172.9/api/v2/monitor/virtual-wan/sla-log
Health check log	https://172.172.172.9/api/v2/monitor/virtual-wan/health-check

A comprehensive list of API calls with sample output is available on the [Fortinet Developer Network](#).

CLI diagnose commands:

```
# diagnose sys sdwan intf-sla-log port13
  Timestamp: Wed Jan 9 18:33:49 2019, used inbandwidth: 3208bps, used outbandwidth:
3453bps, used bibandwidth: 6661bps, tx bytes: 947234bytes, rx bytes: 898622bytes.

Passive WAN health measurement

SD-WAN passive WAN health measurement determines the health check measurements (jitter, latency, and packet loss) using session information captured from the firewall policies that have *Passive Health Check* (`passive-wan-health-measurement`) enabled. Passive measurements analyze session information that is gathered from various TCP sessions can be viewed using the command `diagnose sys link-monitor-passive admin list by-interface`.

Using passive WAN health measurement reduces the amount of configuration required and decreases the traffic that is produced by health check monitor probes doing active measurements. Passive WAN health measurement analyzes real-life traffic; active WAN health measurement using a detection server might not reflect the real-life traffic.

By default, active WAN health measurement is enabled when a new health check is created. It can be changed to passive or prefer passive:

passive

Health is measured using live traffic passing through an SD-WAN link to determine link metrics (jitter, latency, and packet loss) of participating SD-WAN links. No link health monitor needs to be configured.

prefer-passive

Health is measured using live traffic when there is traffic passing through an SD-WAN link to determine link metrics (jitter, latency, and packet loss). If there is no live traffic flowing through an SD-WAN link for three continuous minutes, then the FortiGate sends out active probes to the configured health check server (`set server`) to calculate the link metrics. A link health monitor must be configured, see [Link health monitor](#) for details.

When `passive-wan-health-measurement` is enabled, `auto-asic-offload` will be disabled.

Example

In this example, the FortiGate is configured to load-balance between two WAN interfaces, port15 and port16. A health check is configured in passive mode, and SLA thresholds are set. Passive WAN health measurement is enabled on the SD-WAN policy.

Measurements are taken from YouTube traffic generated by the PC. When latency is introduced to the traffic on port15, the passive health check trigger threshold is exceeded and traffic is rerouted to port16.

To configure the SD-WAN in the GUI:

1. Create the SD-WAN zone:
 - a. Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab.
 - b. Click *Create New > SD-WAN Zone*.
 - c. Enter a name for the zone, such as *SD-WAN*.
 - d. Click *OK*.
2. Create the SD-WAN members:
 - a. Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab.
 - b. Click *Create New > SD-WAN Member*.
 - c. Set *Interface* to *port15*, *SD-WAN Zone* to *SD-WAN*, and *Gateway* set to *172.16.209.2*.
 - d. Click *OK*.
 - e. Click *Create New > SD-WAN Member* again.
 - f. Set *Interface* to *port16*, *SD-WAN Zone* to *SD-WAN*, and *Gateway* set to *172.16.210.2*.
 - g. Click *OK*.
3. Create a performance SLA:

- a. Go to *Network > SD-WAN* and select the *Performance SLAs* tab.
- b. Edit an existing health check, or create a new one.
- c. Set *Probe mode* to *Passive*.
- d. Set *Participants* to *Specify* and add *port15* and *port16*.
- e. Configure two SLA targets. Note that the second SLA target must be configured in the CLI.

- f. Configure the remaining settings as needed.
- g. Click *OK*.

The SLA list shows the probe mode in the *Detect Server* column, if the probe mode is passive or prefer passive.

Probe packets can only be disabled in the CLI and when the probe mode is not passive.

4. Create SD-WAN rules:

- a. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
- b. Configure the first rule:

Name	Background_Traffic
Source address	172.16.205.0
Application	Click in the field, and in the <i>Select Entries</i> pane search for <i>YouTube</i> and select all of the entries
Strategy	Maximize Bandwidth (SLA)
Interface preference	port15 and port16
Required SLA target	Passive_Check#2

- c. Click *OK*.

- d. Click *Create New* again and configure the second rule:

Name	Foreground_Traffic
Source address	172.16.205.0
Address	all
Protocol number	Specify - 1
Strategy	Lowest Cost (SLA)
Interface preference	port15 and port16
Required SLA target	Passive_Check#1

- e. Click *OK*.

To configure the firewall policy in the GUI:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the policy:

Name	SD-WAN-HC-policy
Incoming Interface	port5
Outgoing Interface	SD-WAN
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT
Passive Health Check	Enabled Passive health check can only be enabled in a policy when the outgoing interface is an SD-WAN zone.

3. Click *OK*.

To configure the SD-WAN in the CLI:

```
config system sdwan
  set status enable
  config zone
    edit "SD-WAN"
    next
  end
  config members
    edit 1
      set zone "SD-WAN"
      set interface "port15"
      set gateway 172.16.209.2
    next
```

```
edit 2
    set zone "SD-WAN"
    set interface "port16"
    set gateway 172.16.210.2
next
end
config health-check
    edit "Passive_Check"
        set detect-mode passive
        set members 1 2
        config sla
            edit 1
                set latency-threshold 500
                set jitter-threshold 500
                set packetloss-threshold 10
            next
            edit 2
                set latency-threshold 1000
                set jitter-threshold 1000
                set packetloss-threshold 10
            next
        end
    next
end
config service
    edit 1
        set name "Background_Traffic"
        set mode load-balance
        set src "172.16.205.0"
        set internet-service enable
        set internet-service-app-ctrl 31077 33321 41598 31076 33104 23397 30201 16420
17396 38569 25564
        config sla
            edit "Passive_Check"
                set id 2
            next
        end
        set priority-member 1 2
    next
    edit 2
        set name "Foreground_Traffic"
        set mode sla
        set src "172.16.205.0"
        set protocol 1
        set dst "all"
        config sla
            edit "Passive_Check"
                set id 1
            next
        end
        set priority-member 1 2
    next
end
end
```

To configure the firewall policy in the CLI:

```

config firewall policy
  edit 1
    set name "SD-WAN-HC-policy"
    set srcintf "port5"
    set dstintf "SD-WAN"
    set nat enable
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set passive-wan-health-measurement enable
    set auto-asic-offload disable
  next
end

```

Results**When both links pass the SLA:**

```

# diagnose sys link-monitor-passive admin list by-interface
Interface port16 (28):
  Default(0x00000000): latency=10.0    15:46:36, jitter=5.0    15:46:37, pktloss=0.0  %
10:09:21

Interface port15 (27):
  Default(0x00000000): latency=60.0    15:46:36, jitter=0.0    15:46:37, pktloss=0.0  %
10:39:24

# diagnose sys sdwan health-check
Health Check(Passive_Check):
Seq(1 port15): state(alive), packet-loss(0.000%) latency(60.000), jitter(0.750) sla_map=0x3
Seq(2 port16): state(alive), packet-loss(0.000%) latency(10.000), jitter(5.000) sla_map=0x3

# diagnose sys sdwan service 2

Service(2): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(1: 1->65535), Mode(sla), sla-compare-order
  Members(2):
    1: Seq_num(1 port15), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
    2: Seq_num(2 port16), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected

    8.8.8.8-8.8.8.8
```

Passive measurement

Passive measurement allows SLA information per internet service/application to be differentiated and collected when internet services/applications are defined in an SD-WAN rule that uses passive or prefer passive SLA. The SLA metrics (jitter, latency, and packet loss) on each SD-WAN member in the rule are calculated based on the relevant internet services/applications SLA information. These metrics help analyze the performance of different applications using the same WAN link. See [Passive health-check measurement by internet service and application on page 646](#) for more information.

Passive health-check measurement by internet service and application

Active probing relies on checking the performance metrics of underlying infrastructure using layer 3 probes (ping) and layer 4 probes (tcp-echo, http, dns, and others) to provide limited information about an application's true performance.

Passive WAN health measurement uses passive probing to provide more realistic application performance information by collecting the performance metrics (jitter, latency, and packet loss) of live traffic that is passing through the firewall policies. See [Passive WAN health measurement on page 640](#).

Different applications can have different performance on the same WAN link, depending on the application's implementation. Passive measurement can be used to measure the performance of different internet services/applications that use the same WAN link.

The following is required:

1. Firewall policy configuration:
 - Enable passive WAN health measurement (`set passive-wan-health-measurement enable`).
 - Disable hardware offloading (`set auto-asic-offload disable`).
 - Use an application control security profile to identify applications.
2. SD-WAN rule configuration:
 - Use passive or prefer passive performance SLA.
 - Use ISDB/application signatures or ISDB/application signature groups to identify applications.
 - Enable passive measurement (`set passive-measurement enable`).

If internet services or applications are defined in an SD-WAN rule with passive or prefer passive performance SLA, SLA information for each service or application will be differentiated and collected. SLA metrics (jitter, latency, and packet loss) on each SD-WAN member in the rule are then calculated based on the relevant internet service's or application's SLA information.

In this example, three SD-WAN rules are created:

- Rule 1: Best quality (latency) using passive SLA for the internet services Alibaba and Amazon.
- Rule 2: Best quality (latency) using passive SLA for the applications Netflix and YouTube.
- Rule 3: Best quality (latency) using passive SLA for all other traffic.

After passive application measurement is enabled for rules one and two, the SLA metric of rule one is the average latency of the internet services Alibaba and Amazon, and the SLA metric of rule two is the average latency of the applications Netflix and YouTube.

To configure the SD-WAN:

1. Configure the SD-WAN members:

```
config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
  end
  config members
    edit 1
      set interface "dmz"
      set gateway 172.16.208.2
    next
    edit 2
      set interface "port15"
      set gateway 172.16.209.2
    next
  end
end
```

2. Configure the passive mode health check:

```
config health-check
  edit "Passive_HC"
    set detect-mode passive
    set members 1 2
  next
end
```

3. Configure SD-WAN service rules:

```
config service
  edit 1
    set name "1"
    set mode priority
    set src "172.16.205.0"
    set internet-service enable
    set internet-service-name "Alibaba-Web" "Amazon-Web"
    set health-check "Passive_HC"
```

```

        set priority-members 1 2
        set passive-measurement enable //Enable "passive application measurement", it
is a new command which is introduced in this project.
    next
    edit 2
        set name "2"
        set mode priority
        set src "172.16.205.0"
        set internet-service enable
        set internet-service-app-ctrl 18155 31077
        set health-check "Passive_HC"
        set priority-members 1 2
        set passive-measurement enable ////Enable "passive application measurement"
    next
    edit 3
        set name "3"
        set mode priority
        set dst "all"
        set src "172.16.205.0"
        set health-check "Passive_HC"
        set priority-members 1 2
    next
end

```

4. Configure SD-WAN routes:

```

config router static
    edit 1
        set distance 1
        set sdwan-zone "virtual-wan-link"
    next
end

```

5. Configure the firewall policy with passive WAN health measurement enabled:

```

config firewall policy
    edit 1
        set uuid 972345c6-1595-51ec-66c5-d705d266f712
        set srcintf "port5"
        set dstintf "virtual-wan-link"
        set action accept
        set srcaddr "172.16.205.0"
        set dstaddr "all"
        set schedule "always"
        set service "ALL"
        set passive-wan-health-measurement enable
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set application-list "g-default"
        set auto-asic-offload disable
    next
end

```

To verify the results:

1. On the PC, open the browser and visit the internet services and applications.
2. On the FortiGate, check the collected SLA information to confirm that each server or application on the SD-WAN members was measured individually:

```
# diagnose sys link-monitor-passive admin list by-interface

Interface dmz (5):
  Default(0x00000000): latency=3080.0  11:57:54, jitter=5.0      11:58:08,
pktloss=0.0 % NA
  Alibaba-Web(0x00690001): latency=30.0  11:30:06, jitter=25.0  11:29:13,
pktloss=0.0 % NA
  YouTube(0x00007965): latency=100.0  12:00:35, jitter=2.5   12:00:30,
pktloss=0.0 % NA
  Netflix(0x000046eb): latency=10.0  11:31:24, jitter=10.0  11:30:30,
pktloss=0.0 % NA
  Amazon-Web(0x00060001): latency=80.0  11:31:52, jitter=35.0  11:32:07,
pktloss=0.0 % NA

Interface port15 (27):
  Default(0x00000000): latency=100.0  12:00:42, jitter=0.0   12:00:42,
pktloss=0.0 % NA
  Amazon-Web(0x00060001): latency=30.0  11:56:05, jitter=0.0   11:55:21,
pktloss=0.0 % NA
  Alibaba-Web(0x00690001): latency=0.0  11:26:08, jitter=35.0  11:27:08,
pktloss=0.0 % NA
  YouTube(0x00007965): latency=100.0  11:33:34, jitter=0.0   11:33:50,
pktloss=0.0 % NA
  Netflix(0x000046eb): latency=0.0  11:26:29, jitter=0.0   11:29:03,
pktloss=0.0 % NA
```

The Default (0x00000000) applications are other, unidentified applications that do not have ISDB or application signatures configured in SD-WAN rules. The latency of default/application is taken into account in per SD-WAN rule calculations only if passive-measurement is disabled in any one of the SD-WAN rules.

3. Verify that the SLA metrics on the members are calculated as expected:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x600 use-shortcut-sla
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(priority), link-cost-factor

```

The latency on each member interface per SD-WAN rule is the average of the latency of the application identified by respective SD-WAN rules.

The SLA metrics listed for each member interface per SD-WAN rule shown by the `diagnose sys sdwan service` command are derived from the output of the SLA information for the applications shown in the output of the `diagnose sys link-monitor-passive admin list by-interface` command.

Until the applications are identified, their SLA metrics are not used to calculate SLA metrics for each member per SD-WAN rule. Applications are identified only when there is (or was) any application traffic passing through a member interface.

SD-WAN rules

SD-WAN rules, which are sometimes called *service rules*, identify traffic of interest, and then route the traffic based on a strategy and the condition of the route or *link* between two devices. You can use many strategies to select the outgoing interface and many performance service level agreements (SLAs) to evaluate the link conditions.

Use the following topics to learn about and create SD-WAN rules for your needs:

- [SD-WAN rules overview on page 651](#)

SD-WAN rules overview

SD-WAN rules control how sessions are distributed to SD-WAN members. You can configure SD-WAN rules from the GUI and CLI.

From the GUI, go to *Network > SD-WAN > SD-WAN Rules*. When creating a new SD-WAN rule, or editing an existing SD-WAN rule, use the *Source* and *Destination* sections to identify traffic, and use the *Outgoing interfaces* section to configure WAN intelligence for routing traffic.

The screenshot shows the 'Priority Rule' configuration window. It includes fields for Name, IP Version (IPv4 and IPv6), Source (Source address and User group), Destination (Address, Internet Service, and Application), and Outgoing Interfaces (Manual and Best Quality). The Best Quality option is selected. An Additional Information panel on the right contains links for API Preview, SD-WAN Rules Setup Guides (Implicit Rule, Best Quality, Lowest Cost (SLA), Maximize Bandwidth (SLA)), and Documentation (Online Help, Video Tutorials).

From the CLI, use the following command to configure SD-WAN rules:

```
config system sdwan
  config service
    edit <ID>
    next
  end
end
```

The following topics describe the fields used to configure SD-WAN rules:

- [Fields for identifying traffic on page 652](#)
- [Fields for configuring WAN intelligence on page 655](#)

- [Additional fields for configuring WAN intelligence on page 657](#)

Fields for identifying traffic

This topic describes the fields in an SD-WAN rule used for defining the traffic to which the rule applies. Some fields are available only in the CLI.

SD-WAN rules can identify traffic by a variety of means:

Address type	Source	Destination
IPv4/6	✓	✓
MAC	✓	✓
Group	✓	✓
FABRIC_DEVICE dynamic address	✓	✓
Users	✓	✓
User groups	✓	✓
Application control (application aware routing)		✓
Internet service database (ISDB)		✓
BGP route tags		✓
Differentiated Services Code Point (DSCP) tags		✓

In the GUI, go to *Network > SD-WAN > SD-WAN Rules*. Click *Create New*, or double-click an existing rule to open it for editing. The *Source* and *Destination* sections are used to identify traffic for the rule:

In the CLI, edit the service definition ID number to identify traffic for the rule:

```
config system sdwan
  config service
    edit <ID>
      <CLI commands from the following tables>
      ...
    end
  end
end
```

The following table describes the fields used for the name, ID, and IP version of the SD-WAN rule:

Name, ID, and IP version		
Field	CLI	Description
Name	<code>set name <string></code>	The name does not need to relate to the traffic being matched, but it is good practice to have intuitive rule names.
ID	<code>config system sdwan config service edit <ID> next end end</code>	ID is generated when the rule is created. You can only specify the ID from the CLI.
IP version	<code>set addr-mode <ipv4 ipv6></code>	The addressing mode can be IPv4 or IPv6. To configure in the GUI, IPv6 must be enabled from <i>System > Feature Visibility</i> page.

The following table describes the fields used for source section of the SD-WAN rule:

Source		
Field	CLI	Description
Source address	<code>set src <object></code> May be negated from the CLI with <code>set src-negate</code> .	One or more address objects.
User group	<code>set users <user object></code> <code>set groups <group object></code>	Individual users or user groups
Source interface (input-device)	<code>set input-device <interface name></code> May be negated with <code>set input-device-negate enable</code> .	CLI only. Select one or more source interfaces.

The following table describes the fields used for the destination section of the SD-WAN rule:

Destination		
Field	CLI	Description
Address	<code>set dst <object></code> <code>set protocol <integer></code> <code>set start-port <integer></code> , <code>set end-port <integer></code>	One or more address objects. One protocol and one port range can be combined with the address object.

Destination		
Field	CLI	Description
	Use <code>set dst-negate enable</code> to negate the address object.	If it is necessary for an SD-WAN rule to match multiple protocols or multiple port ranges, you can create a custom Internet Service.
Internet Service	<pre>set internet-service enable set internet-service-name <string> set internet-service-group <string></pre>	<p>One or more internet services or service groups.</p> <p>This applies only to IPv4 rules, and cannot be used in conjunction with an address object.</p>
Application	<pre>set internet-service-app-ctrl <integer> set internet-service-app-ctrl-group <integer></pre>	<p>One or more applications or application groups.</p> <p>This applies only to IPv4 rules, and cannot be used in conjunction with an address object.</p> <p>May be used with internet services or service group.</p>
Route tag (route-tag)	<code>set route-tag <integer></code>	<p>CLI only.</p> <p>This replaces the <code>dst</code> field (if previously configured) and matches a BGP route tag configured in a route map. See Using BGP tags with SD-WAN rules on page 721.</p>
TOS mask (tos-mask)	<code>set tos-mask <8-bit hex value></code>	<p>CLI only.</p> <p>In order to leverage type of service (TOS) matching or DSCP matching on the IP header, the SD-WAN rule must specify the bit mask of the byte holding the TOS value. For example, a TOS mask of 0xe0 (11100000) matches the upper 3 bits.</p>
TOS (tos)	<code>set tos <8 bit hex value></code>	<p>CLI only.</p> <p>The value specified here is matched after the <code>tos-mask</code> is applied.</p> <p>For example, the FortiGate receives DSCP values 110000 and 111011. (DSCP is the upper 6 bits of the TOS field – 11000000 and 11101100 respectively). Using the TOS value 0xe0 (11100000), only the second DSCP value is matched.</p>

Fields for configuring WAN intelligence

This topic describes the fields in an SD-WAN rule used for configuring WAN intelligence, which processes and routes traffic that matches the SD-WAN rule.

In the GUI, go to *Network > SD-WAN > SD-WAN Rules*. Click *Create New*, or double-click an existing rule to open it for editing. The *Outgoing Interfaces* section is used to configure WAN intelligence for the rule:

WAN intelligence is comprised of the following parts:

- [Interface or zone preference on page 655](#)
- [Strategy on page 656](#)
- [Performance SLA on page 656](#)

Interface or zone preference

By default, the configured order of interfaces and/or zones in a rule are used. Interfaces and zones that are selected first have precedence over interfaces selected second and so on.

You can specify both interfaces and zones. When a zone is specified in the *Zone preference* field, it is equivalent to selecting each of the contained interface members in the *Interface preference* section. Interface members in a zone have lower priority than interfaces configured in the *Interface preference* section.

For example:

- There are 3 interfaces: port1, port2 and port3.
 - Port2 is in Zone1
 - Port1 and port3 belong to the default *virtual-wan-link* zone.
- An SD-WAN rule is created with *Interface preference* set to *port3* and *port1*, and *Zone preference* set to *Zone1*.

The SD-WAN rule prefers the interfaces in the following order:

1. port3
2. port1
3. port2

You can configure the interface and zone preference in the CLI:

```
config system sdwan
  config service
    edit <ID>
      set priority-members <integer>
      set priority-zone <interface>
    next
  end
end
```

Strategy

Strategy dictates how the interface and/or zone order changes as link conditions change. You can use the following strategies:

- Automatic (`auto`): interfaces are assigned a priority based on quality. See [Automatic strategy on page 662](#).
- Manual (`manual`): interfaces are manually assigned a priority. See [Manual strategy on page 663](#).
- Best Quality (`priority`): interfaces are assigned a priority based on the `link-cost-factor` of the interface. See [Best quality strategy on page 664](#).
- Lowest cost (SLA) (`sla`): interfaces are assigned a priority based on selected SLA settings. See [Lowest cost \(SLA\) strategy on page 668](#).
- Maximize Bandwidth (SLA) (`load-balance`): traffic is distributed among all available links based on the selected load balancing algorithm. See [Maximize bandwidth \(SLA\) strategy on page 671](#).

Performance SLA

The best quality, lowest cost, and maximize bandwidth strategies are the most intelligent modes, and they leverage SLA health checks to provide meaningful metrics for a given link. FortiGate uses the metrics to make intelligent decisions to route traffic.

Automatic and manual strategies have pre-configured logic that do not leverage SLA health checks.

The goal of the performance SLA is to measure the quality of each SD-WAN member link. The following methods can be used to measure the quality of a link:

- Active measurement
 - Health-check traffic is sent to a server with a variety of protocols options.
 - The following SLA metrics are measured on this probe traffic:
 - Latency
 - Jitter
 - Packet loss
- Passive measurement
 - SLA metrics are measured on real or live traffic, reducing the amount of probe traffic that is sent and received.
 - There is the option (`prefer passive`) to initiate probe traffic when no live traffic is present.

Performance SLA is utilized by `auto`, *Lowest Cost (SLA)*, *Maximize Bandwidth (SLA)*, and *Best Quality* strategies. *Lowest Cost (SLA)* and *Maximize Bandwidth SLA* use SLA targets in a pass or fail style to evaluate whether a link is considered for traffic. *Best Quality* compares a specific metric of the SLA to pick the best result.

Therefore it is integral to select or create an SLA target(s) that relates to the traffic targeted by the rule. It does not make sense to evaluate a public resource, such as YouTube, when the rule matches Azure traffic.

See [Performance SLA on page 629](#) for more details.

Additional fields for configuring WAN intelligence

This topic describes the fields in an SD-WAN rule used for configuring WAN intelligence for egress traffic:

- [Forward and/or reverse differentiated services code point \(DSCP\) on page 657](#)
- [Default and gateway options on page 657](#)

For information about accessing fields for configuring WAN intelligence, see [Fields for configuring WAN intelligence on page 655](#).

Forward and/or reverse differentiated services code point (DSCP)

The FortiGate differentiated services feature can be used to change the DSCP value for all packets accepted by a policy.

The packet's DSCP field for traffic initiating a session (forward) or for reply traffic (reverse) can be changed and enabled in each direction separately by configuring it in the firewall policy using the *Forward DSCP* and *Reverse DSCP* fields.

From the CLI:

```
config system sdwan
  config service
    edit <ID>
      ...
      set dscp-forward enable
      ...
    next
  end
end
```

set dscp-forward enable	Enable use of forward DSCP tag.
set dscp-forward-tag 000000	Forward traffic DSCP tag.
set dscp-reverse enable	Enable use of reverse DSCP tag.
set dscp-reverse-tag 000000	Reverse traffic DSCP tag.

Default and gateway options

Following are additional gateway options that can be set only in the CLI:

```
config system sdwan
  config service
    edit <ID>
      ...
      set default enable
      ...
    next
  end
end
```

<code>set default</code> <code>[enable disable]</code>	Enable or disable use of SD-WAN as default service.
<code>set gateway</code> <code>[enable disable]</code>	Enable or disable SD-WAN service gateway.

By default, these settings are set to `disable`.

These two commands help adjust FortiGate route selection by affecting how the FortiGate consults the Forward Information Base (FIB).

In order to decide whether an SD-WAN policy-route can be matched, FortiGate performs the following FIB lookups:

- FIB best match for the destination must return an SD-WAN member.
- FIB route to the destination must exist over the desired SD-WAN member.

When `set default enable` is used with `set gateway enable`, FortiGate bypasses the FIB checks, and instead routes any matching traffic of the SD-WAN rule to the chosen SD-WAN member using the member's configured gateway. SD-WAN members must have a gateway configured.

When `set default disable` is used with `set gateway enable`, FortiGate keeps the first rule in effect but causes the second rule to change to:

- FIB route to the gateway IP address must exist over any interface.

See also [Fields for configuring WAN intelligence on page 655](#).

Implicit rule

SD-WAN rules define specific policy routing options to route traffic to an SD-WAN member. When no explicit SD-WAN rules are defined, or if none of the rules are matched, then the default implicit rule is used.

In an SD-WAN configuration, the default route usually points to the SD-WAN interface, so each active member's gateway is added to the routing table's default route. FortiOS uses equal-cost multipath (ECMP) to balance traffic between the interfaces. One of five load balancing algorithms can be selected:

Source IP (<code>source-ip-based</code>)	Traffic is divided equally between the interfaces, including the SD-WAN interface. Sessions that start at the same source IP address use the same path. This is the default selection.
Sessions (<code>weight-based</code>)	The workload is distributing based on the number of sessions that are connected through the interface. The weight that you assign to each interface is used to calculate the percentage of the total sessions that are allowed to connect through an interface, and the sessions are distributed to the interfaces accordingly. Sessions with the same source and destination IP addresses (<code>src-ip</code> and <code>dst-ip</code>) are forwarded to the same path, but are still considered in later session ratio calculations. An interface's weight value cannot be zero.
Spillover (<code>usage-based</code>)	The interface is used until the traffic bandwidth exceeds the ingress and egress thresholds that you set for that interface. Additional traffic is then sent through the next SD-WAN interface member.

Source-Destination IP (<code>source-dest-ip-based</code>)	Traffic is divided equally between the interfaces. Sessions that start at the same source IP address and go to the same destination IP address use the same path.
Volume (<code>measured-volume-based</code>)	<p>The workload is distributing based on the number of packets that are going through the interface.</p> <p>The volume weight that you assign to each interface is used to calculate the percentage of the total bandwidth that is allowed to go through an interface, and the bandwidth is distributed to the interfaces accordingly.</p> <p>An interface's volume value cannot be zero.</p>

You cannot exclude an interface from participating in load balancing using the implicit rule. If the weight or volume were set to zero in a previous FortiOS version, the value is treated as a one.

When using dynamic routes for routing, sessions are distributed equally regardless of weight. Interfaces with static routes can be excluded from ECMP if they are configured with a lower priority than other static routes.

Examples

The following four examples demonstrate how to use the implicit rules (load-balance mode).

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

Example 1

Outgoing traffic is equally balanced between wan1 and wan2, using *source-ip-based* or *source-dest-ip-based* mode.

Using the GUI:

1. On the FortiGate, enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 608](#) for details.

2. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab.
3. Edit the *sd-wan* rule (the last default rule).
4. For the *Load Balancing Algorithm*, select either *Source IP* or *Source-Destination IP*.
5. Click *OK*.

Using the CLI:

1. Enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 608](#) for details.

2. Set the load balancing algorithm:

Source IP based:

```
config system sdwan
    set load-balance-mode source-ip-based
end
```

Source-Destination IP based:

```
config system sdwan
    set load-balance-mode source-dest-ip-based
end
```

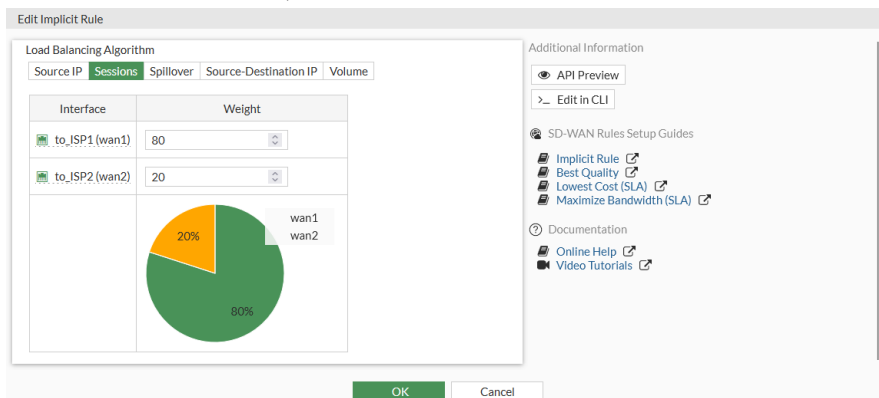

Example 2

Outgoing traffic is balanced between wan1 and wan2 with a customized ratio, using *weight-based* mode: wan1 runs 80% of the sessions, and wan2 runs 20% of the sessions.

Sessions with the same source and destination IP addresses (*src-ip* and *dst-ip*) will be forwarded to the same path, but will still be considered in later session ratio calculations.

Using the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab.
2. Edit the *sd-wan* rule (the last default rule).
3. For the *Load Balancing Algorithm*, select *Sessions*.
4. Enter 80 in the *wan1* field, and 20 in the *wan2* field.

5. Click *OK*.

Using the CLI:

```
config system sdwan
  set load-balance-mode weight-based
  config members
    edit 1
      set interface "wan1"
      set weight 80
    next
    edit 2
      set interface "wan2"
      set weight 20
    next
  end
end
```

Example 3

Outgoing traffic is balanced between wan1 and wan2 with a customized ratio, using *measured-volume-based* mode: wan1 runs 80% of the volume, and wan2 runs 20% of the volume.

Using the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab.
2. Edit the *sd-wan* rule (the last default rule).
3. For the *Load Balancing Algorithm*, select *Volume*.
4. Enter 80 in the *wan1* field, and 20 in the *wan2* field.
5. Click *OK*.

Using the CLI:

```
config system sdwan
  set load-balance-mode measured-volume-based
  config members
    edit 1
      set interface "wan1"
      set volume-ratio 80
    next
    edit 2
      set interface "wan2"
      set volume-ratio 20
    next
  end
end
```

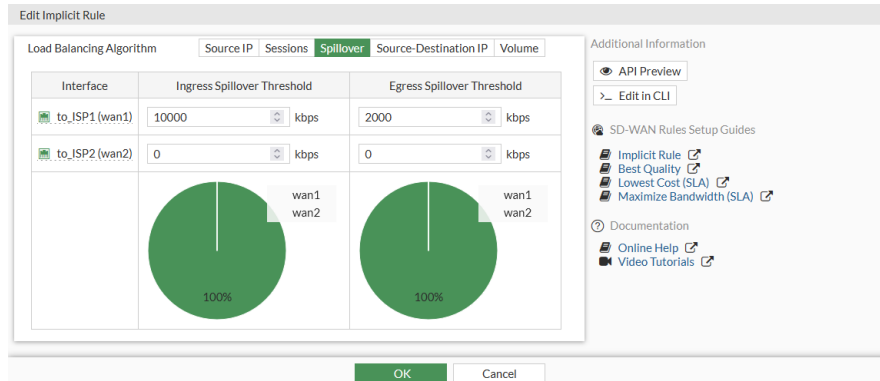

Example 4

Load balancing can be used to reduce costs when internet connections are charged at different rates. For example, if wan2 charges based on volume usage and wan1 charges a fixed monthly fee, we can use wan1 at its maximum bandwidth, and use wan2 for overflow.

In this example, wan1's bandwidth is 10Mbps down and 2Mbps up. Traffic will use wan1 until it reaches its spillover limit, then it will start to use wan2. Note that *auto-asic-offload* must be disabled in the firewall policy.

Using the GUI:

1. On the FortiGate, enable SD-WAN and add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 608](#) for details.
2. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab.
3. Edit the *sd-wan* rule (the last default rule).
4. For the *Load Balancing Algorithm*, select *Spillover*.
5. Enter 10000 in the *wan1 Ingress Spillover Threshold* field, and 2000 in the *wan1 Egress Spillover Threshold* field.

6. Click **OK**.

Using the CLI:

```
config system sdwan
  set load-balance-mode usage-based
  config members
    edit 1
      set interface "wan1"
      set spillover-threshold 2000
      set ingress-spillover-threshold 10000
    next
  end
end
```

Automatic strategy

The automatic strategy is a legacy rule that lets you select an outgoing interface based on its performance ranking compared to the other SD-WAN interfaces. This is achieved by applying a performance SLA to rank the interfaces, and then selecting the desired rank.

In this example, you have three SD-WAN interfaces to three different ISPs that all go to the public internet. WAN1 is your highest quality link and should be reserved for business critical traffic. WAN2 and WAN3 are redundant backup links. You noticed one non-critical application is taking up a lot of bandwidth and want to prioritize it to the lowest quality link at any given time.

To configure automatic SD-WAN rules from the CLI:

```
config system sdwan
  config members
    edit 1
```

```

        set interface "wan1"
    next
    edit 2
        set interface "wan2"
    next
    edit 3
        set interface "wan3"
    next
end
config health-check
    edit "non-critical application"
        set server "noncritical.application.com"
        set members 1 2 3
        config sla
            edit 1
                set latency-threshold 250
                set jitter-threshold 50
                set packetloss-threshold 3
            next
        end
    next
end
config service
    edit 1
        set name "non-critical application"
        set mode auto
        set quality-link 3
        set dst "non-critical-app-address-object"
        set health-check "non-critical application"
    next
end
end

```

The `auto` option is only available in the CLI. If you use the GUI to edit the rule, the `auto` option will be overwritten because you cannot select `auto` in the GUI.

Manual strategy

In manual mode, no health checks are used. As a result, the decision making closer resembles logic than intelligence. SD-WAN manual rules are similar to regular policy-based routes, but have the added features of application-aware routing and BGP-tag routing. A manual strategy rule is comprised of the following parts:

- Defining the interfaces to be used
- Ordering the interfaces based on preference

To configure manual SD-WAN rules from the GUI:

1. Go to *Network > SD-WAN*.
2. Select the *SD-WAN Rules* tab, and click *Create New*.

3. Set the following options to create a manual rule:

Name	Type a name for the rule.
Source	(Optional) Specify a <i>Source address</i> and/or <i>User group</i> .
Destination	Specify the destination using an <i>Address</i> object or an <i>Internet Service</i> or an <i>Application</i> .
Zone preference	Specify one or more SD-WAN interfaces or zones. The order in which the interfaces or zones are specified determines their priority when the rule is matched.

4. Set the remaining options as desired, and click *OK* to create the rule.

To configure manual SD-WAN rules from the CLI:

```
config system sdwan
  config members
    edit 1
      set interface "wan1"
    next
    edit 2
      set interface "wan2"
    next
  end
  config service
    edit 1
      set name "manual"
      set mode manual
      set priority-members 2 1
      set dst "DC_net"
      set hold-down-time 60
    next
  end
end
```

- The command `set mode manual` will not appear in the configuration because it is the default mode.
- The command `set hold-down-time <integer>` is an optional command that controls how long to wait before switching back to the primary interface in the event of a failover.

Best quality strategy

When using *Best Quality* mode, SD-WAN will choose the best link to forward traffic by comparing the *link-cost-factor*. A link-cost factor is a specific metric of participating link(s) (such as, latency, packet loss, and so on) evaluated against a target that you define (such as a health-check server), for example, the latency of WAN1 and WAN2 to your datacenter. Below is a list of link-cost factors available to you:

GUI	CLI	Description
Latency	latency	Select a link based on latency.
Jitter	jitter	Select a link based on jitter.
Packet Loss	packet-loss	Select a link based on packet loss.
Downstream	inbandwidth	Select a link based on available bandwidth of incoming traffic.
Upstream	outbandwidth	Select a link based on available bandwidth of outgoing traffic.
Bandwidth	bandwidth	Select a link based on available bandwidth of bidirectional traffic.
Customized profile	custom-profile-1	Select link based on customized profile. If selected, set the following weights: <ul style="list-style-type: none"> packet-loss-weight: Coefficient of packet-loss. latency-weight: Coefficient of latency. jitter-weight: Coefficient of jitter. bandwidth-weight: Coefficient of reciprocal of available bidirectional bandwidth.

Although SD-WAN intelligence selects the best quality link according to the selected metric, by default a preference or advantage is given to the first configured SD-WAN member. This default is 10% and may be configured with the CLI command `set link-cost-threshold 10`.

Example of how `link-cost-threshold` works:

```
config system sdwan
  config members
    edit 1
      set interface "wan1"
    next
    edit 2
      set interface "wan2"
    next
  end
  config service
    edit 1
      set name "Best_Quality"
      set mode priority
      set priority-members 2 1
      set dst "DC_net"
      set health-check "DC_HealthCheck"
      set link-cost-factor latency
      set link-cost-threshold 10
    next
  end
end
```

In this example both WAN1 and WAN2 are assumed to have 200ms latency to the health-check server named `DC_HealthCheck`. Because WAN2 is specified before WAN1 in `priority-members`, SD-WAN parses the two interfaces metric as follows:

- WAN1: 200ms
- WAN2: $200\text{ms} / (1+10\%) = \sim 182\text{ms}$

As a result, WAN2 is selected because the latency is lower.

If the *Downstream* (`inbandwidth`), *Upstream* (`outbandwidth`), or *Bandwidth* (`bibandwidth`) quality criteria is used, the FortiGate uses the upstream and downstream bandwidth values configured on the member interfaces to calculate bandwidth.

The interface bandwidth configuration can be done manually, or the interface speedtest can be used to populate the bandwidth values based on the speedtest results. See [Manual interface speedtest on page 674](#) for details.

To manually configure the upstream and downstream interface bandwidth values:

```
config system interface
  edit <interface>
    set estimated-upstream-bandwidth <speed in kbps>
    set estimated-downstream-bandwidth <speed in kbps>
  next
end
```

Example

In this example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet, and you want Gmail services to use the link with the least latency.

To configure an SD-WAN rule to use Best Quality:

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 608](#) for more details.
2. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*. See [Health checks](#) for more details.
4. Click *OK*.
5. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
6. Enter a name for the rule, such as *gmail*.
7. Configure the following settings:

Priority Rule

Name: gmail

Source

Source address: +

User group: +

Destination

Address: +

Internet Service: Google-Gmail

Application: +

Outgoing Interfaces

Select a strategy for how outgoing interfaces will be chosen.

Manual
Manually assign outgoing interfaces.

Best Quality
The interface with the best measured performance is selected.

Lowest Cost (SLA)
The interface that meets SLA targets is selected. When there is a tie, the interface with the lowest assigned cost is selected.

Maximize Bandwidth (SLA)
Traffic is load balanced among interfaces that meet SLA targets.

Interface preference

to_ISP1 (wan1) x

to_ISP2 (wan2) x

Zone preference: +

Measured SLA: google

Quality criteria: Latency

Forward DSCP:

Reverse DSCP:

Status: Enable Disable

- Video Tutorials

OK Cancel

Internet Service	Google-Gmail
Strategy	Best Quality
Interface preference	wan1 and wan2
Measured SLA	google
Quality criteria	Latency

8. Click **OK**.

To configure an SD-WAN rule to use priority:

```
config system sdwan
  config health-check
    edit "google"
      set server "google.com"
      set members 1 2
    next
  end
  config service
    edit 1
      set name "gmail"
      set mode priority
      set internet-service enable
      set internet-service-id 65646
      set health-check "google"
```

```

        set link-cost-factor latency
        set priority-members 1 2
    next
end
end

```

To diagnose the Performance SLA status:

```
FGT # diagnose sys sdwan health-check google
```

```
Health Check(google):
```

```
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
```

```
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0
```

```
FGT # diagnose sys sdwan service 1
```

```
Service(1):
```

```
TOS(0x0/0x0), protocol(0: 1->65535), Mode(priority), link-cost-facotr(latency), link-
cost-threshold(10), health-check(google) Members:
```

```
1: Seq_num(2), alive, latency: 12.633, selected
```

```
2: Seq_num(1), alive, latency: 14.563, selected
```

```
Internet Service: Google-Gmail(65646)
```

As wan2 has a smaller latency, SD-WAN will put Seq_num(2) on top of Seq_num(1) and wan2 will be used to forward Gmail traffic.

Lowest cost (SLA) strategy

When using *Lowest Cost (SLA)* mode (`sla` in the CLI), SD-WAN will choose the lowest cost link that satisfies SLA to forward traffic. The lowest possible cost is 0. If multiple eligible links have the same cost, the *Interface preference* order will be used to select a link.

In this example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet. The cost of wan2 is less than that of wan1. You want to configure Gmail services to use the lowest cost interface, but the link quality must meet a standard of latency: 10ms, and jitter: 5ms.

To configure an SD-WAN rule to use Lowest Cost (SLA):

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 608](#) for more details.
2. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*.
4. Enable *SLA Target*. Set the *Latency threshold* to *10 ms*, and the *Jitter threshold* to *5 ms*. See [Health checks](#) for more details.
5. Click *OK*.
6. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
7. Enter a name for the rule, such as *gmail*.
8. Configure the following settings:

The screenshot shows the configuration page for a Priority Rule named 'gmail'. The configuration is as follows:

- Name:** gmail
- Source:**
 - Source address: +
 - User group: +
- Destination:**
 - Address: +
 - Internet Service: Google-Gmail
 - Application: +
- Outgoing Interfaces:**
 - Select a strategy for how outgoing interfaces will be chosen.
 - Manual: Manually assign outgoing interfaces.
 - Best Quality: The interface with the best measured performance is selected.
 - Lowest Cost (SLA)**: The interface that meets SLA targets is selected. When there is a tie, the interface with the lowest assigned cost is selected.
 - Maximize Bandwidth (SLA): Traffic is load balanced among interfaces that meet SLA targets.
 - Interface preference: to_JSP1 (wan1), to_JSP2 (wan2)
 - Zone preference: +
 - Required SLA target: google
 - Forward DSCP:
 - Reverse DSCP:
 - Status: Enable Disable

SLA Details Table:

	Packet Loss	Latency	Jitter
google		10.00ms	5.00ms
to_JSP1 (wan1)	0.00%	4.76ms	0.39ms
to_JSP2 (wan2)	0.00%	4.68ms	0.33ms

Buttons: OK, Cancel

Internet Service	Google-Gmail
Strategy	Lowest Cost (SLA)
Interface preference	wan1 and wan2
Required SLA target	google

9. Click *OK*.

To configure an SD-WAN rule to use SLA:

```

config system sdwan
  config members
    edit 1
      set interface "wan1"
      set cost 10
    next
    edit 2
      set interface "wan2"
      set cost 5
    next
  end
  config health-check
    edit "google"
      set server "google.com"
      set members 1 2
      config sla
        edit 1
          set latency-threshold 10
          set jitter-threshold 5
        next
      end
    next
  end
  config service
    edit 1
      set name "gmail"
      set mode sla
      set internet-service enable
      set internet-service-id 65646
      config sla
        edit "google"
          set id 1
        next
      end
      set priority-members 1 2
    next
  end
end

```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

The CLI command `set minimum-sla-meet-members` allows you to specify the number of links that must meet SLA for the rule to take effect. If the number of members is less than the minimum set with this command, the rule will not take effect.

To diagnose the Performance SLA status:

```

FGT # diagnose sys sdwan health-check google
Health Check(google):

```

```
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0
```

```
FGT # diagnose sys sdwan service 1
```

```
Service(1): Address Mode(IPV4) flags=0x0
```

```
TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla)
```

```
Members:<<BR>>
```

```
1: Seq_num(2), alive, sla(0x1), cfg_order(1), selected
```

```
2: Seq_num(1), alive, sla(0x1), cfg_order(0), selected
```

```
Internet Service: Google.Gmail(65646)
```

When both wan1 and wan2 meet the SLA requirements, Gmail traffic will only use wan2. If only wan1 meets the SLA requirements, Gmail traffic will only use wan1, even though it has a higher cost. If neither interface meets the requirements, wan2 will be used.

If both interface had the same cost and both met the SLA requirements, the first link configured in `set priority-members` would be used.

Maximize bandwidth (SLA) strategy

When using *Maximize Bandwidth* mode (`load-balance` in the CLI), SD-WAN will choose all of the links that satisfies SLA to forward traffic based on a load balancing algorithm. The load balancing algorithm, or hash method, can be one of the following:

round-robin	All traffic are distributed to selected interfaces in equal portions and circular order. This is the default method, and the only option available when using the GUI.
source-ip-based	All traffic from a source IP is sent to the same interface.
source-dest-ip-based	All traffic from a source IP to a destination IP is sent to the same interface.
inbandwidth	All traffic are distributed to a selected interface with most available bandwidth for incoming traffic.
outbandwidth	All traffic are distributed to a selected interface with most available bandwidth for outgoing traffic.
bibandwidth	All traffic are distributed to a selected interface with most available bandwidth for both incoming and outgoing traffic.

When the `inbandwidth`, `outbandwidth`, or `bibandwidth` load balancing algorithm is used, the FortiGate will compare the bandwidth based on the configured upstream and downstream bandwidth values.

The interface speedtest can be used to populate the bandwidth values based on the speedtest results. See [Manual interface speedtest on page 674](#) for details.

To manually configure the upstream and downstream bandwidth values:

```
config system interface
  edit <interface>
    set estimated-upstream-bandwidth <speed in kbps>
    set estimated-downstream-bandwidth <speed in kbps>
```

```
next
end
```

ADVPN is not supported in this mode.

In this example, your wan1 and wan2 SD-WAN interfaces connect to two ISPs that both go to the public internet. You want to configure Gmail services to use both of the interface, but the link quality must meet a standard of latency: 10ms, and jitter: 5ms. This can maximize the bandwidth usage.

To configure an SD-WAN rule to use Maximize Bandwidth (SLA):

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route. See [SD-WAN quick start on page 608](#) for details.
2. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
3. Enter a name for the performance SLA, such as *google*, and set the *Server* to *google.com*.
4. Enable *SLA Target*. Set the *Latency threshold* to *10 ms*, and the *Jitter threshold* to *5 ms*. See [Health checks](#) for more details.
5. Click *OK*.
6. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
7. Enter a name for the rule, such as *gmail*.

8. Configure the following settings:

Priority Rule

Name: gmail

Source

Source address: +

User group: +

Destination

Address: +

Internet Service: Google-Gmail

Application: +

Outgoing Interfaces

Select a strategy for how outgoing interfaces will be chosen.

Manual
Manually assign outgoing interfaces.

Best Quality
The interface with the best measured performance is selected.

Lowest Cost (SLA)
The interface that meets SLA targets is selected. When there is a tie, the interface with the lowest assigned cost is selected.

Maximize Bandwidth (SLA)
Traffic is load balanced among interfaces that meet SLA targets.

Interface preference: to_JSP1 (wan1), to_JSP2 (wan2)

Zone preference: +

Required SLA target: google

Forward DSCP:

Reverse DSCP:

Status: Enable Disable

SLA Details

	Packet Loss	Latency	Jitter
google		10.00ms	5.00ms
to_JSP1 (wan1)	0.00%	4.76ms	0.39ms
to_JSP2 (wan2)	0.00%	4.68ms	0.33ms

Additional Information

SD-WAN Rules Setup Guides

- Implicit Rule
- Best Quality
- Lowest Cost (SLA)
- Maximize Bandwidth (SLA)

Documentation

- Online Help
- Video Tutorials

OK Cancel

Field	Setting
Internet Service	Google-Gmail
Strategy	Maximize Bandwidth (SLA)
Interface preference	wan1 and wan2
Required SLA target	google

9. Click OK.

To configure an SD-WAN rule to use SLA:

```

config system sdwan
  config health-check
    edit "google"
      set server "google.com"
      set members 1 2
      config sla
        edit 1
          set latency-threshold 10
          set jitter-threshold 5
        next
      end
    next
  end
end
config service

```

```

edit 1
    set name "gmail"
    set addr-mode ipv4
    set mode load-balance
    set hash-mode round-robin
    set internet-service enable
    set internet-service-name Google-Gmail
    config sla
        edit "google"
            set id 1
        next
    end
    set priority-members 1 2
next
end
end

```

The CLI command `set minimum-sla-meet-members` allows you to specify the number of links that must meet SLA for the rule to take effect. If the number of members is less than the minimum set with this command, the rule will not take effect.

To diagnose the performance SLA status:

```
FGT # diagnose sys sdwan health-check google
```

```
Health Check(google):
```

```
Seq(1): state(alive), packet-loss(0.000%) latency(14.563), jitter(4.334) sla_map=0x0
```

```
Seq(2): state(alive), packet-loss(0.000%) latency(12.633), jitter(6.265) sla_map=0x0
```

```
FGT # diagnose sys sdwan service 1
```

```
Service(1): Address Mode(IPV4) flags=0x0
```

```
TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance)
```

```
Members:<<BR>>
```

```
1: Seq_num(1), alive, sla(0x1), num of pass(1), selected
```

```
2: Seq_num(2), alive, sla(0x1), num of pass(1), selected
```

```
Internet Service: Google.Gmail(65646)
```

When both wan1 and wan2 meet the SLA requirements, Gmail traffic will use both wan1 and wan2. If only one of the interfaces meets the SLA requirements, Gmail traffic will only use that interface.

If neither interface meets the requirements but health-check is still alive, then wan1 and wan2 tie. The traffic will try to balance between wan1 and wan2, using both interfaces to forward traffic.

Manual interface speedtest

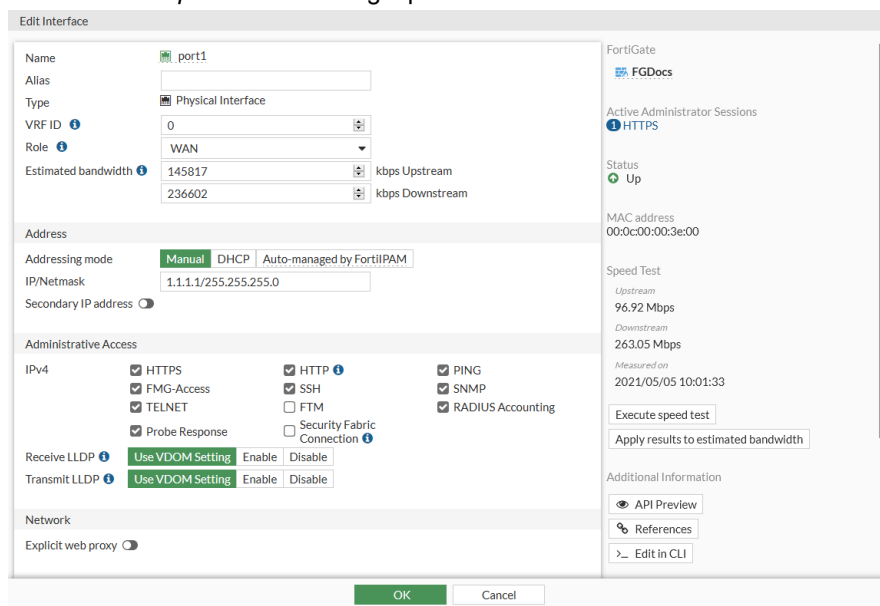

An interface speedtest can be manually performed on WAN interfaces in the GUI. The results of the test can be added to the interface's *Estimated bandwidth*. The estimated upstream and downstream bandwidths can be used in SD-WAN service rules to determine the best link to use when either Maximize Bandwidth or Best Quality strategies are selected.

An SD-WAN Network Monitor license is required to use the speedtest. The *License* widget and the *System > FortiGuard* page show the license status.

To run an interface speedtest in the GUI:

1. Go to *Network > Interfaces*.
2. Edit a WAN interface. The interfaces can be grouped by role using the grouping dropdown on the right side of the toolbar.
3. Click *Execute speed test* in the right pane.

4. When the test completes, click *OK* in the *Confirm* pane to apply the results to the estimated bandwidth. The results can also be applied later by clicking *Apply results to estimated bandwidth*. The speedtest results are used to populate the *Estimated bandwidth* fields.
5. Click *OK*.

The FortiGate must be connected to FortiGuard, and able to reach either the AWS or Google speedtest servers.

Scheduled interface speedtest

The SD-WAN Network Monitor service supports running a speed test based on a schedule. The test results are automatically updated in the interface `measured-upstream-bandwidth` and `measured-downstream-bandwidth` fields. These fields do not impact the interface inbound bandwidth, outbound bandwidth, estimated upstream bandwidth, or estimated downstream bandwidth settings.

An SD-WAN Network Monitor license is required to use the speedtest. The *License* widget and the *System > FortiGuard* page show the license status.

When the scheduled speed tests run, it is possible to temporarily bypass the bandwidth limits set on the interface and configure custom maximum or minimum bandwidth limits. These configurations are optional.

```
config system speed-test-schedule
  edit <interface>
    set schedules <schedule> ...
    set update-inbandwidth enable {enable | disable}
    set update-outbandwidth enable {enable | disable}
    set update-inbandwidth-maximum <integer>
    set update-inbandwidth-minimum <integer>
    set update-outbandwidth-maximum <integer>
    set update-outbandwidth-minimum <integer>
  next
end
```

update-inbandwidth enable {enable disable}	Enable/disable bypassing the interface's inbound bandwidth setting.
update-outbandwidth enable {enable disable}	Enable/disable bypassing the interface's outbound bandwidth setting.
update-inbandwidth-maximum <integer>	Maximum downloading bandwidth to be used in a speed test, in Kbps (0 - 16776000).
update-inbandwidth-minimum <integer>	Minimum downloading bandwidth to be considered effective, in Kbps (0 - 16776000).
update-outbandwidth-maximum <integer>	Maximum uploading bandwidth to be used in a speed test, in Kbps (0 - 16776000).
update-outbandwidth-minimum <integer>	Minimum uploading bandwidth to be considered effective, in Kbps (0 - 16776000).

In the following example, a speed test is scheduled on port1 at 10:00 AM, and another one at 14:00 PM.

To run a speed test based on a schedule:

1. Configure the recurring schedules:

```
config firewall schedule recurring
  edit "10"
    set start 10:00
    set end 12:00
    set day monday tuesday wednesday thursday friday
  next
  edit "14"
    set start 14:00
    set end 16:00
    set day monday tuesday wednesday thursday friday
  next
end
```

2. Configure the speed test schedule:

```

config system speed-test-schedule
  edit "port1"
    set schedules "10" "14"
    set update-inbandwidth enable
    set update-outbandwidth enable
    set update-inbandwidth-maximum 60000
    set update-inbandwidth-minimum 10000
    set update-outbandwidth-maximum 50000
    set update-outbandwidth-minimum 10000
  next
end

```

3. View the speed test results:

```

config system interface
  edit port1
    get | grep measure
    measured-upstream-bandwidth: 23691
    measured-downstream-bandwidth: 48862
    bandwidth-measure-time: Wed Jan 27 14:00:39 2021
  next
end

```

SD-WAN traffic shaping and QoS

Use a traffic shaper in a firewall shaping policy to control traffic flow. You can use it to control maximum and guaranteed bandwidth, or put certain traffic to one of the three different traffic priorities: high, medium, or low.

An advanced shaping policy can classify traffic into 30 groups. Use a shaping profile to define the percentage of the interface bandwidth that is allocated to each group. Each group of traffic is shaped to the assigned speed limit based on the outgoing bandwidth limit configured on the interface.

For more information, see [Traffic shaping on page 984](#).

Sample topology

Sample configuration

This example shows a typical customer usage where the customer's SD-WAN uses the default zone, and has two member: wan1 and wan2, each set to 10Mb/s.

An overview of the procedures to configure SD-WAN traffic shaping and QoS with SD-WAN includes:

1. Give HTTP/HTTPS traffic high priority and give FTP low priority so that if there are conflicts, FortiGate will forward HTTP/HTTPS traffic first.
2. Even though FTP has low priority, configure FortiGate to give it a 1Mb/s guaranteed bandwidth on each SD-WAN member so that if there is no FTP traffic, other traffic can use all the bandwidth. If there is heavy FTP traffic, it can still be guaranteed a 1Mb/s bandwidth.
3. Traffic going to specific destinations such as a VOIP server uses wan1 to forward, and SD-WAN forwards with an Expedited Forwarding (EF) DSCP tag 101110.

To configure SD-WAN traffic shaping and QoS with SD-WAN in the GUI:

1. On the FortiGate, add wan1 and wan2 as SD-WAN members, then add a policy and static route.
See [SD-WAN quick start on page 608](#).
2. Add a firewall policy with *Application Control* enabled. See [Configuring firewall policies for SD-WAN on page 611](#).
3. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shapers* tab, and edit *low-priority*.
 - a. Enable *Guaranteed Bandwidth* and set it to 1000 kbps.
4. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shaping Policies* tab, and click *Create New*.
 - a. Name the traffic shaping policy, for example, *HTTP-HTTPS*.
 - b. Set the following:

Source	<i>all</i>
Destination	<i>all</i>
Service	<i>HTTP and HTTPS</i>
Outgoing interface	<i>virtual-wan-link</i>
Shared Shaper	Enable and set to <i>high-priority</i>
Reverse Shaper	Enable and set to <i>high-priority</i>

- c. Click *OK*.
5. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shaping Policies* tab, and click *Create New*.
 - a. Name the traffic shaping policy, for example, *FTP*.
 - b. Set the following:

Source	<i>all</i>
Destination	<i>all</i>
Service	<i>FTP, FTP_GET, and FTP_PUT</i>
Outgoing interface	<i>virtual-wan-link</i>
Shared Shaper	Enable and set to <i>low-priority</i>
Reverse Shaper	Enable and set to <i>low-priority</i>

- c. Click *OK*

6. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
 - a. Enter a name for the rule, such as *Internet*.
 - b. In the *Destination* section, click *Address* and select the VoIP server that you created in the firewall address.
 - c. Under *Outgoing Interfaces* select *Manual*.
 - d. For *Interface preference* select *wan1*.
 - e. Click *OK*.
7. Use CLI commands to modify DSCP settings. See the DSCP CLI commands below.

To configure the firewall policy using the CLI:

```
config firewall policy
  edit 1
    set name "1"
    set srcintf "dmz"
    set dstintf "virtual-wan-link"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set ssl-ssh-profile "certificate-inspection"
    set application-list "default"
    set nat enable
  next
end
```

To configure the firewall traffic shaper priority using the CLI:

```
config firewall shaper traffic-shaper
  edit "high-priority"
    set maximum-bandwidth 1048576
    set per-policy enable
  next
  edit "low-priority"
    set guaranteed-bandwidth 1000
    set maximum-bandwidth 1048576
    set priority low
    set per-policy enable
  next
end
```

To configure the firewall traffic shaping policy using the CLI:

```
config firewall shaping-policy
  edit 1
    set name "http-https"
    set service "HTTP" "HTTPS"
    set dstintf "virtual-wan-link"
    set traffic-shaper "high-priority"
    set traffic-shaper-reverse "high-priority"
    set srcaddr "all"
    set dstaddr "all"
  next
```

```

edit 2
    set name "FTP"
    set service "FTP" "FTP_GET" "FTP_PUT"
    set dstintf "virtual-wan-link"
    set traffic-shaper "low-priority"
    set traffic-shaper-reverse "low-priority"
    set srcaddr "all"
    set dstaddr "all"
next
end

```

To configure SD-WAN traffic shaping and QoS with SD-WAN in the CLI:

```

config system sdwan
    set status enable
    config members
        edit 1
            set interface "wan1"
            set gateway 172.16.20.2
        next
        edit 2
            set interface "wan2"
            set gateway 10.100.20.2
        next
    end
    config service
        edit 1
            set name "SIP"
            set priority-members 1
            set dst "voip-server"
            set dscp-forward enable
            set dscp-forward-tag 101110
        next
    end
end

```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To use the diagnose command to check if specific traffic is attached to the correct traffic shaper:

```

# diagnose firewall iprope list 100015

policy index=1 uuid_idx=0 action=accept
flag (0):
shapers: orig=high-priority(2/0/134217728) reply=high-priority(2/0/134217728)
cos_fwd=0 cos_rev=0
group=00100015 av=00000000 au=00000000 split=00000000
host=0 chk_client_info=0x0 app_list=0 ips_view=0
misc=0 dd_type=0 dd_mode=0
zone(1): 0 -> zone(2): 36 38
source(1): 0.0.0.0-255.255.255.255, uuid_idx=6,
dest(1): 0.0.0.0-255.255.255.255, uuid_idx=6,

```

```

service(2):
    [6:0x0:0/(1,65535)->(80,80)] helper:auto
    [6:0x0:0/(1,65535)->(443,443)] helper:auto

policy index=2 uuid_idx=0 action=accept
flag (0):
shapers: orig=low-priority(4/128000/134217728) reply=low-priority(4/128000/134217728)
cos_fwd=0 cos_rev=0
group=00100015 av=00000000 au=00000000 split=00000000

```

SDN dynamic connector addresses in SD-WAN rules

SDN dynamic connector addresses can be used in SD-WAN rules. FortiGate supports both public (AWS, Azure, GCP, OCI, AliCloud) and private (Kubernetes, VMware ESXi and NSX, OpenStack, ACI, Nuage) SDN connectors.

The configuration procedure for all of the supported SDN connector types is the same. This example uses an Azure public SDN connector.

There are four steps to create and use an SDN connector address in an SD-WAN rule:

1. Configure the FortiGate IP address and network gateway so that it can reach the Internet.
2. [Create an Azure SDN connector.](#)
3. [Create a firewall address to associate with the configured SDN connector.](#)
4. [Use the firewall address in an SD-WAN service rule.](#)

To create an Azure SDN connector:

1. Go to *Security Fabric > External Connectors*.
2. Click *Create New*.
3. In the *Public SDN* section, click *Microsoft Azure*.
4. Enter the following:

Name	azure1
Status	Enabled
Update Interval	Use Default
Server region	Global
Directory ID	942b80cd-1b14-42a1-8dcf-4b21dece61ba
Application ID	14dbd5c5-307e-4ea4-8133-68738141feb1
Client secret	xxxxxx
Resource path	disabled

5. Click *OK*.

To create a firewall address to associate with the configured SDN connector:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address*.
3. Enter the following:

Category	Address
Name	azure-address
Type	Dynamic
Sub Type	Fabric Connector Address
SDN Connector	azure1
SDN address type	Private
Filter	SecurityGroup=edsouza-centos
Interface	Any

4. Click **OK**.

To use the firewall address in an SD-WAN service rule:

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Set the *Name* to *Azure1*.
3. For the *Destination Address* select *azure-address*.
4. Configure the remaining settings as needed. See [SD-WAN rules on page 650](#) for details.
5. Click **OK**.

Diagnostics

Use the following CLI commands to check the status of and troubleshoot the connector.

To see the status of the SDN connector:

```
# diagnose sys sdn status
SDN Connector      Type      Status      Updating      Last update
-----
azure1             azure     connected   no            n/a
```

To debug the SDN connector to resolve the firewall address:

```
# diagnose debug application azd -1
Debug messages will be on for 30 minutes.

...
azd sdn connector azure1 start updating IP addresses
azd checking firewall address object azure-address-1, vd 0
IP address change, new list:
10.18.0.4
10.18.0.12
...
...

# diagnose sys sdwan service

Service(2): Address Mode(IPV4) flags=0x0
TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Service role: standalone
```

```

Member sub interface:
Members:
  1: Seq_num(1), alive, selected
Dst address:
  10.18.0.4 - 10.18.0.4
  10.18.0.12 - 10.18.0.12
  ... ..
  ... ..
  ... ..
    
```

Application steering using SD-WAN rules

This topic covers how to use application steering in a topology with multiple WAN links. The following examples illustrate how to use different strategies to perform application steering to accommodate different business needs:

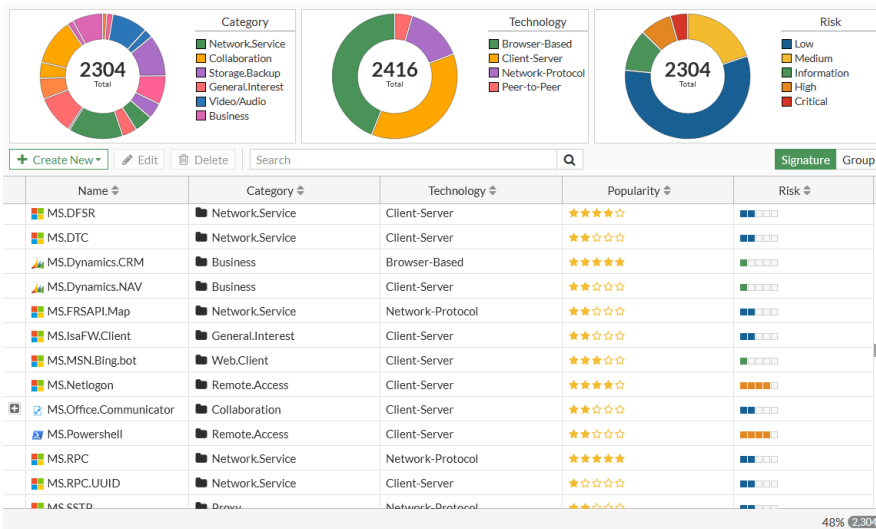

- [Application matching on page 685](#)
- [Static application steering with a manual strategy on page 686](#)
- [Dynamic application steering with lowest cost and best quality strategies on page 688](#)

For application based steering to work, application control must be enabled in a policy. See [Application control on page 1289](#).

Application matching

To apply application steering, SD-WAN service rules match traffic based on the applications that are in the application signature database. To view the signatures, go to *Security Profiles > Application Signatures* and select *Signature*.

On the first session that passes through, the IPS engine processes the traffic in the application layer to match it to a signature in the application signature database. The first session does not match any SD-WAN rules because the signature has not been recognized yet. When the IPS engine recognizes the application, it records the 3-tuple IP

address, protocol, and port in the application control Internet Service ID list. To view the application and corresponding 3-tuple:

```
# diagnose sys sdwan internet-service-app-ctrl-list [app ID]
52.114.142.254
Microsoft.Teams(43541 4294837333): 52.114.142.254 6 443 Fri Jun 18 13:52:18 2021
```

The recognized application and 3-tuple stay in the application control list for future matches to occur. If there are no hits on the entry for eight hours, the entry is deleted.

For services with multiple IP addresses, traffic might not match the expected SD-WAN rule because the traffic is destined for an IP address that has not previously been recognized by the FortiGate. The `diagnose sys sdwan internet-service-app-ctrl-list` command can be used to help troubleshoot such situations.

Static application steering with a manual strategy

This example covers a typical usage scenario where the SD-WAN has two members: MPLS and DIA. DIA is primarily used for direct internet access to internet applications, such as Office365, Google applications, Amazon, and Dropbox. MPLS is primarily used for SIP, and works as a backup when DIA is not working.

This example configures all SIP traffic to use MPLS while all other traffic uses DIA. If DIA is not working, the traffic will use MPLS.

To configure an SD-WAN rule to use SIP and DIA in the GUI:

1. Add port1 (DIA) and port2 (MPLS) as SD-WAN members, and configure a static route. See [Configuring the SD-WAN interface on page 609](#) for details.
2. Create a firewall policy with an *Application Control* profile configured. See [Configuring firewall policies for SD-WAN on page 611](#) for details.
3. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
4. Enter a name for the rule, such as *SIP*.
5. Click the *Application* field and select the applicable SIP applications from the *Select Entries* panel.
6. Under *Outgoing Interfaces*, select *Manual*.
7. For *Interface preference*, select *MPLS*.
8. Click *OK*.

9. Click *Create New* to create another rule.
10. Enter a name for the rule, such as *Internet*.
11. Click the *Address* field and select *all* from the panel.
12. Under *Outgoing Interfaces*, select *Manual*.
13. For *Interface preference*, select *DIA*.
14. Click *OK*.

To configure the firewall policy using the CLI:

```
config firewall policy
  edit 1
    set name "1"
    set srcintf "dmz"
    set dstintf "virtual-wan-link"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set fsso disable
    set application-list "default"
    set ssl-ssh-profile "certificate-inspection"
    set nat enable
  next
end
```

To configure an SD-WAN rule to use SIP and DIA using the CLI:

```
config system sdwan
  set status enable
  config members
    edit 1
      set interface "MPLS"
    next
    edit 2
      set interface "DIA"
    next
  end
  config service
    edit 1
      set name "SIP"
      set internet-service enable
      set internet-service-app-ctrl 34640 152305677 38938 26180 26179 30251
      set priority-members 2
    next
    edit 2
      set name "Internet"
      set dst "all"
      set priority-members 1
    next
  end
end
```

All SIP traffic uses MPLS. All other traffic goes to DIA. If DIA is broken, the traffic uses MPLS. If you use VPN instead of MPLS to run SIP traffic, you must configure a VPN interface, for example vpn1, and then replace member 1 from MPLS to vpn1 for SD-WAN member.

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To use the diagnose command to check performance SLA status using the CLI:

```
# diagnose sys sdwan service 1

Service(1): Address Mode(IPV4) flags=0x0

TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members:<<BR>>

1: Seq_num(1), alive, selected

Internet Service: SIP(4294836224 34640) SIP.Method(4294836225 152305677) SIP.Via.NAT
(4294836226 38938) SIP_Media.Type.Application(4294836227 26180) SIP_Message(4294836228
26179) SIP_Voice(4294836229 30251)

# diagnose sys sdwan service 2

Service(2): Address Mode(IPV4) flags=0x0

TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Members:<<BR>>

1: Seq_num(2), alive, selected

Dst address: 0.0.0.0-255.255.255.255

# diagnose sys sdwan internet-service-app-ctrl-list
Ctrl application(SIP 34640):Internet Service ID(4294836224)
Ctrl application(SIP.Method 152305677):Internet Service ID(4294836225)
Ctrl application(SIP.Via.NAT 38938):Internet Service ID(4294836226)
Ctrl application(SIP_Media.Type.Application 26180):Internet Service ID(4294836227)
Ctrl application(SIP_Message 26179):Internet Service ID(4294836228)
Ctrl application(SIP_Voice 30251):Internet Service ID(4294836229)
```

Dynamic application steering with lowest cost and best quality strategies

In this example, the SD-WAN has three members: two ISPs (DIA_1 and DIA_2) that are used for access to internet applications, and an MPLS link that is used exclusively as a backup for business critical applications.

Business applications, such as Office365, Google, Dropbox, and SIP, use the *Lowest Cost (SLA)* strategy to provide application steering, and traffic falls back to MPLS only if both ISP1 and ISP2 are down. Non-business applications, such as Facebook and Youtube, use the *Best Quality* strategy to choose between the ISPs.

To configure the SD-WAN members, static route, and firewall policy in the GUI:

1. Add port1 (DIA_1), port2 (DIA_2), and port3 (MPLS) as SD-WAN members. Set the cost of DIA_1 and DIA_2 to 0, and MPLS to 20. See [Configuring the SD-WAN interface on page 609](#) for details.
2. Configure a static route. See [Adding a static route on page 610](#) for details.
3. Create a firewall policy to allow traffic out on SD-WAN, with an *Application Control* profile configured. See [Configuring firewall policies for SD-WAN on page 611](#) for details.

To configure the SD-WAN rule and performance SLA checks for business critical application in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Set the name to *BusinessCriticalApps*.
This rule will steer your business critical traffic to the appropriate link based on the *Lowest Cost (SLA)*.
3. Set *Source address* to *all*.
4. Under *Destination*, set *Application* to your required applications. In this example: *Microsoft.Office.365*, *Microsoft.Office.Online*, *Google.Docs*, *Dropbox*, and *SIP*.
5. Under *Outgoing Interfaces*, select *Lowest Cost (SLA)*.
The lowest cost is defined in the SD-WAN member interface settings (see [Configuring the SD-WAN interface on page 609](#)). The lowest possible cost is 0, which represents the most preferred link. In this example, DIA_1 and DIA_2 both have a cost of 0, while MPLS has a cost of 20 because it is used for backup.
6. In *Interface preference*, add the interfaces in order of preference when the cost of the links is tied. In this example, DIA_1, DIA_2, then MPLS.
MPLS will always be chosen last, because it has the highest cost. DIA_1 and DIA_2 have the same cost, so an interface is selected based on their order in the *Interface preference* list.
7. Set *Required SLA target* to ensure that only links that pass your SLA target are chosen in this SD-WAN rule:
 - a. Click in the *Required SLA target* field.
 - b. In the *Select Entries* pane, click *Create*. The *New Performace SLA* pane opens.

c. Set *Name* to *BusinessCriticalApps_HC*.

This health check is used for business critical applications in your SD-WAN rule.

d. Leave *Protocol* set to *Ping*, and add up to two servers, such as *office.com* and *google.com*.

e. Set *Participants* to *Specify*, and add all three interfaces: *DIA_1*, *DIA_2*, and *MPLS*.

f. Enable *SLA Target*.

The attributes in your target determine the quality of your link. The SLA target of each link is compared when determining which link to use based on the lowest cost. Links that meet the SLA target are preferred over links that fail, and move to the next step of selection based on cost. If no links meet the SLA target, then they all move to the next step.

In this example, disable *Latency threshold* and *Jitter threshold*, and set *Packet loss threshold* to 1.

g. Click *OK*.

h. Select the new performance SLA to set it as the *Required SLA target*.

When multiple SLA targets are added, you can choose which target to use in the SD-WAN rule.

The screenshot shows the 'Priority Rule' configuration window. The 'Name' is 'BusinessCriticalApps'. The 'Source' is 'all'. The 'Destination' section includes 'Application' with a list: Dropbox, Google Docs, Microsoft.Office.365, Microsoft.Office.Online, and SIP. Under 'Outgoing Interfaces', the 'Maximize Bandwidth (SLA)' option is selected. The 'Required SLA target' is 'BusinessCriticalApps_HC'. The 'Status' is 'Enable'.

SLA Details			
	Packet Loss	Latency	Jitter
BusinessCriticalApps_HC	1.00%		
DIA_1 (port1)	0.00%	12.52ms	1.29ms
DIA_2 (port2)	0.00%	12.76ms	1.45ms
MPLS (port3)	0.00%	12.72ms	1.45ms

8. Click *OK* to create the SD-WAN rule.

To configure the SD-WAN rule and performance SLA checks for non-business critical application in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.

2. Set the name to *NonBusinessCriticalApps*.

This rule will steer your non-business critical traffic to the appropriate link based on the *Best Quality*. No SLA target must be met, as the best link is selected based on the configured quality criteria and interface preference order.

3. Set *Source address* to *all*.
4. Under *Destination*, set *Application* to your required applications. In this example: *Facebook*, and *Youtube*.
5. Under *Outgoing Interfaces*, select *Best Quality*.
6. In *Interface preference*, add the interfaces in order of preference.
By default, a more preferred link has an advantage of 10% over a less preferred link. For example, when latency is used, the preferred link's calculated latency = real latency / (1+10%).

The preferred link advantage can be customized in the CLI when the mode is `priority` (*Best Quality*) or `auto`:

```
config system sdwan
  config service
    edit <id>
      set link-cost-threshold <integer>
    next
  end
end
```

7. Create and apply a new performance SLA profile:
 - a. Click in the *Measured SLA* field.
 - b. In the drop-down list, click *Create*. The *New Performace SLA* pane opens.
 - c. Set *Name* to *NonBusinessCritical_HC*.
This health check is used for non-business critical applications in your SD-WAN rule.
 - d. Leave *Protocol* set to *Ping*, and add up to two servers, such as *youtube.com* and *facebook.com*.
 - e. Set *Participants* to *Specify*, and add the *DIA_1* and *DIA_2* interfaces. In this example, MPLS is not used for non-business critical applications.
 - f. Leave *SLA Target* disabled.
 - g. Click *OK*.
 - h. Select the new performance SLA from the list to set it as the *Measured SLA*.
8. Set *Quality criteria* as required. In this example, *Latency* is selected.
For bandwidth related criteria, such as *Downstream*, *Upstream*, and *Bandwidth* (bi-directional), the selection is based on available bandwidth. An estimated bandwidth should be configured on the interface to provide a baseline, maximum available bandwidth.

The screenshot shows the 'Priority Rule' configuration window in FortiOS. The rule name is 'NonBusinessCriticalApps'. The source is set to 'all'. The destination is empty. The application list includes Facebook and YouTube. Under 'Outgoing Interfaces', the 'Best Quality' strategy is selected. The interface preference list includes 'DIA_1 (port1)' and 'DIA_2 (port2)'. The zone preference is empty. The measured SLA is 'NonBusinessCriticalApps_HC' and the quality criteria is 'Latency'. The 'Forward DSCP' and 'Reverse DSCP' options are disabled. The status is 'Enable'.

9. Click **OK** to create the SD-WAN rule.

To configure the SD-WAN members, static route, and firewall policy in the CLI:

1. Configure the interfaces:

```
config system interface
  edit "port1"
    set ip <class_ip&net_netmask>
    set alias "DIA_1"
    set role wan
  next
  edit "port2"
    set ip <class_ip&net_netmask>
    set alias "DIA_2"
    set role wan
  next
  edit "port3"
    set ip <class_ip&net_netmask>
    set alias "MPLS"
    set role wan
  next
end
```

2. Configure the SD-WAN members:

```
config system sdwan
  set status enable
  config members
```

```

edit 1
    set interface "port1"
    set gateway 172.16.20.2
next
edit 2
    set interface "port2"
    set gateway 172.17.80.2
next
edit 3
    set interface "port3"
    set gateway 10.100.20.2
    set cost 20
next
end
end
end

```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

3. Configure a static route. See [Adding a static route on page 610](#) for details.
4. Create a firewall policy to allow traffic out on SD-WAN, with an *Application Control* profile configured. See [Configuring firewall policies for SD-WAN on page 611](#) for details.

To configure the SD-WAN rule and performance SLA checks for business critical application in the CLI:

1. Configure the *BusinessCriticalApps_HC* health-check:

```

config system sdwan
    config health-check
        edit "BusinessCriticalApps_HC"
            set server "office.com" "google.com"
            set members 1 2 3
            config sla
                edit 1
                    set link-cost-factor packet-loss
                    set packetloss-threshold 1
                next
            end
        next
    end
end
end

```

2. Configure the *BusinessCriticalApps* service to use *Lowest Cost (SLA)*:

```

config system sdwan
    config service
        edit 1
            set name "BusinessCriticalApps"
            set mode sla
            set src "all"
            set internet-service enable
            set internet-service-app-ctrl 17459 16541 33182 16177 34640
            config sla
                edit "BusinessCriticalApps_HC"
                    set id 1
            end
        end
    end
end

```

```
        next
      end
      set priority-members 1 2 3
    next
  end
end
```

To configure the SD-WAN rule and performance SLA checks for non-business critical application in the CLI:

1. Configure the *nonBusinessCriticalApps_HC* health-check:

```
config system sdwan
  config health-check
    edit "NonBusinessCriticalApps_HC"
      set server "youtube.com" "facebook.com"
      set members 1 2
    next
  end
end
```

2. Configure the *NonBusinessCriticalApps* service to use *Lowest Cost (SLA)*:

```
config system sdwan
  config service
    edit 4
      set name "NonBusinessCriticalApps"
      set mode priority
      set src "all"
      set internet-service enable
      set internet-service-app-ctrl 15832 31077
      set health-check "NonBusinessCriticalApps_HC"
      set priority-members 1 2
    next
  end
end
```

Verification

Check the following GUI pages, and run the following CLI commands to confirm that your traffic is being steered by the SD-WAN rules.

Health checks

To verify the status of each of the health checks in the GUI:

1. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and select each of the health checks from the list.

To verify the status of each of the health checks in the CLI:

```
# diagnose sys sdwan health-check
Health Check(BusinessCritical_HC):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(12.884), jitter(0.919) sla_map=0x1
Seq(2 port2): state(alive), packet-loss(0.000%) latency(13.018), jitter(0.723) sla_map=0x1
Seq(3 port3): state(alive), packet-loss(0.000%) latency(13.018), jitter(0.923) sla_map=0x1
Health Check(NonBusinessCritical_HC):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(6.888), jitter(0.953) sla_map=0x0
Seq(2 port2): state(alive), packet-loss(0.000%) latency(6.805), jitter(0.830) sla_map=0x0
```

Rule members and hit count

To verify the active members and hit count of the SD-WAN rule in the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab.

ID	Name	Source	Destination	Criteria	Members	Hit Count
1	BusinessCriticalApps	all	Dropbox Google.Docs Microsoft.Office.365 Microsoft.Office.Online SIP	SLA	DIA_1 (port1) ✓ DIA_2 (port2) MPLS (port3)	45
4	NonBusinessCriticalApps	all	Facebook YouTube	Latency	DIA_1 (port1) ✓ DIA_2 (port2)	32
Implicit						
sd-wan	all	all	Source IP	any		

The interface that is currently selected by the rule has a checkmark next to its name in the *Members* column. Hover the cursor over the checkmark to open a tooltip that gives the reason why that member is selected. If multiple members are selected, only the highest ranked member is highlighted (unless the mode is *Maximize Bandwidth (SLA)*).

To verify the active members and hit count of the SD-WAN rule in the CLI:

```
# diagnose sys sdwan service
```

```
Service(3): Address Mode(IPV4) flags=0x0
```

```
Gen(13), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
```

```
Members:
```

```
1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
2: Seq_num(2 port2), alive, sla(0x1), cfg_order(1), cost(0), selected
3: Seq_num(3 port3), alive, sla(0x1), cfg_order(2), cost(20), selected
```

```

```

Applications and sessions

To verify sessions in FortiView:

1. Go to a dashboard and add the *FortiView Cloud Applications* widget sorted by bytes. See [Cloud application view on page 131](#) for details.

2. Drill down on an application, such as *YouTube*, then select the *Sessions* tab.

To verify applications identified by Application Control in SD-WAN:

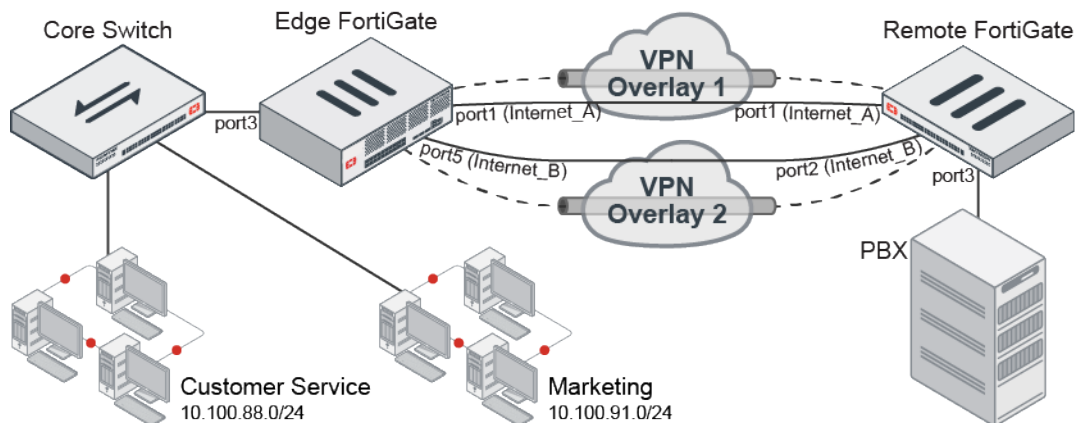

```
# diagnose sys sdwan internet-service-app-ctrl-list
```

```

DSCP tag-based traffic steering in SD-WAN

Differentiated Services Code Point (DSCP) tags can be used to categorize traffic for quality of service (QoS). SD-WAN traffic steering on an edge device can be provided based on the DSCP tags.

This section provides an example of using DSCP tag-based traffic steering using secure SD-WAN. Traffic from the customer service and marketing departments at a headquarters are marked with separate DSCP tags by the core switch and passed to the edge FortiGate. The edge FortiGate reads the tags, then steers traffic to the preferred interfaces based on the defined SD-WAN rules.

VoIP and social media traffic are steered. VoIP traffic from the customer service department is more important than social media traffic. The edge FortiGate identifies the tagged traffic based on SD-WAN rules then steers the traffic:

- VoIP traffic is marked with DSCP tag 011100 and steered to the VPN overlay with the lowest jitter, to provide the best quality voice communication with the remote PBX server.
- Social media traffic is marked with the DSCP tag 001100 and steered to the internet connection with the lowest cost.

The following is assumed to be already configured:

- Two IPsec tunnels (IPsec VPNs on page 1437):
 - Branch-HQ-A on Internet_A (port 1)
 - Branch-HQ-B on Internet_B (port 5)
- Four SD-WAN members in two zones (Configuring the SD-WAN interface on page 609):
 - Overlay zone includes members Branch-HQ-A and Branch-HQ-B
 - virtual-wan-link zone includes members Internet_A and Internet_B
 Internet_A has a cost of 0 and Internet_B has a cost of 10. When using the lowest cost strategy, Internet_A will be preferred. Both members are participants in the Default_DNS performance SLA.
- A static route that points to the SD-WAN interface (Adding a static route on page 610).
- Two firewall policies:

Name	SD-WAN-OUT	Overlay-OUT
From	port3	port3
To	virtual-wan-link	Overlay
Source	all	all
Destination	all	all
Schedule	always	always
Service	all	all
Action	Accept	Accept
NAT	enabled	enabled

After the topology is configured, you can proceed with the configuration of the edge FortiGate:

- [Configuring SD-WAN rules on page 699](#)
- [Results on page 700](#)

Configuring SD-WAN rules

Configure SD-WAN rules to govern the steering of DSCP tag-based traffic to the appropriate interfaces. Traffic is steered based on the criteria that are configured in the SD-WAN rules.

In this example, three SD-WAN rules are configured to govern DSCP tagged traffic:

- *VoIP-Steer* for [VoIP traffic](#).
- *Facebook-DSCP-steer* for [Social media traffic](#).
- *All-traffic* for all of the [Other web traffic](#).

After configuring the rules, go to *Network > SD-WAN* and select the *SD-WAN Rules* tab to check the rules.

VoIP traffic

VoIP traffic is steered to the *Overlay* zone.

DSCP values are usually 6-bit binary numbers that are padded with zeros at the end. VoIP traffic with DSCP tag 011100 will become 01110000. This 8-bit binary number is represented in its hexadecimal form, 0x70, as the type of service bit pattern (`tos`) value. The type of service evaluated bits (`tos-mask`) hexadecimal value of 0xf0 (11110000 in binary) is used to check the four most significant bits in the `tos` value. The four most significant bits of the `tos` (0111) are used to match the first four bits of the DSCP tag. Only the non-zero bit positions in the `tos-mask` are used for comparison; the zero bit positions are ignored.

The *Best quality* (`priority` mode) strategy is used to select the preferred interface, with the *Quality criteria* (`link-cost-members`) set to *Jitter*. The interface with the lowest amount of jitter is selected. For more information about configuring SD-WAN rules with the *Best Quality* strategy, see [Best quality strategy on page 664](#).

To configure the rule for DSCP tagged VoIP traffic using the CLI:

```
config sys sdwan
  config service
    edit 5
      set name "VoIP-Steer"
      set mode priority
      set tos 0x70
      set tos-mask 0xf0
      set dst "all"
      set health-check "Default_DNS"
      set link-cost-factor jitter
      set priority-members 4 3
    next
  end
end
```

Social media traffic

Social media traffic is steered to the *virtual-wan-link* zone.

DSCP values are usually 6-bit binary numbers that are padded with zeros at the end. Social media traffic traffic with DSCP tag 001100 will become 00110000. This 8-bit binary number is represented in its hexadecimal form, 0x30, as the `tos` value. The `tos-mask` hexadecimal value of 0xf0 (11110000 in binary) is used to check the four most significant bits in the `tos` value. The four most significant bits of the `tos` (0011) are used to match the first four bits of the DSCP tag. Only the non-zero bit positions in the `tos-mask` are used for comparison; the zero bit positions are ignored.

The *Manual* (manual mode) strategy is used to select the preferred interface. Internet_B (port5, priority member 2) is set as the preferred interface to steer all social media traffic to. For more information about configuring SD-WAN rules with the manual strategy, see [Manual strategy on page 663](#).

To configure SD-WAN rule for DSCP tagged social media traffic using the CLI:

```
config system sdwan
  config service
    edit 3
      set name "Facebook-DSCP-steer"
      set mode manual
      set tos 0x30
      set tos-mask 0xf0
      set dst "all"
      set priority-members 2 1
    next
  end
end
```

Other web traffic

Other web traffic is steered to the *virtual-wan-link* zone.

The *Lowest Cost (SLA)* (sla mode) strategy is used to select the preferred interface. The interface that meets the defined SLA targets (*Default_DNS* in this case) is selected. If there is a tie, the interface with the lowest cost is selected, Internet_A (port1) in this case.

For more information about configuring SD-WAN rules with the *Lowest Cost (SLA)* strategy, see [Lowest cost \(SLA\) strategy on page 668](#).

To configure SD-WAN rule for all other web traffic using the CLI:

```
config system sdwan
  config service
    edit 2
      set name "All-traffic"
      set mode sla
      set dst "all"
      config sla
        edit "Default_DNS"
          set id 1
        next
      end
      set priority-members 1 2
    next
  end
end
```

Results

These sections show the function of SD-WAN with respect to DSCP tagged traffic steering, and can help confirm that it is running as expected:

- Verifying the DSCP tagged traffic on FortiGate on page 701
- Verifying the service rules on page 702
- Verifying traffic steering on the SD-WAN rules on page 702
- Verifying that steered traffic is leaving from the expected interface on page 703

Verifying the DSCP tagged traffic on FortiGate

Packet sniffing is used to verify the incoming DSCP tagged traffic. See [Using the FortiOS built-in packet sniffer](#) for more information.

Wireshark is used to verify that VoIP traffic is tagged with the expected DSCP tag, 0x70 or 0x30.

VoIP traffic marked with DSCP tag 0x70:

```
# diagnose sniffer packet any '(ip and ip[1] & 0xfc == 0x70)' 6 0 1
```

The screenshot shows a Wireshark packet capture interface. The packet list pane displays several packets, with packet 11 selected. The packet details pane shows the following information:

- Frame 1: 242 bytes on wire (1936 bits), 242 bytes captured (1936 bits)
- Ethernet II, Src: Fortinet_00:03:01 (00:09:0f:00:03:01), Dst: 00:00:00:00:00:01 (00:00:00:00:00:01)
- Internet Protocol Version 4, Src: 10.100.88.171, Dst: 10.1.0.102
 - 0100 ... = Version: 4
 - ... 0101 = Header Length: 20 bytes (5)
 - Differentiated Services Field: 0x70 (DSCP: AF32, ECN: Not-ECT)** (highlighted with a red box)
 - Total Length: 228
 - Identification: 0x49de (18910)
 - Flags: 0x0000
 - Fragment offset: 0
 - Time to live: 127
 - Protocol: UDP (17)
 - Header checksum: 0x8345 [validation disabled]
 - [Header checksum status: Unverified]
 - Source: 10.100.88.171
 - Destination: 10.1.0.102
- User Datagram Protocol, Src Port: 65477, Dst Port: 5061
- Data (200 bytes)

The packet bytes pane shows the hex representation of the packet data, with a red circle highlighting the DSCP field (0x70) in the IP header.

Web traffic marked with DSCP tag 0x30:

```
# diagnose sniffer packet any '(ip and ip[1] & 0xfc == 0x30)' 6 0 1
```

Verifying the service rules

To check that the expected DSCP tags and corresponding interfaces are used by the SD-WAN rules to steer traffic:

```
# diagnose sys sdwan service
```

```
Service(5): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x70/0xf0), Protocol(0: 1->65535), Mode(manual)
  Members:
    1: Seq_num(4 Branch-HQ-B), alive, selected
  Dst address:
    0.0.0.0-255.255.255.255
```

```
Service(3): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x30/0xf0), Protocol(0: 1->65535), Mode(manual)
  Members:
    1: Seq_num(2 port5), alive, selected
  Dst address:
    0.0.0.0-255.255.255.255
```

```
Service(2): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Members:
    1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
    2: Seq_num(2 port5), alive, sla(0x1), cfg_order(1), cost(10), selected
  Dst address:
    0.0.0.0-255.255.255.255
```

Verifying traffic steering on the SD-WAN rules

Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab to check the *Hit Count* on the SD-WAN interfaces.

ID	Name	Source	Destination	Criteria	Members	Hit Count
IPv4						
5	VoIP-Steer		all	Jitter	VPN_B_Tunnel (Branch-HQ-B) VPN_A_Tunnel (Branch-HQ-A)	8,090
3	Facebook-DSCP-steer		all		Internet_B (port5) Internet_A (port1)	184
2	All-traffic		all	SLA	Internet_A (port1) Internet_B (port5)	23,505
Implicit						
	sd-wan	all	all	Source IP	any	

Updated: 15:48:39

Verifying that steered traffic is leaving from the expected interface

To confirm that web traffic (port 443) flows through the correct underlay interface members, and VoIP traffic flows through the correct overlay interface members, go to *Dashboard > FortiView Policies* and double click on the policy name.

Web traffic is expected to leave on *Interface_A (port1)* or *Interface_B (port5)*:

Source	Device	Destination	Application	Protocol	Source Port	Destination Port	Bytes	Packets	Duration (seconds)	Destination Interface
10.100.88.151	00:09:0f:00:03:01	216.58.192.226	Google Ads	TCP	28454	443	12.65 kB	47	35s	Internet_A (port1)
10.100.88.151	00:09:0f:00:03:01	216.58.192.132	HTTPS.BROWSER	TCP	28432	443	12.85 kB	89	39s	Internet_A (port1)
10.100.88.151	00:09:0f:00:03:01	13.249.135.106	HTTPS.BROWSER	TCP	28447	443	13.93 kB	30	36s	Internet_A (port1)
10.100.88.151	00:09:0f:00:03:01	13.249.135.36	HTTPS.BROWSER	TCP	28485	443	7.75 kB	22	21s	Internet_A (port1)
10.100.88.161	00:09:0f:00:03:01	157.240.2.25	Facebook	TCP	28449	443	321.46 kB	264	35s	Internet_B (port5)
10.100.88.151	00:09:0f:00:03:01	69.147.64.34	Yahoo.Services	TCP	28436	443	8.80 kB	28	39s	Internet_A (port1)
10.100.88.161	00:09:0f:00:03:01	157.240.18.19	Facebook	TCP	28413	443	8.45 kB	33	2m 13s	Internet_B (port5)
10.100.88.161	00:09:0f:00:03:01	157.240.18.174	Instagram	TCP	28411	443	193.70 kB	267	2m 14s	Internet_B (port5)
10.100.88.161	00:09:0f:00:03:01	69.171.250.63	Instagram	TCP	28410	443	23.42 kB	58	2m 16s	Internet_B (port5)
10.100.88.161	00:09:0f:00:03:01	69.171.250.63	Instagram	TCP	28412	443	10.87 kB	40	2m 14s	Internet_B (port5)

VoIP traffic is expected to leave on the preferred *VPN_B_Tunnel (Branch-HQ-B)* interface:

Source	Device	Destination	Application	Protocol	Source Port	Destination Port	Bytes	Packets	Duration (seconds)	Destination Interface
10.100.88.171	00:09:0f:00:03:01	10.1.0.102	TCP/5061	TCP	34779	5061	728 B	14	17s	VPN_B_Tunnel (Branch-HQ-B)
10.100.88.171	00:09:0f:00:03:01	10.1.0.102	UDP/5061	UDP	65477	5061	1.84 MB	8,084	3m 16s	VPN_B_Tunnel (Branch-HQ-B)
10.100.88.171	00:09:0f:00:03:01	10.1.0.102	UDP/5061	UDP	65478	5061	32 B	1	2m 4s	VPN_B_Tunnel (Branch-HQ-B)

ECMP support for the longest match in SD-WAN rule matching

The longest match SD-WAN rule can match ECMP best routes. The rule will select the egress ports on ECMP specific routes, and not the less specific routes, to transport traffic.

The service mode determines which egress port on the ECMP specific routes is selected to forward traffic:

- Manual (`manual`): The first configured alive port is selected.
- Best Quality (`priority`): The best quality port is selected.
- Lowest Cost (`sla`): The first configured or lower cost port in SLA is selected.

Example

By default, SD-WAN selects the outgoing interface from all of the links that have valid routes to the destination. In some cases, it is required that only the links that have the best (or longest match) routes (single or ECMP) to the destination are considered.

In this example, four SD-WAN members in two zones are configured. The remote PC (PC_2 - 10.1.100.22) is accessible on port15 and port16, even though there are valid routes for all of the SD-WAN members. A single SD-WAN service rule is configured that allows traffic to be balanced between all four of the members, but only chooses between port15 and port16 for the specific 10.1.100.22 address.

A performance SLA health check is configured to monitor 10.1.100.2. An SD-WAN service rule in Lowest Cost (SLA) mode is configured to select the best interface to steer the traffic. In the rule, the method of selecting a member if more than one meets the SLA (`tie-break`) is configured to select members that meet the SLA and match the longest prefix in the routing table (`fib-best-match`). If there are multiple ECMP routes with the same destination, the FortiGate will take the longest (or best) match in the routing table, and choose from those interface members.

To configure the SD-WAN:

```
config system sdwan
  config zone
    edit "virtual-wan-link"
    next
    edit "z1"
    next
  end
  config members
    edit 1
    set interface "port1"
    set gateway 172.16.200.2
    next
    edit 2
```

```

        set interface "dmz"
        set gateway 172.16.208.2
    next
    edit 3
        set interface "port15"
        set zone "z1"
        set gateway 172.16.209.2
    next
    edit 4
        set interface "port16"
        set zone "z1"
        set gateway 172.16.210.2
    next
end
config health-check
    edit "1"
        set server "10.1.100.2"
        set members 0
        config sla
            edit 1
                next
            end
        next
end
config service
    edit 1
        set name "1"
        set mode sla
        set dst "all"
        set src "172.16.205.0"
        config sla
            edit "1"
                set id 1
            next
        end
        set priority-members 1 2 3 4
        set tie-break fib-best-match
    next
end
end

```

To check the results:

1. The debug shows the SD-WAN service rule. All of the members meet SLA, and because no specific costs are attached to the members, the egress interface is selected based on the interface priority order that is configured in the rule:

```

FGT_A (root) # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(4), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Members(4):
  1: Seq_num(1 port1), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
  2: Seq_num(2 dmz), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
  3: Seq_num(3 port15), alive, sla(0x1), gid(0), cfg_order(2), cost(0), selected
  4: Seq_num(4 port16), alive, sla(0x1), gid(0), cfg_order(3), cost(0), selected

```

```

Src address(1):
  172.16.205.0-172.16.205.255
Dst address(1):
  0.0.0.0-255.255.255.255

```

2. The routing table shows that there are ECMP default routes on all of the members, and ECMP specific (or best) routes only on port15 and port16:

```

FGT_A (root) # get router info routing-table static
Routing table for VRF=0
S*      0.0.0.0/0 [1/0] via 172.16.200.2, port1
          [1/0] via 172.16.208.2, dmz
          [1/0] via 172.16.209.2, port15
          [1/0] via 172.16.210.2, port16
S       10.1.100.22/32 [10/0] via 172.16.209.2, port15
          [10/0] via 172.16.210.2, port16

```

Because `tie-break` is set to `fib-best-match`, the first configured member from port15 and port16 is selected to forward traffic to PC_2. For all other traffic, the first configured member from all four of the interfaces is selected to forward traffic.

3. On PC-1, generate traffic to PC-2:

```
ping 10.1.100.22
```

4. On FGT_A, sniff for traffic sent to PC_2:

```

# diagnose sniffer packet any 'host 10.1.100.22' 4
interfaces=[any]
filters=[host 10.1.100.22]
2.831299 port5 in 172.16.205.11 -> 10.1.100.22: icmp: echo request
2.831400 port15 out 172.16.205.11 -> 10.1.100.22: icmp: echo request

```

Traffic is leaving on port15, the first configured member from port15 and port16.

Override quality comparisons in SD-WAN longest match rule matching

In SD-WAN rules, the longest match routes will override the quality comparisons when all of the specific routes are out of SLA.

With this feature in an SD-WAN rule:

- **Lowest Cost (`sla`):** Even though all of the egress ports on specific routes (longest matched routes) are out of SLA, the SD-WAN rule still selects the first configured or lower-cost port from the egress ports to forward traffic.
- **Best Quality (`priority`):** Even though the egress ports on specific routes (longest matched routes) have worse quality than all other ports on less specific routes, the SD-WAN rule still selects the best quality port from the ports on specific routes to forward traffic.

This feature avoids a situation where, if the members on specific routes (longest matched routes) are out of SLA or have worse quality, the traffic might be forwarded to the wrong members in SLA (higher quality) on the default or aggregate routes.

Example

In this example, four SD-WAN members in two zones are configured. The remote PC (PC_2 - 10.1.100.22) is accessible on port15 and port16, even though there are valid routes for all of the SD-WAN members. A single SD-WAN service rule is configured that allows traffic to be balanced between all four of the members, but only chooses between port15 and port16 for the specific 10.1.100.22 address. If neither port15 nor port16 meet the SLAs, traffic will be forwarded on one of these interfaces, instead of on port1 or dmz.

A performance SLA health check is configured to monitor 10.1.100.2. An SD-WAN service rule in Lowest Cost (SLA) mode is configured to select the best interface to steer the traffic. In the rule, the method of selecting a member if more than one meets the SLA (*tie-break*) is configured to select members that meet the SLA and match the longest prefix in the routing table (*fib-best-match*). If there are multiple ECMP routes with the same destination, the FortiGate will take the longest (or best) match in the routing table, and choose from those interface members.

To configure the SD-WAN:

```
config system sdwan
  config zone
    edit "virtual-wan-link"
    next
    edit "z1"
    next
  end
  config members
    edit 1
      set interface "port1"
      set gateway 172.16.200.2
    next
    edit 2
      set interface "dmz"
      set gateway 172.16.208.2
    next
    edit 3
      set interface "port15"
      set zone "z1"
      set gateway 172.16.209.2
    next
    edit 4
      set interface "port16"
      set zone "z1"
      set gateway 172.16.210.2
    next
  end
  config health-check
```

```

    edit "1"
        set server "10.1.100.2"
        set members 0
        config sla
            edit 1
            next
        end
    next
end
config service
    edit 1
        set name "1"
        set mode sla
        set dst "all"
        set src "172.16.205.0"
        config sla
            edit "1"
                set id 1
            next
        end
        set priority-members 1 2 3 4
        set tie-break fib-best-match
    next
end
end

```

To check the results:

1. The debug shows the SD-WAN service rule. Both port15 and port16 are up, but out of SLA:

```

FGT_A (root) # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Members(4):
  1: Seq_num(1 port1), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
  2: Seq_num(2 dmz), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
  3: Seq_num(3 port15), alive, sla(0x0), gid(0), cfg_order(2), cost(0), selected
  4: Seq_num(4 port16), alive, sla(0x0), gid(0), cfg_order(3), cost(0), selected
Src address(1):
  172.16.205.0-172.16.205.255

Dst address(1):
  0.0.0.0-255.255.255.255

```

2. The routing table shows that there are ECMP default routes on all of the members, and ECMP specific (or best) routes only on port15 and port16:

```

FGT_A (root) # get router info routing-table static
Routing table for VRF=0
S*   0.0.0.0/0 [1/0] via 172.16.200.2, port1
      [1/0] via 172.16.208.2, dmz
      [1/0] via 172.16.209.2, port15
      [1/0] via 172.16.210.2, port16
S    10.1.100.22/32 [10/0] via 172.16.209.2, port15
      [10/0] via 172.16.210.2, port16

```

Because `tie-break` is set to `fib-best-match`, even though both `port15` and `port16` are out of SLA, the first configured member of the two (`port15`) is selected to forward traffic to `PC_2`. For all other traffic, the first configured member from all of the interfaces that are in SLA is selected to forward traffic (`port1`).

3. On PC-1, generate traffic to PC-2:

```
ping 10.1.100.22
```

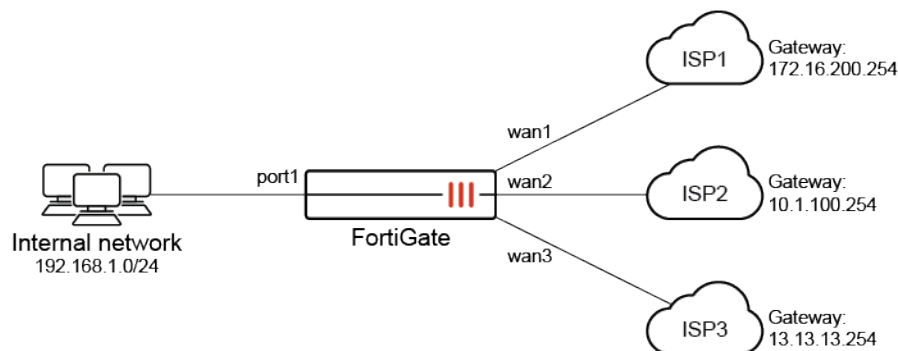

4. On FGT_A, sniff for traffic sent to PC_2:

```
# diagnose sniffer packet any 'host 10.1.100.22' 4
interfaces=[any]
filters=[host 10.1.100.22]
2.831299 port5 in 172.16.205.11 -> 10.1.100.22: icmp: echo request
2.831400 port15 out 172.16.205.11 -> 10.1.100.22: icmp: echo request
```

Traffic is leaving on `port15`, the first configured member from `port15` and `port16`, even though both are out of SLA.

Use SD-WAN rules for WAN link selection with load balancing

This example covers a use case where a user has multiple WAN links and wants to optimize the WAN link selection and performance while limiting the use of more expensive and bandwidth intensive interfaces, such as 5G or LTE.

In this scenario, the user has three WAN links. The goal is to balance the load between `wan1` and `wan2`; however, `wan3`, which is quite costly to operate, should only be used if both `wan1` and `wan2` are unavailable.

This configuration involves the following steps:

1. [Configuring the SD-WAN members](#)
2. [Configuring the maximize bandwidth SD-WAN rule](#)
3. [Configuring a static route](#)
4. [Configuring a firewall policy for SD-WAN](#)
5. [Verifying the configuration](#)

Configuring the SD-WAN members

SD-WAN must be enabled first, and member interfaces must be selected and added to a zone. See [Configuring the SD-WAN interface on page 609](#) for more information.

To configure the SD-WAN members in the GUI:

1. Configure the wan1, wan2, and wan3 interfaces (see [Interface settings on page 143](#) for more details).
 - a. Set the wan1 interface *IP/Netmask* to *172.16.200.1 255.255.255.0*.
 - b. Set the wan2 interface *IP/Netmask* to *10.1.100.1 255.255.255.0*.
 - c. Set the wan3 interface *IP/Netmask* to *13.13.13.1 255.255.255.0*.
2. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
3. Configure the wan1 SD-WAN member:
 - a. Set the *Interface* to *wan1*.
 - b. Leave the *SD-WAN Zone* as *virtual-wan-link*.
 - c. Set the *Gateway* to *172.16.200.254*.
 - d. Set the *Status* to *Enable*
 - e. Click *OK*.
4. Repeat step 3 for wan2 and wan3.
 - a. For wan2, set the *Gateway* to the ISP's gateway, *10.1.100.254*.
 - b. For wan3, set the *Gateway* to the ISP's gateway, *13.13.13.254*.

To configure the SD-WAN members in the CLI:

```
config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
  end
  config members
    edit 1
      set interface "wan1"
      set gateway 172.16.200.254
    next
    edit 2
      set interface "wan2"
      set gateway 10.1.100.254
    next
    edit 3
      set interface "wan3"
      set gateway 13.13.13.254
    next
  end
end
```

Configuring the maximize bandwidth SD-WAN rule

SD-WAN rules define specific routing options to route traffic to an SD-WAN member. See [SD-WAN rules on page 650](#) and [Maximize bandwidth \(SLA\) strategy on page 671](#) for more information.

To configure a maximize bandwidth SD-WAN rule in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Configure the following settings:

Name	<i>test</i>
Source address	<i>all</i>
Destination > Address	<i>all</i>
Outgoing Interfaces	<i>Maximize bandwidth (SLA)</i>
Interface preference	<i>wan1, wan2</i>
Required SLA target	<i>Default_DNS</i>

3. Configure the other settings as needed.
4. Click *OK*.

To configure a maximize bandwidth SD-WAN rule in the CLI:

```
config system sdwan
  config service
    edit 1
      set name "test"
      set mode load-balance
      set dst "all"
      set src "all"
      config sla
        edit "Default_DNS"
          set id 1
        next
      end
      set priority-members 1 2
    next
  end
end
```

Configuring a static route

A default route for SD-WAN must be configured. See [Adding a static route on page 610](#) for more information.

To configure a static route for SD-WAN in the GUI:

1. Go to *Network > Static Routes* and click *Create New*. The *New Static Route* page opens.
2. Set the *Destination* to *Subnet*, and leave the IP address and subnet mask as *0.0.0.0/0.0.0.0*.
3. Set the *Interface* to the SD-WAN zone, *virtual-wan-link*.
4. Set the *Status* to *Enabled*.
5. Click *OK*.

To configure a static route for SD-WAN in the CLI:

```
config router static
  edit 1
    set distance 1
    set sdwan-zone "virtual-wan-link"
```

```

next
end

```

Configuring a firewall policy for SD-WAN

A firewall policy must be configured that allows traffic from the organization's internal network to the SD-WAN zone. See [Configuring firewall policies for SD-WAN on page 611](#) for more information.

To configure the firewall policy for SD-WAN in the GUI:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following settings:

Name	<i>sd-wan</i>
Incoming Interface	<i>port1</i>
Outgoing Interface	<i>virtual-wan-link</i>
Source	<i>all</i>
Destination	<i>all</i>
Schedule	<i>always</i>
Service	<i>ALL</i>
Action	<i>ACCEPT</i>
NAT	Enable and select <i>NAT</i> .
IP Pool Configuration	<i>Use Outgoing Interface Address</i>
Enable this policy	Enable this setting.

3. Configure the other settings as needed.
4. Click *OK*.

To configure the firewall policy for SD-WAN in the CLI:

```

config firewall policy
  edit 1
    set name "sd-wan"
    set srcintf "port1"
    set dstintf "virtual-wan-link"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set schedule "always"
    set service "ALL"
    set nat enable
  next
end

```

Verifying the configuration

To verify the SD-WAN member status:

```
# diagnose sys sdwan member
Member(1): interface: wan1, flags=0x0 , gateway: 172.16.200.254, priority: 1 1024, weight: 0
Member(2): interface: wan2, flags=0x0 , gateway: 10.1.100.254, priority: 1 1024, weight: 0
Member(3): interface: wan3, flags=0x0 , gateway: 13.13.13.254, priority: 1 1024, weight: 0
```

To verify the configuration when both wan1 and wan2 are up:

1. Verify the SD-WAN service rules status:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance hash-mode=round-robin)
Members(2):
  1: Seq_num(1 wan1), alive, sla(0x0), gid(1), num of pass(0), selected
  2: Seq_num(2 wan2), alive, sla(0x0), gid(1), num of pass(0), selected
Src address(1):
  0.0.0.0-255.255.255.255

Dst address(1):
  0.0.0.0-255.255.255.255
```

This output indicates that both wan1 and wan2 are operational.

2. Verify the policy route list:

```
# diagnose firewall proute list
list route policy info(vf=root):

id=2130771969(0x7f010001) vwl_service=1(test) vwl_mbr_seq=1 2 dscp_tag=0xff 0xff
flags=0x10 load-balance hash-mode=round-robin tos=0x00 tos_mask=0x00 protocol=0
sport=0-65535 iif=0(any) dport=1-65535 path(2) oif=3(wan1) num_pass=0 oif=6(wan2) num_
pass=0
source(1): 0.0.0.0-255.255.255.255
destination(1): 0.0.0.0-255.255.255.255
hit_count=8056 last_used=2023-11-10 05:07:11
```

This output indicates that both wan1 and wan2 are used to steer traffic.

To verify the configuration when wan2 is down and wan1 is up:

1. Verify the SD-WAN service rules status:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance hash-mode=round-robin)
Members(2):
  1: Seq_num(1 wan1), alive, sla(0x0), gid(1), num of pass(0), selected
  2: Seq_num(2 wan2), dead, sla(0x0), gid(1), num of pass(0)
Src address(1):
  0.0.0.0-255.255.255.255
```

```
Dst address(1):
    0.0.0.0-255.255.255.255
```

This output indicates that wan1 is operational, and wan2 is not.

2. Verify the policy route list:

```
# diagnose firewall proute list
list route policy info(vf=root):

id=2130771969(0x7f010001) vwl_service=1(test) vwl_mbr_seq=1 dscp_tag=0xff 0xff
flags=0x10 load-balance hash-mode=round-robin tos=0x00 tos_mask=0x00 protocol=0
sport=0-65535 iif=0(any) dport=1-65535 path(1) oif=3(wan1) num_pass=0
source(1): 0.0.0.0-255.255.255.255
destination(1): 0.0.0.0-255.255.255.255
hit_count=8126 last_used=2023-11-10 05:10:55
```

This output indicates that wan1 is used to steer traffic.

To verify the configuration when wan1 is down and wan2 is up:

1. Verify the SD-WAN service rules status:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance hash-mode=round-robin)
Members(2):
    1: Seq_num(2 port2), alive, sla(0x0), gid(1), num of pass(0), selected
    2: Seq_num(1 port1), dead, sla(0x0), gid(1), num of pass(0)
Src address(1):
    0.0.0.0-255.255.255.255

Dst address(1):
    0.0.0.0-255.255.255.255
```

This output indicates that wan2 is operational, and wan1 is not.

2. Verify the policy route list:

```
# diagnose firewall proute list
list route policy info(vf=root):

id=2130771969(0x7f010001) vwl_service=1(test) vwl_mbr_seq=2 dscp_tag=0xff 0xff
flags=0x10 load-balance has
h-mode=round-robin tos=0x00 tos_mask=0x00 protocol=0 sport=0-65535 iif=0(any) dport=1-
65535
path(1) oif=6(wan2) num_pass=0
source(1): 0.0.0.0-255.255.255.255
destination(1): 0.0.0.0-255.255.255.255
hit_count=8309 last_used=2023-11-10 05:18:37
```

This output indicates that wan2 is used to steer traffic.

To verify the configuration when both wan1 and wan2 down, and traffic is steered using wan3:

```
# diagnose sniffer packet wan3
Using Original Sniffing Mode
interfaces=[wan3]
```

```
filters=[none]
3.144417 13.13.13.1.52665 -> 204.79.197.239.443: 1610731732 ack 236747780
3.155250 204.79.197.239.443 -> 13.13.13.1.52665: ack 1610731733
5.047264 13.13.13.1.52613 -> 20.185.212.106.443: 1421254032 ack 3784884456
5.126008 20.185.212.106.443 -> 13.13.13.1.52613: ack 1421254033
```

This output indicates that wan3 is used to steer traffic.

To verify the configuration when either wan1 or wan2 is restored, and traffic ceases to be steered through wan3:

1. Verify the SD-WAN service rules status:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x200 use-shortcut-sla
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance hash-mode=round-robin)
  Members(2):
    1: Seq_num(1 wan1), alive, sla(0x0), gid(1), num of pass(0), selected
    2: Seq_num(2 wan2), dead, sla(0x0), gid(1), num of pass(0)
  Src address(1):
    0.0.0.0-255.255.255.255

  Dst address(1):
    0.0.0.0-255.255.255.255
```

This output indicates that wan1 is operational.

2. Verify the policy route list:

```
# diagnose firewall proute list
list route policy info(vf=root):

id=2130771969(0x7f010001) vw1_service=1(test) vw1_mbr_seq=1 dscp_tag=0xff 0xff
flags=0x10 load-balance hash-mode=round-robin tos=0x00 tos_mask=0x00 protocol=0
sport=0-65535 iif=0(any) dport=1-65535 path(1) oif=3(wan1) num_pass=0
source(1): 0.0.0.0-255.255.255.255
destination(1): 0.0.0.0-255.255.255.255
hit_count=8182 last_used=2023-11-10 05:14:34
```

This output indicates that wan1 is used to steer traffic.

Advanced routing

The following topics provide instructions on SD-WAN advanced routing:

- [Local out traffic on page 716](#)
- [Using BGP tags with SD-WAN rules on page 721](#)
- [BGP multiple path support on page 724](#)
- [Controlling traffic with BGP route mapping and service rules on page 727](#)
- [Applying BGP route-map to multiple BGP neighbors on page 733](#)

Local out traffic

Local out, or self-originating, traffic is traffic that originates from the FortiGate going to external servers and services. The traffic can be from Syslog, FortiAnalyzer logging, FortiGuard services, remote authentication, and others.

By default, local out traffic relies on routing table lookups to determine the egress interface that is used to initiate the connection. However, many types of local out traffic support selecting the egress interface based on SD-WAN or manually specified interfaces. When manually specifying the egress interface, the source IP address can also be manually configured.

Go to *Network > Local Out Routing* to configure the available types of local out traffic. Some types of traffic can only be configured in the CLI.

By default *Local Out Routing* is not visible in the GUI. Go to *System > Feature Visibility* to enable it. See [Feature visibility on page 2292](#) for more information.

When VDOMs are enabled, the following entries are available on the local out routing page:

Global view	VDOM view
External Resources	LDAP Servers
AWS_IP_Blacklist	ldap
AWS_Malware_Hash	Log
Log	Log FortiAnalyzer Override Settings
Log FortiAnalyzer Setting	Log Syslogd Override Settings
Log FortiAnalyzer Cloud Setting	RADIUS Servers
FortiGate Cloud Log Settings	fac_radius_server
Log Syslogd Setting	TACACS+
System	TACACS
System DNS	
System FortiGuard	
System FortiSandbox	

If a service is disabled, it is grayed out. To enable it, select the service and click *Enable Service*. If a service is enabled, there is a *Local Out Setting* button in the gutter of that service's edit page to directly configure the local-out settings.

Examples

To configure DNS local-out routing:

1. Go to *Network > Local Out Routing* and double-click *System DNS*.
2. For *Outgoing interface*, select one of the following:

Auto	Select the outgoing interface automatically based on the routing table.
SD-WAN	Select the outgoing interface using the configured SD-WAN interfaces and rules.
Specify	Select the outgoing interface from the dropdown.
Use Interface IP	Use the primary IP, which cannot be configured by the user.
Manually	Selected an IP from the list, if the selected interface has multiple IPs configured.

3.

If *Specify* is selected, select a setting for *Source IP*:

The screenshot shows the 'Edit Local Out Setting' dialog box. The 'Name' field is 'LDAP Servers'. The 'Outgoing interface' dropdown is set to 'Specify'. The 'Source IP' dropdown is set to '10.100.64.101'. There are 'OK' and 'Cancel' buttons at the bottom.

4. Click *OK*.

To edit local-out settings from a RADIUS server entry:

1. Go to *User & Authentication > RADIUS Servers* and double-click an entry to edit it.
2. Click *Local Out Setting*.

The screenshot shows the 'Edit RADIUS Server' dialog box. The 'Name' field is 'fac_radius_server'. The 'Authentication method' dropdown is set to 'Default'. The 'NAS IP' field is '10.100.88.9'. The 'Include in every user group' checkbox is checked. The 'Primary Server' section has 'IP/Name' as '10.100.88.9' and 'Secret' as '*****'. The 'Secondary Server' section is empty. There are 'OK' and 'Cancel' buttons at the bottom.

The *Edit Local Out Setting* pane opens.

3. Configure the settings for *Outgoing interface* and *Source IP*.

4. Click **OK**.

To edit multiple entries concurrently:

1. Go to *Network > Local Out Routing*.
2. If applicable, select *IPv4* or *IPv6*. *IPv4+IPv6* does not support multi-select.
3. Click *Multi-Select Mode*. All of the local out settings that can be edited concurrently are shown.
4. Select the specific entries, or click *Select All* to select all of the entries.

	Name	Source IP	Outgoing Interface	IP Version
Log	FortiGate Cloud Log Settings	Dynamic	Auto	IPv4
System	System DNS	Dynamic	Auto	IPv4
	System FortiGuard	Dynamic	Auto	IPv4

5. Click **Edit** and configure the local out settings as required.

6. Click **OK**.
7. Click *Exit Multi-Select Mode* to return to the normal view.

Configuring local out routing in the CLI

Some local out routing settings can only be configured using the CLI.

PING

IPv4 and IPv6 pings can be configured to use SD-WAN rules:

```
execute ping-options use-sdwan {yes | no}
execute ping6-options use-sdwan {yes | no}
```

Traceroute

IPv4 traceroute can be configured to use SD-WAN rules:

```
execute traceroute-options use-sdwan {yes | no}
```

Central management

Central management traffic can use SD-WAN rules or a specific interface:

```
config system central-management
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
end
```

NTP server

NTP server traffic can use SD-WAN rules or a specific interface:

```
config system ntp
    config ntpserver
        edit <id>
            set interface-select-method {auto | sdwan | specify}
            set interface <interface>
        next
    end
end
```

DHCP proxy

DHCP proxy traffic can use SD-WAN rules or a specific interface:

```
config system settings
    set dhcp-proxy-interface-select-method {auto | sdwan | specify}
    set dhcp-proxy-interface <interface>
end
```

dhcp-proxy-interface-select-method {auto | sdwan | specify}

Select the interface selection method:

- **auto:** Set the outgoing interface automatically (default).
- **sdwan:** Set the interface by SD-WAN or policy routing rules.
- **specify:** Set the interface manually.

dhcp-proxy-interface <interface>

Specify the outgoing interface. This option is only available and must be configured when `interface-select-method` is `specify`.

DHCP relay

DHCP relay traffic can use SD-WAN rules or a specific interface:

```
config system interface
    edit <interface>
        set dhcp-relay-interface-select-method {auto | sdwan | specify}
```

```

    set dhcp-relay-interface <interface>
  next
end

```

dhcp-relay-interface-select-method {auto sdwan specify}	Select the interface selection method: <ul style="list-style-type: none"> • auto: Set the outgoing interface automatically (default). • sdwan: Set the interface by SD-WAN or policy routing rules. • specify: Set the interface manually.
dhcp-relay-interface <interface>	Specify the outgoing interface. This option is only available and must be configured when <code>interface-select-method</code> is <code>specify</code> .

CA and local certificate renewal with SCEP

Certificate renewal with SCEP traffic can use SD-WAN rules or a specific interface:

```

config vpn certificate setting
  set interface-select-method {auto | sdwan | specify}
  set interface <interface>
end

```

IPS TLS protocol active probing

TLS active probing can use SD-WAN rules or a specific interface:

```

config ips global
  config tls-active-probe
    set interface-selection-method {auto | sdwan | specify}
    set interface <interface>
    set vdom <VDOM>
    set source-ip <IPv4 address>
    set source-ip6 <IPv6 address>
  end
end

```

interface-select-method {auto sdwan specify}	Select the interface selection method: <ul style="list-style-type: none"> • auto: Set the outgoing interface automatically (default). • sdwan: Set the interface by SD-WAN or policy routing rules. • specify: Set the interface manually.
interface <interface>	Specify the outgoing interface. This option is only available and must be configured when <code>interface-select-method</code> is <code>specify</code> .
vdom <VDOM>	Specify the VDOM. This option is only available and must be configured when <code>interface-select-method</code> is <code>sdwan</code> or <code>specify</code> .
source-ip <IPv4 address>	Specify the source IPv4 address. This option is only available and must be configured when <code>interface-select-method</code> is <code>sdwan</code> or <code>specify</code> .
source-ip6 <IPv6 address>	Specify the source IPv6 address. This option is only available and must be configured when <code>interface-select-method</code> is <code>sdwan</code> or <code>specify</code> .

Netflow and sflow

Netflow and sflow can use SD-WAN rules or a specific interface:

```

config system {netflow | sflow | vdom-netflow | vdom-sflow}
  set interface-select-method {auto | sdwan | specify}
  set interface <interface>
end

```

interface-select-method {auto sdwan specify}	Select the interface selection method: <ul style="list-style-type: none"> • auto: Set the outgoing interface automatically (default). • sdwan: Set the interface by SD-WAN or policy routing rules. • specify: Set the interface manually.
interface <interface>	Specify the outgoing interface. This option is only available and must be configured when <code>interface-select-method</code> is <code>specify</code> .

FortiClient EMS

FortiClient EMS endpoint control traffic can use SD-WAN rules or a specific interface:

```

config endpoint-control fctems
  edit fctems1
    set interface-select-method {auto | sdwan | specify}
    set interface <interface>
  end
end

```

Using BGP tags with SD-WAN rules

SD-WAN rules can use Border Gateway Protocol (BGP) learned routes as dynamic destinations.

In this example, a customer has two ISP connections, wan1 and wan2. wan1 is used primarily for direct access to internet applications, and wan2 is used primarily for traffic to the customer's data center.

The customer could create an SD-WAN rule using the data center's IP address range as the destination to force that traffic to use wan2, but the data center's IP range is not static. Instead, a BGP tag can be used.

For this example, wan2's BGP neighbor advertises the data center's network range with a community number of 30:5.

This example assumes that SD-WAN is enabled on the FortiGate, wan1 and wan2 are added as SD-WAN members in the *virtual-wan-link* SD-WAN zone, and a policy and static route have been created. See [SD-WAN quick start on page 608](#) for details.

FortiOS supports IPv4 and IPv6 route tags.

To configure BGP tags with SD-WAN rules:**1. Configure the community list:**

```
config router community-list
  edit "30:5"
    config rule
      edit 1
        set action permit
        set match "30:5"
      next
    end
  next
end
```

2. Configure the route map:

```
config router route-map
  edit "comm1"
    config rule
      edit 1
        set match-community "30:5"
        set set-route-tag 15
      next
    end
  next
end
```

3. Configure BGP:

```
config router bgp
  set as xxxxx
  set router-id xxxx
  config neighbor
    edit "10.100.20.2"
      set soft-reconfiguration enable
      set remote-as xxxxx
      set route-map-in "comm1"
    next
  end
end
```

4. Configure a firewall policy:

```
config firewall policy
  edit 1
    set name "1"
    set srcintf "dmz"
    set dstintf "virtual-wan-link"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
  next
end
```

5. Edit the SD-WAN configuration:

```

config system sdwan
  set status enable
  config members
    edit 1
      set interface "wan1"
      set gateway 172.16.20.2
    next
    edit 2
      set interface "wan2"
    next
  end
config service
  edit 1
    set name "DataCenter"
    set mode manual
    set route-tag 15
    set priority-members 2
  next
end
end
end

```

Troubleshooting BGP tags with SD-WAN rules**Check the network community**

Use the `get router info bgp network` command to check the network community:

```

# get router info bgp network
BGP table version is 5, local router ID is 1.1.1.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete

```

Check dynamic BGP addresses

Use the `get router info route-map-address` command to check dynamic BGP addresses:

```

# get router info route-map-address
Extend-tag: 15, interface(wan2:16)
  10.100.11.0/255.255.255.0

```

Check dynamic BGP addresses used in policy routes

Use the `diagnose firewall proute list` command to check dynamic BGP addresses used in policy routes:

```

# diagnose firewall proute list
list route policy info(vf=root):

id=4278779905 vwl_service=1(DataCenter) flags=0x0 tos=0x00 tos_mask=0x00 protocol=0
sport=0:65535 iif=0 dport=1-65535 oif=16
source wildcard(1): 0.0.0.0/0.0.0.0
destination wildcard(1): 10.100.11.0/255.255.255.0

```

BGP multiple path support

BGP supports multiple paths, allowing an ADVPN to advertise multiple paths. This allows BGP to extend and keep additional network paths according to [RFC 7911](#).

In this example, Spoke1 and Spoke2 each have four VPN tunnels that are connected to the Hub with ADVPN. The Spoke-Hub has established four BGP neighbors on all four tunnels.

Spoke 1 and Spoke 2 can learn four different routes from each other.

To configure the hub:

```
config router bgp
  set as 65505
  set router-id 11.11.11.11
  set ibgp-multipath enable
  set additional-path enable
  set additional-path-select 4
  config neighbor-group
    edit "gr1"
      set capability-default-originate enable
      set remote-as 65505
      set additional-path both
      set adv-additional-path 4
      set route-reflector-client enable
    next
  end
  config neighbor-range
    edit 1
      set prefix 10.10.0.0 255.255.0.0
      set neighbor-group "gr1"
    next
  end
  config network
    edit 12
      set prefix 11.11.11.11 255.255.255.255
    next
  end
end
```

To configure a spoke:

```
config router bgp
  set as 65505
  set router-id 2.2.2.2
  set ibgp-multipath enable
```

```

set additional-path enable
set additional-path-select 4
config neighbor
  edit "10.10.100.254"
    set soft-reconfiguration enable
    set remote-as 65505
    set additional-path both
    set adv-additional-path 4
  next
  edit "10.10.200.254"
    set soft-reconfiguration enable
    set remote-as 65505
    set additional-path both
    set adv-additional-path 4
  next
  edit "10.10.203.254"
    set soft-reconfiguration enable
    set remote-as 65505
    set additional-path both
    set adv-additional-path 4
  next
  edit "10.10.204.254"
    set soft-reconfiguration enable
    set remote-as 65505
    set additional-path both
    set adv-additional-path 4
  next
end
config network
  edit 3
    set prefix 22.1.1.0 255.255.255.0
  next
end
end

```

To view the BGP routing table on a spoke:

```

Spoke1 # get router info routing-table bgp
Routing table for VRF=0
B*   0.0.0.0/0 [200/0] via 10.10.200.254, vd2-2, 03:57:26
     [200/0] via 10.10.203.254, vd2-3, 03:57:26
     [200/0] via 10.10.204.254, vd2-4, 03:57:26
     [200/0] via 10.10.100.254, vd2-1, 03:57:26

[200/0] via 10.10.200.3, vd2-2, 03:57:26
[200/0] via 10.10.100.3, vd2-1, 03:57:26

```

Controlling traffic with BGP route mapping and service rules

SD-WAN allows you to select different outbound WAN links based on performance SLAs. It is important that BGP neighbors are aware of these settings, and changes to them.

BGP can adapt to changes in SD-WAN link SLAs in the following ways:

- Applying different route-maps based on the SD-WAN's health checks. For example, different BGP community strings can be advertised to BGP neighbors when SLAs are not met.
- Traffic can be selectively forwarded based on the active BGP neighbor. If the SD-WAN service's role matches the active SD-WAN neighbor, the service is enabled. If there is no match, then the service is disabled.

Example

In this topology, a branch FortiGate has two SD-WAN gateways serving as the primary and secondary gateways. The gateways reside in different datacenters, but have a full mesh network between them.

This example shows how route-maps and service rules are selected based on performance SLAs and the member that is currently active. Traffic flows through the primary gateway unless the neighbor's health check is outside of its SLA. If that happens, traffic routes to the secondary gateway.

BGP NBR1 is the primary neighbor and BGP NBR2 is the secondary neighbor.

The branch FortiGate's wan1 and wan2 interfaces are members of the SD-WAN. When the SD-WAN neighbor status is primary, it will advertise community `20:1` to BGP NBR1 and `20:5` to BGP NBR2. When the SD-WAN neighbor status is secondary, it will advertise `20:5` to BGP NBR1 and `20:2` to BGP NBR2.

Only one of the primary or secondary neighbors can be active at one time. The SD-WAN neighbor status is used to decide which neighbor is selected:

- **Primary:** The primary neighbor takes precedence if its SLAs are met.
- **Secondary:** If the primary neighbor's SLAs are not met, the secondary neighbor becomes active if its SLAs are met.
- **Standalone:** If neither the primary or secondary neighbor's SLAs are met, the SD-WAN neighbor status becomes standalone.

Route map

SD-WAN is configured to let BGP advertise different communities when the SLA status changes. When the SLA is missed, it triggers BGP to advertise a different community to its BGP neighbor based on its route-map. The BGP neighbors can use the received community string to select the best path to reach the branch.

To configure BGP route-maps and neighbors:

1. Configure an access for the routes to be matched:

```
config router access-list
  edit "net192"
    config rule
      edit 1
        set prefix 192.168.20.0 255.255.255.0
      next
    end
  next
end
```

2. Configure the primary neighbor's preferred route-map:

```
config router route-map
  edit "comm1"
    config rule
      edit 1
        set match-ip-address "net192"
        set set-community "20:1"
      next
    end
  next
end
```

3. Configure the secondary neighbor's preferred route-map:

```
config router route-map
  edit "comm2"
    config rule
      edit 1
        set match-ip-address "net192"
        set set-community "20:2"
      next
    end
  next
end
```

4. Configure the failed route-map:

```
config router route-map
  edit "comm5"
    config rule
      edit 1
        set match-ip-address "net192"
        set set-community "20:5"
      next
    end
  next
end
```

5. Configure BGP neighbors:

```
config router bgp
  set as 65412
  set router-id 1.1.1.1
  set ibgp-multipath enable
  config neighbor
    edit "10.100.1.1"
      set soft-reconfiguration enable
      set remote-as 20
      set route-map-out "comm5"
      set route-map-out-preferable "comm1"
    next
    edit "10.100.1.5"
      set soft-reconfiguration enable
      set remote-as 20
      set route-map-out "comm5"
      set route-map-out-preferable "comm2"
    next
  end
end
```

When SLAs are met, `route-map-out-preferable` is used. When SLAs are missed, `route-map-out` is used.

To configure SD-WAN:**1. Configure the SD-WAN members:**

```
config system sdwan
  set status enable
  config members
    edit 1
      set interface "port1"
    next
    edit 2
      set interface "port2"
    next
  end
end
```

2. Configure health checks for each member:

```
config system sdwan
  config health-check
    edit "ping"
```

```

        set server "10.100.2.22"
        set members 1
        config sla
            edit 1
                set link-cost-factor packet-loss
                set packetloss-threshold 1
            next
        end
    next
edit "ping2"
    set server "10.100.2.23"
    set members 2
    config sla
        edit 1
            set link-cost-factor packet-loss
            set packetloss-threshold 1
        next
    end
next
end
end
end

```

3. Configure the SD-WAN neighbors and assign them a role and the health checks used to determine if the neighbor meets the SLA:

SD-WAN neighbors can only be configured in the CLI.

```

config system sdwan
    config neighbor
        edit "10.100.1.1"
            set member 1
            set role primary
            set health-check "ping"
            set sla-id 1
        next
        edit "10.100.1.5"
            set member 2
            set role secondary
            set health-check "ping2"
            set sla-id 1
        next
    end
end
end

```

Service rules

Create SD-WAN service rules to direct traffic to the primary neighbor when its SLAs are met, and to the secondary neighbor when the primary neighbor's SLAs are missed.

To configure the SD-WAN service rules:

```

config system sdwan
    config service
        edit 1
            set name "Primary-Out"
            set role primary
            set dst "all"
        end
    end
end

```

```

        set src "all"
        set priority-members 1
    next
    edit 2
        set name "Secondary-Out"
        set role secondary
        set dst "all"
        set src "all"
        set priority-members 2
    next
end
end

```

If neither the primary nor secondary neighbors are active, the SD-WAN neighbor status becomes standalone. Only service rules with `standalone-action` enabled will continue to pass traffic. This option is disabled by default.

Verification

To verify when the primary neighbor is passing traffic:

1. Verify the health check status:

```

FortiGate-Branch # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 port1): state(alive), packet-loss(0.000%) latency(0.569), jitter(0.061) sla_
map=0x1
Health Check(ping2):
Seq(2 port2): state(alive), packet-loss(0.000%) latency(3.916), jitter(2.373) sla_
map=0x1

```

2. Verify SD-WAN neighbor status:

```

FortiGate-Branch # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
Selected role(primary) last_secondary_select_time/current_time in seconds 0/572
Neighbor(10.100.1.1): member(1) role(primary)
    Health-check(ping:1) sla-pass selected alive
Neighbor(10.100.1.5): member(2) role(secondary)
    Health-check(ping2:1) sla-pass alive

```

3. Verify service rules status:

```

FortiGate-Branch # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Service role: primary
Members:
    1: Seq_num(1 port1), alive, selected
Src address:
    0.0.0.0-255.255.255.255

Dst address:
    0.0.0.0-255.255.255.255

```

```

Service(2): Address Mode(IPV4) flags=0x0
Gen(6), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
Service role: secondary, disabled by unselected.
Members:
  1: Seq_num(2 port2), alive, selected
Src address:
  0.0.0.0-255.255.255.255

Dst address:
  0.0.0.0-255.255.255.255

```

4. Verify neighbor routers:

a. Primary neighbor router:

```

FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
Not advertised to any peer
64512
  10.100.1.2 from 10.100.1.2 (192.168.122.98)
    Origin IGP metric 0, localpref 100, valid, external, best
    Community: 20:1
    Last update: Thu Apr 30 13:41:40 2020

```

b. Secondary neighbor router:

```

FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
Not advertised to any peer
Original VRF 0
64512
  10.100.1.6 from 10.100.1.6 (192.168.122.98)
    Origin IGP metric 0, localpref 100, valid, external, best
    Community: 20:5
    Last update: Thu Apr 30 13:41:39 2020

```

To verify when the secondary neighbor is passing traffic:

1. Verify the health check status:

```

FortiGate-Branch # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 port1): state(dead), packet-loss(54.000%) sla_map=0x0
Health Check(ping2):
Seq(2 port2): state(alive), packet-loss(0.000%) latency(4.339), jitter(3.701) sla_
map=0x1

```

2. Verify SD-WAN neighbor status:

```

FortiGate-Branch # diagnose sys sdwan neighbor
SD-WAN neighbor status: hold-down(disable), hold-down-time(0), hold_boot_time(0)
Selected role(secondary) last_secondary_select_time/current_time in seconds
936/936
Neighbor(10.100.1.1): member(1) role(primary)
  Health-check(ping:1) sla-fail dead
Neighbor(10.100.1.5): member(2) role(secondary)
  Health-check(ping2:1) sla-pass selected alive

```

3. Verify service rules status:

```
FortiGate-Branch # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
  Gen(4), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Service role: primary, disabled by unselected.
  Members:
    1: Seq_num(1 port1), alive, selected
  Src address:
    0.0.0.0-255.255.255.255

  Dst address:
    0.0.0.0-255.255.255.255

Service(2): Address Mode(IPV4) flags=0x0
  Gen(7), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Service role: secondary
  Members:
    1: Seq_num(2 port2), alive, selected
  Src address:
    0.0.0.0-255.255.255.255

  Dst address:
    0.0.0.0-255.255.255.255
```

4. Verify neighbor routers:

a. Primary neighbor router:

```
FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    10.100.1.2 from 10.100.1.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:5
      Last update: Thu Apr 30 15:41:58 2020
```

b. Secondary neighbor router:

```
FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    10.100.1.6 from 10.100.1.6 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 20:2
      Last update: Thu Apr 30 15:42:07 2020
```

Applying BGP route-map to multiple BGP neighbors

[Controlling traffic with BGP route mapping and service rules](#) explained how BGP can apply different route-maps to the primary and secondary SD-WAN neighbors based on SLA health checks.

In this example, SD-WAN neighbors that are not bound to primary and secondary roles are configured.

The FortiGate has multiple SD-WAN links and has formed BGP neighbors with both ISPs.

ISP1 is used primarily for outbound traffic, and has an SD-WAN service rule using the lowest cost algorithm applied to it. When SLAs for ISP1 are not met, it will fail over to the MPLS line.

Inbound traffic is allowed by both WAN links, with each WAN advertising a community string when SLAs are met. When SLAs are not met, the WAN links advertise a different community string.

This example uses two SD-WAN links. The topology can be expanded to include more links as needed.

To configure BGP route-maps and neighbors:

1. Configure an access list for routes to be matched:

```
config router access-list
  edit "net192"
    config rule
      edit 1
        set prefix 192.168.20.0 255.255.255.0
      next
    end
  next
end
```

2. Configure route-maps for neighbor ISP1:

```
config router route-map
  edit "comm1"
    config rule
      edit 1
        set match-ip-address "net192"
        set set-community "64511:1"
      next
    end
  next
  edit "comm-fail1"
    config rule
      edit 1
        set match-ip-address "net192"
        set set-community "64511:5"
      next
    end
  next
end
```

```
        end
    next
end
```

3. Configure route-maps for neighbor ISP2:

```
config router route-map
    edit "comm2"
        config rule
            edit 1
                set match-ip-address "net192"
                set set-community "64522:1"
            next
        end
    next
edit "comm-fail2"
    config rule
        edit 1
            set match-ip-address "net192"
            set set-community "64522:5"
        next
    end
next
end
```

4. Configure the BGP neighbors:

```
config router bgp
    set as 64512
    set keepalive-timer 1
    set holdtime-timer 3
    config neighbor
        edit "192.168.2.1"
            set soft-reconfiguration enable
            set remote-as 64511
            set route-map-out "comm-fail1"
            set route-map-out-preferable "comm1"
        next
        edit "172.31.0.1"
            set soft-reconfiguration enable
            set remote-as 64522
            set route-map-out "comm-fail2"
            set route-map-out-preferable "comm2"
        next
    end
    config network
        edit 1
            set prefix 192.168.20.0 255.255.255.0
        next
    end
end
```

When SLAs are met, `route-map-out-preferable` is used. When SLAs are missed, `route-map-out` is used.

To configure SD-WAN:**1. Configure the SD-WAN members:**

```
config system sdwan
  set status enable
  config members
    edit 1
      set interface "port1"
      set gateway 192.168.2.1
    next
    edit 2
      set interface "MPLS"
      set cost 20
    next
  end
end
```

2. Configure the health checks that must be met:

```
config system sdwan
  config health-check
    edit "pingserver"
      set server "8.8.8.8"
      set members 2 1
      config sla
        edit 1
          set link-cost-factor packet-loss
          set packetloss-threshold 2
        next
      end
    next
  end
end
```

3. Configure the SD-WAN neighbors and assign them a role and the health checks used to determine if the neighbor meets the SLA:

When no role is defined, the default role, standalone, is used.

```
config system sdwan
  config neighbor
    edit "192.168.2.1"
      set member 1
      set health-check "pingserver"
      set sla-id 1
    next
    edit "172.31.0.1"
      set member 2
      set health-check "pingserver"
      set sla-id 1
    next
  end
end
```

Service rules

Create SD-WAN service rules to direct traffic to the SD-WAN links based on the lowest cost algorithm. The same SLA health check and criteria that are used for the SD-WAN neighbor are used for this SD-WAN service rule.

When no roles are defined in the service rule, the default role, `standalone`, is used.

To configure the SD-WAN service rule:

```
config system sdwan
  config service
    edit 1
      set name "OutboundAll"
      set mode sla
      set dst "all"
      set src "all"
      config sla
        edit "pingserver"
          set id 1
        next
      end
      set priority-members 1 2
    next
  end
end
```

Verification

To verify that when both SLAs are met, port1 is selected due to its lower cost:

1. Verify the health check status:

```
FortiGate-Branch # diagnose sys sdwan health-check
Health Check(pingserver):
Seq(2 MPLS): state(alive), packet-loss(0.000%) latency(24.709), jitter(14.996) sla_
map=0x1
Seq(1 port1): state(alive), packet-loss(0.000%) latency(28.771), jitter(14.840) sla_
map=0x1
```

2. Verify SD-WAN neighbor status:

```
FortiGate-Branch # diagnose sys sdwan neighbor
Neighbor(192.168.2.1): member(1) role(standalone)
  Health-check(pingserver:1) sla-pass selected alive
Neighbor(172.31.0.1): member(2) role(standalone)
  Health-check(pingserver:1) sla-pass selected alive
```

3. Verify service rules status:

Because the service role is `standalone`, it matches both neighbors. The mode (SLA) determines that port1 is lower cost.

```
FortiGate-Branch # diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Service role: standalone
  Members:
```

```

1: Seq_num(1 port1), alive, sla(0x1), cfg_order(0), cost(0), selected
2: Seq_num(2 MPLS), alive, sla(0x1), cfg_order(1), cost(20), selected
Src address:
    0.0.0.0-255.255.255.255

Dst address:
    0.0.0.0-255.255.255.255

```

4. Verify neighbor routers:

a. Primary neighbor router:

```

FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
Not advertised to any peer
64512
192.168.2.5 from 192.168.2.5 (192.168.122.98)
Origin IGP metric 0, localpref 100, valid, external, best
Community: 64511:1
Last update: Thu Apr 30 23:59:05 2020

```

b. Secondary neighbor router:

```

FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
Not advertised to any peer
Original VRF 0
64512
172.31.0.2 from 172.31.0.2 (192.168.122.98)
Origin IGP metric 0, localpref 100, valid, external, best
Community: 64522:1
Last update: Fri May 1 00:11:28 2020

```

To verify that when neighbor ISP1 misses SLAs, MPLS is selected and BGP advertises a different community string for ISP1:

1. Verify the health check status:

```

FortiGate-Branch # diagnose sys sdwan health-check
Health Check(pingserver):
Seq(2 MPLS): state(alive), packet-loss(0.000%) latency(25.637), jitter(17.820) sla_
map=0x1
Seq(1 port1): state(dead), packet-loss(16.000%) sla_map=0x0

```

2. Verify SD-WAN neighbor status:

```

FortiGate-Branch # diagnose sys sdwan neighbor
Neighbor(192.168.2.1): member(1) role(standalone)
Health-check(pingserver:1) sla-fail dead
Neighbor(172.31.0.1): member(2) role(standalone)
Health-check(pingserver:1) sla-pass selected alive

```

3. Verify service rules status:

As SLA failed for neighbor ISP1, MPLS is preferred.

```

FortiGate-Branch # diagnose sys sdwan service

```

```

Service(1): Address Mode(IPV4) flags=0x0
  Gen(3), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
  Service role: standalone
Members:
  1: Seq_num(2 MPLS), alive, sla(0x1), cfg_order(1), cost(20), selected
  2: Seq_num(1 port1), dead, sla(0x0), cfg_order(0), cost(0)
Src address:
  0.0.0.0-255.255.255.255

Dst address:
  0.0.0.0-255.255.255.255

```

4. Verify neighbor routers:

The community received on ISP1 is updated.

a. Primary neighbor router:

```

FGT-NBR1 # get router info bgp network 192.168.20.0
BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  64512
    192.168.2.5 from 192.168.2.5 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 64511:5
      Last update: Fri May 1 00:33:26 2020

```

b. Secondary neighbor router:

```

FGT-NBR2 # get router info bgp network 192.168.20.0
VRF 0 BGP routing table entry for 192.168.20.0/24
Paths: (1 available, best #1, table Default-IP-Routing-Table)
  Not advertised to any peer
  Original VRF 0
  64512
    172.31.0.2 from 172.31.0.2 (192.168.122.98)
      Origin IGP metric 0, localpref 100, valid, external, best
      Community: 64522:1
      Last update: Fri May 1 00:22:42 2020

```

VPN overlay

The following topics provide instructions on SD-WAN VPN overlays:

- [ADVPN and shortcut paths on page 740](#)
- [SD-WAN monitor on ADVPN shortcuts on page 753](#)
- [Hold down time to support SD-WAN service strategies on page 754](#)
- [SD-WAN integration with OCVPN on page 756](#)
- [Adaptive Forward Error Correction on page 763](#)
- [Dual VPN tunnel wizard on page 767](#)
- [Duplicate packets on other zone members on page 768](#)
- [Duplicate packets based on SD-WAN rules on page 771](#)

- [Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 772](#)
- [Interface based QoS on individual child tunnels based on speed test results on page 779](#)

ADVPN and shortcut paths

This topic provides an example of how to use SD-WAN and ADVPN together.

ADVPN (Auto Discovery VPN) is an IPsec technology that allows a traditional hub-and-spoke VPN's spokes to establish dynamic, on-demand, direct tunnels between each other to avoid routing through the topology's hub device. The primary advantage is that it provides full meshing capabilities to a standard hub-and-spoke topology. This greatly reduces the provisioning effort for full spoke-to-spoke low delay reachability, and addresses the scalability issues associated with very large fully meshed VPN networks.

If a customer's head office and branch offices all have two or more internet connections, they can build a dual-hub ADVPN network. Combined with SD-WAN technology, the customer can load-balance traffic to other offices on multiple dynamic tunnels, control specific traffic using specific connections, or choose better performance connections dynamically.

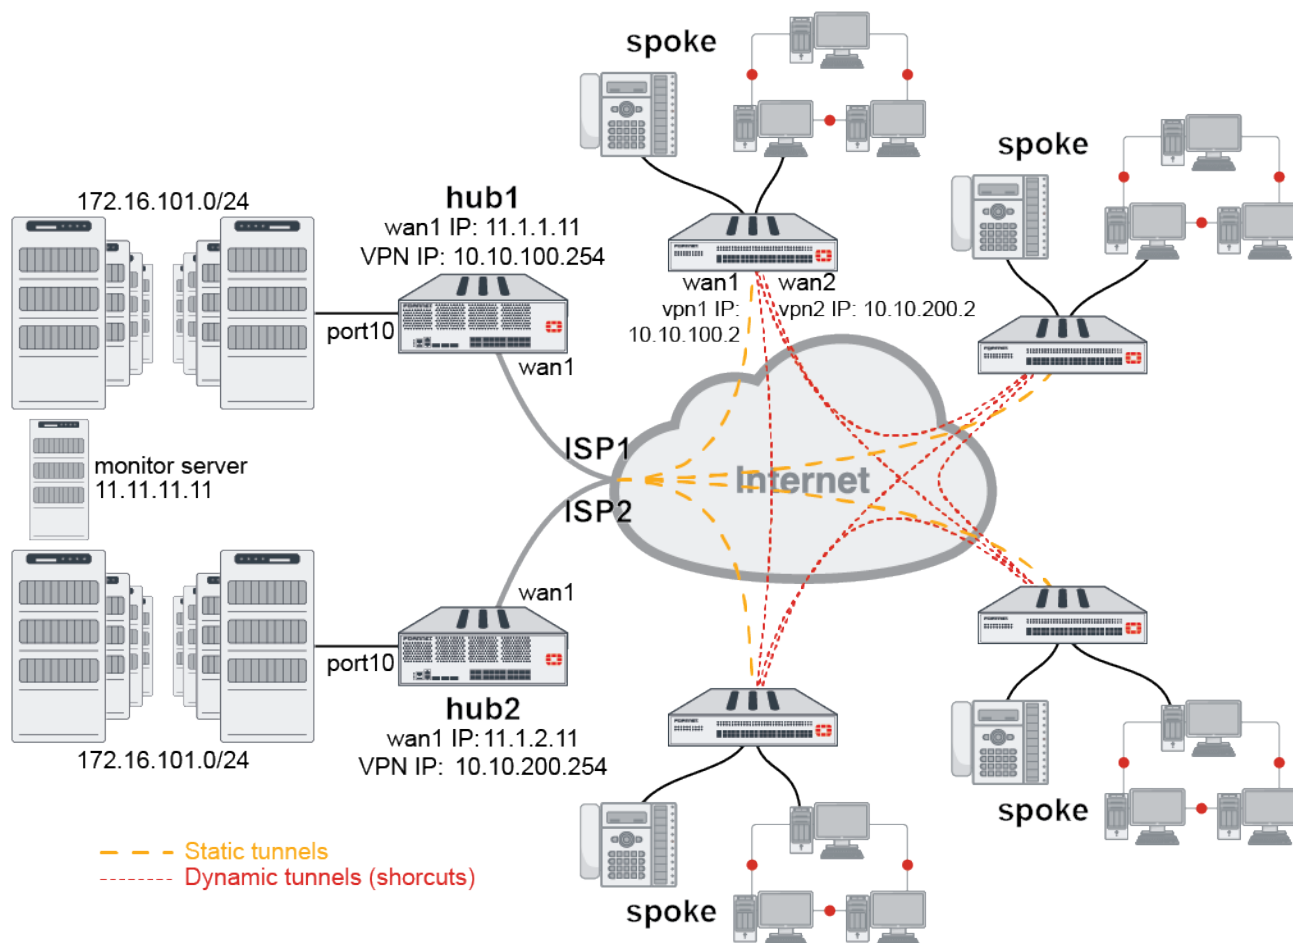

SD-WAN load-balance mode rules (or services) do not support ADVPN members. Other modes' rules, such as SLA and priority, support ADVPN members.

This topic covers three parts:

1. Configure dual-hub ADVPN with multiple branches.
2. Configure BGP to exchange routing information among hubs and spokes.
3. Configure SD-WAN on spoke to do load-balancing and control traffic.

Configuration example

A typical ADVPN configuration with SD-WAN usually has two hubs, and each spoke connects to two ISPs and establishes VPN tunnels with both hubs.

This example shows a hub-and-spoke configuration using two hubs and one spoke:

- Hub1 and Hub2 both use wan1 to connect to the ISPs and port10 to connect to internal network.
- Spoke1 uses wan1 to connect to ISP1 and wan2 to connect to ISP2.
- wan1 sets up VPN to hub1.
- wan2 sets up VPN to hub2.

The SD-WAN is configured on the spoke. It uses the two VPN interfaces as members and two rules to control traffic to headquarters or other spokes using ADVPN VPN interfaces. You can create more rules if required.

For this example:

- Use SD-WAN member 1 (via ISP1) and its dynamic shortcuts for financial department traffic if member 1 meets SLA requirements. If it doesn't meet SLA requirements, it will use SD-WAN member 2 (via ISP2).
- Use SD-WAN member 2 (via ISP2) and its dynamic shortcuts for engineering department traffic.
- Load balance other traffic going to hubs and other spokes between these two members.
- Set up all other traffic to go with their original ISP connection. All other traffic does not go through SD-WAN.
- Set up basic network configuration to let all hubs and spokes connect to their ISPs and the Internet.

Hub internal network	172.16.101.0/24
Spoke1 internal network	10.1.100.0/24
ADVPN 1 network	10.10.100.0/24
ADVPN 2 network	10.10.200.0/24
Hub1 wan1 IP	11.1.1.11
Hub2 wan1 IP	11.1.2.11
Hub1 VPN IP	10.10.100.254
Hub2 VPN IP	10.10.200.254
Spoke1 to hub1 VPN IP	10.10.100.2
Spoke1 to hub2 VPN IP	10.10.200.2
Ping server in Headquarters	11.11.11.11
Internal subnet of spoke1	22.1.1.0/24
Internal subnet of spoke2	33.1.1.0/24
Firewall addresses	Configure hub_subnets and spoke_subnets before using in policies. These can be customized.

The GUI does not support some ADVPN related options, such as auto-discovery-sender, auto-discovery-receiver, auto-discovery-forwarder, and IBGP neighbor-group setting, so this example only provides CLI configuration commands.

Hub1 sample configuration

To configure the IPsec phase1 and phase2 interface:

```

config vpn ipsec phase1-interface
  edit "hub-phase1"
    set type dynamic

  next
end

```

When `net-device` is disabled, a tunnel ID is generated for each dynamic tunnel. This ID, in the form of an IP address, is used as the gateway in the route entry to that tunnel. The `tunnel-search` option is removed in FortiOS 7.0.0 and later.

To configure the VPN interface and BGP:

```
config system interface
  edit "hub-phase1"
    set ip 10.10.100.254 255.255.255.255
    set remote-ip 10.10.100.253 255.255.255.0
  next
end
config router bgp
  set as 65505
  config neighbor-group
    edit "advpn"
      set link-down-failover enable
      set remote-as 65505
      set route-reflector-client enable
    next
  end
  config neighbor-range
    edit 1
      set prefix 10.10.100.0 255.255.255.0
      set neighbor-group "advpn"
    next
  end
  config network
    edit 1
      set prefix 172.16.101.0 255.255.255.0
    next
    edit 2
      set prefix 11.11.11.0 255.255.255.0
    next
  end
end
```

To configure the firewall policy:

```
config firewall policy
  edit 1
    set name "spoke2hub"
    set srcintf "hub-phase1"
    set dstintf "port10"
    set srcaddr "spoke_subnets"
    set dstaddr "hub_subnets"
    set action accept
    set schedule "always"
    set service "ALL"
    set comments "allow traffic from spokes to headquarter"
  next
  edit 2
    set name "spoke2spoke"
    set srcintf "hub-phase1"
```

```

        set dstintf "hub-phase1"
        set srcaddr "spoke_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from spokes to spokes"
    next
    edit 3
        set name "internal2spoke"
        set srcintf "port10"
        set dstintf "hub-phase1"
        set srcaddr "hub_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from headquarter to spokes"
    next
end

```

Hub2 sample configuration

Hub2 configuration is the same as hub1 except the wan1 IP address, VPN interface IP address, and BGP neighbor-range prefix.

To configure the IPsec phase1 and phase2 interface:

```

config vpn ipsec phase1-interface
    edit "hub-phase1"
        set type dynamic
        set interface "wan1"
        set peertype any
        set net-device disable
        set proposal aes128-sha256 aes256-sha256 3des-sha256 aes128-sha1 aes256-sha1 3des-
sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-sender enable
        set psksecret sample
        set dpd-retryinterval 5
    next
end
config vpn ipsec phase2-interface
    edit "hub-phase2"
        set phase1name "hub-phase1"
        set proposal aes128-sha1 aes256-sha1 3des-sha1 aes128-sha256 aes256-sha256 3des-
sha256
    next
end

```

To configure the VPN interface and BGP:

```

config system interface
    edit "hub-phase1"

```

```
        set ip 10.10.200.254 255.255.255.255
        set remote-ip 10.10.200.253 255.255.255.0
    next
end
config router bgp
    set as 65505
    config neighbor-group
        edit "advpn"
            set link-down-failover enable
            set remote-as 65505
            set route-reflector-client enable
        next
    end
    config neighbor-range
        edit 1
            set prefix 10.10.200.0 255.255.255.0
            set neighbor-group "advpn"
        next
    end
    config network
        edit 1
            set prefix 172.16.101.0 255.255.255.0
        next
        edit 2
            set prefix 11.11.11.0 255.255.255.0
        next
    end
end
```

To configure the firewall policy:

```
config firewall policy
    edit 1
        set name "spoke2hub"
        set srcintf "hub-phase1"
        set dstintf "port10"
        set srcaddr "spoke_subnets"
        set dstaddr "hub_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from spokes to headquarter"
    next
    edit 2
        set name "spoke2spoke"
        set srcintf "hub-phase1"
        set dstintf "hub-phase1"
        set srcaddr "spoke_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from spokes to spokes"
    next
    edit 3
        set name "internal2spoke"
```

```

        set srcintf "port10"
        set dstintf "hub-phase1"
        set srcaddr "hub_subnets"
        set dstaddr "spoke_subnets"
        set action accept
        set schedule "always"
        set service "ALL"
        set comments "allow traffic from headquarter to spokes"
    next
end

```

Spoke1 sample configuration

To configure the IPsec phase1 and phase2 interface:

```

config vpn ipsec phase1-interface
    edit "spoke1-phase1"
        set interface "wan1"
        set peertype any
        set net-device enable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-receiver enable
        set remote-gw 11.1.1.11
        set psksecret sample
        set dpd-retryinterval 5
    next
    edit "spoke1-2-phase1"
        set interface "wan2"
        set peertype any
        set net-device enable
        set proposal aes128-sha256 aes256-sha256 aes128-sha1 aes256-sha1
        set add-route disable
        set dpd on-idle
        set auto-discovery-receiver enable
        set remote-gw 11.1.2.11
        set psksecret sample
        set dpd-retryinterval 5
    next
end
config vpn ipsec phase2-interface
    edit "spoke1-phase2"
        set phasename "spoke1-phase1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm aes256gcm
        chacha20poly1305
        set auto-negotiate enable
    next
    edit "spoke1-2-phase2"
        set phasename "spoke1-2-phase1"
        set proposal aes128-sha1 aes256-sha1 aes128-sha256 aes256-sha256 aes128gcm aes256gcm
        chacha20poly1305
        set auto-negotiate enable
    next
end

```

To configure the VPN interface and BGP:

```
config system interface
  edit "spoke1-phase1"
    set ip 10.10.100.2 255.255.255.255
    set remote-ip 10.10.100.254 255.255.255.0
  next
  edit "spoke1-2-phase1"
    set ip 10.10.200.2 255.255.255.255
    set remote-ip 10.10.200.254 255.255.255.0
  next
end
config router bgp
  set as 65505
  config neighbor
    edit "10.10.100.254"
      set advertisement-interval 1
      set link-down-failover enable
      set remote-as 65505
    next
    edit "10.10.200.254"
      set advertisement-interval 1
      set link-down-failover enable
      set remote-as 65505
    next
  end
  config network
    edit 1
      set prefix 10.1.100.0 255.255.255.0
    next
  end
end
```

To configure SD-WAN:

```
config system sdwan
  set status enable
  config members
    edit 1
      set interface "spoke1-phase1"
    next
    edit 2
      set interface "spoke1-2-phase1"
    next
  end
  config health-check
    edit "ping"
      set server "11.11.11.11"
      set members 1 2
      config sla
        edit 1
          set latency-threshold 200
          set jitter-threshold 50
          set packetloss-threshold 5
        next
      end
    end
```

```

    next
end
config service
  edit 1
    set mode sla
    set dst "financial-department"
    config sla
      edit "ping"
        set id 1
      next
    end
    set priority-members 1 2
  next
  edit 2
    set priority-members 2
    set dst "engineering-department"
  next
end
end

```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To configure the firewall policy:

```

config firewall policy
  edit 1
    set name "outbound_advpn"
    set srcintf "internal"
    set dstintf "virtual-wan-link"
    set srcaddr "spoke_subnets"
    set dstaddr "spoke_subnets" "hub_subnets"
    set action accept
    set schedule "always"
    set service "ALL"
    set comments "allow internal traffic going out to headquarter and other spokes"
  next
  edit 2
    set name "inbound_advpn"
    set srcintf "virtual-wan-link"
    set dstintf "internal"
    set srcaddr "spoke_subnets" "hub_subnets"
    set dstaddr "spoke_subnets"
    set action accept
    set schedule "always"
    set service "ALL"
    set comments "allow headquarter and other spokes traffic coming in"
  next
end

```

Troubleshooting ADVPN and shortcut paths

Before spoke vs spoke shortcut VPN is established

Use the following CLI commands to check status before spoke vs spoke shortcut VPN is established.

get router info bgp summary

```

```

SD-WAN monitor on ADVPN shortcuts

SD-WAN monitors ADVPN shortcut link quality by dynamically creating link monitors for each ADVPN link. The dynamic link monitor on the spoke will use ICMP probes and the IP address of the gateway as the monitored server. These ICMP probes will not be counted as actual user traffic that keeps the spoke-to-spoke tunnel alive.

- When no shortcut is established:

```

# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel-1): state(alive), packet-loss(0.000%) latency(0.038), jitter(0.006) sla_
map=0x3
Seq(2 tunnel-2): state(alive), packet-loss(0.000%) latency(0.035), jitter(0.004) sla_
map=0x3

```

- When one shortcut is established:

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel-1): state(alive), packet-loss(0.000%) latency(0.039), jitter(0.003) sla_
map=0x3
Seq(1 tunnel-1_0): state(alive), packet-loss(0.000%) latency(0.060), jitter(0.023) sla_
map=0x3
Seq(2 tunnel-2): state(alive), packet-loss(0.000%) latency(0.035), jitter(0.002) sla_
map=0x3
```

- When more than one shortcut is established:

```
# diagnose sys sdwan health-check
Health Check(ping):
Seq(1 tunnel-1): state(alive), packet-loss(0.000%) latency(0.036), jitter(0.004) sla_
map=0x3
Seq(1 tunnel-1_0): state(alive), packet-loss(0.000%) latency(0.041), jitter(0.009) sla_
map=0x3
Seq(2 tunnel-2): state(alive), packet-loss(0.000%) latency(0.030), jitter(0.005) sla_
map=0x3
Seq(2 tunnel-2_0): state(alive), packet-loss(0.000%) latency(0.031), jitter(0.004) sla_
map=0x3
```

Hold down time to support SD-WAN service strategies

In a hub and spoke SD-WAN topology with shortcuts created over ADVPN, a downed or recovered shortcut can affect which member is selected by an SD-WAN service strategy. When a downed shortcut tunnel recovers and the shortcut is added back into the service strategy, the shortcut is held at a low priority until the hold down time has elapsed.

By default, the hold down time is zero seconds. It can be set to 0 - 10000000 seconds.

To configure the hold down time:

```
config system sdwan
  config service
    edit 1
      set hold-down-time <integer>
    next
  end
end
```

Example

In this example, the hold down time is set to 15 seconds, and then the SD-WAN service is looked at before and after the hold down elapses after a downed shortcut recovers.

To configure the hold down time:

```
config system sdwan
  config service
    edit 1
      set hold-down-time 15
    next
  end
end
```

To view which SD-WAN member is selected before and after the hold down time elapses:

Before the hold down time has elapsed:

```
# diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(34), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(priority), link-cost-factor(packet-
  loss), link-cost-threshold(0), heath-check(ping)
Hold down time(15) seconds, Hold start at 2003 second, now 2010
Member sub interface(4):

  33.1.1.101-33.1.1.200\

```

SD-WAN integration with OCVPN

OCVPN has the capability to enable SD-WAN in order to dynamically add its tunnel interfaces as SD-WAN members. Users can configure SD-WAN health checks and service rules to direct traffic over the OCVPN tunnels.

The following example uses a dual hub and spoke topology. Each hub and spoke has two WAN link connections to the ISP. The spokes generate two IPsec tunnels to each hub (four tunnels in total). BGP neighbors are established over each tunnel and routes from the hubs and other spokes learned from all neighbors, which forms an ECMP scenario. All tunnels are placed as SD-WAN members, so traffic can be distributed across tunnels based on the configured SD-WAN service rules.

To integrate SD-WAN with OCVPN in the GUI:

1. Configure the primary hub:
 - a. Go to *VPN > Overlay Controller VPN* and set the *Status* to *Enable*.
 - b. For *Role*, select *Primary Hub*.

- c. Enter the WAN interfaces (*port15* and *port16*) and tunnel IP allocation block (*10.254.0.0/16*).

The WAN interface is position sensitive, meaning a tunnel will be created with the first position interface on the hub to the first position interface on the spoke, and so on. In this example, FGT_A (primary hub) will create two tunnels with FGT_C (spoke):

- FGT_A port15 <==> FGT_C internal1
- FGT_A port16 <==> FGT_C internal2

- d. Enable *Auto-discovery shortcuts*.
- e. Enable *Add OCVPN tunnels to SD-WAN*. The IPsec tunnels will be added automatically to the SD-WAN members if SD-WAN is enabled.

2. Configure the overlays on the primary hub:

- a. In the *Overlays* section, click *Create New*.
- b. Enter a name and add the local interface (*port2*). Note the overlay is either based on local subnets or local interfaces, but not both.

By default, inter-overlay traffic is not enabled. Toggle *Allow traffic from other overlays* to enable it.

- c. Click *OK* and repeat these steps to create the second overlay (*loop1*).

Overlay Controller VPN

Overlay Controller VPN

Guides

- Full Mesh OCVPN
- Hub-Spoke OCVPN with ADVPN Shortcut
- Hub-Spoke OCVPN with Inter-Overlay Source NAT
- OCVPN Portal
- OCVPN Troubleshooting

Documentation

- Online Help
- Video Tutorials

- d. Click *Apply*.

3. Configure the secondary hub with the same settings as the primary hub.

4. Configure the spoke:

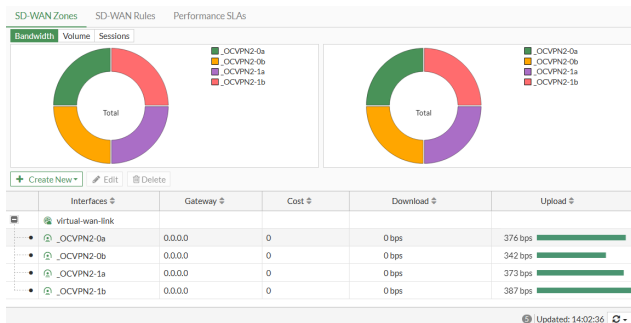

- a. Go to *VPN > Overlay Controller VPN* and set the *Status* to *Enable*.
- b. For *Role*, select *Spoke*.
- c. Enter the WAN interfaces (*internal1* and *internal2*).
- d. Enable *Auto-discovery shortcuts*.
- e. Enable *Add OCVPN tunnels to SD-WAN*. The IPsec tunnels will be added automatically to the SD-WAN members if SD-WAN is enabled.
- f. Configure the overlays.

The overlay names on the spokes must match the names on the hub for the traffic to be allowed through the same overlay.

- g. Click *Apply*.

- Configure the other spoke with the same settings.
- On a spoke, go to *Network > SD-WAN* and select the *SD-WAN Zones* tab to view the configuration generated by OCVPN.

Firewall policies will be automatically generated by OCVPN between the local interfaces and the SD-WAN interface. Each policy will define the proper local and remote networks for its source and destination addresses.

To integrate SD-WAN with OCVPN in the CLI:

- Configure the primary hub:

```
config vpn ocvpn
  set role primary-hub
  set sdwan enable
  set wan-interface "port15" "port16"
  set ip-allocation-block 10.254.0.0 255.255.0.0
  config overlays
    edit "overlay1"
      config subnets
        edit 1
          set type interface
          set interface "port2"
        next
      end
    next
    edit "overlay2"
      config subnets
        edit 1
          set type interface
          set interface "loop1"
        next
      end
    next
  end
end
```

- Configure the secondary hub with the same settings as the primary hub.
- Configure the spoke:

```
config vpn ocvpn
  set status enable
  set sdwan enable
  set wan-interface "internal1" "internal2"
  config overlays
    edit "overlay1"
      config subnets
```

```

        edit 1
            set type interface
            set interface "wan2"
        next
    end
next
edit "overlay2"
    config subnets
        edit 1
            set type interface
            set interface "loop1"
        next
    end
next
end
end
end

```

4. Configure the other spoke with the same settings.

5. Configure SD-WAN:

```

config system sdwan
    set status enable
    config members
        edit 1
            set interface "_OCVPN2-0a"
        next
        edit 2
            set interface "_OCVPN2-0b"
        next
        edit 3
            set interface "_OCVPN2-1a"
        next
        edit 4
            set interface "_OCVPN2-1b"
        next
    end
end
end

```

Firewall policies will be automatically generated by OCVPN between the local interfaces and the SD-WAN interface. Each policy will define the proper local and remote networks for its source and destination addresses.

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

To verify the integration is working after the ADVPN shortcut is triggered:

1. Check the routing table on the spoke:

```

FGT_C # get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
O - OSPF, IA - OSPF inter area
N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
E1 - OSPF external type 1, E2 - OSPF external type 2
i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area

```

* - candidate default

Routing table for VRF=0

Health Check(ocvpn):
Seq(1 _OCVPN2-0a): state(alive), packet-loss(0.000%) latency(0.364), jitter(0.028) sla_
map=0x0
Seq(2 _OCVPN2-0b): state(alive), packet-loss(0.000%) latency(0.287), jitter(0.026) sla_
map=0x0
Seq(3 _OCVPN2-1a): state(dead), packet-loss(100.000%) sla_map=0x0
Seq(4 _OCVPN2-1b): state(dead), packet-loss(100.000%) sla_map=0x0
Seq(4 _OCVPN2-1b_0): state(alive), packet-loss(0.000%) latency(0.289), jitter(0.029)
sla_map=0x0
```

Adaptive Forward Error Correction

Forward Error Correction (FEC) is used to control and correct errors in data transmission by sending redundant data across the VPN in anticipation of dropped packets occurring during transit. The mechanism sends out x number of redundant packets for every y number of base packets.

Adaptive FEC considers link conditions and dynamically adjusts the FEC packet ratio:

- The FEC base and redundant packet relationship is dynamically adjusted based on changes to the network SLA metrics defined in the SD-WAN SLA health checks. For example, when there is no or low packet loss in the network, FEC can work on a low redundant level sending only one redundant packet for every 10 base packets. As packet loss increases, the number of redundant packets sent can rise accordingly.
- FEC can be applied only to streams that are sensitive to packet loss. For Example, policies that allow the UDP based VoIP protocol can enable FEC, while TCP based traffic policies do not. This reduces unnecessary bandwidth consumption by FEC.
- Because FEC does not support NPU offloading, the ability to specify streams and policies that do not require FEC allows those traffic to be offloaded. This means that not all traffic suffers a performance impact.

In this example, an IPsec tunnel is configured between two FortiGates that have FEC enabled and supporting configuration to protect traffic that egresses FortiGate A and ingresses FortiGate B. The tunnel is an SD-WAN zone, and an SLA health-check is used to monitor the quality of the VPN overlay. The intention is to apply FEC to UDP traffic that is passing through the VPN overlay, while allowing all other traffic to pass through without FEC. An FEC profile is configured to adaptively increase redundant levels if the link quality exceeds a 10% packet loss threshold, or the bandwidth exceeds 950 Mbps.

The DMZ interface and IPsec tunnel vd1-p1 are SD-WAN members. FEC is enabled on vd1-p1, and health-check works on vd1-p1.

To configure the FortiGates:

1. On FortiGate A, enable FEC for egress traffic and NPU offloading on the IPsec tunnel vd1-p1:

```
config vpn ipsec phase1-interface
  edit "vd1-p1"
    set npu-offload enable
    set fec-egress enable
  next
end
```

2. On FortiGate B, enable FEC for ingress traffic and NPU offloading on the IPsec tunnel vd1-p1:

```
config vpn ipsec phase1-interface
  edit "vd1-p1"
    set npu-offload enable
    set fec-ingress enable
  next
end
```

3. On FortiGate A, configure SD-WAN:

The VPN overlay member (vd1-p1) must be included in the health-check and configured as the higher priority member in the SD-WAN rule.

```
config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
  end
  config members
    edit 1
      set interface "dmz"
      set gateway 172.16.208.2
    next
    edit 2
      set interface "vd1-p1"
    next
  end
  config health-check
    edit "1"
      set server "2.2.2.2"
      set members 2
      config sla
        edit 1
        next
      end
```

```

    next
  end
  config service
    edit 1
      set name "1"
      set dst "all"
      set src "172.16.205.0"
      set priority-members 2 1
    next
  end
end

```

4. On FortiGate A, create a policy to specify performing FEC on UDP traffic, and a policy for other traffic:

```

config firewall policy
  edit 1
    set srcintf "port5"
    set dstintf "virtual-wan-link"
    set action accept
    set srcaddr "172.16.205.0"
    set dstaddr "all"
    set schedule "always"
    set service "ALL_UDP"
    set fec enable
  next
  edit 2
    set srcintf "any"
    set dstintf "any"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set schedule "always"
    set service "ALL"
  next
end

```

5. On FortiGate A, configure FEC mapping to bind network SLA metrics and FEC base and redundant packets:

```

config vpn ipsec fec
  edit "m1"
    config mappings
      edit 1
        set base 8
        set redundant 2
        set packet-loss-threshold 10
      next
      edit 2
        set base 9
        set redundant 3
        set bandwidth-up-threshold 950000
      next
    end
  next
end

```

The mappings are matched from top to bottom: packet loss greater than 10% with eight base and two redundant packets, and then uploading bandwidth greater than 950 Mbps with nine base and three redundant packets.

6. On FortiGate A, apply the FEC mappings on vd1-p1:

```

config vpn ipsec phase1-interface
  edit "vd1-pl"
    set fec-health-check "1"
    set fec-mapping-profile "m1"
    set fec-base 10
    set fec-redundant 1
  next
end

```

The FEC base and redundant values are used when the link quality has not exceeded the limits specified in the FEC profile mapping. If `fec-codec` is set to `xor` the base and redundant packet values will not be updated.

To verify the results:

1. Send TCP and UDP traffic from PC1 to PC2, then check the sessions on FortiGate A:

```

# diagnose sys session list

session info: proto=6 proto_state=01 duration=12 expire=3587 timeout=3600 flags=00000000

```

```

rpdb_link_id=ff000001 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x5040000
no_ofld_reason: non-npu-intf

```

Non-FEC protected TCP traffic is offloaded, while FEC protected UDP traffic is not offloaded

2. On FortiGate A, check the health-check result and the corresponding FEC base and redundant packets:

```

# diagnose sys sdwan health-check
Health Check(1):
Seq(2 vdl-p1): state(alive), packet-loss(0.000%) latency(0.168), jitter(0.021),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x1

```

Because bandwidth-up is more than 950000kbps, base and redundant are set to 9 and 3:

```

# diagnose vpn tunnel fec vdl-p1
egress:
  enabled=1 base=9 redundant=3 codec=0 timeout=10(ms)
  encode=6621 encode_timeout=6621 encode_fail=0
  tx_data=6880 tx_parity=18601
ingress:
  enabled=0 timeout=0(ms)
  fasm_cnt=0 fasm_full=0
  ipsec_fec_chk_fail=0 complete=0
  rx_data=0 rx_parity=0
  recover=0 recover_timeout=0 recover_fail=0
  rx=0 rx_fail=0

```

3. Make packet loss more than 10%, then check the health-check result and the corresponding FEC base and redundant packets again on FortiGate A:

```

# diagnose sys sdwan health-check
Health Check(1):
Seq(2 vdl-p1): state(alive), packet-loss(15.000%) latency(0.168), jitter(0.017),
bandwidth-up(999999), bandwidth-dw(999998), bandwidth-bi(1999997) sla_map=0x0

```

Because packet loss is more than 10%, entry one in FEC mapping is first matched, and base and redundant are set to 8 and 2:

```

# diagnose vpn tunnel fec vdl-p1
egress:
  enabled=1 base=8 redundant=2 codec=0 timeout=10(ms)
  encode=6670 encode_timeout=6670 encode_fail=0
  tx_data=6976 tx_parity=18748
ingress:
  enabled=0 timeout=0(ms)
  fasm_cnt=0 fasm_full=0
  ipsec_fec_chk_fail=0 complete=0
  rx_data=0 rx_parity=0
  recover=0 recover_timeout=0 recover_fail=0
  rx=0 rx_fail=0

```

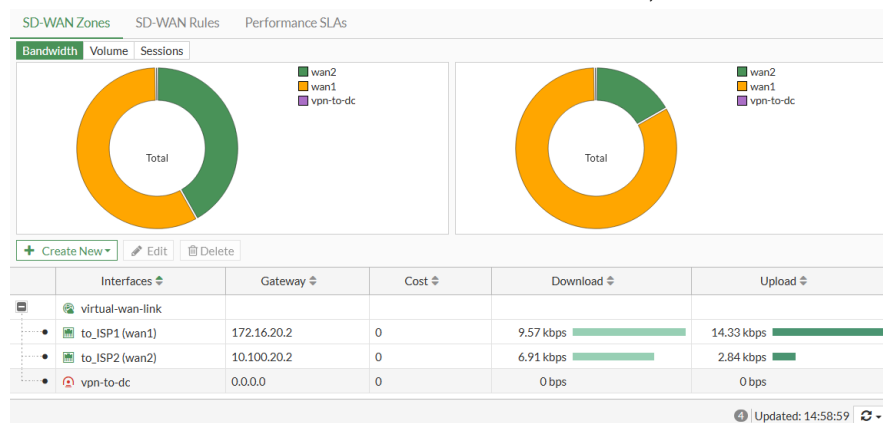

Dual VPN tunnel wizard

This wizard is used to automatically set up multiple VPN tunnels to the same destination over multiple outgoing interfaces. This includes automatically configuring IPsec, routing, and firewall settings, avoiding cumbersome and error-prone configuration steps.

To create a new SD-WAN VPN interface using the tunnel wizard:

1. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
2. In the *Interface* drop-down, click *+VPN*. The *Create IPsec VPN for SD-WAN members* pane opens.

3. Enter the required information, then click *Next*.
4. Review the settings then click *Create*.
5. Click *Close* to return to the SD-WAN page.
The newly created VPN interface will be highlighted in the *Interface* drop-down list.
6. Select the VPN interface to add it as an SD-WAN member, then click *OK*.

Duplicate packets on other zone members

When duplication rules are used, packets are duplicated on other good links within the SD-WAN zone and de-duplicated on the destination FortiGate. Use *force* mode to force duplication on other links within the SD-WAN zone, or use *on-demand* mode to trigger duplication only when SLA fails on the selected member.

The duplication rule is configured in the CLI by using the `config duplication` command. The following options can be configured:

Parameter	Description
srcaddr	Source address or address group names.
dstaddr	Destination address or address group names.
srcaddr6	Source IPv6 address or IPv6 address group names.
dstaddr6	Destination IPv6 address or IPv6 address group names.
srcintf	Incoming (ingress) interfaces or zones.
dstintf	Outgoing (egress) interfaces or zones.
service	Service and service group names.
packet-duplication	Configure packet duplication method. <ul style="list-style-type: none"> • disable: Disable packet duplication (default). • force: Duplicate packets across all interface members of the SD-WAN zone. • on-demand: Duplicate packets across all interface members of the SD-WAN zone based on the link quality.
packet-de-duplication	Enable/disable discarding of packets that have been duplicated (default = disable).

The `duplication-max-num <integer>` option under `config system sdwan` is the maximum number of interface members that a packet is duplicated on in the SD-WAN zone (2 - 4, default = 2). If this value is set to 3, the original packet plus two more copies are created. If there are three member interfaces in the SD-WAN zone and the `duplication-max-num` is set to 2, the packet duplication follows the configuration order, so the packets are duplicated on the second member.

Example

The packet duplication feature works best in a spoke-spoke or hub-and-spoke topology. In this example, a hub-and-spoke ADVPN topology is used. Before shortcuts are established, Hub 1 forwards the duplicate packets from Spoke 1 to Spoke 2. Once shortcuts are established, Hub 1 is transparent, and duplicate packets are exchanged directly between the spokes.

To configure packet duplication between Spoke 1 and Spoke 2:**1. Configure Spoke 1:**

```
config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
    edit "sdwanzone_v4"
    next
  end
  config members
    edit 1
      set interface "t1"
      set zone "sdwanzone_v4"
    next
    edit 4
      set interface "t21"
      set zone "sdwanzone_v4"
    next
    edit 2
      set interface "t2"
      set zone "sdwanzone_v4"
    next
  end
  config health-check
    edit "h1"
      set server "10.34.1.1"
      set interval 1000
      set failtime 10
      set members 1 2
      config sla
        edit 1
          set packetloss-threshold 40
        next
      end
    next
  end
  config duplication
    edit 1
      set srcaddr "all"
      set dstaddr "all"
      set srcintf "port1"
      set dstintf "sdwanzone_v4"
      set service "ALL"
      set packet-duplication force
      set packet-de-duplication enable
    next
  end
end
```

2. Configure Spoke 2 with similar settings.

Duplicate packets based on SD-WAN rules

SD-WAN duplication rules can specify SD-WAN service rules to trigger packet duplication. This allows the duplication to occur based on an SD-WAN rule instead of the source, destination, and service parameters in the duplication rule.

1. Packets can be forced to duplicate to all members of the same SD-WAN zone. See [Duplicate packets on other zone members on page 768](#) for details.

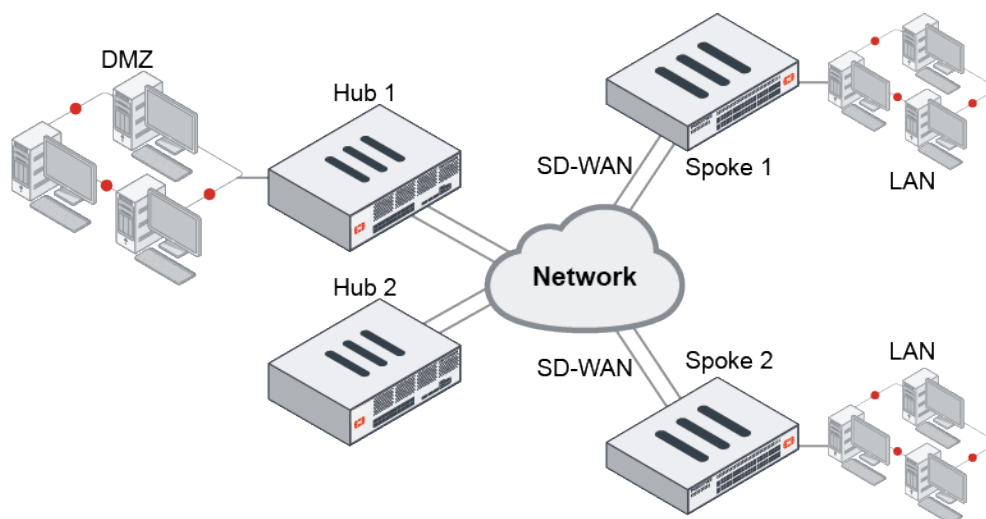

For example, in Spoke 1 set `packet-duplication` to `force` so that when a client sends a packet to the server, it is duplicated to all members of the same zone as long as its health check is alive. If a members health check is dead, then the member is removed from the SD-WAN duplication zone.

2. Packets can be duplicated to other members of the SD-WAN zone on-demand only when the condition of the link is not good enough.

Set `packet-duplication` to `on-demand` so that, when all the SLAs of the member exceed threshold (`sla_map=0`), the packet is duplicated. But when the SLAs are within threshold (`sla_map!=0`), the packet is not duplicated.

3. Packets can be duplicated to all members of the same SD-WAN zone when the traffic matches one or more regular SD-WAN service rules.

The following example shows the third type of packet duplication.

In this example, SD-WAN is configured with three members: `vpn1`, `vpn2`, and `vpn3`. Service rule 1 controls all traffic from `10.100.20.0/24` to `172.16.100.0/24` using member 1.

To send a duplicate of the traffic that matches service rule 1 using member 2, members 1 and 2 are added to the same SD-WAN zone, and a duplication rule is configured with `service-id` set to 1.

To send a duplicate of the traffic that matches service rule 1 using member 2:

```
config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
    edit "zone2"
    next
  end
```

```
config members
  edit 1
    set interface "vpn1"
  next
  edit 2
    set interface "vpn2"
  next
  edit 3
    set interface "vpn3"
    set zone "zone2"
  next
end
config service
  edit 1
    set dst "172.16.100.0"
    set src "10.100.20.0"
    set priority-members 1
  next
end
config duplication
  edit 1
    set service-id 1
    set packet-duplication force
  next
end
end
```

Speed tests run from the hub to the spokes in dial-up IPsec tunnels

In a hub and spoke SD-WAN topology that uses dial-up VPN overlays, QoS can be applied on individual tunnels based on the measured bandwidth between the hub and spokes. The FortiGate can use the built in speed test to dynamically populate the egress bandwidth to individual dial-up tunnels from the hub.

SD-WAN members on a spoke can switch routes when the speed test is running from the hub to the spoke. The speed test results can be cached for reuse when a tunnel comes back after going down.

CLI commands

Allow upload speed tests to be run from the hub to spokes on demand for dial-up IPsec tunnel:

```
config system speed-test-schedule
  edit <interface>
    set dynamic-server {enable | disable}
  next
end
```

<interface>	The dial-up IPsec tunnel interface on the hub.
dynamic-server {enable disable}	Enable/disable the dynamic speed test server (default = disable).

To limit the maximum and minimum bandwidth used in the speed test, enable `set update-inbandwidth` and `set update-outbandwidth`. See [Scheduled interface speedtest on page 675](#) for more information.

```
config system global
  set speedtest-server {enable | disable}
end
```

<code>speedtest-server {enable disable}</code>	Enable/disable the speed test server on the spoke (default = disable). This setting must be enabled on spoke FortiGates. This enables iPerf in server mode, which listens on the default iPerf TCP port 5201.
--	---

Allow an SD-WAN member on the spoke to switch routes when it is on speed test from the hub to spokes:

```
config system sdwan
  set speedtest-bypass-routing {enable | disable}
  config neighbor
    edit <bgp neighbor>
      set mode speedtest
    next
  end
end
```

<code>speedtest-bypass-routing {enable disable}</code>	Enable/disable bypass routing when doing a speed test on an SD-WAN member (default = disable).
<code>set mode speedtest</code>	Use the speed test to select the neighbor.

Manually run uploading speed test on the physical interfaces of each tunnel of an dial-up IPsec interface:

```
execute speed-test-dynamic <interface> <tunnel_name> <'y'/'n'> <max-out> <min-out>
```

<code><interface></code>	IPsec phase1 interface name.
<code><tunnel_name></code>	The tunnel name, or <code>all</code> for all tunnels.
<code><'y'/'n'></code>	Apply the result to the tunnels' shaper or not.
<code><max-out></code>	The maximum speed used in a speed test, in kbps.
<code><min-out></code>	The minimum speed used in a speed test, in kbps.

Manually run a non-blocking uploading speed test:

```
diagnose netlink interface speed-test-tunnel <interface> <tunnel_name>
```

Debug and test commands:

<code>diagnose debug application speedtest <int></code>	Enable debug of the speed test module in the forticron daemon.
<code>diagnose debug application speedtestd <int></code>	Enable debug of the speed test server daemon.
<code>diagnose test application forticron 9</code>	List the scheduled speed tests.
<code>diagnose test application forticron 10</code>	Show the cached speed test results.
<code>diagnose test application forticron 11</code>	Write the cached speed test results to disk.
<code>diagnose test application forticron 12</code>	Load the speed test results from disk.
<code>diagnose test application forticron 99</code>	Cancel all pending speed tests.

Example

In this example, the hub is configured as a VPN dial-up server and both of the spokes are connected to the hub. It is assumed that the VPN configuration is already done, with a dynamic gateway type and kernel device creation (`net-device`) disabled. Only one SD-WAN interface is used, so there is only one VPN overlay member in the SD-WAN zone. Multiple WAN interfaces and VPN overlays could be used.

The VPN interfaces and IP addresses are:

FortiGate	Interface	IP Address
FGT_A (Hub)	hub-phase1	10.10.100.254
FGT_B (Spoke)	spoke11-p1	10.10.100.2
FGT_D (Spoke)	spoke21-p1	10.10.100.3

A recurring speed test is configured that runs on the hub over the dial-up interfaces. The speed tests are performed over the underlay interface from the hub to the spoke. Each spoke is configured to operate as a speed test server and to allow the speed test to run on its underlay interface. The spokes establish BGP peering with the hub over the VPN interface, and advertises its loopback network to the hub. The specific configuration is only shown for FGT_B.

When the speed test is running, routing through the VPN overlay can be bypassed, and route maps are used to filter the routes that are advertised to peers. The spoke's route map does not advertise any routes to the peer, forcing the hub to use others paths to reach the spoke's network.

When no speed tests are running, the spoke's route map allows its network to be advertised on the hub.

When the speed test is complete, the measured egress bandwidth is dynamically applied to the VPN tunnel on the hub, and the result is cached for future use, in case the tunnel is disconnected and reconnected again.

To configure the hub FortiGate (FGT_A):

1. Configure a shaping profile:

```
config firewall shaping-profile
  edit "profile_1"
    config shaping-entries
      edit 1
        set class-id 2
        set priority low
        set guaranteed-bandwidth-percentage 10
        set maximum-bandwidth-percentage 10
      next
    end
    set default-class-id 2
  next
end
```

Three classes are used in the profile for low, medium, and high priority traffic. Each class is assigned a guaranteed and maximum bandwidth as a percentage of the measured bandwidth from the speed test.

2. Use the shaping profile in the interface:

```
config system interface
  edit "hub-phase1"
    set egress-shaping-profile "profile_1"
  next
end
```

3. Configure a schedule to use for the speed tests:

```
config firewall schedule recurring
  edit "speedtest_recurring"
    set start 01:00
    set end 23:00
    set day monday tuesday wednesday thursday friday saturday
  next
end
```

4. Configure the speed test schedule:

```
config system speed-test-schedule
  edit "hub-phase1"
    set schedules "speedtest_recurring"
    set dynamic-server enable
  next
end
```

To configure the spoke FortiGates (FGT_B and FGT_D):**1. Enable the speed test daemon:**

```
config system global
    set speedtest-server enable
end
```

2. Allow speed tests on the interface:

```
config system interface
    edit "port1"
        append allowaccess speed-test
    next
end
```

3. Configure SD-WAN with bypass routing enabled for speed tests on member *spoke11-p1*:

```
config system sdwan
    set speedtest-bypass-routing enable
    config members
        edit 1
            set interface "spoke11-p1"
        next
    end
    config neighbor
        edit "10.10.100.254"
            set member 1
            set mode speedtest
        next
    end
end
```

4. Configure BGP routing:

```
config router route-map
    edit "No_Speed-Test"
        config rule
            edit 1
                set action permit
            next
        end
    next
    edit "Start_Speed-Test"
        config rule
            edit 1
                set action deny
            next
        end
    next
end

config router bgp
    set as 65412
    config neighbor
        edit "10.10.100.254"
            set remote-as 65412
            set route-map-out "Start_Speed-Test"
            set route-map-out-preferable "No_Speed-Test"
        end
    end
end
```

```

    next
  end
  config network
    edit 1
      set prefix 2.2.2.2 255.255.255.255
    next
    edit 2
      set prefix 10.1.100.0 255.255.255.0
    next
  end
end
end

```

To manually run the speed test:

```

# execute speed-test-dynamic hub-phase1 all y 1000 100
Start testing the speed of each tunnel of hub-phase1
[6400d9] hub-phase1_0: physical_intf=port1, local_ip=172.16.200.1, server_ip=172.16.200.2
Wait for test 6400d9 to finish...
Speed-test result for test ID 6400d9:
  Completed
  measured upload bandwidth is 1002 kbps
  measured time Sun Jun 20 15:56:34 2021

```

The tested out-bandwidth is more than the set maximum accepted value 1000. Will update the tunnel's shaper by the set update-outbandwidth-maximum.

Apply shaping profile 'profile_1' with bandwidth 1000 to tunnel hub-phase1_0 of interface hub-phase1

```

[6400e0] hub-phase1_1: physical_intf=port1, local_ip=172.16.200.1, server_ip=172.16.200.4
Wait for test 6400e0 to finish...

```

```

Speed-test result for test ID 6400e0:
  Completed
  measured upload bandwidth is 1002 kbps
  measured time Sun Jun 20 15:56:39 2021

```

The tested out-bandwidth is more than the set maximum accepted value 1000. Will update the tunnel's shaper by the set update-outbandwidth-maximum.

Apply shaping profile 'profile_1' with bandwidth 1000 to tunnel hub-phase1_1 of interface hub-phase1

```

# diagnose netlink interface speed-test-tunnel hub-phase1 all
send speed test request for tunnel 'hub-phase1_0' of 'hub-phase1': 172.16.200.1 ->
172.16.200.2
send speed test request for tunnel 'hub-phase1_1' of 'hub-phase1': 172.16.200.1 ->
172.16.200.4

```

Results

1. Before the speed test starts, FGT_A can receive the route from FGT_B by BGP:

```

# get router info routing-table bgp
Routing table for VRF=0
B      2.2.2.2/32 [200/0] via 10.10.100.2 (recursive via 172.16.200.2, hub-phase1),
00:00:10
B      10.1.100.0/24 [200/0] via 10.10.100.2 (recursive via 172.16.200.2, hub-phase1),
00:00:10

```

2. At the scheduled time, the speed test starts for the hub-phase1 interface from hub to spoke:

```
# diagnose test application forticron 9
Speed test schedules:
  Interface      Server      Update      Up/Down-limit (kbps)      Days
H:M      TOS      Schedule
-----
      hub-phase1      dynamic
14:41      0x00      speedtest_recurring      1111111
Active schedules:
      64002f: hub-phase1 (port1) 172.16.200.2      hub-phase1_1
      64002e: hub-phase1 (port1) 172.16.200.4      hub-phase1_0
```

The diagnose debug application speedtest -1 command can be used on both the hub and spokes to check the speed test execution.

3. While the speed test is running, FGT_A does not receive the route from FGT_B by BGP:

```
# get router info routing-table bgp
Routing table for VRF=0
```

4. Speed tests results can be dynamically applied to the dial-up tunnel for egress traffic shaping:

```
# diagnose vpn tunnel list
-----
name=hub-phase1_0 ver=2 serial=c 172.16.200.1:0->172.16.200.4:0 tun_id=172.16.200.4 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
      bandwidth=737210 (kbps) lock_hit=0 default_class=2 n_active_class=3
      class-id=2      allocated-bandwidth=73720 (kbps)      guaranteed-
bandwidth=73720 (kbps)
      max-bandwidth=73720 (kbps)      current-bandwidth=0 (kbps)
      priority=low      forwarded_bytes=52
      dropped_packets=0      dropped_bytes=0
      class-id=3      allocated-bandwidth=221163 (kbps)      guaranteed-
bandwidth=221162 (kbps)
      max-bandwidth=294883 (kbps)      current-bandwidth=0 (kbps)
      priority=medium      forwarded_bytes=0
      dropped_packets=0      dropped_bytes=0
      class-id=4      allocated-bandwidth=442325 (kbps)      guaranteed-
bandwidth=147441 (kbps)
      max-bandwidth=442325 (kbps)      current-bandwidth=0 (kbps)
      priority=high      forwarded_bytes=0
      dropped_packets=0      dropped_bytes=0
-----
name=hub-phase1_1 ver=2 serial=d 172.16.200.1:0->172.16.200.2:0 tun_id=172.16.200.2 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
      bandwidth=726813 (kbps) lock_hit=0 default_class=2 n_active_class=3
      class-id=2      allocated-bandwidth=72681 (kbps)      guaranteed-
bandwidth=72681 (kbps)
      max-bandwidth=72681 (kbps)      current-bandwidth=0 (kbps)
      priority=low      forwarded_bytes=123
      dropped_packets=0      dropped_bytes=0
      class-id=3      allocated-bandwidth=218044 (kbps)      guaranteed-
bandwidth=218043 (kbps)
      max-bandwidth=290725 (kbps)      current-bandwidth=0 (kbps)
```

```

                priority=medium          forwarded_bytes=0
                dropped_packets=0        dropped_bytes=0
class-id=4      allocated-bandwidth=436087 (kbps)    guaranteed-
bandwidth=145362 (kbps)
                max-bandwidth=436087 (kbps)    current-bandwidth=0 (kbps)
                priority=high    forwarded_bytes=0
                dropped_packets=0    dropped_bytes=0

```

5. Speed test results can be cached, indexed, and written to disk:

```

# diagnose test application forticron 10
Speed test results:
1: vdom=root, phaselintf=hub-phase1, peer-id='spoke11-p1', bandwidth=737210, last_
log=1624226603
2: vdom=root, phaselintf=hub-phase1, peer-id='spoke21-p1', bandwidth=726813, last_
log=1624226614

# diagnose test application forticron 11
Write 2 logs to disk.

# diagnose test application forticron 12
load 2 results.

```

Disable then reenable the IPsec VPN tunnel and the cached speed test results can be applied to the tunnel again:

```

# diagnose vpn tunnel list
-----
name=hub-phase1_0 ver=2 serial=c 172.16.200.1:0->172.16.200.4:0 tun_id=172.16.200.4 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
    bandwidth=737210 (kbps) lock_hit=0 default_class=2 n_active_class=3
-----
name=hub-phase1_1 ver=2 serial=d 172.16.200.1:0->172.16.200.2:0 tun_id=172.16.200.2 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
    bandwidth=726813 (kbps) lock_hit=0 default_class=2 n_active_class=3

```

Interface based QoS on individual child tunnels based on speed test results

In a hub and spoke SD-WAN topology that uses dial-up VPN overlays, QoS can be applied on individual tunnels based on the measured bandwidth between the hub and spokes. The FortiGate can use the built in speed test to dynamically populate the egress bandwidth to individual dial-up tunnels from the hub.

A bandwidth limit, derived from the speed test, and a traffic shaping profile can be applied on the dial-up IPsec tunnel interface on the hub. A class ID and percentage based QoS settings can be applied to individual child tunnels using a traffic shaping policy and profile.

CLI commands

If the interface is an IPsec dial-up server, then egress shaping profile type can only be set to `policing`; it cannot be set to `queuing`:

```

config firewall shaping-profile
    edit <profile-name>

```

```

    set type policing
  next
end

```

The outbandwidth value is dynamically obtained from the speed test results for each individual child tunnel, and should not be set manually:

```

config system interface
  edit <dialup-server-phase1-name>
    set egress-shaping-profile <profile-name>
    set outbandwidth <bandwidth>
  next
end

```

Example

In this example, the hub is configured as a VPN dial-up server and both of the spokes are connected to the hub. It is assumed that the VPN configuration is already done, with a dynamic gateway type and kernel device creation (`net-device`) disabled. Only one SD-WAN interface is used, so there is only one VPN overlay member in the SD-WAN zone. Multiple WAN interfaces and VPN overlays could be used.

The VPN interfaces and IP addresses are:

FortiGate	Interface	IP Address
FGT_A (Hub)	hub-phase1	10.10.100.254
FGT_B (Spoke)	spoke11-p1	10.10.100.2
FGT_D (Spoke)	spoke21-p1	10.10.100.3

The hub VPN has two child tunnels, one to each spoke.

The speed test configuration is shown in [Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 772](#). This example shows applying a shaping profile to the hub's tunnel interface in order to apply interface based traffic shaping to the child tunnels.

A traffic shaping policy is used to match and assign traffic to the classes in the shaping profile.

To configure the hub FortiGate (FGT_A) and check the results:

1. Configure the hub FortiGate (FGT_A) as in [Speed tests run from the hub to the spokes in dial-up IPsec tunnels on page 772](#).

2. Configure the shaping profile:

```

config firewall shaping-profile
  edit "profile_1"
    config shaping-entries
      edit 1
        set class-id 2
        set priority low
        set guaranteed-bandwidth-percentage 10
        set maximum-bandwidth-percentage 10
      next
      edit 2
        set class-id 3
        set priority medium
        set guaranteed-bandwidth-percentage 30
        set maximum-bandwidth-percentage 40
      next
      edit 3
        set class-id 4
        set priority high
        set guaranteed-bandwidth-percentage 20
        set maximum-bandwidth-percentage 60
      next
    end
    set default-class-id 2
  next
end

```

3. Configure a traffic shaping policy:

```

config firewall shaping-policy
  edit 2
    set service "ALL"
    set schedule "always"
    set dstintf "hub-phase1"
    set class-id 3
    set srcaddr "all"
    set dstaddr "all"
  next
end

```

In this example, all traffic through the hub-phase1 interface is put into class ID 3. Class IDs can be assigned based on your traffic requirements.

- 4.** At the scheduled time, the speed test will start for the hub-phase1 interface from the hub to the spokes. The speed test results can then be dynamically applied on individual child tunnels as egress traffic shaping, and the class ID percentage based QoS settings is applicable on them as templates.

```

# diagnose vpn tunnel list
-----
name=hub-phase1_0 ver=2 serial=c 172.16.200.1:0->172.16.200.4:0 tun_id=172.16.200.4 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
  bandwidth=737210 (kbps) lock_hit=0 default_class=2 n_active_class=3
  class-id=2 allocated-bandwidth=73720 (kbps) guaranteed-
bandwidth=73720 (kbps)
  max-bandwidth=73720 (kbps) current-bandwidth=0 (kbps)

```

```

        priority=low    forwarded_bytes=52
        dropped_packets=0    dropped_bytes=0
        class-id=3    allocated-bandwidth=221163 (kbps)    guaranteed-
bandwidth=221162 (kbps)
        max-bandwidth=294883 (kbps)    current-bandwidth=0 (kbps)
        priority=medium    forwarded_bytes=0
        dropped_packets=0    dropped_bytes=0
        class-id=4    allocated-bandwidth=442325 (kbps)    guaranteed-
bandwidth=147441 (kbps)
        max-bandwidth=442325 (kbps)    current-bandwidth=0 (kbps)
        priority=high    forwarded_bytes=0
        dropped_packets=0    dropped_bytes=0
-----
name=hub-phase1_1 ver=2 serial=d 172.16.200.1:0->172.16.200.2:0 tun_id=172.16.200.2 dst_
mtu=1500 dpd-link=on remote_location=0.0.0.0 weight=1
...
egress traffic control:
    bandwidth=726813 (kbps) lock_hit=0 default_class=2 n_active_class=3
    class-id=2    allocated-bandwidth=72681 (kbps)    guaranteed-
bandwidth=72681 (kbps)
        max-bandwidth=72681 (kbps)    current-bandwidth=0 (kbps)
        priority=low    forwarded_bytes=123
        dropped_packets=0    dropped_bytes=0
        class-id=3    allocated-bandwidth=218044 (kbps)    guaranteed-
bandwidth=218043 (kbps)
        max-bandwidth=290725 (kbps)    current-bandwidth=0 (kbps)
        priority=medium    forwarded_bytes=0
        dropped_packets=0    dropped_bytes=0
        class-id=4    allocated-bandwidth=436087 (kbps)    guaranteed-
bandwidth=145362 (kbps)
        max-bandwidth=436087 (kbps)    current-bandwidth=0 (kbps)
        priority=high    forwarded_bytes=0
        dropped_packets=0    dropped_bytes=0

```

The guaranteed and maximum bandwidths equal 10% of the speed test result, as expected.

Advanced configuration

The following topics provide instructions on SD-WAN advanced configuration:

- [SD-WAN with FGCP HA on page 782](#)
- [Configuring SD-WAN in an HA cluster using internal hardware switches on page 789](#)
- [SD-WAN configuration portability on page 793](#)

See also [Packet distribution for aggregate static IPsec tunnels in SD-WAN on page 1596](#).

SD-WAN with FGCP HA

This example shows how to convert a standalone FortiGate SD-WAN solution to a FGCP HA cluster with full-mesh WAN set up. This configuration allows you to load balance your internet traffic between multiple ISP links. It also provides redundancy for your internet connection if your primary ISP is unavailable, or if one of the FortiGates in the HA cluster fails.

This example assumes that a standalone FortiGate has already been configured for SD-WAN by following the [SD-WAN quick start on page 608](#).

Standalone FortiGate:

FGCP HA cluster:

The following devices are required to convert the topology to HA:

- A second FortiGate that is the same model running the same firmware version.
- Two switches for connecting each FortiGate's WAN interface to the corresponding ISP modem.

Before you begin:

- Ensure that the licenses and subscriptions on both HA members match.
- Ensure that there are one or more ports reserved for HA heartbeat.
- Ensure you have physical access to both HA members.

Enabling HA and re-cabling the WAN interfaces will cause network interruptions.
This procedure should be performed during a maintenance window.

Configuring the standalone FortiGate for HA

After running the following commands, the FortiGate negotiates to establish an HA cluster. You might temporarily lose connectivity with the FortiGate as FGCP negotiations take place and the MAC addresses of the FortiGate interfaces are changed to HA virtual MAC addresses.

This configurations sets the HA mode to active-passive.

The ha1 and ha2 interfaces are configured as the heartbeat interfaces, with priorities set to 200 and 100 respectively. Setting different priorities for the heartbeat interfaces is a best practice, but is not required.

If you have more than one cluster on the same network, each cluster should have a different group ID. Changing the group ID changes the cluster interface's virtual MAC addresses. If the group IP causes a MAC address conflict on your network, select a different group ID.

Enabling override and increasing the device priority means that this FortiGate always becomes the primary unit.

To configure the standalone FortiGate for HA in the GUI:

1. Go to *System > Settings* and change the *Host name* so that the FortiGate can be easily identified as the primary unit.
2. Go to *System > HA* and configure the following options:

Mode	Active-Passive
Device priority	250
Group name	My-cluster
Password	<password>
Heartbeat interfaces	ha1 and ha2
Heartbeat Interface Priority	port2 (ha1): 200 port3 (ha2): 100

Override and the group ID can only be configured from the CLI.

3. Click **OK**.
Connectivity with the FortiGate will temporarily be lost.

To configure the standalone FortiGate for HA in the CLI:

1. Change the host name so that the FortiGate can be easily identified:

```
config system global
    set hostname primary_FG
end
```

2. Configure HA:

```
config system ha
    set mode a-p
    set group-id 100
    set group-name My-cluster
    set password <password>
    set priority 250
    set override enable
    set hbdev ha1 200 ha2 100
end
```

If HA mode does not start after running the above steps, ensure that none of the FortiGate's interfaces use DHCP or PPPoE addressing.

Configuring the secondary FortiGate for HA

The secondary FortiGate must be the same model and running the same firmware version as the primary FortiGate. The HA settings are the same as the for the primary unit, except the secondary device has a lower priority and override is not enabled.

It is best practice to reset the FortiGate to factory default settings prior to configuring HA. This reduces the chance of synchronization problems.

```
# execute factoryreset
This operation will reset the system to factory default!
Do you want to continue? (y/n) y
```

This is unnecessary if the device is new from the factory.

To configure the secondary FortiGate for HA in the GUI:

1. Go to *System > Settings* and change the *Host name* so that the FortiGate can be easily identified as the backup unit.
2. Go to *System > HA* and configure the options the same as for the primary FortiGate, except with a lower priority:

Mode	Active-Passive
Device priority	128
Group name	My-cluster
Password	<password>
Heartbeat interfaces	ha1 and ha2
Heartbeat Interface Priority	port2 (ha1): 200 port3 (ha2): 100

3. Click *OK*.

To configure the secondary FortiGate for HA in the CLI:

1. Change the host name so that the secondary FortiGate can be easily identified:

```
config system global
  set hostname secondary_FG
end
```

2. Configure HA:

```
config system ha
  set mode a-p
  set group-id 100
  set group-name My-cluster
  set password <password>
  set priority 128
  set hbdev ha1 200 ha2 100
end
```

Connecting the heartbeat interfaces between the FortiGates

To connect and check the heartbeat interfaces:

1. Connect the heartbeat interfaces ha1 and ha2 between the primary and secondary FortiGate.
 - a. An HA primary device is selected. Because the primary FortiGate has a higher priority and override enabled, it assumes the role of HA primary.

b. The secondary FortiGate synchronizes its configuration from the primary device.

2. Verify that the checksums match between the primary and secondary FortiGates:

```
# diagnose sys ha checksum cluster

===== FG5H0XXXXXXXXXX0 =====

is_manage_primary()=1, is_root_primary()=1
debugzone
global: 2b e9 81 38 c2 9d 4f db b7 0e 1f 49 42 c6 1e fb
root: af a6 48 c5 c2 9a 8b 81 a5 53 fb 27 e9 ae 01 6a
all: 89 1f 63 77 48 8a 30 ee 57 06 ca eb 71 e6 8e ad

checksum
global: 2b e9 81 38 c2 9d 4f db b7 0e 1f 49 42 c6 1e fb
root: af a6 48 c5 c2 9a 8b 81 a5 53 fb 27 e9 ae 01 6a
all: 89 1f 63 77 48 8a 30 ee 57 06 ca eb 71 e6 8e ad

===== FG5H0XXXXXXXXXX1 =====

is_manage_primary()=0, is_root_primary()=0
debugzone
global: 2b e9 81 38 c2 9d 4f db b7 0e 1f 49 42 c6 1e fb
root: af a6 48 c5 c2 9a 8b 81 a5 53 fb 27 e9 ae 01 6a
all: 89 1f 63 77 48 8a 30 ee 57 06 ca eb 71 e6 8e ad

checksum
global: 2b e9 81 38 c2 9d 4f db b7 0e 1f 49 42 c6 1e fb
root: af a6 48 c5 c2 9a 8b 81 a5 53 fb 27 e9 ae 01 6a
all: 89 1f 63 77 48 8a 30 ee 57 06 ca eb 71 e6 8e ad
```

If all of the cluster members have identical checksums, then their configurations are synchronized. If the checksums are not the same, wait for a few minutes, then repeat the command. Some parts of the configuration might take a significant amount of time to synchronize (tens of minutes).

Connecting other traffic interfaces

After the device configurations are synchronized, you can connect the rest of the traffic interfaces. Making these connections will disrupt traffic as cables are disconnected and reconnected.

Switches must be used between the cluster and the ISPs, and between the cluster and the internal network, as shown in the topology diagram.

Checking cluster operations

The *HA Status* dashboard widget shows the synchronization status. Hover over the host names of each FortiGate in the widget to verify that they are synchronized and have the same checksum.

To view more information about the cluster status, including the number of sessions passing through the cluster members, go to *System > HA*.

See [Check HA synchronization status on page 2141](#) for more information.

Results

1. Browse the internet on a computer in the internal network.
2. Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab to see the bandwidth, volume, and sessions for traffic on the SD-WAN interfaces. See [Results on page 613](#) for details.
3. Go to *Dashboard > Network*, and expand the *SD-WAN* widget to see information about each interface, such as the number of sessions and the bit rate.

Interface	Status	Sessions	Upload	Download
sd-wan				
wan1		49	190 bps	51 bps
wan2		33	2.97 kbps	6.75 kbps

Updated: 14:30:42

Testing HA failover

All traffic should currently be flowing through the primary FortiGate. If it becomes unavailable, traffic fails over to the secondary FortiGate. When the primary FortiGate rejoins the cluster, the secondary FortiGate continues to operate as the primary FortiGate.

To test this, ping a reliable IP address from a computer in the internal network, and then power off the primary FortiGate.

There will be a momentary pause in the ping results until traffic diverts to the backup FortiGate, allowing the ping traffic to continue:

```
64 bytes from 184.25.76.114: icmp_seq=69 ttl=52 time=8.719 ms\  
64 bytes from 184.25.76.114: icmp_seq=70 ttl=52 time=8.822 ms\  
64 bytes from 184.25.76.114: icmp_seq=74 ttl=52 time=8.901 ms\  
Request timeout for icmp_seq 75\  
64 bytes from 184.25.76.114: icmp_seq=76 ttl=52 time=8.860 ms\  
64 bytes from 184.25.76.114: icmp_seq=77 ttl=52 time=9.174 ms\  
64 bytes from 184.25.76.114: icmp_seq=83 ttl=52 time=8.639 ms}
```

If you are using port monitoring, you can also unplug the primary FortiGate's internet facing interface to test failover.

After the secondary FortiGate becomes the primary, you can log into the cluster using the same IP address as before the fail over. If the primary FortiGate is powered off, you will be logged into the backup FortiGate. Check the host name to verify what device you have logged into. The FortiGate continues to operate in HA mode, and if you restart the primary FortiGate, it will rejoin the cluster and act as the backup FortiGate. Traffic is not disrupted when the restarted FortiGate rejoins the cluster.

You can also use the CLI to force an HA failover. See [Force HA failover for testing and demonstrations on page 2167](#) for information.

Testing ISP failover

To test a failover of the redundant internet configuration, you need to simulate a failed internet connection to one of the ports. You can do this by disconnecting power from the wan1 switch, or by disconnecting the wan1 interfaces of both FortiGates from ISP1.

After disconnecting, verify that users still have internet access

- Go to *Dashboard > Network*, and expand the *SD-WAN* widget. The *Upload* and *Download* columns for wan1 show that traffic is not going through that interface.

Interface	Status	Sessions	Upload	Download
sd-wan				
wan1	🟢	12	0 bps	0 bps
wan2	🟢	33	2.97 kbps	6.75 kbps

Updated: 14:30:42

- Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab. The *Bandwidth*, *Volume*, and *Sessions* tabs show that traffic is entirely diverted to wan2.

Users on the network should not notice the wan1 failure. If you are using the wan1 gateway IP address to connect to the administrator dashboard, it will appear as though you are still connecting through wan1.

After verifying a successful failover, reestablish the connection to ISP1.

Configuring SD-WAN in an HA cluster using internal hardware switches

In this SD-WAN configuration, two FortiGates in an active-passive (A-P) HA pair are used to provide hardware redundancy. Instead of using external switches to provide a mesh network connection to the ISP routers, the FortiGates use their built-in hardware switches to connect to the ISP routers.

Only FortiGate models that have hardware switches can be used for this solution. Ports in a software switch are not in a forwarding state when a FortiGate is acting as a secondary device in a A-P cluster.

In this topology:

- Two hardware switches are created, HD_SW1 and HD_SW2.
- HD_SW1 is used to connect to ISP 1 Router and includes the internal1 and internal2 ports.
- HD_SW2 is used to connect to ISP 2 Router and includes the internal3 and internal4 ports.
- Another interface on each device is used as the HA heartbeat interface, connecting the two FortiGates in HA.

The FortiGates create two hardware switches to connect to ISP 1 and ISP2. When FGT_A is the primary device, it reaches ISP 1 on internal1 in HD_SW1 and ISP 2 on internal4 in HD_SW2. When FGT_B is the primary device, it reaches ISP 1 on internal2 in HD_SW1 and ISP 2 on internal3 on HD_SW2.

HA failover

This is not a standard HA configuration with external switches. In the case of a device failure, one of the ISPs will no longer be available because the switch that is connected to it will be down.

For example, If FGT_A loses power, HA failover will occur and FGT_B will become the primary unit. Its connection to internal2 on HD_SW1 will also be down, so it will be unable to connect to ISP 1. Its SD-WAN SLAs will be broken, and traffic will only be routed through ISP 2.

A link on a hardware switch cannot be monitored in HA monitor, so it is impossible to perform link failure when a port in either of the hardware switches fails. Performing a link failure is unnecessary in this configuration though, because any link failure on the hardware switch will be experienced by both cluster members. SD-WAN SLA health checks should be used to monitor the health of each ISP.

Failure on a hardware switch or ISP router

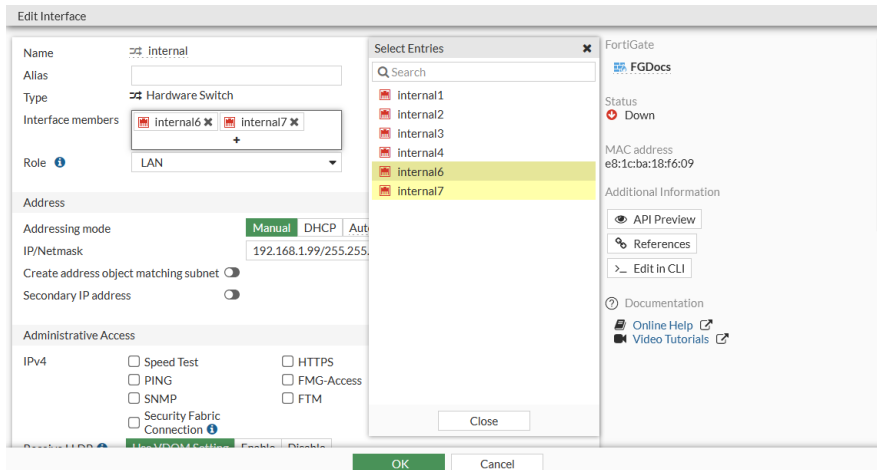

If a hardware switch or switch interface is down, or the ISP router is down, the SD-WAN can detect the broken SLA and continue routing to the other ISP.

For example, if FGT_A is the primary unit, and ISP 2 Router becomes unreachable, the SLA health checks on SD-WAN will detect the broken SLA and cause traffic to stop routing to ISP 2.

Configuration

To configure the HA A-P cluster with internal hardware switches:

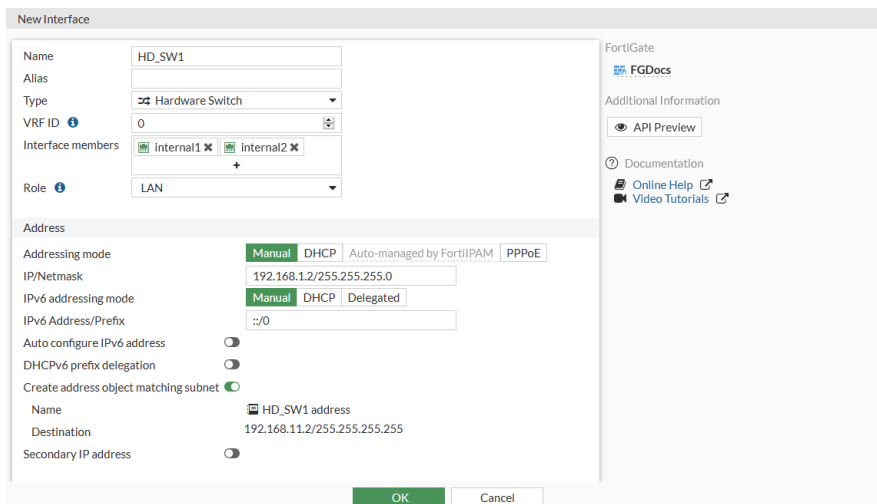

1. Configure two FortiGates with internal switches in an A-P HA cluster (follow the steps in [HA active-passive cluster setup on page 2131](#)), starting by connecting the heartbeat interface.
2. When the HA cluster is up, connect to the primary FortiGate's GUI.
3. Remove the existing interface members from the default hardware switch:
 - a. Go to *Network > Interfaces*.
 - b. In the *LAN* section, double-click the *internal* interface to edit it.
 - c. In *Interface Members*, remove all of the interfaces

d. Click **OK**.

4. Configure the hardware switch interfaces for the two ISPs:

- a. Go to *Network > Interfaces* and click *Create New > Interface*.
- b. Enter a name (*HD_SW1*).
- c. Set *Type* to *Hardware Switch*.
- d. In *Interface Members*, add two interfaces (*internal1* and *internal2*).
- e. Set *IP/Netmask* to *192.168.1.2/24*.
- f. Configure the remaining settings as needed.

g. Click **OK**.

- h. Repeat these steps to create a second hardware switch interface (*HD_SW2*) with two interface members

(*internal3* and *internal4*) and *IP/Netmask* set to *192.168.3.2/24*.

To connect the devices as shown in the topology:

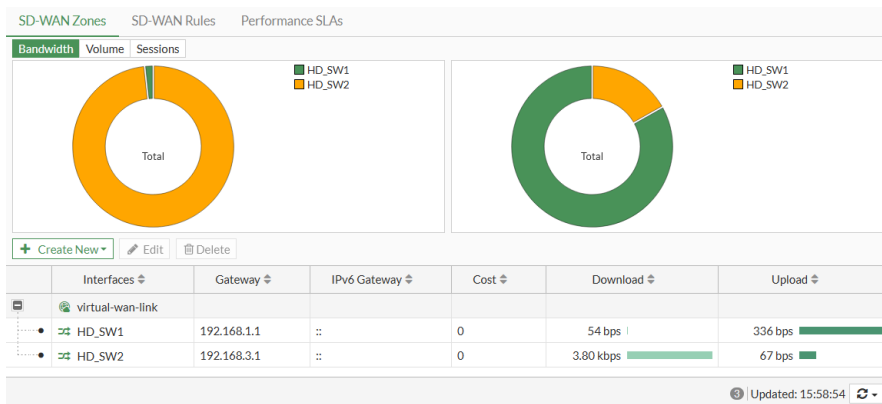

1. Connect the incoming interface to the internal switch on both FortiGates.
2. On FGT_A, connect internal1 of HD_SW1 to ISP 1 Router.
3. On FGT_B, connect internal3 of HD_SW2 to ISP 2 Router.
4. For HD_SW1, connect FGT_A internal2 directly to FGT_B internal2.
5. For HD_SW2, connect FGT_A internal4 directly to FGT_B internal4.

To configure SD-WAN:

The primary FortiGate makes all the SD-WAN decisions.

1. On the primary FortiGate, go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
2. In the *Interface* dropdown, select *HD_SW1*.
3. Leave *SD-WAN Zone* set to *virtual-wan-link*.
4. Enter the *Gateway* address *192.168.1.1*.
5. Click *OK*.
6. Repeat these steps to add the second interface (*HD_SW2*) with the gateway *192.168.3.1*.
7. Click *Apply*.

8. Create a health check:
 - a. Go to *Network > SD-WAN*, select the *Performance SLA* tab, and click *Create New*.
 - b. Set *Name* to *GW_HC*.
 - c. Set *Protocol* to *Ping* and *Servers* to *8.8.8.8*.
 - d. Set *Participants* to *All SD-WAN Members*.
 - e. Enable *SLA Target* and leave the default values.
 - f. Click *OK*.
9. Create SD-WAN rules as needed. The SLA health check can be used to determine when the ISP connections are in or out of SLA, and to failover accordingly.

SD-WAN configuration portability

When configuring SD-WAN, adding interfaces to members is optional.

This allows the SD-WAN to be configured without associating any interfaces to SD-WAN members. It also allows a configuration to be copied directly from one device to another, without requiring the devices to have interfaces with the same names.

After the configuration is created, add interfaces to the members make it functional.

Example 1

In this example, we create a template with two SD-WAN members configured without assigned interfaces that are used in a performance SLA and SD-WAN rule. The template can be used to configure new devices, as in [Example 2 on page 797](#). Interfaces are then assigned to the members, and the configuration becomes active.

To create the SD-WAN members in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
2. Leave all the settings set to their default values and click *OK*.

The screenshot shows the 'New SD-WAN Member' configuration window. On the left, there are several input fields: 'Interface' (set to 'None'), 'SD-WAN Zone' (set to 'virtual-wan-link'), 'Gateway' (set to '0.0.0.0'), 'IPv6 Gateway' (set to '::'), and 'Cost' (set to '0'). Below these is a 'Status' section with 'Enabled' selected and 'Disabled' unselected. On the right, there is an 'Additional Information' section with an 'API Preview' button and several links under 'SD-WAN Setup Guides' and 'Documentation'. At the bottom, there are 'OK' and 'Cancel' buttons.

3. Repeat the above steps to create a second member.
The empty members are listed on the *SD-WAN Zones* tab.

The screenshot shows the 'SD-WAN Zones' tab in the GUI. It has three sub-tabs: 'Bandwidth', 'Volume', and 'Sessions'. The 'Bandwidth' and 'Volume' tabs are active, both showing 'No results'. Below the tabs is a '+ Create New' button and 'Edit' and 'Delete' icons. At the bottom, there is a table listing the SD-WAN members.

	Interfaces	Gateway	IPv6 Gateway	Cost	Download	Upload
virtual-wan-link						
Member 1		0.0.0.0	::	0		
Member 2		0.0.0.0	::	0		

At the bottom right of the table, there is a status bar: 'Updated: 16:08:17' with a refresh icon.

The members are disabled until interfaces are configured, but can still be used in performance SLAs and SD-WAN rules.

To create a performance SLA in the GUI:

1. Go to *Network > SD-WAN* and select the *Performance SLAs* tab.
2. Click *Create New*.

3. Configure the performance SLA, specifying the empty members as participants.

New Performance SLA

Name: office

IP Version: IPv4 IPv6

Detection Mode: Active Passive Prefer Passive

Protocol: Ping HTTP DNS

Server: office365.com

Participants: All SD-WAN Members Specify
Member 2 Member 1

Enable probe packets:

SLA Target:

Latency threshold: 300 ms

Jitter threshold: 200 ms

- Online Help
- Video Tutorials

OK Cancel

4. Click OK.

To create an SD-WAN rule in the GUI:

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Configure the rule, adding both members to the *Interface preference* field:

Priority Rule

Name: Office365

IP Version: IPv4 IPv6

Source:

Source address: +

User group: +

Destination:

Address: +

Internet Service: +

Application: Microsoft.Office.365

Outgoing Interfaces

Select a strategy for how outgoing interfaces will be chosen.

Manual
Manually assign outgoing interfaces.

Best Quality
The interface with the best measured performance is selected.

Lowest Cost (SLA)
The interface that meets SLA targets is selected. When there is a tie, the interface with the lowest assigned cost is selected.

Maximize Bandwidth (SLA)
Traffic is load balanced among interfaces that meet SLA targets.

Interface preference: Member 1 Member 2

Zone preference: +

Required SLA target: office

Forward DSCP:

Reverse DSCP:

Status: Enable Disable

SLA Details

	Packet Loss	Latency	Jitter
office	0.00%	300.00ms	200.00ms
Member 1	?	?	?
Member 2	?	?	?

OK Cancel

3. Click OK.

To assign interfaces to the SD-WAN members in the GUI:

1. Go to *Network > SD-WAN* and select the *SD-WAN Zones* tab.
2. Edit the first member

3. Set *Interface* to an actual interface.

4. Click *OK*.

5. Repeat the above steps to assign an interface to the second member.

To configure the SD-WAN in the CLI:

1. Create SD-WAN members:

```
config system sdwan
  set status enable
  config members
    edit 1
    next
    edit 2
    next
  end
end
```

2. Create a health check (performance SLA):

```
config system sdwan
  config health-check
    edit "office"
      set server "office365.com"
      set protocol http
      set sla-fail-log-period 300
      set sla-pass-log-period 300
      set members 2 1
      config sla
        edit 1
          set latency-threshold 300
          set jitter-threshold 200
        next
        edit 2
          set link-cost-factor latency
          set latency-threshold 20
        next
      end
    next
  end
end
```

3. Create a service (rule):

```
config system sdwan
  config service
    edit 3
      set name "Office365"
```

```
        set mode sla
        set internet-service enable
        set internet-service-app-ctrl 33182
        config sla
            edit "office"
                set id 2
            next
        end
        set priority-members 1 2
    next
end
end
```

The SD-WAN configuration can now be used in as a template for new spokes, as in [Example 2 on page 797](#).

To assign interfaces to the SD-WAN members in the CLI:

```
config system sdwan
    config members
        edit 1
            set interface "_OCVPN4-0.0"
        next
        edit 2
            set interface "_OCVPN4-0.1"
        next
    end
end
```

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

Example 2

In this example, the configuration from [Example 1](#) is copied onto a new FortiGate.

Using the CLI console and the GUI

To copy the SD-WAN configuration from the original FortiGate:

1. Optionally, change the console screen paging setting. See [Screen paging on page 49](#) for details.
2. Open the CLI console.
3. If necessary, click *Clear console* to empty the console.
4. Enter the following command:

```
show system sdwan
```
5. Either click *Download* and open the file in a text editor, or click *Copy to clipboard* and paste the content into a text editor.

```

CLIConsole(1)
set protocol http
set members 2 1
config sla
edit 1
set latency-threshold 300
set jitter-threshold 200
next
end
next
end
config service
edit 1
set name "Office365"
set mode sla
set internet-service enable
set internet-service-app-ctrl 33182
config sla
edit "office"
set id 1
next
end
set priority-members 1 2
next
end
end
FGDocs #

```

6. Edit the CLI configuration as necessary. For example, the first line that shows the `show` command should be deleted, and the default health checks can be removed.
7. If required, save the CLI configuration as a text file.

To paste the SD-WAN configuration onto a new FortiGate:

1. Copy the SD-WAN configuration from the text editor.
2. On the new FortiGate, open the CLI console.
3. Press `Ctrl + v` to paste the CLI commands.
4. In necessary, press `Enter` to apply the last `end` command.

The SD-WAN configuration is copied to the new FortiGate.

If the interfaces do not exist, the SD-WAN members are created without interfaces, and are disabled until interfaces are configured.

To assign interfaces to the SD-WAN members:

1. Go to `Network > SD-WAN` and select the `SD-WAN Zones` tab.
2. Edit the first member
3. Set `Interface` to an actual interface.
4. Click `OK`.
5. Repeat the above steps to assign an interface to the second member.

Using a terminal emulator

The following instructions use [PuTTY](#). The steps may vary in other terminal emulators.

To copy the SD-WAN configuration from the original FortiGate:

1. Connect to the FortiGate. See [Connecting to the CLI on page 41](#) for details.
2. Enter the following command:
`show system sdwan`
3. Select the output, press `Ctrl + c` to copy it, and then paste it into a text editor.
4. Edit the CLI configuration as necessary. For example, the default health checks can be removed.
5. If required, save the CLI configuration as a text file.

To paste the SD-WAN configuration onto a new FortiGate:

1. Connect to the new FortiGate. See [Connecting to the CLI on page 41](#) for details.
2. Copy the SD-WAN configuration from the text editor.
3. Right-click to paste the SD-WAN configuration.
4. In necessary, press *Enter* to apply the last `end` command.

The SD-WAN configuration is copied to the new FortiGate.

If the interfaces do not exist, the SD-WAN members are created without interfaces, and are disabled until interfaces are configured.

To assign interfaces to the SD-WAN members in the CLI:

```
config system sdwan
  config members
    edit 1
      set interface "_OCVPN4-0.0"
    next
    edit 2
      set interface "_OCVPN4-0.1"
    next
  end
end
```

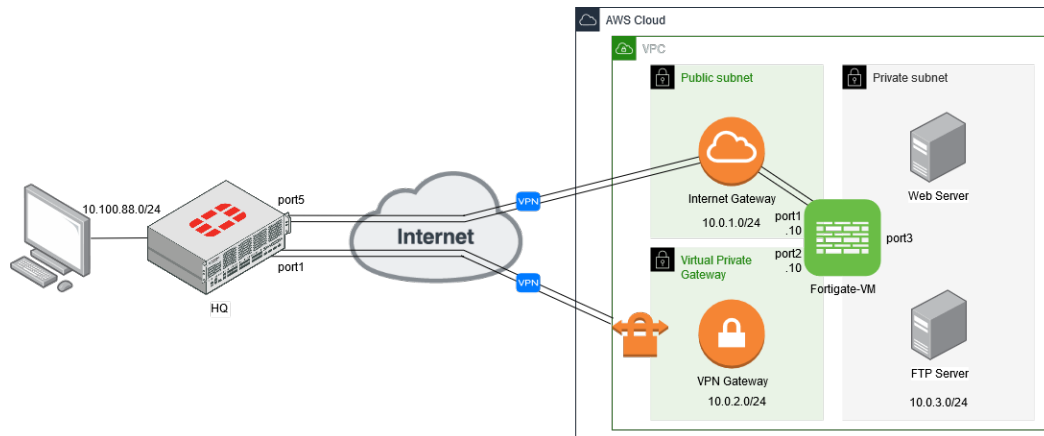

If no SD-WAN zone is specified, members are added to the default *virtual-wan-link* zone.

SD-WAN cloud on-ramp

In this example, you configure a connection to a new cloud deployment that has some remote servers. SD-WAN is used to steer traffic through the required overlay tunnel.

The on-premise FortiGate has two internet connections, each with a single VPN connection. The two VPN gateways are configured on the cloud for redundancy, one terminating at the FortiGate-VM, and the other at the native AWS VPN Gateway.

This example uses AWS as the Infrastructure as a Service (IaaS) provider, but the same configuration can also apply to other services. A full mesh VPN setup is not shown, but can be added later if required.

To connect to the servers that are behind the cloud FortiGate-VM, virtual IP addresses (VIPs) are configured on port2 to map to the servers:

- VPN traffic terminating on port1 is routed to the VIP on port2 to access the web servers.
- VPN traffic terminating on the VPN gateway accesses the VIPs on port2 directly.

There are four major steps to configure this setup:

1. [Configuring the VPN overlay between the HQ FortiGate and cloud FortiGate-VM on page 800](#)
2. [Configuring the VPN overlay between the HQ FortiGate and AWS native VPN gateway on page 805](#)
3. [Configuring the VIP to access the remote servers on page 808](#)
4. [Configuring the SD-WAN to steer traffic between the overlays on page 811](#)

After the configuration is complete, verify the traffic to ensure that the configuration is working as expected, see [Verifying the traffic on page 815](#).

Configuring the VPN overlay between the HQ FortiGate and cloud FortiGate-VM

Configure the cloud FortiGate-VM

To create an address for the VPN gateway:

1. Go to *Policy & Objects > Addresses* and click *Create New > Address*.
2. Set *Name* to *local_subnet_10_0_2_0*.
3. Set *IP/Netmask* to *10.0.2.0/24*.

The screenshot shows the 'New Address' configuration page in FortiGate. The Name is 'local_subnet_10_0_2_0', Color is 'Change', Type is 'Subnet', IP/Netmask is '10.0.2.0/24', and Interface is 'any'. The Static route configuration is disabled. The FortiGate is 'FortiGate-VM'. The page includes a 'Dynamic Address' section with links to guides for various cloud providers: Configuring an AWS Dynamic Address, Configuring an Azure Dynamic Address, Configuring a Google Cloud Platform Dynamic Address, Configuring an Oracle Cloud Infrastructure Dynamic Address, and Configuring an OpenStack Dynamic Address. There is also a 'Documentation' section with links to Online Help and Video Tutorials.

4. Click *OK*.

To configure a custom IPsec VPN:

1. Go to *VPN > IPsec Wizard*.
2. Set *Name* to *Core_Dialup*.
3. Set *Template type* to *Custom*.

VPN Creation Wizard

VPN Setup

Name: Core_Dialup

Template type: Site to Site | Hub-and-Spoke | Remote Access | **Custom**

< Back Next > Cancel

4. Click *Next*.
5. Configure *Network* settings:

Remote Gateway	Dialup User
Interface	port1
NAT Traversal	Enable

6. Configure *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	Enter the pre-shared key.
Version	1
Mode	Aggressive This setting allows the peer ID to be specified.
Accept Types	Specific peer ID
Peer ID	laaS The other end of the tunnel needs to have its local ID set to laaS.

New VPN Tunnel

Authentication

Method: Pre-shared Key

Pre-shared Key: [redacted]

IPsec VPNs

Guides

- IPsec VPN Cookbook Recipes
- VPN Setup on FortiClient
- Configuring an IPsec VPN Connection

Documentation

- Online Help
- Video Tutorials

7. Leave the default *Phase 1 Proposal* settings and disable *XAUTH*.

8. Configure the *Phase 2 Selector* settings:

Name	Ent_Core
Local Address	Named Address - <i>local_subnet_10_0_2_0</i>
Remote Address	Named Address - <i>all</i> This setting allows traffic originating from both the remote subnet 10.100.88.0 and the health checks from the VPN interface on the remote FortiGate. For increased security, each subnet can be specified individually.

9. Click *OK*.

To configure remote and local tunnel IP addresses:

1. Go to *Network > Interfaces* and edit the *Core_Dialup* interface under *port1*.
2. Set *IP* to *172.16.200.1*.
3. Set *Remote IP/Netmask* to *172.16.200.2 255.255.255.0*. This is where remote health check traffic will come from.
4. Enable *Administrative access* for *HTTPS*, *PING*, and *SSH*.

The screenshot shows the 'Edit Interface' configuration for 'Core_Dialup'. The interface is set to 'port1' and 'Tunnel Interface'. The IP address is '172.16.200.1' and the Remote IP/Netmask is '172.16.200.2 255.255.255.0'. Under 'Administrative Access', the following options are checked: IPv4 HTTPS, SSH, PING, and Security Fabric Connection. Other options like SNMP, FMG-Access, and FTM are unchecked. The DHCP Server option is also unchecked. The status is 'Up'.

5. Click *OK*.

To configure a route to the remote subnet through the tunnel:

1. Go to *Network > Static Routes* and click *Create New*.
2. Set *Destination* to *Subnet* and enter the IP address and netmask: *10.100.88.0/255.255.255.0*.
3. Set *Interface* to *Core_Dialup*.

The screenshot shows the 'New Static Route' configuration page. The destination is set to 'Subnet' with the IP address and netmask '10.100.88.0/255.255.255.0'. The interface is set to 'Core_Dialup' and the Administrative Distance is '10'. The status is 'Enabled'. There are buttons for 'API Preview', 'Documentation', 'Online Help', and 'Video Tutorials'.

4. Click *OK*.

To configure a firewall policy to allow traffic from the tunnel to port2:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following:

Name	Core_Dialup-to-port2
Incoming Interface	Core_Dialup
Outgoing Interface	port2
Source	all
Destination	local_subnet_10_0_2_0
Schedule	always
Service	ALL
Action	ACCEPT

3. Configure the remaining settings as required.
4. Click *OK*.

Configure the HQ FortiGate

To create an address for the VPN gateway:

1. Go to *Policy & Objects > Addresses* and click *Create New > Address*.
2. Set *Name* to *remote_subnet_10_0_2_0*.
3. Set *IP/Netmask* to *10.0.2.0/24*.
4. Click *OK*.

To configure a custom IPsec VPN:

1. Go to *VPN > IPsec Wizard*.
2. Set *Name* to *FGT_AWS_Tun*.
3. Set *Template type* to *Custom*.
4. Click *Next*.
5. Configure *Network* settings:

Remote Gateway	Static IP Address
IP Address	100.21.29.17
Interface	port5
NAT Traversal	Enable

6. Configure *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	Enter the pre-shared key.
Version	1
Mode	Aggressive This setting allows the peer ID to be specified.
Accept Types	Any peer ID

7. Leave the default *Phase 1 Proposal* settings, except set *Local ID* to *laaS*.

8. Disable *XAUTH*.

9. Configure the *Phase 2 Selector* settings:

Name	FGT_AWS_Tun
Local Address	Named Address - <i>all</i> This setting allows traffic originating from both the local subnet 10.100.88.0 and the health checks from the VPN interface. For increased security, each subnet can be specified individually.
Remote Address	Named Address - <i>remote_subnet_10_0_2_0</i>

10. Click *OK*.

To configure local and remote tunnel IP addresses:

1. Go to *Network > Interfaces* and edit the *FGT_AWS_Tun* interface under *port5*.
2. Set *IP* to *172.16.200.2*.
3. Set *Remote IP/Netmask* to *172.16.200.1 255.255.255.0*.
4. Enable *Administrative access* for *HTTPS*, *PING*, and *SSH*.
5. Click *OK*.

Routing is defined when creating the SD-WAN interface. The firewall policy is created after the SD-WAN interface is defined.

Configuring the VPN overlay between the HQ FortiGate and AWS native VPN gateway

This example uses static routing. It is assumed that the AWS VPN Gateway is already configured, and that proper routing is applied on the corresponding subnet.

Verify the AWS configuration

See [Creating routing tables and associate subnets in the AWS Administration Guide](#) for configuration details.

To check the AWS configuration:

1. Go to *Virtual Private Network (VPN) > Customer Gateways* to confirm that the customer gateway defines the FortiGate IP address as its Gateway IP address, in this case **34.66.121.231**.

2. Go to *Virtual Private Network (VPN) > Virtual Private Gateways* to confirm that a virtual private gateway (VPG) has been created. In this case it is attached to the *Cloud_onRamp* VPC that contains the FortiGate and servers.

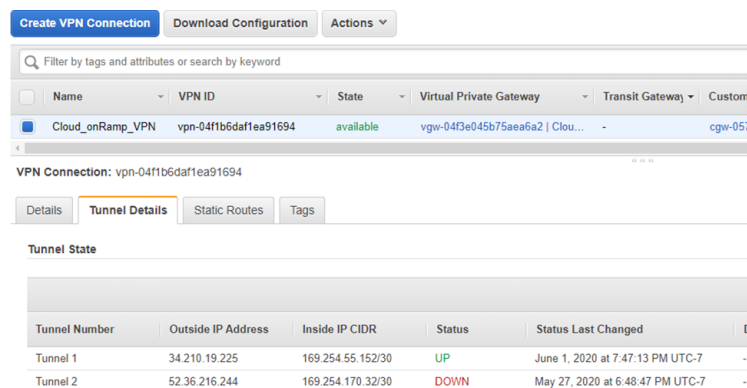

3. Go to *Virtual Private Network (VPN) > Site-to-Site VPN Connections* to confirm that site-to-site VPN connections have been created and attached to the customer gateway and virtual private gateway.

If *Routing Options* is *Static*, the IP prefix of the remote subnet on the HQ FortiGate (10.100.88.0) is entered here.

AWS site-to-site VPN always creates two VPN tunnels for redundancy. In this example, only Tunnel 1 is used.

4. Click *Download Configuration* to download the FortiGate's tunnel configurations. The configuration can be referred to when configuring the FortiGate VPN.

5. The new VPG is attached to your VPC, but to successfully route traffic to the VPG, proper routing must be defined. Go to *Virtual Private Cloud > Subnets*, select the *Cloud-OnRamp-VPN*, and select the *Route Table* tab to verify that there are at least two routes to send traffic over the VPG.

The screenshot shows the AWS Management Console interface for configuring a subnet's route table. The 'Route Table' tab is active, displaying a table of routes. The table has columns for 'Destination' and 'Target'. There are three routes listed:

Destination	Target
169.254.0.0/16	vgw-04f3e045b75aea6a2
10.0.0.0/16	local
10.100.0.0/16	vgw-04f3e045b75aea6a2

- *169.254.0.0/24* defines the tunnel IP address. Health check traffic originating from the FortiGate will come from this IP range.
 - *10.100.0.0/16* defines the remote subnet from the HQ FortiGate.
 - Both routes point to the just created VPG *vgw-04xxxx*.
6. On the cloud FortiGate-VM EC2 instances, ensure that port1 and port2 both have *Source/Dest. Check* set to *false*. This allows the FortiGate to accept and route traffic to and from a different network. If you launched the instance from the AWS marketplace, this setting defaults to *true*.

The screenshot shows the configuration for Network Interface eth0. The 'Source/Dest. Check' setting is set to 'false'.

Property	Value
Interface ID	eni-00e636a0812a17130
VPC ID	vpc-0731da92869a30352
Attachment Owner	585196279398
Attachment Status	attached
Attachment Time	Wed May 27 18:38:55 GMT-700 2020
Delete on Terminate	true
Private IP Address	10.0.1.10
Private DNS Name	-
Public IP Address	1.1.1.1
Source/Dest. Check	false
Description	Primary network interface
Security Groups	Fortinet FortiGate Next-Generation Firewall-v6-4-0-AutogenByAWSMP-
Elastic Fabric Adapter	Disabled

Configure routing to the VPG on the cloud FortiGate-VM

To configure routing to the VPG on the cloud FortiGate-VM:

1. Go to *Network > Static Routes* and click *Create New*.
2. Set *Destination* to *Subnet* and enter the IP address and netmask: *10.100.88.0/255.255.255.0*.
3. Set *Gateway Address* to *Specify* and enter *10.0.2.1*.

4. Set *Interface* to *port2*.

The new route must have the same *Administrative Distance* as the route that was created for traffic through the *Core_Dialup* tunnel to ensure that both routes are added to the routing table (see [To configure a route to the remote subnet through the tunnel](#)).

The *Gateway Address* is arbitrarily set to 10.0.2.1. The VPG does not have an IP address, but the address defined here allows the FortiGate to route traffic out of *port2*, while AWS routes the traffic based on its routing table.

5. Click *OK*.

6. Go to *Network > Static Routes* to view the configured static routes:

Destination	Gateway IP	Interface	Status	Comments
10.100.88.0/24	1.0.0.0	Core_Dialup	Enabled	
10.100.88.0/24	10.0.2.1	port2	Enabled	

7. If *Optimal* dashboards is selected, go to *Dashboard > Network* and expand the Routing widget to view the routing table.

If *Comprehensive* dashboards is selected, go to *Dashboard > Routing Monitor* and select *Static & Dynamic* in the widget toolbar to view the routing table:

Network	Gateway IP	Interfaces	Distance	Type
10.100.88.0/24	1.0.0.0	Core_Dialup	10	Static
10.100.88.0/24	10.0.2.1	port2	10	Static
172.16.200.1/32	0.0.0.0	Core_Dialup	0	Connected

Updated: 04:43:02

Configure IPsec VPN on the HQ FortiGate

To configure a custom IPsec VPN:

- Go to *VPN > IPsec Wizard*.
- Set *Name* to *AWS_VPG*.
- Set *Template type* to *Custom*.
- Click *Next*.
- Configure *Network* settings:

Remote Gateway	Static IP Address
IP Address	34.210.19.225 This address is taken from the downloaded AWS configuration file.
Interface	port1
NAT Traversal	Enable

6. Configure *Authentication* settings:

Method	Pre-shared Key
Pre-shared Key	Enter the pre-shared key.
Version	1
Mode	Main

7. Configure the *Phase 1 Proposal* settings using information from the downloaded AWS configuration file.

8. Disable *XAUTH*.
9. Configure the *Phase 2 Selector* settings:

Name	AWS_VPG
Local Address	Named Address - <i>all</i> This setting allows traffic originating from both the local subnet 10.100.88.0 and the health checks from the VPN interface. For increased security, each subnet can be specified individually.
Remote Address	Named Address - <i>remote_subnet_10_0_2_0</i>

10. Click *OK*.

To configure local and remote tunnel IP addresses:

1. Go to *Network > Interfaces* and edit the *AWS_VPG* interface under *port1*.
2. Set *IP* to *169.254.55.154*.
3. Set *Remote IP/Netmask* to *169.254.55.153 255.255.255.0*.
4. Enable *Administrative access* for *HTTPS* and *PING*.
5. Click *OK*.

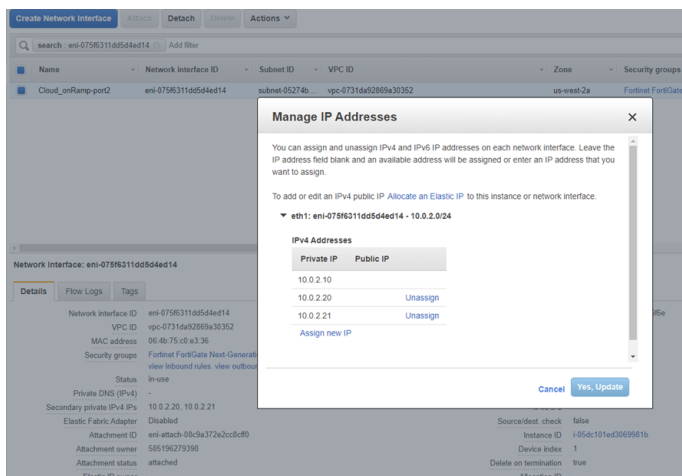

Routing is defined when creating the SD-WAN interface. The firewall policy is created after the SD-WAN interface is defined.

Configuring the VIP to access the remote servers

VIPs, interface IP addresses, and policies are created on the cloud FortiGate-VM to allow access to the remote servers.

To configure additional private IPs on AWS for the FortiGate VIP:

1. On the FortiGate EC2 instance, edit the *Elastic Network Interface* that corresponds to *port2*. In this example, Network Interface *eth1*.
2. Go to *Actions > Manage IP Addresses*.
3. Add two private IP address in the 10.0.2.0/24 subnet.
These address will be used in the VIPs on the FortiGate. This ensures that traffic to these IP addresses is routed to the FortiGate by AWS.

4. Click **Yes, Update**.

To configure VIPs on the cloud FortiGate-VM:

1. Go to *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP*.
2. Configure the following:

Name	VIP-HTTP
Interface	port2
External IP address/range	10.0.2.20
Map to IPv4 address/range	10.0.3.33

3. Click **OK**.

4. Create a second VIP for the FTP server with the following settings:

Name	VIP-FTP
Interface	port2
External IP address/range	10.0.2.21
Map to IPv4 address/range	10.0.3.44

Name	Details	Interfaces	Services	Ref.
IPv4 Virtual IP				
VIP-HTTP	10.0.2.20 → 10.0.3.33	port2		0
VIP-FTP	10.0.2.21 → 10.0.3.44	port2		0

To configure firewall policies to allow traffic from port2 to port3:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following:

Name	To-WebServer
Incoming Interface	port2
Outgoing Interface	port3
Source	all
Destination	VIP-HTTP
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enabled

3. Configure the remaining settings as required.
4. Click *OK*.
5. Create a second policy for the FTP VIP with the following settings:

Name	To-FTP
Incoming Interface	port2
Outgoing Interface	port3
Source	all
Destination	VIP-FTP
Schedule	always
Service	ALL
Action	ACCEPT

NAT Enabled

6. Click OK.

Name	Source	Destination	Schedule	Service	Action	NAT	Security Profiles	Log	Bytes
Core_Dialup → port2	all	local_subnet_10_0_2_0	always	ALL	ACCEPT	Enabled	ssl, no-inspection	UTM	0 B
port2 → port3	all	VIP-HTTP	always	ALL	ACCEPT	Enabled	ssl, no-inspection	UTM	0 B
To-WebServer	all	VIP-HTTP	always	ALL	ACCEPT	Enabled	ssl, no-inspection	UTM	0 B
To-FTP	all	VIP-FTP	always	ALL	ACCEPT	Enabled	ssl, no-inspection	UTM	0 B
Implicit									

0 Security Rating Issues Updated: 05:12:29

Configuring the SD-WAN to steer traffic between the overlays

Configure the HQ FortiGate to use two overlay tunnels for SD-WAN, steering HTTPS and HTTP traffic through the FGT_AWS_Tun tunnel, and SSH and FTP through the AWS_VPG tunnel.

1. Add SD-WAN member interfaces
2. Configure a route to the remote network
3. Configure firewall policies
4. Configure a health check
5. Configure SD-WAN rules

To add SD-WAN member interfaces:

1. Go to *Network > SD-WAN*, select the *SD-WAN Zones* tab, and click *Create New > SD-WAN Member*.
2. Set *Interface* to *AWS_VPG* then click *OK*.

New SD-WAN Member

Interface:

SD-WAN Zone:

Gateway:

Cost:

Status: Enabled Disabled

Additional Information

API Preview

SD-WAN Setup Guides

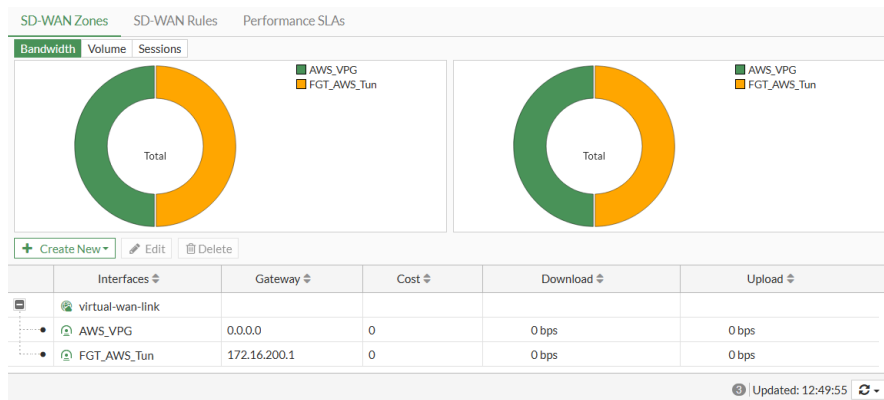

- [Creating the SD-WAN Interface](#)
- [MPLS \(SIP and Backup\) + DIA \(Cloud Apps\)](#)
- [SD-WAN Traffic Shaping and QoS with SD-WAN](#)
- [Per Packet Distribution and Tunnel Aggregation](#)

Documentation

- [Online Help](#)
- [Video Tutorials](#)

3. Click *Create New > SD-WAN Member* again.
4. Set *Interface* to *FGT_AWS_Tun*.
5. Set *Gateway* to *172.16.200.1*.

6. Click OK.

To configure a route to the remote network 10.0.2.0/24:

1. Go to *Network > Static Routes* and click *Create New*.
2. Set *Destination* to *Subnet* and enter the IP address and netmask: *10.0.2.0/255.255.255.0*.
3. Set *Interface* to *virtual-wan-link*.

4. Click OK.

Individual routes to each tunnel are automatically added to the routing table with the same distance:

Network	Gateway IP	Interfaces	Distance	Type
0.0.0.0/0	192.168.0.97	port1	10	Static
169.254.55.154/32	0.0.0.0	AWS_VPG	0	Connected
172.16.200.0/24	100.21.29.17	FGT_AWS_Tun	5	Static
172.16.200.2/32	0.0.0.0	FGT_AWS_Tun	0	Connected
192.168.0.0/24	0.0.0.0	port1	0	Connected

To configure firewall policies to allow traffic from the internal subnet to SD-WAN:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the following:

Name	ISFW-to-iaaS
-------------	--------------

Incoming Interface	port3
Outgoing Interface	virtual-wan-link
Source	all
Destination	all
Schedule	always
Service	ALL
Action	ACCEPT
NAT	Enabled

3. Configure the remaining settings as required.
4. Click **OK**.

Once the firewall policies are configured, the VPN tunnels should come up when there is traffic.

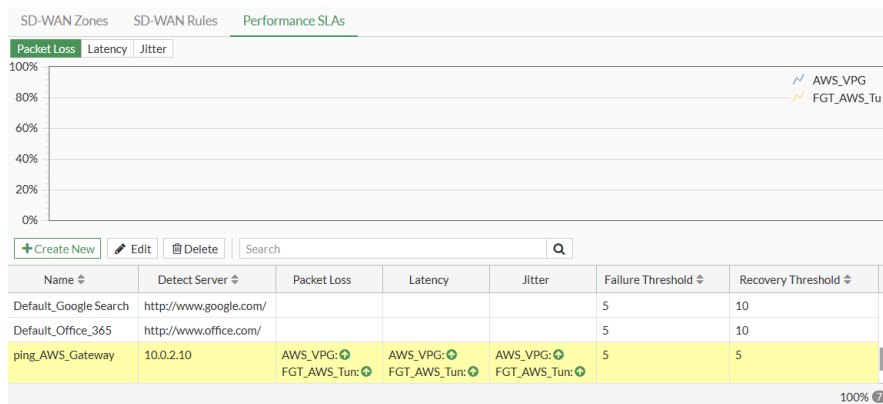

To configure a health check to monitor the status of the tunnels:

As you are accessing the servers on the 10.0.2.0/24 subnet, it is preferable to use the FortiGate port2 interface as the ping server for detection. This ensures that, if the gateway is not reachable in either tunnel, its routes are brought down and traffic continues on the other tunnel.

1. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, and click *Create New*.
2. Configure the following:

Name	ping_AWS_Gateway
Protocol	Ping
Server	10.0.2.10
Participants	Specify Add AWS_VPG and FGT_AWS_Tun as participants.

3. Click **OK**.

Health check probes originate from the VPN interface's IP address. This is why the phase2 selectors are configured with *Local Address* set to *all*.

To configure SD-WAN rules to steer traffic:

HTTPS and HTTP traffic is steered to the FGT_AWS_Tun tunnel, and SSH and FTP traffic is steered to the AWS_VPG tunnel. The Manual algorithm is used in this example.

1. Go to *Network > SD-WAN*, select the *SD-WAN Rules* tab, and click *Create New*.
2. Configure the following:

Name	http-to-FGT_AWS_Tun
Source Address	all
Address	remote_subnet_10_0_2_0
Protocol	TCP
Port range	80 - 80
Outgoing Interfaces	Manual
Interface preference	FGT_AWS_Tun

3. Click *OK*.
4. Create other SD-WAN rules as required:

The screenshot shows the SD-WAN Rules configuration page. At the top, there are tabs for 'SD-WAN Zones', 'SD-WAN Rules', and 'Performance SLAs'. Below the tabs is a table with columns: ID, Name, Source, Destination, Criteria, Members, and Hit Count. The table contains four entries under the 'IPv4' group and one entry under the 'Implicit' group. The 'http-to-FGT_AWS_Tun' rule is highlighted in dark grey.

ID	Name	Source	Destination	Criteria	Members	Hit Count
1	http-to-FGT_AWS_Tun	all	remote_subnet_10_0_2_0		FGT_AWS_Tun	1
2	ssh-to-AWS_VPG	all	remote_subnet_10_0_2_0		AWS_VPG	1
3	https-to-FGT_AWS_Tun	all	remote_subnet_10_0_2_0		FGT_AWS_Tun	1
4	ftp-to-AWS_VPG	all	FTP-Server		AWS_VPG	1
Implicit						
	sd-wan	all	all	Source IP	any	

Verifying the traffic

To verify that pings are sent across the IPsec VPN tunnels

- On the HQ FortiGate, run the following CLI command:

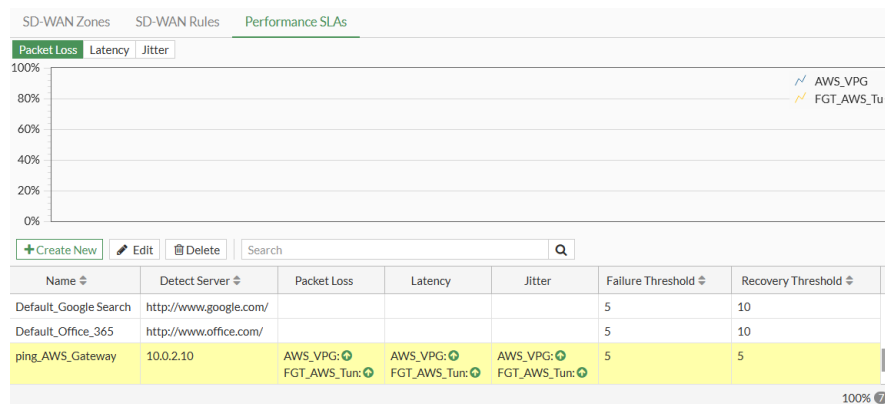

```
# diagnose sniffer packet any 'host 10.0.2.10' 4 0 1 interfaces=[any]
Using Original Sniffing Mode
interfaces=[any]
filters=[host 10.0.2.10]
pcap_snapshot: snaplen raised from 0 to 262144
2021-06-05 11:35:14.822600 AWS_VPG out 169.254.55.154 -> 10.0.2.10: icmp: echo request
2021-06-05 11:35:14.822789 FGT_AWS_Tun out 172.16.200.2 -> 10.0.2.10: icmp: echo request
2021-06-05 11:35:14.877862 FGT_AWS_Tun in 10.0.2.10 -> 172.16.200.2: icmp: echo reply
2021-06-05 11:35:14.878887 AWS_VPG in 10.0.2.10 -> 169.254.55.154: icmp: echo reply
```

- On the cloud FortiGate-VM, run the following CLI command:

```
# diagnose sniffer packet any 'host 10.0.2.10' 4 0 1 interfaces=[any]
Using Original Sniffing Mode
interfaces=[any]
filters=[host 10.0.2.10]
pcap_snapshot: snaplen raised from 0 to 262144
2021-06-05 11:37:57.176329 port2 in 169.254.55.154 -> 10.0.2.10: icmp: echo request
2021-06-05 11:37:57.176363 port2 out 10.0.2.10 -> 169.254.55.154: icmp: echo reply
2021-06-05 11:37:57.176505 Core_Dialup in 172.16.200.2 -> 10.0.2.10: icmp: echo request
2021-06-05 11:37:57.176514 Core_Dialup out 10.0.2.10 -> 172.16.200.2: icmp: echo reply
```

To verify the SLA health checks on the HQ FortiGate:

- Go to *Network > SD-WAN*, select the *Performance SLAs* tab, select *Packet Loss*, and click the *ping_AWS_Gateway* SLA:

- Run the following CLI command:

```
# diagnose sys sdwan health-check
...
Seq(1 AWS_VPG): state(alive), packet-loss(0.000%) latency(56.221), jitter(0.290) sla_map=0x0
Seq(2 FGT_AWS_Tun): state(alive), packet-loss(0.000%) latency(55.039), jitter(0.223) sla_map=0x0
```

To verify service rules:

1. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab:

SD-WAN Zones							SD-WAN Rules		Performance SLAs	
ID	Name	Source	Destination	Criteria	Members	Hit Count				
IPv4										
1	http-to-FGT_AWS_Tun	all	remote_subnet_10.0.2.0		FGT_AWS_Tun	1				
2	ssh-to-AWS_VPG	all	remote_subnet_10.0.2.0		AWS_VPG	1				
3	https-to-FGT_AWS_Tun	all	remote_subnet_10.0.2.0		FGT_AWS_Tun	1				
4	ftp-to-AWS_VPG	all	FTP-Server		AWS_VPG	1				
Implicit										
	sd-wan	all	all	Source IP	any					

Updated: 13:26:33

2. Run the following CLI command:

```
# diagnose sys sdwan service
```

```
Service(1): Address Mode(IPV4) flags=0x0
  Gen(1), TOS(0x0/0x0), Protocol(6: 80->80), Mode(manual)
  Members:
    1: Seq_num(2 FGT_AWS_Tun), alive, selected
  Src address:
    0.0.0.0-255.255.255.255
  Dst address:
    10.0.2.0-10.0.2.255

Service(2): Address Mode(IPV4) flags=0x0

```

To verify that sessions are going to the correct tunnel:

1. Run the following CLI command to verify that HTTPS and HTTP traffic destined for the Web server at 10.0.2.20 uses FGT_AWS_Tun:

```
# diagnose sys session filter dst 10.0.2.20
# diagnose sys session list

session info: proto=6 proto_state=11 duration=2 expire=3597 timeout=3600 flags=00000000
socktype=0 sockport=0 av_idx=0 use=4
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=FGT_AWS_Tun/ vlan_cos=0/255
state=log may_dirty npu f00 csf_syncd_log app_valid
statistic(bytes/packets/allow_err): org=593/4/1 reply=3689/5/1 tuples=3

```

To simulate an issue on an overlay VPN tunnel:

On the cloud FortiGate-VM, disable the firewall policy allowing Core_Dialup to port2.

1. Health-checks through the FGT_AWS_Tun tunnel fail:
 - a. Go to *Network > SD-WAN*, select the *Performance SLAs* tab, select *Packet Loss*, and click the *ping_AWS_Gateway SLA*:

- b. Run the following CLI command:

```
# diagnose sys sdwan health-check
...
Seq(1 AWS_VPG): state(alive), packet-loss(0.000%) latency(52.746), jitter(0.713) sla_map=0x0
Seq(2 FGT_AWS_Tun): state(dead), packet-loss(19.000%) sla_map=0x0
```

2. Service rules show that the member is down:

- a. Go to *Network > SD-WAN* and select the *SD-WAN Rules* tab:

ID	Name	Source	Destination	Criteria	Members	Hit Count
IPv4						
1	http-to-FGT_AWS_Tun	all	remote_subnet_10_0_2_0		FGT_AWS_Tun	1
2	ssh-to_AWS_VPG	all	remote_subnet_10_0_2_0		AWS_VPG	2
3	https-to-FGT_AWS_Tun	all	remote_subnet_10_0_2_0		FGT_AWS_Tun	1
4	ftp-to_AWS_VPG	all	FTP-Server		AWS_VPG	2
Implicit						
	sd-wan	all	all	Source IP	any	

- b. Run the following CLI command:

```
# diagnose sys sdwan service

Service(1): Address Mode(IPV4) flags=0x0
Gen(2), TOS(0x0/0x0), Protocol(6: 80->80), Mode(manual)
Members:
  1: Seq_num(2 FGT_AWS_Tun), dead
Src address:
  0.0.0.0-255.255.255.255
Dst address:
  10.0.2.0-10.0.2.255

Service(2): Address Mode(IPV4) flags=0x0

```

4. Routes to the `FGT_AWS_Tun` tunnel are removed:

- a. If *Optimal* dashboards is selected, go to *Dashboard > Network* and expand the Routing widget to view the routing table.

If *Comprehensive* dashboards is selected, go to *Dashboard > Routing Monitor* and select *Static & Dynamic* in the widget toolbar to view the routing table:

Network	Gateway IP	Interfaces	Distance	IP Version	Type
IPv4 40					
0.0.0.0/0	10.100.64.254	Internet_A (port1)	1	IPv4	Static
0.0.0.0/0	10.100.65.254	Internet_B (port5)	1	IPv4	Static
10.0.2.0/24	169.254.55.153	AWS_VPG	1	IPv4	Static
10.0.10.0/24	0.0.0.0	VPN_A_Tunnel (Branch-HQ-A)	0	IPv4	Connected
10.0.10.1/32	0.0.0.0	VPN_A_Tunnel (Branch-HQ-A)	0	IPv4	Connected

- b. Run the following CLI command:

```

# get router info routing-table all
Codes: K - kernel, C - connected, S - static, R - RIP, B - BGP
       O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default

```

```

Routing table for VRF=0
S*    0.0.0.0/0 [1/0] via 10.100.64.254, port1
      [1/0] via 10.100.65.254, port5
S     10.0.2.0/24 [1/0] via 169.254.55.153, AWS_VPG
C     10.0.10.0/24 is directly connected, Branch-HQ-A
C     10.0.10.1/32 is directly connected, Branch-HQ-A
...

```

Hub and spoke SD-WAN deployment example

This topology diagram shows an overview of the network that is configured in this example:

Datacenter configuration

The datacenter is configured to support:

- Zero touch provisioning of new spokes
- Point to multipoint VPN
- Central management of access with the datacenter firewall
- Dynamic peering, to share routing information between branches and the datacenter
- VDOM compatibility, with inter-VDOM links for isolation and segmentation

To configure the datacenter, complete the following steps:

1. [Configure dial-up \(dynamic\) VPN](#)
2. [Configure VPN interfaces](#)
3. [Configure loopback interface](#)
4. [Configure BGP](#)
5. [Firewall policies](#)
6. [Configure a blackhole route](#)

Configure dial-up (dynamic) VPN

Dial-up, or dynamic, VPNs are used to facilitate zero touch provisioning of new spokes to establish VPN connections to the hub FortiGate.

The `exchange-interface-ip` option is enabled to allow the exchange of IPsec interface IP addresses. This allows a point to multipoint connection to the hub FortiGate.

The `add-route` option is disabled to allow multiple dial-up tunnels to be established to the same host that is advertising the same network. This dynamic network discovery is facilitated by the BGP configuration; see [Configure BGP on page 825](#) for details.

Wildcard security associations are defined for the phase2 interface because routing is used to determine if traffic is subject to encryption and transmission through the IPsec VPN tunnel. The phase1 interface name must be 11 characters or less.

A dynamic VPN configuration must be defined for each interface that connects to the internet.

To configure the IPsec phase1 interfaces:

```
config vpn ipsec phase1-interface
  edit "vpn-isp-a"
    set type dynamic
    set interface "port2"
    set peertype any
    set exchange-interface-ip enable
    set proposal aes256-sha256
    set add-route disable
    set dhgrp 5
    set net-device enable
    set psksecret *****
  next
  edit "vpn-isp-b"
    set type dynamic
    set interface "port3"
    set peertype any
    set exchange-interface-ip enable
    set proposal aes256-sha256
    set add-route disable
    set dhgrp 5
    set net-device enable
    set psksecret *****
  next
end
```

To configure the IPsec phase2 interfaces:

```
config vpn ipsec phase2-interface
  edit "vpn-isp-a_p2"
    set phase1name "vpn-isp-a"
    set proposal aes256-sha256
    set pfs disable
    set replay disable
  next
  edit "vpn-isp-b_p2"
    set phase1name "vpn-isp-b"
    set proposal aes256-sha256
    set pfs disable
    set replay disable
  next
end
```

Configure VPN interfaces

To establish the BGP session, IP addresses must be assigned to the tunnel interfaces that BGP will use to peer.

The hub IP address is set to the address that the tunnels connect to. The remote IP address is set to highest unused IP address that is part of the tunnel network. This establishes two connected routes directly back to the branch FortiGate in the hub FortiGate's routing table.

Ping is allowed on the virtual interface to confirm that a point to point tunnel has been established between the hub and branch FortiGates.

To define IP addresses for VPN interfaces:

```
config system interface
  edit "vpn-isp-a"
    set vdom "root"
    set ip 10.254.0.1 255.255.255.255
    set allowaccess ping
    set type tunnel
    set remote-ip 10.254.0.254 255.255.255.0
    set interface "port2"
  next
  edit "vpn-isp-b"
    set vdom "root"
    set ip 10.254.1.1 255.255.255.255
    set allowaccess ping
    set type tunnel
    set remote-ip 10.254.1.254 255.255.255.0
    set interface "port3"
  next
end
```

Configure loopback interface

A loopback interface must be defined on the hub FortiGate to be used as a common probe point for the FortiGates that are using SD-WAN. The FortiGates send a probe packet from each of their SD-WAN member interfaces so that they can determine the best route according to their policies. Ping is allowed so that it can be used for measurements.

To configure the loopback interface on the hub FortiGate:

```
config system interface
  edit "loopback_0"
    set vdom "root"
    set ip 10.255.255.1 255.255.255.255
    set allowaccess ping
    set type loopback
  next
end
```

Configure BGP

Network route discovery is facilitated by BGP.

EBGP is used to prevent the redistribution of routes that are in the same Autonomous System (AS) number as the host. It is also required to influence route selection on the branches with AS-Path prepending. EBGP multipath is enabled so that the hub FortiGate can dynamically discover multiple paths for networks that are advertised at the branches.

The neighbor range and group settings are configured to allow peering relationships to be established without defining each individual peer. Connecting branches have their tunnel interfaces configured within the range of the BGP peer.

In order to facilitate the fastest route failovers, configure the following timers to their lowest levels: `scan-time`, `advertisement-interval`, `keep-alive-timer`, and `holdtime-timer`.

To configure BGP on the hub FortiGate:

```
config router bgp
  set as 65500
  set router-id 10.10.0.1
  set ebgp-multipath enable
  set graceful-restart enable
  config neighbor-group
    edit "branch-peers-1"
      set soft-reconfiguration enable
      set remote-as 65501
    next
    edit "branch-peers-2"
      set soft-reconfiguration enable
      set remote-as 65501
    next
  end
  config neighbor-range
    edit 1
      set prefix 10.254.0.0 255.255.255.0
      set neighbor-group "branch-peers-1"
    next
    edit 2
      set prefix 10.254.1.0 255.255.255.0
      set neighbor-group "branch-peers-2"
    next
  end
  config network
    edit 1
      set prefix 10.200.1.0 255.255.255.0
```

```

    next
    edit 2
        set prefix 10.200.0.0 255.255.255.0
    next
    edit 3
        set prefix 10.200.3.0 255.255.255.0
    next
end
end

```

Firewall policies

Centralized access is controlled from the hub FortiGate using Firewall policies. In addition to layer three and four inspection, security policies can be used in the policies for layer seven traffic inspection.

It is best practice to only allow the networks and services that are required for communication through the firewall. The following rules are the minimum that must be configured to allow SD-WAN to function:

Source Interface	Destination Interface	Source Address	Destination Address	Action	Schedule	Service	Comments
<vpn interfaces>	<internal Interface>	<branch tunnel IP addresses>	<hub FortiGate internal interface>	Accept	Always	ICMP	Allow health checks to the hub FortiGate
<vpn interfaces>	<internal Interface>	<branch networks>	<datacenter networks>	Accept	Always	<allowed services>	Allow traffic from branch networks

For this example, a simple policy that allows all traffic is configured.

To configure a firewall policy:

```

config firewall policy
    edit 1
        set name "Allow All"
        set srcintf "any"
        set dstintf "any"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
    next
end

```

Configure a blackhole route

If there is a temporary loss of connectivity to the branch routes, it is best practice to send the traffic that is destined for those networks into a blackhole until connectivity is restored.

To configure a blackhole route for branch networks:

```
config router static
  edit 6
    set dst 10.0.0.0/14
    set distance 254
    set blackhole enable
  next
end
```

Branch configuration

The branches are configured to support:

- Client side SD-WAN with intelligent load balancing based on link quality
- Easy to create configuration templates for quick spoke deployment
- Split tunnel deployment for local internet access
- VDOM compatibility, with inter-VDOM links for isolation and segmentation

To configure a branch, complete the following steps:

1. [Configure VPN to the hub](#)
2. [Configure VPN interfaces](#)
3. [Configure BGP](#)
4. [Configure SD-WAN](#)
5. [Firewall configuration](#)

Configure VPN to the hub

The branch uses a normal site-to-site VPN configuration.

Wildcard security associations are define in the phase2 configuration because dynamic routing with BGP determines what traffic must traverse the VPN tunnel for encryption/transmission.

To make sure that the VPN is established, `auto-negotiate` is enabled.

To configure the IPsec phase1 interfaces:

```
config vpn ipsec phase1-interface
  edit "vpn_dc1-1"
    set interface "port2"
    set peertype any
    set exchange-interface-ip enable
    set proposal aes256-sha256
    set dhgrp 5
    set remote-gw 172.16.0.78
    set psksecret *****
  next
  edit "vpn_dc1-2"
    set interface "port3"
    set peertype any
    set exchange-interface-ip enable
```

```
        set proposal aes256-sha256
        set dhgrp 5
        set remote-gw 172.16.0.82
        set psksecret *****
    next
end
```

To configure the IPsec phase2 interfaces:

```
config vpn ipsec phase2-interface
    edit "vpn_dc1-1_p2"
        set phaselname "vpn_dc1-1"
        set proposal aes256-sha256
        set pfs disable
        set replay disable
        set auto-negotiate enable
    next
    edit "vpn_dc1-2_p2"
        set phaselname "vpn_dc1-2"
        set proposal aes256-sha256
        set pfs disable
        set replay disable
        set auto-negotiate enable
    next
end
```

Configure VPN interfaces

The branch must define its local tunnel interface IP address, and the remote tunnel interface IP address of the datacenter FortiGate, to establish the point to multipoint VPN.

To define IP addresses for VPN interfaces:

```
config system interface
    edit "vpn_dc1-1"
        set vdom "root"
        set ip 10.255.0.2 255.255.255.255
        set allowaccess ping
        set type tunnel
        set remote-ip 10.255.0.1 255.255.255.255
        set interface "port2"
    next
    edit "vpn_dc1-2"
        set vdom "root"
        set ip 10.255.1.2 255.255.255.255
        set allowaccess ping
        set type tunnel
        set remote-ip 10.255.1.1 255.255.255.255
        set interface "port3"
    next
end
```

Configure BGP

BGP enables learning dynamic routes from the datacenter. The BGP configuration is normal, with the definition of the datacenter FortiGate tunnel IP addresses set as BGP peers.

Routes that have the same network mask, administrative distance, priority, and AS length are automatically considered for SD-WAN when the interfaces that those routes are on are added to the SD-WAN interface group.

In order to facilitate the fastest route failovers, configure the following timers to their lowest levels: `scan-time`, `advertisement-interval`, `keep-alive-timer`, and `holdtime-timer`.

The `distance-external` option might need to be configured if you need routes that are learned from BGP to take precedence over static routes.

To configure BGP on the branch FortiGate:

```
config router bgp
  set as 65501
  set router-id 10.254.0.2
  set ebgp-multipath enable
  config neighbor
    edit "10.254.0.1"
      set soft-reconfiguration enable
      set remote-as 65500
    next
    edit "10.254.1.1"
      set soft-reconfiguration enable
      set remote-as 65500
    next
  end
end
```

Configure SD-WAN

SD-WAN configuration is required to load balance based on the quality of the links. It can be configured to select the best link based on characteristics such as jitter, packet loss, and latency. A policy route is created by the FortiGate to select the best link based on the defined criteria.

For SD-WAN interfaces, or members, the peer is defined to reference the BGP neighbor that is tied to that specific interface.

The health check is the ping server that gathers the link characteristics used for link selection. It is recommended that the minimum `failtime` be set to 2.

The service definition defines the criteria for the policy routes. It can match based on the following characteristics:

- Protocol
- Destination Address
- Source Address
- Identity Based Group
- Internet Service Definition
- Source Port
- Destination Port
- Destination Route Tag

To dynamically determine the networks of the policy routes, routes that are learned from a BGP neighbor are matched against a route map, and a tag is defined for the matching routes. The service rules learn the networks based on these tags, instead of defining objects based on the learned addresses' network prefixes. See [Dynamic definition of SD-WAN routes on page 832](#) for details on configuring the FortiGate to use the destination tags for the SD-WAN service definition.

To define the SD-WAN member interfaces:

```
config system sdwan
  set status enable
  config members
    edit 1
      set interface "vpn_dc1-1"
    next
    edit 2
      set interface "vpn_dc1-2"
    next
  end
end
```

To define the SD-WAN health checks:

```
config system sdwan
  config health-check
    edit "datacenter1"
      set server "10.200.1.1"
      set interval 1
      set failtime 2
      set recoverytime 10
    next
  end
end
```

To define the SD-WAN service rules:

```
config system sdwan
  config service
    edit 1
      set mode priority
      set dst n-corporate
      set health-check "datacenter1"
      set priority-members 1 2
    next
  end
end
```

Firewall configuration

Centralized access is controlled from the hub FortiGate using Firewall policies. In addition to layer three and four inspection, security policies can be used in the policies for layer seven traffic inspection.

It is best practice to only allow the networks and services that are required for communication through the firewall. The following rules are the minimum that must be configured to allow SD-WAN to function:

Source Interface	Destination Interface	Source Address	Destination Address	Action	Schedule	Service	Comments
<internal interface>	<virtual wan link>	<branch networks>	<datacenter networks>	Accept	Always	<allowed services>	Allow traffic from branch to datacenter
<virtual wan link>	<internal Interface>	<datacenter networks>	<branch networks>	Accept	Always	<allowed services>	Allow traffic from datacenter to branch

For this example, a simple policy that allows all traffic is configured.

To configure a firewall policy:

```
config firewall policy
  edit 1
    set name "Allow All"
    set srcintf "any"
    set dstintf "any"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
  next
end
```

Validation

The following commands can be used to validate the connections on the datacenter and branches.

Datacenter

Routing table:

```
# get router info routing-table all
```

VPN establishment:

```
# diagnose vpn ike gateway list
```

Branch

SD-WAN validation:

```
# diagnose sys sdwan member
# diagnose sys sdwan service
# diagnose sys sdwan health-check
```

Routing table:

```
# get router info routing-table all
# get router info route-map-address
# get router info bgp route-map <route-map-name>
```

VPN establishment:

```
# diagnose vpn ike gateway list
```

Dynamic definition of SD-WAN routes

Dynamic definitions of SD-WAN routes alleviate administrators from needing to know the destination of the traffic that is being load balanced, which, in an environment where routes are constantly added and removed, required a significant amount of administrative overhead.

The FortiGate can be configured to apply a route map to a BGP neighbor, and tag the routes that are learned from that neighbor with the `set-route-tag` command. After those routes are assigned a tag ID in the route map, the ID can be referenced in the SD-WAN rule.

To define the route map to apply to the BGP neighbor:

```
config router route-map
  edit "map-comm1"
    config rule
      edit 1
        set match-origin igp
        set set-route-tag 12
      next
      edit 2
        set match-ip-address "pf-all-in"
        set set-route-tag 11
      next
    end
  next
end
```

To apply the route map to the BGP neighbor:

```
config router bgp
  config neighbor
    edit "10.254.0.1"
      set route-map-in "map-comm1"
    next
  end
end
```

To reference tagged routes in an SD-WAN rule:

```
config system sdwan
  config service
    edit 1
```

```

        set mode priority
        set dst-tag 11
        set health-check "datacenter1"
        set priority-members 1 2
    next
end
end

```

Adding another datacenter

Datacenter FortiGates should be configured to establish an OSPF neighbor relationship with the internal core router. This allows the dynamic redistribution of routes to the branches that are receiving updates from the datacenter FortiGates.

To ensure the fastest failover with OSPF, the following timers are set to their minimum levels: `spf-timers`, `hello-interval`, `dead-interval`.

Bi-directional forwarding is enabled to allow the fastest convergence time if there is a failure with a peering neighbor.

To configure OSPF:

```

config router ospf
    set router-id 10.10.10.10
    set spf-timers 0 1
    set distribute-list-in "pf-datacenter2-tunnel"
    set restart-mode graceful-restart
    config area
        edit 10.10.10.10
            next
        end
    config ospf-interface
        edit "port5"
            set interface "port5"
            set dead-interval 3
            set hello-interval 1
            set bfd enable
        next
    end
    config network
        edit 1
            set prefix 192.168.100.0 255.255.255.252
            set area 10.10.10.10
        next
    end
    config redistribute "connected"
        set status enable
        set routemap "redistribute-branch-tunnel"
    end
    config redistribute "static"
    end
    config redistribute "rip"
    end
    config redistribute "bgp"
        set status enable
        set routemap "redistribute-branch-networks"
    end
end

```

```

end
config redistribute "isis"
end
end

```

Troubleshooting SD-WAN

The following topics provide instructions on SD-WAN troubleshooting:

- [Tracking SD-WAN sessions on page 834](#)
- [Understanding SD-WAN related logs on page 834](#)
- [SD-WAN related diagnose commands on page 837](#)
- [SD-WAN bandwidth monitoring service on page 842](#)
- [Using SNMP to monitor health check on page 845](#)

Tracking SD-WAN sessions

You can check the destination interface in *Dashboard > FortiView Sessions* in order to see which port the traffic is being forwarded to.

The example below demonstrates a source-based load-balance between two SD-WAN members:

- If the source IP address is an *even* number, it will go to *port13*.
- If the source IP address is an *odd* number, it will go to *port12*.

Source	Device	Destination	Application	Protocol	Source Port	Destination Port	Bytes	Packets	Duration (secon...)	Destination Interface
10.2.0.21	00:00:00:00:00:00	50.200.244.000	UDP/123	UDP	123	123	152 B	2		port12
10.2.0.15	00:00:00:00:00:00	95.217.180.000	UDP/123	UDP	123	123	152 B	2	2m 11s	port12
10.2.0.16	00:00:00:00:00:00	4.53.100.000	UDP/123	UDP	123	123	152 B	2	1m 49s	port13
10.1.0.16	00:00:00:00:00:00	90.245.170.000	UDP/123	UDP	123	123	152 B	2	12s	port13
10.100.88.4	00:00:00:00:00:00	209.020.047.000	Fortiguard.Search	UDP	45932	53	0 B	0	56s	port13
10.1.0.11	00:00:00:00:00:00	66.80.78.000	UDP/123	UDP	123	123	152 B	2	2m 1s	port12
10.100.88.4	00:00:00:00:00:00	209.200.147.000	Fortiguard.Search	UDP	44624	53	0 B	0	1m 36s	port13
10.1.0.14	00:00:00:00:00:00	50.205.240.000	UDP/123	UDP	123	123	152 B	2	58s	port13
10.1.0.16	00:00:00:00:00:00	104.105.082.000	UDP/123	UDP	123	123	152 B	2	12s	port13
10.2.0.16	00:00:00:00:00:00	90.217.188.000	UDP/123	UDP	123	123	152 B	2	1m 49s	port13
10.1.0.14	00:00:00:00:00:00	206.209.0.000	UDP/123	UDP	123	123	152 B	2	58s	port13
10.2.0.17	00:00:00:00:00:00	4.50.160.000	UDP/123	UDP	123	123	152 B	2	1m 26s	port12
10.100.88.4	00:00:00:00:00:00	209.220.147.000	Fortiguard.Search	UDP	56358	53	0 B	0	1m 26s	port13
10.100.88.4	00:00:00:00:00:00	96.40.30.000	Fortiguard.Search	UDP	28454	53	0 B	0	2m 44s	port13
10.100.88.2	00:00:00:00:00:00	90.40.33.000	HTTPS.BROWSER	TCP	42908	443	1.77 kB	11	46s	port13
10.100.88.4	00:00:00:00:00:00	90.45.30.000	Fortiguard.Search	UDP	27164	53	0 B	0	1m 14s	port13

Understanding SD-WAN related logs

This topic lists the SD-WAN related logs and explains when the logs will be triggered.

Health-check detects a failure:

- When health-check detects a failure, it will record a log:

```

1: date=2021-04-20 time=17:06:31 eventtime=1618963591590008160 tz="-0700"
logid="0100022921" type="event" subtype="system" level="critical" vd="root"

```

```
logdesc="Routing information changed" name="test" interface="R150" status="down"
msg="Static route on interface R150 may be removed by health-check test. Route:
(10.100.1.2->10.100.2.22 ping-down)"
```

- When health-check detects a recovery, it will record a log:

```
2: date=2021-04-20 time=17:11:46 eventtime=1618963906950174240 tz="-0700"
logid="0100022921" type="event" subtype="system" level="critical" vd="root"
logdesc="Routing information changed" name="test" interface="R150" status="up"
msg="Static route on interface R150 may be added by health-check test. Route:
(10.100.1.2->10.100.2.22 ping-up)"
```

Health-check has an SLA target and detects SLA qualification changes:

- When health-check has an SLA target and detects SLA changes, and changes to fail:

```
1: date=2021-04-20 time=21:32:33 eventtime=1618979553388763760 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Health Check" healthcheck="test" slatargetid=1 oldvalue="2"
newvalue="1" msg="Number of pass member changed."

2: date=2021-04-20 time=21:32:33 eventtime=1618979553388751880 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Health Check" healthcheck="test" slatargetid=1 member="1" msg="Member
status changed. Member out-of-sla."
```

- When health-check has an SLA target and detects SLA changes, and changes to pass:

```
1: date=2021-04-20 time=21:38:49 eventtime=1618979929908765200 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Health Check" healthcheck="test" slatargetid=1 oldvalue="1"
newvalue="2" msg="Number of pass member changed."

2: date=2021-04-20 time=21:38:49 eventtime=1618979929908754060 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="information" vd="root"
logdesc="SDWAN status" eventtype="Health Check" healthcheck="test" slatargetid=1
member="1" msg="Member status changed. Member in sla."
```

SD-WAN calculates a link's session/bandwidth over/under its ratio and stops/resumes traffic:

- When SD-WAN calculates a link's session/bandwidth over its configured ratio and stops forwarding traffic:

```
1: date=2021-04-20 time=21:55:14 eventtime=1618980914728863220 tz="-0700"
logid="0113022924" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
volume status" eventtype="Volume" interface="R160" member="2" msg="Member enters into
conservative status with limited ability to receive new sessions for too much traffic."
```

- When SD-WAN calculates a link's session/bandwidth according to its ratio and resumes forwarding traffic:

```
2: date=2021-04-20 time=22:12:52 eventtime=1618981972698753360 tz="-0700"
logid="0113022924" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
volume status" eventtype="Volume" interface="R160" member="2" msg="Member resume normal
status to receive new sessions for internal adjustment"
```

The SLA mode service rule's SLA qualified member changes:

- When the SLA mode service rule's SLA qualified member changes. In this example R150 fails the SLA check, but is still alive:

```
1: date=2021-04-20 time=22:40:46 eventtime=1618983646428803040 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" seq="2,1" msg="Service
prioritized by SLA will be redirected in sequence order."
```

- When the SLA mode service rule's SLA qualified member changes. In this example R150 changes from fail to pass:

```
2: date=2021-04-20 time=22:41:51 eventtime=1618983711678827920 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" seq="1,2" msg="Service
prioritized by SLA will be redirected in sequence order."
```

The priority mode service rule member's link status changes:

- When priority mode service rule member's link status changes. In this example R150 changes to better than R160, and both are still alive:

```
1: date=2021-04-20 time=22:56:55 eventtime=1618984615708804760 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" metric="packet-loss" seq="2,1"
msg="Service prioritized by performance metric will be redirected in sequence order."
```

- When priority mode service rule member's link status changes. In this example R160 changes to better than R150, and both are still alive:

```
2: date=2021-04-20 time=22:56:58 eventtime=1618984618278852140 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" metric="packet-loss" seq="1,2"
msg="Service prioritized by performance metric will be redirected in sequence order."
```

SD-WAN member is used in service and it fails the health-check:

- When SD-WAN member fails the health-check, it will stop forwarding traffic:

```
1: date=2021-04-20 time=23:04:32 eventtime=1618985072898756700 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" interface="R150" member="1" serviceid=1 service="test"
gateway=10.100.1.1 msg="Member link is unreachable or miss threshold. Stop forwarding
traffic. "
```

- When SD-WAN member passes the health-check again, it will resume forwarding logs:

```
2: date=2021-04-20 time=23:06:08 eventtime=1618985168018789600 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" interface="R150" member="1" serviceid=1 service="test"
gateway=10.100.1.1 msg="Member link is available. Start forwarding traffic. "
```

Load-balance mode service rule's SLA qualified member changes:

- When load-balance mode service rule's SLA qualified member changes. In this example R150 changes to not meet SLA:

```
1: date=2021-04-20 time=23:10:24 eventtime=1618985425048820800 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" member="2 (R160)" msg="Service
will be load balanced among members with available routing."
```

- When load-balance mode service rule's SLA qualified member changes. In this example R150 changes to meet SLA:

```
2: date=2021-04-20 time=23:11:34 eventtime=1618985494478807100 tz="-0700"
logid="0113022923" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
status" eventtype="Service" serviceid=1 service="test" member="2 (R160),1 (R150) "
msg="Service will be load balanced among members with available routing."
```

SLA link status logs, generated with interval sla-fail-log-period or sla-pass-log-period:

- When SLA fails, SLA link status logs will be generated with interval sla-fail-log-period:

```
1: date=2021-04-20 time=23:18:10 eventtime=1618985890469018260 tz="-0700"
logid="0113022925" type="event" subtype="sdwan" level="notice" vd="root" logdesc="SDWAN
SLA information" eventtype="SLA" healthcheck="test" slatargetid=1 interface="R150"
status="up" latency="0.061" jitter="0.004" packetloss="2.000%"
inbandwidthavailable="0kbps" outbandwidthavailable="200.00Mbps"
bibandwidthavailable="200.00Mbps" inbandwidthused="1kbps" outbandwidthused="1kbps"
bibandwidthused="2kbps" slamap="0x0" metric="packetloss" msg="Health Check SLA status.
SLA failed due to being over the performance metric threshold."
```

- When SLA passes, SLA link status logs will be generated with interval sla-pass-log-period:

```
2: date=2021-04-20 time=23:18:12 eventtime=1618985892509027220 tz="-0700"
logid="0113022925" type="event" subtype="sdwan" level="information" vd="root"
logdesc="SDWAN SLA information" eventtype="SLA" healthcheck="test" slatargetid=1
interface="R150" status="up" latency="0.060" jitter="0.003" packetloss="0.000%"
inbandwidthavailable="0kbps" outbandwidthavailable="200.00Mbps"
bibandwidthavailable="200.00Mbps" inbandwidthused="1kbps" outbandwidthused="1kbps"
bibandwidthused="2kbps" slamap="0x1" msg="Health Check SLA status."
```

SD-WAN related diagnose commands

This topic lists the SD-WAN related diagnose commands and related output.

To check SD-WAN health-check status:

```
FGT # diagnose sys sdwan health-check
Health Check(server):
Seq(1 R150): state(alive), packet-loss(0.000%) latency(0.110), jitter(0.024) sla_map=0x0
Seq(2 R160): state(alive), packet-loss(0.000%) latency(0.068), jitter(0.009) sla_map=0x0

FGT # diagnose sys sdwan health-check
Health Check(ping):
Seq(1 R150): state(alive), packet-loss(0.000%) latency(0.100), jitter(0.017) sla_map=0x0
Seq(2 R160): state(dead), packet-loss(100.000%) sla_map=0x0

FGT # diagnose sys sdwan health-check google
Health Check(google):
Seq(1 R150): state(alive), packet-loss(0.000%) latency(0.081), jitter(0.019) sla_map=0x0
Seq(2 R160): state(alive), packet-loss(0.000%) latency(0.060), jitter(0.004) sla_map=0x0
```

To check SD-WAN member status:

- When SD-WAN load-balance mode is *source-ip-based/source-dest-ip-based*.

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 0
```

```
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 0
```

- When SD-WAN load-balance mode is *weight-based*.

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 33
  Session count: 15
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 66
  Session count: 1
```

- When SD-WAN load-balance mode is *measured-volume-based*.

- Both members are under volume and still have room:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 33
  Config volume ratio: 33, last reading: 218067B, volume room 33MB
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 66
  Config volume ratio: 66, last reading: 202317B, volume room 66MB
```

- Some members are overloaded and some still have room:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 0
  Config volume ratio: 33, last reading: 1287767633B, overload volume 517MB
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 63
  Config volume ratio: 66, last reading: 1686997898B, volume room 63MB
```

- When SD-WAN load balance mode is *usage-based/spillover*.

- When no spillover occurs:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 255
  Egress-spillover-threshold: 400kbit/s, ingress-spillover-threshold: 300kbit/s
  Egress-overbps=0, ingress-overbps=0
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 254
  Egress-spillover-threshold: 0kbit/s, ingress-spillover-threshold: 0kbit/s
  Egress-overbps=0, ingress-overbps=0
```

- When member has reached limit and spillover occurs:

```
FGT # diagnose sys sdwan member
Member(1): interface: R150, gateway: 10.100.1.1 2000:10:100:1::1, priority: 0 1024,
weight: 255
  Egress-spillover-threshold: 400kbit/s, ingress-spillover-threshold: 300kbit/s
  Egress-overbps=1, ingress-overbps=0
Member(2): interface: R160, gateway: 10.100.1.5 2000:10:100:1::5, priority: 0 1024,
weight: 254
  Egress-spillover-threshold: 0kbit/s, ingress-spillover-threshold: 0kbit/s
  Egress-overbps=0, ingress-overbps=0
```

- You can also use the `diagnose netlink dstmac list` command to check if you are over the limit.

```
FGT # diagnose netlink dstmac list R150
dev=R150 mac=00:00:00:00:00:00 vwl rx_tcp_mss=0 tx_tcp_mss=0 egress_overspill_
threshold=50000 egress_bytes=100982 egress_over_bps=1 ingress_overspill_
threshold=37500 ingress_bytes=40 ingress_over_bps=0 sampler_rate=0 vwl_zone_id=1
intf_qua=0
```

To check SD-WAN service rules status:

- **Manual mode service rules.**

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(manual)
  Members(2):
    1: Seq_num(1 R150), alive, selected
    2: Seq_num(2 R160), alive, selected
  Dst address(1):
    10.100.21.0-10.100.21.255
```

- **Auto mode service rules.**

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(auto), link-cost-factor(latency),
  link-cost-threshold(10), heath-check(ping)
  Members(2):
    1: Seq_num(2 R160), alive, latency: 0.066, selected
    2: Seq_num(1 R150), alive, latency: 0.093
  Dst address(1):
    10.100.21.0-10.100.21.255
```

- **Priority mode service rules.**

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(priority), link-cost-factor
  (latency), link-cost-threshold(10), heath-check(ping)
  Members(2):
    1: Seq_num(2 R160), alive, latency: 0.059, selected
    2: Seq_num(1 R150), alive, latency: 0.077, selected
  Dst address(1):
    10.100.21.0-10.100.21.255
```

- **Load-balance mode service rules.**

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
  Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(load-balance hash-mode=round-robin)
  Members(2):
    1: Seq_num(1 R150), alive, sla(0x1), gid(2), num of pass(1), selected
    2: Seq_num(2 R160), alive, sla(0x1), gid(2), num of pass(1), selected
  Dst address(1):
    10.100.21.0-10.100.21.255
```

- **SLA mode service rules.**

```
FGT # diagnose sys sdwan service
Service(1): Address Mode(IPV4) flags=0x200
```

```

Gen(1), TOS(0x0/0x0), Protocol(0: 1->65535), Mode(sla), sla-compare-order
Members(2):
  1: Seq_num(1 R150), alive, sla(0x1), gid(0), cfg_order(0), cost(0), selected
  2: Seq_num(2 R160), alive, sla(0x1), gid(0), cfg_order(1), cost(0), selected
Dst address(1):
  10.100.21.0-10.100.21.255

```

To check interface logs from the past 15 minutes:

```

FGT (root) # diagnose sys sdwan intf-sla-log R150
Timestamp: Wed Apr 21 16:58:27 2021, used inbandwidth: 655bps, used outbandwidth:
81655306bps, used bibandwidth: 81655961bps, tx bys: 3413479982bytes, rx bytes: 207769bytes.
Timestamp: Wed Apr 21 16:58:37 2021, used inbandwidth: 649bps, used outbandwidth:

81688159bps, used bibandwidth: 81688830bps, tx bys: 4026141408bytes, rx bytes: 212726bytes.

```

To check SLA logs in the past 10 minutes:

```

FGT (root) # diagnose sys sdwan sla-log ping 1
Timestamp: Wed Apr 21 17:10:11 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.079, jitter: 0.023, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:12 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.079, jitter: 0.023, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:12 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.081, jitter: 0.024, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:13 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.081, jitter: 0.025, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:13 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.082, jitter: 0.026, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:14 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.083, jitter: 0.026, packet loss: 0.000%.
Timestamp: Wed Apr 21 17:10:14 2021, vdom root, health-check ping, interface: R150, status:
up, latency: 0.084, jitter: 0.026, packet loss: 0.000%.

```

To check Application Control used in SD-WAN and the matching IP addresses:

```

FGT # diagnose sys sdwan internet-service-app-ctrl-list
Gmail(15817 4294836957): 64.233.191.19 6 443 Thu Apr 22 10:10:34 2021
Gmail(15817 4294836957): 142.250.128.83 6 443 Thu Apr 22 10:06:47 2021

YouTube(31077 4294838537): 209.85.200.132 6 443 Thu Apr 22 10:02:03 2021

```

To check the dynamic tunnel status:

```
# diagnose sys link-monitor interface <name> <name>_0
```

For example:

```

# diagnose sys link-monitor interface vd2-2
Interface(vd2-2): state(up, since Tue Jun 15 12:31:28 2021), bandwidth(up:1299bps,
down:0bps), session count(IPv4:2, IPv6:0), tx(2409919 bytes), rx(5292290 bytes), latency
(0.03), jitter(0.00), packet-loss(0.00).

# diagnose sys link-monitor interface vd2-2 vd2-2_0
Interface(vd2-2_0): state(up, since Tue Jun 15 15:21:52 2021), bandwidth(up:640bps,
down:0bps), session count(IPv4:0, IPv6:0), tx(102242 bytes), rx(16388 bytes), latency(0.03),
jitter(0.00), packet-loss(0.00).

```

To check BGP learned routes and determine if they are used in SD-WAN service:

```

FGT # get router info bgp network 10.100.11.0/24
VRF 0 BGP routing table entry for 10.100.11.0/24
Paths: (2 available, best #2, table Default-IP-Routing-Table)
  Advertised to non-peer-group peers:
    10.100.1.1
  Original VRF 0
  20 10
    10.100.1.1 from 10.100.1.1 (5.5.5.5)
      Origin incomplete metric 0, route tag 15, localpref 100, valid, external, best
      Community: 30:5
      Advertised Path ID: 2

SD-WAN bandwidth monitoring service

The bandwidth measuring tool is used to detect true upload and download speeds. Bandwidth tests can be run on demand or automated using a script to measure upload and download speeds up to 1 Gbps of throughput. This can be useful when configuring SD-WAN SLA and rules to balance SD-WAN traffic.

The speed test tool requires a valid SD-WAN Bandwidth Monitoring Service license.

The speed test tool is compatible with iperf3.6 with SSL support. It can test the upload bandwidth to the FortiGate Cloud speed test service. It can initiate the server connection and send download requests to the server. The tool can be run up to 10 times a day .

FortiGate downloads the speed test server list. The list expires after 24 hours. One of the speed test servers is selected, based on user input. The speed test runs, testing upload and download speeds. The test results are shown in the command terminal.

To download the speed test server list:

```

# execute speed-test-server download
Download completed.

```

To check the speed test server list:

```

# execute speed-test-server list
AWS_West valid
    Host: 34.210.67.183 5204 fortinet
    Host: 34.210.67.183 5205 fortinet
    Host: 34.210.67.183 5206 fortinet

```

To run the speed test:

You can run the speed test without specifying a server. The system will automatically choose one server from the list and run the speed test.

```
# execute speed-test auto
The license is valid to run speed test.
Speed test quota for 2/1 is 9
current vdom=root
Run in uploading mode.
Connecting to host 35.230.2.124, port 5206
[ 16] local 172.16.78.185 port 2475 connected to 35.230.2.124 port 5206
[ ID] Interval Transfer Bitrate Retr Cwnd
[ 16] 0.00-1.01 sec 11.0 MBytes 91.4 Mb/s 0 486 KBytes

```

speed test Done

To run the speed test on a server farm or data center:

```
# execute speed-test auto AWS_West
The license is valid to run speed test.
Speed test quota for 2/1 is 8
current vdom=root
Run in uploading mode.
Connecting to host 34.210.67.183, port 5205
```

To run the speed test on a local interface when there are multiple valid routes:

```
# execute speed-test port1 Google_West
The license is valid to run speed test.
Speed test quota for 2/1 is 6
bind to local ip 172.16.78.202
```

```

current vdom=root
Specified interface port1 does not comply with default outgoing interface port2 in routing
table!
Force to use the specified interface!
Run in uploading mode.

speed test Done.

```

To add a script to run a speed test automatically once every 24 hours:

```

config system auto-script
  edit "speedtest"
    set interval 86400
    set repeat 0
    set start auto
    set script "
execute speed-test-server download
execute speed-test"
  next
end

```

To view the results of the speed test script:

```

execute auto-script result speedtest

```

Using SNMP to monitor health check

You can monitor SD-WAN health check related statistics using SNMP. The MIB file can be downloaded by going to *System > SNMP* and clicking *Download FortiGate MIB File*.

The following OIDs can be monitored:

Name	OID	Description
fgVWLHealthCheckLinkNumber	.1.3.6.1.4.1.12356.101.4.9.1	The number of health check links in fgVWLHealthCheckLinkTable
fgVWLHealthCheckLinkTable	.1.3.6.1.4.1.12356.101.4.9.2	SD-WAN health check statistics table. This table has a dependent expansion relationship with fgVdTable. Only health checks with a configured member link are present in this table.
fgVWLHealthCheckLinkTableEntry	.1.3.6.1.4.1.12356.101.4.9.2.1	SD-WAN health check statistics on a virtual domain.
fgVWLHealthCheckLinkID	.1.3.6.1.4.1.12356.101.4.9.2.1.1	SD-WAN health check link ID. Only health checks with configured member link are present in this table. Virtual-wan-link health check link IDs are only unique within a virtual domain.
fgVWLHealthCheckLinkName	.1.3.6.1.4.1.12356.101.4.9.2.1.2	Health check name.
fgVWLHealthCheckLinkSeq	.1.3.6.1.4.1.12356.101.4.9.2.1.3	SD-WAN member link sequence.
fgVWLHealthCheckLinkState	.1.3.6.1.4.1.12356.101.4.9.2.1.4	Health check state on a specific member link.
fgVWLHealthCheckLinkLatency	.1.3.6.1.4.1.12356.101.4.9.2.1.5	The average latency of a health check on a specific member link within last 30 probes, in float number.
fgVWLHealthCheckLinkJitter	.1.3.6.1.4.1.12356.101.4.9.2.1.6	The average jitter of a health check on a specific member link within last 30 probes, in float number.
fgVWLHealthCheckLinkPacketSend	.1.3.6.1.4.1.12356.101.4.9.2.1.7	The total number of packets sent by a health check on a specific member link.
fgVWLHealthCheckLinkPacketRecv	.1.3.6.1.4.1.12356.101.4.9.2.1.8	The total number of packets received by a health check on a specific member link.

Name	OID	Description
fgVWLHealthCheckLinkPacketLoss	.1.3.6.1.4.1.12356.101.4.9.2.1.9	The packet loss percentage of a health check on a specific member link within last 30 probes, in float number.
fgVWLHealthCheckLinkVdom	.1.3.6.1.4.1.12356.101.4.9.2.1.10	The VDOM that the link monitor entry exists in. This name corresponds to the fgVdEntName used in fgVdTable.
fgVWLHealthCheckLinkBandwidthIn	.1.3.6.1.4.1.12356.101.4.9.2.1.11	The available bandwidth of incoming traffic detected by a health check on a specific member link, in Mbps,
fgVWLHealthCheckLinkBandwidthOut	.1.3.6.1.4.1.12356.101.4.9.2.1.12	The available bandwidth of outgoing traffic detected by a health check on a specific member link, in Mbps.
fgVWLHealthCheckLinkBandwidthBi	.1.3.6.1.4.1.12356.101.4.9.2.1.13	The available bandwidth of bi-direction traffic detected by a health check on a specific member link, in Mbps.
fgVWLHealthCheckLinkIfName	.1.3.6.1.4.1.12356.101.4.9.2.1.14	SD-WAN member interface name.

Example

This example shows a SD-WAN health check configuration and its collected statistics.

To configure the SD-WAN health check:

```

config system sdwan
  set status enable
  config zone
    edit "virtual-wan-link"
    next
  end
  config members
    edit 1
      set interface "port1"
      set gateway 192.168.2.1
    next
    edit 2
      set interface "MPLS"
      set zone "SD-Zone2"
      set cost 20
    next
    edit 3
      set interface "port2"

```

```

    next
  end
  config health-check
    edit "pingserver"
      set server "8.8.8.8"
      set sla-fail-log-period 10
      set sla-pass-log-period 20
      set members 2 1 3
      config sla
        edit 1
          set link-cost-factor jitter packet-loss
          set packetloss-threshold 2
        next
      end
    next
  end
end
end
end

```

The collected statistics:

fgVWLHealthCheckLinkID	.1.3.6.1.4.1.12356.101.4.9.2.1.1	1	2	3
fgVWLHealthCheckLinkName	.1.3.6.1.4.1.12356.101.4.9.2.1.2	pingserver	pingserver	pingserver
fgVWLHealthCheckLinkSeq	.1.3.6.1.4.1.12356.101.4.9.2.1.3	2	1	3
fgVWLHealthCheckLinkState	.1.3.6.1.4.1.12356.101.4.9.2.1.4	0	0	0
fgVWLHealthCheckLinkLatency	.1.3.6.1.4.1.12356.101.4.9.2.1.5	39.302	43.124	44.348
fgVWLHealthCheckLinkJitter	.1.3.6.1.4.1.12356.101.4.9.2.1.6	4.346	3.951	5.05
fgVWLHealthCheckLinkPacketSend	.1.3.6.1.4.1.12356.101.4.9.2.1.7	3657689	3657689	3657689

Policy and Objects

This section contains topics on configuring policies and traffic shaping:

- [Policies on page 848](#)
- [Address objects on page 948](#)
- [Protocol options on page 982](#)
- [Traffic shaping on page 984](#)
- [Zero Trust Network Access on page 1034](#)
- [Internet Service on page 1153](#)

Policies

The firewall policy is the axis around which most features of the FortiGate revolve. Many firewall settings end up relating to or being associated with the firewall policies and the traffic they govern. Any traffic going through a FortiGate has to be associated with a policy. These policies are essentially discrete compartmentalized sets of instructions that control the traffic flow going through the firewall. These instructions control where the traffic goes, how it is processed, if it is processed, and whether or not it is allowed to pass through the FortiGate.

When the firewall receives a connection packet, it analyzes the source address, destination address, and service (by port number). It also registers the incoming interface, the outgoing interface it needs to use, and the time of day. Using this information, the FortiGate firewall attempts to locate a security policy that matches the packet. If a policy matches the parameters, then the FortiGate takes the required action for that policy. If it is *Accept*, the traffic is allowed to proceed to the next step. If the action is *Deny* or a match cannot be found, the traffic is not allowed to proceed.

The two basic actions at the initial connection are either *Accept* or *Deny*:

- If the action is *Accept*, the policy permits communication sessions. There may be other packet processing instructions, such as requiring authentication to use the policy or restrictions on the source and destination of the traffic.
- If the action is *Deny*, the policy blocks communication sessions, and you can optionally log the denied traffic. If no security policy matches the traffic, the packets are dropped. A *Deny* security policy is needed when it is required to log the denied traffic, also called *violation traffic*.

One other action can be associated with the policy:

- *IPsec*: this is an *Accept* action that is specifically for IPsec VPNs.

Each field in a firewall policy that accepts multiple inputs, such as `srcaddr` and `dstaddr`, can accept as many inputs as there are unique objects created. The maximum number of objects depends on the model. See the [Maximum Values Table](#) for more details.

The following topics provide instructions on configuring policies:

- [Firewall policy parameters on page 849](#)
- [Profile-based NGFW vs policy-based NGFW on page 850](#)
- [NGFW policy mode application default service on page 854](#)

Firewall policy parameters

For traffic to flow through the FortiGate firewall, there must be a policy that matches its parameters:

- Incoming interface(s)
- Outgoing interface(s)
- Source address(es)
- User(s) identity
- Destination address(es)
- Internet service(s)
- Schedule
- Service

Without all six (possibly eight) of these things matching, the traffic is declined.

Traffic flow initiated from each direction requires a policy, that is, if sessions can be initiated from both directions, each direction requires a policy.

Just because packets can go from point A to point B on port X does not mean that the traffic can flow from point B to point A on port X. A policy must be configured for each direction.

When designing a policy, there is often reference to the traffic flow, but most communication is two-way so trying to determine the direction of the flow might be confusing. If traffic is HTTP web traffic, the user sends a request to the

website, but most of the traffic flow will be coming from the website to the user or in both directions? For the purposes of determining the direction for a policy, the important factor is the direction of the initiating communication. The user is sending a request to the website, so this is the initial communication; the website is responding so the traffic is from the user's network to the Internet.

FortiOS does not perform a reverse-path check on reply traffic that matches an allowed session based on the IP tuple. The request traffic can be sent on one interface and the reply traffic could return on another interface.

Profile-based NGFW vs policy-based NGFW

Profile-based next-generation firewall (NGFW) mode is the traditional mode where you create a profile (antivirus, web filter, and so on) and then apply the profile to a policy.

In policy-based NGFW mode, you allow applications and URL categories to be used directly in security policies, without requiring web filter or application control profiles.

In policy-based mode:

- Central NAT is always enabled. If no Central SNAT policy exists, you must create one. See [Central SNAT on page 866](#) for more information.
- Pre-match rules are defined separately from security policies, and define broader rules, such as SSL inspection and user authentication.
- The IPsec wizard is not supported.

If your FortiGate operates in NAT mode, rather than enabling source NAT in individual NGFW policies, go to *Policy & Objects > Central SNAT* and add source NAT policies that apply to all matching traffic. In many cases, you may only need one SNAT policy for each interface pair.

The NGFW mode is set per VDOM, and it is only available when the VDOM inspection mode is flow-based. You can operate your entire FortiGate or individual VDOMs in NGFW policy mode.

Enabling policy-based NGFW mode

To enable policy-based NGFW mode without VDOMs in the GUI:

1. Go to *System > Settings*.
2. In *NGFW Mode*, select *Policy-based*.
3. Click *Apply*.

To enable policy-based NGFW mode with VDOMs in the GUI:

1. Go to *System > VDOM*.
2. Double-click a VDOM to edit the settings.
3. In *NGFW Mode*, select *Policy-based*.
4. Click *OK*.

To enable policy-based NGFW mode without VDOMs in the CLI:

```
config system settings
    set ngfw-mode policy-based
end
```

To enable policy-based NGFW mode with VDOMs in the CLI:

```
config vdom
    edit <vdom>
        config system settings
            set ngfw-mode policy-based
        end
    next
end
```

Security and SSL Inspection & Authentication policies

Security policies work with SSL Inspection & Authentication policies to inspect traffic. To allow traffic from a specific user or user group, both Security and SSL Inspection & Authentication policies must be configured. A default SSL Inspection & Authentication policy with the certificate-inspection SSL Inspection profile is preconfigured. Traffic will match the SSL Inspection & Authentication policy first. If the traffic is allowed, packets are sent to the IPS engine for application, URL category, user, and user group match, and then, if enabled, UTM inspection (antivirus, IPS, DLP, and email filter) is performed.

SSL Inspection & Authentication policies are used to pre-match traffic before sending the packets to the IPS engine:

- There are no schedule or action options; traffic matching the policy is always redirected to the IPS engine.
- SSL inspection, formerly configured in the VDOM settings, is configured in an SSL Inspection & Authentication policy.
- Users and user groups that require authentication must be configured in an SSL Inspection & Authentication policy.

Edit Policy

ID: 1
 Name: Default
 Incoming Interface: any
 Outgoing Interface: any
 Source: all
 Destination: all
 Service: ALL

Firewall / Network Options

Central NAT is enabled so NAT settings from matching Central SNAT policies will be applied.

Security Profiles

SSL Inspection: certificate-inspection

Comments: Write a comment... 0/1023

 Consolidated Policy Configuration

OK Cancel

Security policies work with SSL Inspection & Authentication policies to inspect traffic:

- Applications and URL categories can be configured directly in the policy.
- Users and user groups that require authentication must also be configured in a security policy.
- The available actions are *Accept* or *Deny*.
- The *Service* option can be used to enforce the standard port for the selected applications. See [NGFW policy mode application default service on page 854](#) for details.
- UTM inspection is configured in a security policy.

To configure policies for Facebook and Gmail access in the CLI:

1. Configure an SSL Inspection & Authentication policy:

```
config firewall policy
  edit 1
    set name "Policy-1"
    set srcintf "port18"
    set dstintf "port17"
    set srcaddr "all"
    set dstaddr "all"
    set service "ALL"
    set ssl-ssh-profile "new-deep-inspection"
    set groups "Dev" "HR" "QA" "SYS"
  next
end
```

2. Configure security policies:

```
config firewall security-policy
  edit 2
    set name "allow-QA-Facebook"
    set srcintf "port18"
    set dstintf "port17"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set application 15832
    set groups "Dev" "QA"
  next
```

```

edit 4
    set name "allow-QA-Email"
    set srcintf "port18"
    set dstintf "port17"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set url-category 23
    set groups "QA"
next
end

```

Logs

In the application control and web filter logs, securityid maps to the security policy ID.

Application control log:

```

date=2019-06-17 time=16:35:47 logid="1059028704" type="utm" subtype="app-ctrl"

Other NGFW policy-based mode options

You can combine *Application Control* and *Web Filter* in the same NGFW mode policy.

The following security profiles can be used in NGFW policy-based mode:

- AntiVirus
- Web Filter
- Intrusion Prevention
- File Filter
- Email Filter

Logging can also be enabled in security policies.

NGFW policy mode application default service

In NGFW policy-based mode, the application default service enforces applications running only on their default service port. The applications specified in the policy are monitored, and if traffic is detected from a nonstandard port, it is blocked, and a log entry is recorded with a *port-violation* event type.

If you are not using the default ports, and need to pick specific services, select *Specify* to select the required services.

Example

In this example, the standard port is enforced for HTTPS traffic using the HTTP.Audio application.

First, an SSL Inspection & Authentication policy is created do to traffic pre-match, and then a security policy is created to allow the HTTP.Audio application when using the default port. Fetching an MP3 file from an HTTP server using port 443 is allowed, but is blocked when using a nonstandard port, such as 8443.

To enforce the HTTP.Audio application using the default port in the GUI:

1. Create a new SSL Inspection & Authentication policy, or use the default policy.
2. Go to *Policy & Objects > Security Policy*, and click *Create New*.
3. Enter a name for the policy, such as *allow_HTTP.Audio*.
4. Configure the ports as needed.
5. Set *Service* to *App Default*.
6. In the *Application* field, select *HTTP.Audio*.

7. Set the *Action to Accept*.

8. Click *OK*.**To enforce the HTTP.Audio application using the default port in the CLI:**

1. Create a firewall policy:

```
config firewall policy
  edit 1
    set name "consolidated_all"
    set srcintf "port13"
    set dstintf "port14"
    set srcaddr "all"
    set dstaddr "all"
    set service "ALL"
    set ssl-ssh-profile "new-deep-inspection"
  next
end
```

2. Create a security policy:

```
config firewall security-policy
  edit 1
    set name "allow_HTTP.Audio"
    set srcintf "port13"
    set dstintf "port14"
    set srcaddr "all"
    set enforce-default-app-port enable
    set action accept
    set schedule "always"
    set logtraffic all
    set application 15879
  next
end
```

Logs

The application logs show logs with an event type of `port-violation` for traffic on port 8443 that is blocked, and an event type of `signature` for traffic on port 443 that is allowed.

Blocked:

```
2: date=2019-06-18 time=16:15:40 logid="1060028736" type="utm" subtype="app-ctrl"
eventtype="port-violation" level="warning" vd="vd1" eventtime=1560899740218875746 tz="-0700"
appid=15879 srcip=10.1.100.22 dstip=172.16.200.216 srcport=52680 dstport=8443
srcintf="port13" srcintfrole="undefined" dstintf="port14" dstintfrole="undefined" proto=6
service="HTTPS" direction="incoming" policyid=1 sessionid=5041 appcat="Video/Audio"
app="HTTP.Audio" action="block" hostname="172.16.200.216" incidentserialno=1906780850
url="/app_data/story.mp3" securityid=2 msg="Video/Audio: HTTP.Audio," apprisk="elevated"
```

Allowed:

```
1: date=2019-06-18 time=16:15:49 logid="1059028704" type="utm" subtype="app-ctrl"
eventtype="signature" level="information" vd="vd1" eventtime=1560899749258579372 tz="-0700"
appid=15879 srcip=10.1.100.22 dstip=172.16.200.216 srcport=54527 dstport=443
srcintf="port13" srcintfrole="undefined" dstintf="port14" dstintfrole="undefined" proto=6
service="HTTPS" direction="incoming" policyid=1 sessionid=5064 appcat="Video/Audio"
app="HTTP.Audio" action="pass" hostname="172.16.200.216" incidentserialno=1139663486
url="/app_data/story.mp3" securityid=2 msg="Video/Audio: HTTP.Audio," apprisk="elevated"
```

Application logging in NGFW policy mode

In NGFW policy mode, if an application, application category, or application group is selected on a security policy, and traffic logging is set to *UTM* or *All*, then application control logs will be generated. In addition, when a signature is set to the *ACCEPT* action under a security policy, all corresponding child signatures will be assessed and logged as well.

To verify application logging:

1. Go to *Policy & Objects > Security Policy* and configure a new policy for YouTube.
2. Set *Action* to *ACCEPT* and *Log Allowed Traffic to Security Events*.

3. Configure the remaining settings as required, then click *OK*.
4. On a client system, play some YouTube videos.

- On FortiOS, go to *Log & Report > Application Control* and view the logs. There are logs not only for *YouTube*, but also for *YouTube_Video.Play*, *YouTube_Video.Access*, and so on, as verified from the *Application Name* column.

Policy views and policy lookup

This topic provides a sample of firewall policy views and firewall policy lookup.

Policy views

In *Policy & Objects* policy list pages, there are two policy views: *Interface Pair View* and *By Sequence* view.

Interface Pair View displays the policies in the order that they are checked for matching traffic, grouped by the pairs of incoming and outgoing interfaces in collapsible sections.

Name	Source	Destination	Schedule	Service	Action	NAT	Security Profiles	Log	Bytes
DMZ Segment (port2) -> WAN_Zone									
DMZ to Internet	all	all	always	ALL	ACCEPT	Enabled	AV default, IPS default, IPS default, SSL certificate-inspection	All	13.86 MB
FortiDEMO -> ISFW (port3)									
vpn_FortiDEMO_remote	FortiDEMO_remote	FortiDEMO_local	always	ALL	ACCEPT	Disabled	SSL no-inspection	All	0 B
ISFW (port3) -> FortiDEMO									
vpn_FortiDEMO_local	FortiDEMO_local	FortiDEMO_remote	always	ALL	ACCEPT	Disabled	SSL no-inspection	All	0 B
ISFW (port3) -> WAN_Zone									
LAN to Internet	all	all	always	ALL	ACCEPT	Enabled	AV default, IPS default, IPS default, SSL certificate-inspection	All	3.75 GB
VPN_Zone -> VPN_Zone									
Branch1 to Branch2	all	all	always	ALL	ACCEPT	Disabled	SSL no-inspection	All	0 B
VPN_Zone -> WAN_Zone									
VPN to Internet	all	all	always	ALL	ACCEPT	Enabled	AV default, IPS default, SSL certificate-inspection	All	144.46 MB
WAN_Zone -> Management (port4)									
WAN to FAC	all	FortiAuthenticator	always	ALL	ACCEPT	Disabled	SSL no-inspection	All	0 B
Implicit									
Implicit Deny	all	all	always	ALL	DENY			All	254.41 kB

By Sequence displays policies in the order that they are checked for matching traffic without any grouping.

ID	Name	From	To	Source	Destination	Schedule	Service	Action	NAT	Security Profiles	Log	Bytes
40	WAN to FAC	WAN_Zone	Management (port4)	all	FortiAuthenticator	always	ALL	ACCEPT	Disabled	no-inspection	All	0 B
13	LAN to Internet	ISFW (port3)	WAN_Zone	all	all	always	ALL	ACCEPT	Enabled	AV default APP default IPS default SSL certificate-inspection	All	3.75 GB
2	DMZ to Internet	DMZ Segment (port2)	WAN_Zone	all	all	always	ALL	ACCEPT	Enabled	AV default DNS default APP default IPS default SSL certificate-inspection	All	13.86 MB
17	Branch1 to Branch2	VPN_Zone	VPN_Zone	all	all	always	ALL	ACCEPT	Disabled	no-inspection	All	0 B
26	VPN to Internet	VPN_Zone	WAN_Zone	all	all	always	ALL	ACCEPT	Enabled	AV default IPS default SSL certificate-inspection	All	144.46 MB
30	vpn_FortiDEMO_local	ISFW (port3)	FortiDEMO	FortiDEMO_local	FortiDEMO_remote	always	ALL	ACCEPT	Disabled	no-inspection	All	0 B
31	vpn_FortiDEMO_remote	FortiDEMO	ISFW (port3)	FortiDEMO_remote	FortiDEMO_local	always	ALL	ACCEPT	Disabled	no-inspection	All	0 B
0	Implicit Deny	any	any	all	all	always	ALL	DENY			All	254.41 kB

The default display is *Interface Pair View*. You can switch between the two views except if *any* or multiple interfaces are applied in the policy. The FortiGate automatically changes the view on the policy list page to *By Sequence* whenever there is a policy containing *any* or multiple interfaces as the *Source* or *Destination* interface. If the *Interface Pair View* is grayed out, it is likely that one or more policies have used the *any* or multiple interfaces.

You can export the current view to CSV and JSON formats by clicking *Export* and selecting *CSV* or *JSON*. The file is automatically downloaded.

Policy lookup

Firewall policy lookup is based on the `Source_interfaces/Protocol/Source_Address/Destination_Address` that matches the `source-port` and `dst-port` of the protocol. Use this tool to find out which policy matches specific traffic from a number of policies. After completing the lookup, the matching firewall policy is highlighted on the policy list page.

The *Policy Lookup* tool has the following requirements:

- Transparent mode does not support policy lookup function.
- When executing the policy lookup, you need to confirm whether the relevant route required for the policy work already exists.

Sample configuration

This example uses the TCP protocol to show how policy lookup works:

1. On a *Policy & Objects* policy list page, click *Policy Lookup* and enter the traffic parameters.

2. Click *Search* to display the policy lookup results.

Policy with source NAT

The following topics provide instructions on configuring policies with source NAT:

- [Static SNAT on page 859](#)
- [Dynamic SNAT on page 860](#)
- [Central SNAT on page 866](#)
- [Configuring an IPv6 SNAT policy on page 871](#)
- [SNAT policies with virtual wire pairs on page 873](#)

Static SNAT

Network Address Translation (NAT) is the process that enables a single device such as a router or firewall to act as an agent between the Internet or Public Network and a local or private network. This agent acts in real time to translate the source or destination IP address of a client or server on the network interface. For the source IP translation, this enables a single public address to represent a significantly larger number of private addresses. For the destination IP translation, the firewall can translate a public destination address to a private address. So we don't have to configure a real public IP address for the server deployed in a private network.

We can subdivide NAT into two types: source NAT (SNAT) and destination NAT (DNAT). This topic is about SNAT, We support three NAT working modes: static SNAT, dynamic SNAT, and central SNAT.

In static SNAT all internal IP addresses are always mapped to the same public IP address. This is a port address translation, Since we have 60416 available port numbers, this one public IP address can handle the conversion of 60,416 internal IP addresses to the same service, where a service is defined by a specified protocol, destination IP address, and destination port.

Internal Source IP	Source Port	Translated Source IP	Translated Source Port
10.1.100.1	11110	172.16.200.1	5117
10.1.100.1	11111	172.16.200.1	5118
10.1.100.2	11112	172.16.200.1	5119
.....	172.16.200.1
.....	172.16.200.1	65533

FortiGate firewall configurations commonly use the Outgoing Interface address.

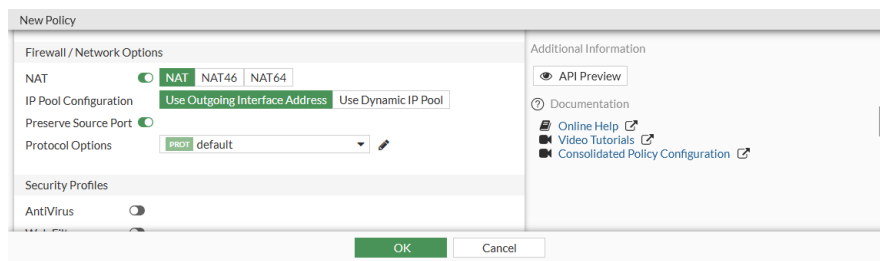

Sample configuration

The following example of static SNAT uses an internal network with subnet 10.1.100.0/24 (vlan20) and an external/ISP network with subnet 172.16.200.0/24 (vlan30).

When the clients in internal network need to access the servers in external network, We need to translate IP addresses from 10.1.100.0/24 to an IP address 172.16.200.0/24, In this example, we implement static SNAT by creating a firewall policy.

To configure static NAT:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Configure the required policy parameters.
3. Enable *NAT* and select *Use Outgoing Interface Address*. For packets that match this policy, its source IP address is translated to the IP address of the outgoing interface.
4. If needed, enable *Preserve Source Port* to keep the same source port for services that expect traffic to come from a specific source port. Disable *Preserve Source Port* to allow more than one connection through the firewall for that service.

5. Click *OK*.

Dynamic SNAT

Dynamic SNAT maps the private IP addresses to the first available public address from a pool of addresses. In the FortiGate firewall, this can be done by using IP pools. IP pools is a mechanism that allows sessions leaving the FortiGate firewall to use NAT. An IP pool defines a single IP address or a range of IP addresses to be used as the source address for the duration of the session. These assigned addresses are used instead of the IP address assigned to that FortiGate interface.

IP pool types

FortiGate uses four types of IPv4 IP pools. This topic focuses on some of the differences between them.

Overload

This type of IP pool is similar to static SNAT mode. We need to define an external IP range that contains one or more IP addresses. When there is only one IP address it is almost the same as static SNAT, the outgoing interface address is used. When it contains multiple IP addresses, it is equivalent to an extended mode of static SNAT.

For instance, if we define an overload type IP pool with two external IP addresses (172.16.200.1—172.16.200.2), since there are 60,416 available port numbers per IP, this IP pool can handle 60,416*2 internal IP addresses to the same service, where a service is defined by a specific protocol, destination IP address, and destination port.

Original Source IP	Original Source Port	Translated Source IP	Translated Source Port
10.1.100.1	11110	172.16.200.1	5117
10.1.100.2	11111	172.16.200.1	5118
*****	*****	172.16.200.1	*****
*****	*****	172.16.200.1	65533
*****	*****	172.16.200.2	5117
*****	*****	*****	*****
*****	*****	172.16.200.2	65533

The mapped IP address can be calculated from the source IP address. The index number of the address in the pool is the remainder of the source IP address, in decimal, divided by the number addresses in the pool.

To calculate the decimal value of the source IP address, either use an online calculator, or use the following equation:

$$a.b.c.d = a * (256)^3 + b * (256)^2 + c * (256) + d$$

For example:

$$192.168.0.1 = 192 * (256)^3 + 168 * (256)^2 + 0 * (256) + 1 = 3232235521$$

If there is one IP pool, where:

- P_1 = the first address in the IP pool
- R_1 = the number of IP addresses in the IP pool
- X = the source IP address as a decimal number
- Y = the mapped IP address

Then the equation to determine the mapped address is:

$$Y = P_1 + X \text{ mod } R_1$$

For example:

IP pool	Source IP address
172.26.73.20 to 172.26.73.90	192.168.1.200

1. Convert the source IP address to a decimal number:

$$192 * (256)^3 + 168 * (256)^2 + 1 * (256) + 200 = 3232235976$$
2. Determine the number of IP addresses in the pool:

$$172.26.73.90 - 172.26.73.20 = 71$$
3. Find the remainder of the source IP address divided by the number of addresses in the pool:

$$3232235976 \text{ mod } 71 = 26$$
4. Add the remainder to the first IP address in the pool:

$$172.26.73.20 + 26 = 172.26.73.46$$

So, the mapped IP address is **172.26.73.46**.

If there are multiple IP pools, the calculation is similar to when there is only one pool.

If there are two IP pools, where:

- P_1 = the first address in the first IP pool
- P_2 = the first address in the second IP pool
- R_1 = the number of IP addresses in the first IP pool
- R_2 = the number of IP addresses in the second IP pool
- X = the source IP address as a decimal number
- Y = the mapped IP address

Then the equations to determine the mapped address are:

$$\text{If } X \bmod (R_1 + R_2) \geq R_1, \text{ then } Y = P_2 + X \bmod R_2$$

$$\text{If } X \bmod (R_1 + R_2) < R_1, \text{ then } Y = P_1 + X \bmod R_1$$

For example:

IP pools	Source IP address
pool01: 172.26.73.20 to 172.26.73.90	192.168.1.200
pool02: 172.26.75.50 to 172.26.75.150	

1. Convert the source IP address to a decimal number:

$$192 * (256)^3 + 168 * (256)^2 + 1 * (256) + 200 = 3232235976$$

2. Determine the total number of IP addresses in the pools:

$$(172.26.73.90 - 172.26.73.20) + (172.26.75.50 - 172.26.75.150) = 71 + 101 = 172$$

3. Find the remainder of the source IP address divided by the number of addresses in the pools:

$$3232235976 \bmod 172 = 108$$

4. The remainder is greater than the number of addresses in pool01, so the address is selected from pool02 and the remainder is recalculated based only on pool02:

$$3232235976 \bmod 101 = 40$$

5. Add the new remainder to the first IP address in pool02:

$$172.26.75.50 + 40 = 172.26.75.90$$

So, the mapped IP address is **172.26.75.90**.

One-to-one

This type of IP pool means that the internal IP address and the external (translated) IP address match one-to-one. The port address translation (PAT) is disabled when using this type of IP pool. For example, if we define a one-to-one type IP pool with two external IP addresses (172.16.200.1 - 172.16.200.2), this IP pool only can handle two internal IP addresses.

Fixed port range

For the overload and one-to-one IP pool types, we do not need to define the internal IP range. For the fixed port range type of IP pool, we can define both internal IP range and external IP range. Since each external IP address and the number of available port numbers is a specific number, if the number of internal IP addresses is also determined, we can calculate the port range for each address translation combination. So we call this type fixed port range. This type of IP pool is a type of port address translation (PAT).

For instance, if we define one external IP address (172.16.200.1) and ten internal IP addresses (10.1.100.1-10.1.100.10), we have translation IP+Port combination like following table:

Original Source IP	Original Source Port	Translated Source IP	Translated Source Port Range
10.1.100.1	172.16.200.1	5117~11157
10.1.100.2	172.16.200.1	11158~17198
10.1.100.3	172.16.200.1
10.1.100.4	172.16.200.1
10.1.100.5	172.16.200.1
10.1.100.6	172.16.200.1
10.1.100.7	172.16.200.1
10.1.100.8	172.16.200.1
10.1.100.9	172.16.200.1	53445~59485
10.1.100.10	172.16.200.1	59486~65526

Port block allocation

This type of IP pool is also a type of port address translation (PAT). It gives users a more flexible way to control the way external IPs and ports are allocated. Users need to define *Block Size/Block Per User* and external IP range. *Block Size* means how many ports each Block contains. *Block per User* means how many blocks each user (internal IP) can use.

The following is a simple example:

- **External IP Range:** 172.16.200.1—172.16.200.1
- **Block Size:** 128
- **Block Per User:** 8

Result:

- **Total-PBAs:** 472 (60416/128)
- **Maximum ports can be used per User (Internal IP Address):** 1024 (128*8)
- **How many Internal IP can be handled:** 59 (60416/1024 or 472/8)

Sample configuration

When an IP pool object is created with *ARP Reply* enabled, the object does not need to be referenced in any policies before a FortiGate interface starts responding to ARP requests for the addresses in the IP pool.

To configure overload IP pool in the GUI:

1. In *Policy & Objects > IP Pools*, click *Create New*.
2. Select *IPv4 Pool* and then select *Overload*.

- Enter the external IP range separated by a hyphen (172.16.200.1-172.16.200.1).

New Dynamic IP Pool

IP Pool Type: **IPv4 Pool** | IPv6 Pool

Name: Overload-ippool

Comments: Write a comment... 0/255

Type: **Overload** | One-to-One | Fixed Port Range | Port Block Allocation

External IP address/range: 172.16.200.1-172.16.200.1

NAT64:

ARP Reply:

FortiGate: FortiGate-VM64

Additional Information: API Preview, Documentation, Online Help, Video Tutorials

OK Cancel

- Click **OK**.

To configure overload IP pool in the CLI:

```
config firewall ippool
  edit "Overload-ippool"
    set startip 172.16.200.1
    set endip 172.16.200.1
  next
end
```

To configure one-to-one IP pool using the GUI:

- In *Policy & Objects > IP Pools*, click *Create New*.
- Select *IPv4 Pool* and then select *One-to-One*.
- Enter the external IP range separated by a hyphen (172.16.200.1-172.16.200.2).

New Dynamic IP Pool

IP Pool Type: **IPv4 Pool** | IPv6 Pool

Name: One-to-One-ippool

Comments: Write a comment... 0/255

Type: Overload | **One-to-One** | Fixed Port Range | Port Block Allocation

External IP address/range: 172.16.200.1-172.16.200.2

ARP Reply:

FortiGate: FortiGate-VM64

Additional Information: API Preview, Documentation, Online Help, Video Tutorials

OK Cancel

- Click **OK**.

To configure one-to-one IP pool in the CLI:

```
config firewall ippool
  edit "One-to-One-ippool"
    set type one-to-one
```

```

set startip 172.16.200.1
set endip 172.16.200.2
next
end

```

To configure fixed port range IP pool in the GUI:

1. In *Policy & Objects > IP Pools*, click *Create New*.
2. Select *IPv4 Pool* and then select *Fixed Port Range*.
3. Enter the external IP range separated by a hyphen *172.16.200.1-172.16.200.1*.
4. Enter the internal IP range separated by a hyphen *10.1.100.1-10.1.100.10*.

The screenshot shows the 'New Dynamic IP Pool' configuration window in the FortiGate GUI. The window is titled 'New Dynamic IP Pool' and contains the following fields and options:

- IP Pool Type:** IPv4 Pool (selected), IPv6 Pool
- Name:** FPR-ippool
- Comments:** Write a comment... (0/255)
- Type:** Overload, One-to-One, Fixed Port Range (selected), Port Block Allocation
- External IP address/range:** 172.16.200.1-172.16.200.1
- Internal IP Range:** 10.1.100.1-10.1.100.10
- Ports Per User:** Disabled (toggle off)
- ARP Reply:** Enabled (toggle on)

At the bottom of the window, there are 'OK' and 'Cancel' buttons. On the right side, there is a sidebar with 'FortiGate' information, 'Additional Information' (API Preview), and 'Documentation' (Online Help, Video Tutorials).

5. Click *OK*.

To configure fixed port range IP pool in the CLI:

```

config firewall ippool
edit "FPR-ippool"
set type fixed-port-range
set startip 172.16.200.1
set endip 172.16.200.1
set source-startip 10.1.100.1
set source-endip 10.1.100.10
next
end

```

To configure port block allocation IP pool in the GUI:

1. In *Policy & Objects > IP Pools*, click *Create New*.
2. Select *IPv4 Pool* and then select *Port Block Allocation*.

3. Enter the external IP range separated by a hyphen *172.16.200.1-172.16.200.1*).

4. Click **OK**.

To configure port block allocation IP pool in the CLI:

```
config firewall ippool
  edit PBA-ippool
    set type port-block-allocation
    set startip 172.16.200.1
    set endip 172.16.200.1
    set block-size 128
    set num-blocks-per-user 8
  next
end
```

IP pools and VIPs as local IP addresses

IP pools and VIPs are considered local IP addresses if responding to ARP requests on these external IP addresses is enabled (`set arp-reply enable`, by default). In this case, the FortiGate is considered a destination for those IP addresses and can receive reply traffic at the application layer successfully.

However, as a side-effect, once an IP pool or VIP has been configured, even if it is never used in a firewall policy, the FortiGate considers it as a local address and will not forward traffic based on the routing table. Therefore, any unused IP pools or VIPs should be deleted to prevent any unexpected behaviour.

For a history of behaviour changes related to IP pools and VIPs, see [Technical Tip: IP pool and virtual IP behaviour changes in FortiOS 6.4, 7.0, 7.2, and 7.4](#).

Central SNAT

The central SNAT table enables you to define and control (with more granularity) the address translation performed by FortiGate. With the NAT table, you can define the rules for the source address or address group, and which IP pool the destination address uses.

FortiGate reads the NAT rules from the top down until it hits a matching rule for the incoming address. This enables you to create multiple NAT policies that dictate which IP pool is used based on source address, destination address, and

source port. NAT policies can be rearranged within the policy list. NAT policies are applied to network traffic after a security policy.

The central SNAT table allows you to create, edit, delete, and clone central SNAT entries.

Central SNAT notes

- The central NAT feature is not enabled by default.
- If central NAT is enabled, the NAT option under IPv4 policies is skipped and SNAT must be done via `central-snat-map`. The firewall policy list and dialog boxes have messages and redirection links to show this information.
- If NGFW mode is policy-based, then it is assumed that central NAT (specifically SNAT) is enabled implicitly.

Sample configuration

To enable central SNAT from the GUI:

1. In *System > Settings*, under *System Operations Settings*, enable *Central SNAT*.
2. Click *Apply*.

To enable or disable central SNAT using the CLI:

```
config system settings
  set central-nat {enable | disable}
end
```

When central NAT is enabled, *Policy & Objects* displays the Central SNAT section.

The Central SNAT policy has many options:

Field	Description
Type	Specify whether you are performing SNAT on IPv4 or IPv6. This option only appears when IPv6 is enabled under <i>Feature Visibility</i> .
Incoming Interface	Specify one or more interfaces for the ingress traffic.
Outgoing Interface	Specify one or more interfaces for the egress traffic.
Source Address	Specify the address or address group of the source.
Destination Address	Specify the address or address group of the destination.
NAT	Enable or disable to perform NAT. When disabled, no source address translation will occur.
IP Pool Configuration	Use outgoing interface address: <ul style="list-style-type: none"> • Use the address of the outgoing interfaces as source address. Use Dynamic IP Pool: <ul style="list-style-type: none"> • Choose an IP Pool to perform source NAT.
Protocol	Choose from any, TCP, UDP, SCTP, or specify the protocol number to match. For example, for ICMP, click <i>specify</i> with the protocol number 1.
Explicit port mapping	Enable in order to match this NAT policy only when the following ports are a match:

Field	Description
	<ul style="list-style-type: none"> Choose an original source port from one to 65535. NAT'd port will be chosen by the FortiGate based on the IP Pool configuration. <p>Explicit port mapping cannot apply to some protocols which do not use ports, such as ICMP. When enabling a NAT policy which uses Explicit port mapping, always consider that ICMP traffic will not match this policy.</p> <p>When using IP Pools, only the Overload type IP Pool allows Explicit port mapping. When Explicit port mapping is applied, you must define an original source port range and a translated sort port range. The source port will map one to one with the translated port.</p> <p>Refer to Dynamic SNAT to understand how each IP Pool type works.</p>
Comments	Enter comments for this NAT policy.
Enable this policy	Enable or disable this policy.

To configure central SNAT using the CLI:

```
cconfig firewall central-snat-map
  edit <policyID number>
    set status {enable | disable}
    set orig-addr <valid address object preconfigured on the FortiGate>
    set srcintf <name of interface on the FortiGate>
    set dst-addr <valid address object preconfigured on the FortiGate>
    set dstintf <name of interface on the FortiGate>
    set protocol <integer for protocol number>
    set orig-port <integer for original port number>
    set nat-port <integer for translated port number>
    set comments <string>
  next
end
```

Example one

Apply SNAT to all traffic from port2 to port3.

To configure from the CLI:

```
config firewall central-snat-map
  edit 1
    set srcintf "port3"
    set dstintf "port2"
    set orig-addr "all"
    set dst-addr "all"
  next
end
```

Example two

Apply an IP Pool to all traffic from port3 to port2 that are TCP. NAT all other traffic using the outgoing interface IP.

To configure from the CLI:

```

config firewall ippool
  edit "Overload-IPPOOL"
    set startip 192.168.2.201
    set endip 192.168.2.202
  next
end
config firewall central-snat-map
  edit 1
    set srcintf "port3"
    set dstintf "port2"
    set orig-addr "all"
    set dst-addr "all"
    set protocol 6
    set nat-ippool "Overload-IPPOOL"
  next
  edit 2
    set srcintf "port3"
    set dstintf "port2"
    set orig-addr "all"
    set dst-addr "all"
  next
end

```

To collect session table output from the CLI:

```
diagnose sys session list
```

The TCP session (protocol 6) is NAT'd with Overload-IPPOOL to 192.168.2.201:

```

session info: proto=6 proto_state=05 duration=14 expire=0 timeout=3600 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty
statistic(bytes/packets/allow_err): org=860/7/1 reply=555/8/1 tuples=2
tx speed(Bps/kbps): 60/0 rx speed(Bps/kbps): 38/0
origin->sink: org pre->post, reply pre->post dev=9->6/6->9 gwy=192.168.2.1/192.168.0.10
hook=post dir=org act=snat 192.168.0.10:49531->23.57.57.114:443 (192.168.2.201:61776)
hook=pre dir=reply act=dnat 23.57.57.114:443->192.168.2.201:61776 (192.168.0.10:49531)
pos/(before,after) 0/(0,0), 0/(0,0)
dst_mac=04:d5:90:5f:a2:2a
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0
serial=00011065 tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x040000

```

A UDP session (protocol 17) is NAT'd to the outgoing interface IP address 192.168.2.86:

```

session info: proto=17 proto_state=01 duration=16 expire=163 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=

```

```

per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ helper=dns-udp vlan_cos=0/255
state=may_dirty
statistic(bytes/packets/allow_err): org=59/1/1 reply=187/1/1 tuples=2
tx speed(Bps/kbps): 3/0 rx speed(Bps/kbps): 11/0
origin->sink: org pre->post, reply pre->post dev=9->6/6->9 gwy=192.168.2.1/192.168.0.10
hook=post dir=org act=snat 192.168.0.10:52177->4.2.2.1:53 (192.168.2.86:61770)
hook=pre dir=reply act=dnat 4.2.2.1:53->192.168.2.86:61770 (192.168.0.10:52177)
dst_mac=04:d5:90:5f:a2:2a
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0
serial=00011061 tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpd_b_link_id=00000000 rpd_b_svc_id=0 ngfwid=n/a
npu_state=0x040000

```

Example three

Apply an IP Pool to all traffic from port3 to port2 that have a specific original port range, mapping the ports to the same NAT'd port range. Nat all other traffic using the outgoing interface IP.

To configure from the CLI:

```

config firewall central-snat-map
  edit 1
    set srcintf "port3"
    set dstintf "port2"
    set orig-addr "all"
    set dst-addr "all"
    set orig-port 50000-65535
    set nat-ippool "Overload-IPPOOL"
    set nat-port 50000-65535
  next
  edit 2
    set srcintf "port3"
    set dstintf "port2"
    set orig-addr "all"
    set dst-addr "all"
  next
end

```

To collect session table output from the CLI:

```
diagnose sys session list
```

Traffic with original port in the range between 50000-65535 will be NAT'd with the Overload type IP Pool. The mapped port is in the same port range:

```

session info: proto=17 proto_state=01 duration=3 expire=176 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ helper=dns-udp vlan_cos=0/255
state=may_dirty
statistic(bytes/packets/allow_err): org=71/1/1 reply=123/1/1 tuples=2
tx speed(Bps/kbps): 23/0 rx speed(Bps/kbps): 40/0

```

```

origin->sink: org pre->post, reply pre->post dev=9->6/6->9 gwy=192.168.2.1/192.168.0.10
hook=post dir=org act=snat 192.168.0.10:52540->4.2.2.1:53(192.168.2.201:52540)
hook=pre dir=reply act=dnat 4.2.2.1:53->192.168.2.201:52540(192.168.0.10:52540)
dst_mac=04:d5:90:5f:a2:2a
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0
serial=00011399 tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x040000

```

Traffic with original port outside the range of 50000-65535 will be NAT'd to the outgoing interface IP:

```

session info: proto=6 proto_state=01 duration=3 expire=3597 timeout=3600 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty
statistic(bytes/packets/allow_err): org=2262/10/1 reply=2526/11/1 tuples=2
tx speed(Bps/kbps): 741/5 rx speed(Bps/kbps): 828/6
origin->sink: org pre->post, reply pre->post dev=9->6/6->9 gwy=192.168.2.1/192.168.0.10
hook=post dir=org act=snat 192.168.0.10:49805->142.250.68.66:443(192.168.2.86:62214)
hook=pre dir=reply act=dnat 142.250.68.66:443->192.168.2.86:62214(192.168.0.10:49805)
pos/(before,after) 0/(0,0), 0/(0,0)
dst_mac=04:d5:90:5f:a2:2a
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0
serial=0001139a tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x040000

```

Protocols which do not use ports, such as ICMP, will be NAT'd to the outgoing interface IP:

```

session info: proto=1 proto_state=00 duration=7 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=may_dirty
statistic(bytes/packets/allow_err): org=480/8/1 reply=480/8/1 tuples=2
tx speed(Bps/kbps): 66/0 rx speed(Bps/kbps): 66/0
origin->sink: org pre->post, reply pre->post dev=9->6/6->9 gwy=192.168.2.1/192.168.0.10
hook=post dir=org act=snat 192.168.0.10:1->4.2.2.1:8(192.168.2.86:62209)
hook=pre dir=reply act=dnat 4.2.2.1:62209->192.168.2.86:0(192.168.0.10:1)
dst_mac=04:d5:90:5f:a2:2a
misc=0 policy_id=2 auth_info=0 chk_client_info=0 vd=0
serial=0001138b tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x040000

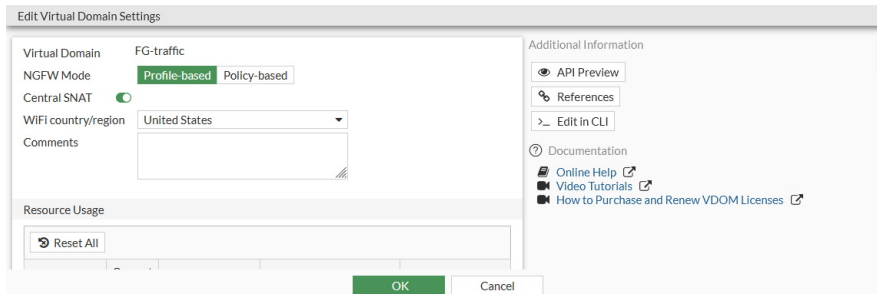

```

Configuring an IPv6 SNAT policy

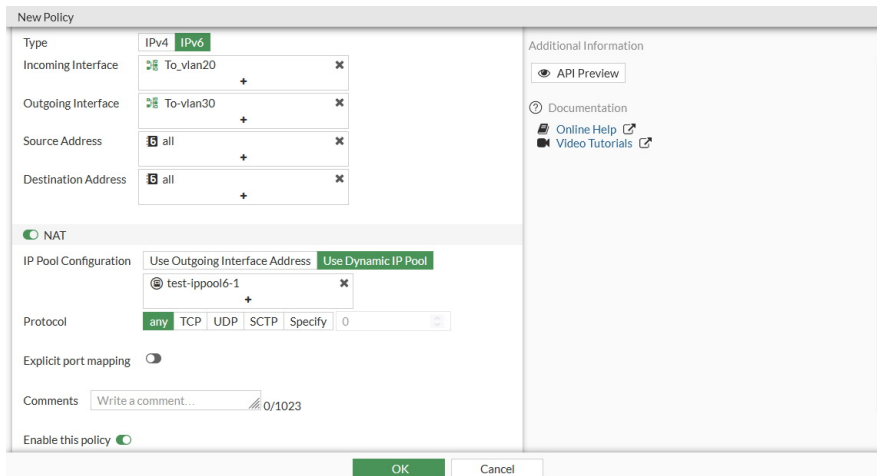

IPv4 and IPv6 central SNAT maps are displayed in the same table.

To configure an IPv6 policy with central SNAT in the GUI:

1. Enable central SNAT:
 - a. In the Global VDOM, go to *System > VDOM*.
 - b. Select a VDOM and click *Edit*. The *Edit Virtual Domain Settings* pane opens.
 - c. Enable *Central SNAT*.

- d. Click *OK*.
2. In the VDOM with central SNAT enabled (FG-traffic in this example), go to *Policy & Objects > Central SNAT* and click *Create New*.
3. Configure the policy settings:
 - a. For *Type*, select *IPv6*.
 - b. Enter the interface, address, and IP pool information.
 - c. Configure the remaining settings as needed.

- d. Click *OK*.
The matching SNAT traffic will be handled by the IPv6 central SNAT map.

To configure an IPv6 policy with central SNAT in the CLI:

1. Enable central SNAT:

```
config vdom
  edit FG-traffic
    config system settings
      set central-nat enable
    end
```

```

    next
end

```

2. Create an IPv6 central SNAT policy:

```

config vdom
  edit FG-traffic
    config firewall central-snat-map
      edit 2
        set type ipv6
        set srcintf "wan2"
        set dstintf "wan1"
        set orig-addr6 "all"
        set dst-addr6 "all"
        set nat-ippool6 "test-ippool6-1"
      next
    end
  next
end

```

3. Verify the SNAT traffic:

```

(FG-traffic) # diagnose sniffer packet any icmp6 4
interfaces=[any]
filters=[icmp6]
3.602891 wan2 in 2000:10:1:100::41 -> 2000:172:16:200::55: icmp6: echo request seq 0
3.602942 wan1 out 2000:172:16:200::199 -> 2000:172:16:200::55: icmp6: echo request seq 0
3.603236 wan1 in 2000:172:16:200::55 -> 2000:172:16:200::199: icmp6: echo reply seq 0
3.603249 wan2 out 2000:172:16:200::55 -> 2000:10:1:100::41: icmp6: echo reply seq 0
4.602559 wan2 in 2000:10:1:100::41 -> 2000:172:16:200::55: icmp6: echo request seq 1
4.602575 wan1 out 2000:172:16:200::199 -> 2000:172:16:200::55: icmp6: echo request seq 1
4.602956 wan1 in 2000:172:16:200::55 -> 2000:172:16:200::199: icmp6: echo reply seq 1
4.602964 wan2 out 2000:172:16:200::55 -> 2000:10:1:100::41: icmp6: echo reply seq 1
^C
8 packets received by filter
0 packets dropped by kernel

```

SNAT policies with virtual wire pairs

Source NAT (SNAT) can be configured in IPv4 and IPv6 policies with virtual wire pair (VWP) interfaces, and between VWP interfaces when central NAT is enabled.

To configure a policy using SNAT and a VWP interface when central NAT is disabled:

1. Create the VWP interface:

```

config system virtual-wire-pair
  edit "test-vw-1"
    set member "port1" "port4"
  next
end

```

2. Create the IP pool. The IP pool must have a different subnet than the VWP peers.

```

config firewall ippool
  edit "vwp-pool-1"
    set startip 172.16.222.99

```

```

        set endip 172.16.222.100
    next
end

```

3. Configure the firewall policy:

```

config firewall policy
    edit 88
        set srcintf "port4"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set nat enable
        set ippool enable
        set poolname "vwp-pool-1"
    next
end

```

4. Verify the IP pool functions as expected and traffic passes through:

```

# diagnose sniffer packet any icmp 4
interfaces=[any]
filters=[icmp]
23.438095 port4 in 172.16.200.11 -> 172.16.200.156: icmp: echo request
23.438126 port1 out 172.16.222.100 -> 172.16.200.156: icmp: echo request
23.438492 port1 in 172.16.200.156 -> 172.16.222.100: icmp: echo reply
23.438501 port4 out 172.16.200.156 -> 172.16.200.11: icmp: echo reply
24.439305 port4 in 172.16.200.11 -> 172.16.200.156: icmp: echo request
24.439319 port1 out 172.16.222.100 -> 172.16.200.156: icmp: echo request
24.439684 port1 in 172.16.200.156 -> 172.16.222.100: icmp: echo reply
24.439692 port4 out 172.16.200.156 -> 172.16.200.11: icmp: echo reply

8 packets received by filter
0 packets dropped by kernel

```

To configure a SNAT between VWP interfaces when central NAT is enabled:

1. Enable central NAT:

```

config system settings
    set central-nat enable
end

```

2. Create the VWP interface:

```

config system virtual-wire-pair
    edit "test-vw-1"
        set member "port1" "port4"
    next
end

```

3. Create the IP pool. The IP pool must have a different subnet than the VWP peers.

```

config firewall ippool
    edit "vwp-pool-1"

```

```
        set startip 172.16.222.99
        set endip 172.16.222.100
    next
end
```

4. Configure the SNAT policy:

```
config firewall central-snat-map
    edit 2
        set srcintf "port4"
        set dstintf "port1"
        set orig-addr "all"
        set dst-addr "all"
        set nat-ippool "vwp-pool-1"
    next
end
```

5. Configure the firewall policy:

```
config firewall policy
    edit 90
        set srcintf "port4"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set logtraffic all
    next
end
```

Policy with destination NAT

The following topics provide instructions on configuring policies with destination NAT:

- [Static virtual IPs on page 875](#)
- [Virtual IP with services on page 879](#)
- [Virtual IPs with port forwarding on page 880](#)
- [Virtual server load balance on page 882](#)
- [Central DNAT on page 890](#)
- [Configure FQDN-based VIPs on page 894](#)
- [VIP groups on page 895](#)

Static virtual IPs

Static Virtual IPs (VIP) are used to map external IP addresses to internal IP addresses. This is also called destination NAT, where a packet's destination is being NAT'd, or mapped, to a different address.

Static VIPs are commonly used to map public IP addresses to resources behind the FortiGate that use private IP addresses. A static one-to-one VIP is when the entire port range is mapped. A port forwarding VIP is when the mapping is configured on a specific port or port range.

Some of the VIP configuration options are:

Setting	Description
VIP Type	<ul style="list-style-type: none"> IPv4 (<code>config firewall vip</code>) - The source and destination are both IPv4. IPv6 (<code>config firewall vip6</code>) - The source and destination are both IPv6. <p>Note: IPv6 is only available when IPv6 is enabled in the <i>Feature Visibility</i>.</p>
Interface (<code>extintf</code>)	<p>The external interface that the firewall policy source interface must match. For example, if the external interface is port1, then the VIP can be used in a policy from port1 to port3, but not in a policy from port2 to port3.</p> <p>If the external interface is <i>any</i>, then the VIP can be used in any firewall policy.</p>
Type (<code>type</code>)	<ul style="list-style-type: none"> Static NAT - Use an external IP address or address range. FQDN - Use an external IP or FQDN address. load-balance (CLI only) - Load balance traffic. server-load-balance - Load balance traffic across multiple servers. SSL processing can be offloaded to the FortiGate. This type of VIP is configure from <i>Policy & Objects > Virtual Servers</i>. dns-translation (CLI only) - DNS translation. access-proxy - Used for ZTNA. See ZTNA HTTPS access proxy example on page 1053 for details.
External IP address/range (<code>extip</code>)	<p>In a static NAT VIP, the external IP address is the IP address that the FortiGate listens for traffic on.</p> <p>When the external interface is not <i>any</i>, 0.0.0.0 can be used to make the external IP address equivalent to the external interface's IP address.</p> <p>The external IP address is also used to perform SNAT for the mapped server when the server outbound traffic with a destination interface that matches the external interface. The firewall policy must also have NAT enabled.</p>
IPv4 address/range (<code>mappedip</code>)	The IPv4 address or range that the internal resource is being mapped to.
IPv6 address/range (<code>ipv6-mappedip</code>)	The IPv6 address or range that the internal resource is being mapped to.
<code>srcintf-filter</code> (CLI only)	<p>Listen for traffic to the external IP address only on the specified interface. While the external interface restricts the policies where the VIP can be used, it does not restrict listening to only the external interface. To restrict listening to only a specific interface, <code>srcint-filter</code> must be configured.</p>
<code>nat-source-vip</code> (CLI only)	<p>Force all of the traffic from the mapped server to perform SNAT with the external IP address, regardless of the destination interface.</p> <p>If <code>srcint-filter</code> is defined, then <code>nat-source-vip</code> only forces SNAT to be performed when the destination matches the <code>srcintf-filter</code> interface.</p> <p>In both cases, the firewall policy must have NAT enabled.</p>
<code>arp-reply</code> (CLI only)	Enable/disable responding to ARP requests on the external IP address (default = enable).

Setting	Description
	When a VIP object is created with <code>arp-reply</code> enabled, the object does not need to be referenced in any policies before a FortiGate interface starts responding to ARP requests for the addresses in the VIP.
Source address (<code>src-filter</code>)	Restrict the source IP address, address range, or subnet that is allowed to access the VIP.
Services (<code>service</code>)	Set the services that are allowed to be mapped.
Port Forwarding (<code>portforward</code>)	Enable port forwarding to specify the port (<code>mappedport</code>) to map to. If no services are configured, you can configure the protocol (<code>protocol</code>) to use when forwarding packets, the external service port range (<code>extport</code>) to be mapped to a port range on the destination network, and the mapped port range (<code>mappedport</code> and <code>ipv6-mappedport</code>) on the destination network.
Port Mapping Type	<ul style="list-style-type: none"> One to one - Each external service port is mapped to one port. A range is allowed, but the number of ports should be the same. Many to Many - The port mapping can be one to one, one to many, or many to one. There are no restrictions on how many external ports must map to internal ports.

After creating a VIP, if you try creating a second VIP that uses the same external IP and interface, this triggers a VIP overlap check and the new configuration will fail.

Sample configuration

To create a virtual IP in the GUI:

1. In *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP*.
2. Select a *VIP Type* based on the IP versions used.
3. Enter a unique name for the virtual IP.
4. Enter values for the external IP address/range and map to IPv4/IPv6 address/range fields.

5. Click **OK**.

To create a virtual IP in the CLI:

```
config firewall vip
  edit "Internal_WebServer"
    set extip 10.1.100.199
    set extintf "any"
    set mappedip "172.16.200.55"
  next
end
```

To apply a virtual IP to policy in the CLI:

```
config firewall policy
  edit 8
    set name "Example_Virtual_IP_in_Policy"
    set srcintf "wan2"
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "Internal_WebServer"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
  next
end
```

IP pools and VIPs as local IP addresses

IP pools and VIPs are considered local IP addresses if responding to ARP requests on these external IP addresses is enabled (`set arp-reply enable`, by default). In this case, the FortiGate is considered a destination for those IP addresses and can receive reply traffic at the application layer successfully.

However, as a side-effect, once an IP pool or VIP has been configured, even if it is never used in a firewall policy, the FortiGate considers it as a local address and will not forward traffic based on the routing table. Therefore, any unused IP pools or VIPs should be deleted to prevent any unexpected behaviour.

For a history of behaviour changes related to IP pools and VIPs, see [Technical Tip: IP pool and virtual IP behaviour changes in FortiOS 6.4, 7.0, 7.2, and 7.4](#).

Virtual IP with services

Virtual IP with services is a more flexible virtual IP mode. This mode allows users to define services to a single port number mapping.

This topic shows how to use virtual IP with services enabled. This example has one public external IP address. We map TCP ports 8080, 8081, and 8082 to an internal WebServer TCP port 80. This allows remote connections to communicate with a server behind the firewall.

Sample configuration

To create a virtual IP with services in the GUI:

1. In *Policy & Objects* > *Virtual IP*s and click *Create New* > *Virtual IP*.
2. Set *VIP Type* to *IPv4*.
3. Enter a unique name for the virtual IP and fill in the other fields.
4. Configure the fields in the *Network* section. For example:
 - Set *Interface* to *any*.
 - Set *External IP Address/Range* to *10.1.100.199*.
 - Set *Mapped IP Address/Range* to *172.16.200.55*.
5. Enable *Optional Filters* and then enable *Services*.
6. In the *Services* field click + to display the *Services* pane.
7. In the *Services* pane select *TCP_8080*, *TCP_8081*, and *TCP_8082*.
8. Enable *Port Forwarding* and set *Map to IPv4 port* to *80*.

The screenshot shows the 'New Virtual IP' configuration window in FortiOS. The configuration is as follows:

- General:**
 - VIP type: IPv4
 - Name: WebServer_VIP_Services
 - Comments: Write a comment...
 - Color: Change
- Network:**
 - Interface: any
 - Type: Static NAT
 - External IP address/range: 10.1.100.199-10.1.100.199
 - Map to:
 - IPv4 address/range: 172.16.200.55 - 172.16.200.55
 - IPv6 address/range: Starting IPv6 address
- Optional Filters:**
 - Source address: Disabled
 - Services: Enabled
- Port Forwarding:**
 - Protocol: TCP
 - Port Mapping Type: One to one
 - External service port: 1 to 65535
 - Map to IPv4 port: 1 to 65535
 - Map to IPv6 port: 1 to 65535

9. Click *OK*.

To see the results:

1. Apply the above virtual IP to the firewall policy.
2. The results are:
 - Access 10.1.100.199:8080 from external network and FortiGate maps to 172.16.200.55:80 in internal network.
 - Access 10.1.100.199:8081 from external network and FortiGate maps to 172.16.200.55:80 in internal network.
 - Access 10.1.100.199:8082 from external network and FortiGate maps to 172.16.200.55:80 in internal network.

To create a virtual IP with services in the CLI:

```
config firewall vip
  edit "WebServer_VIP_Services"
    set service "TCP_8080" "TCP_8081" "TCP_8082"
    set extip 10.1.100.199
    set extintf "any"
    set portforward enable
    set mappedip "172.16.200.55"
    set mappedport 80
  next
end
```

Virtual IPs with port forwarding

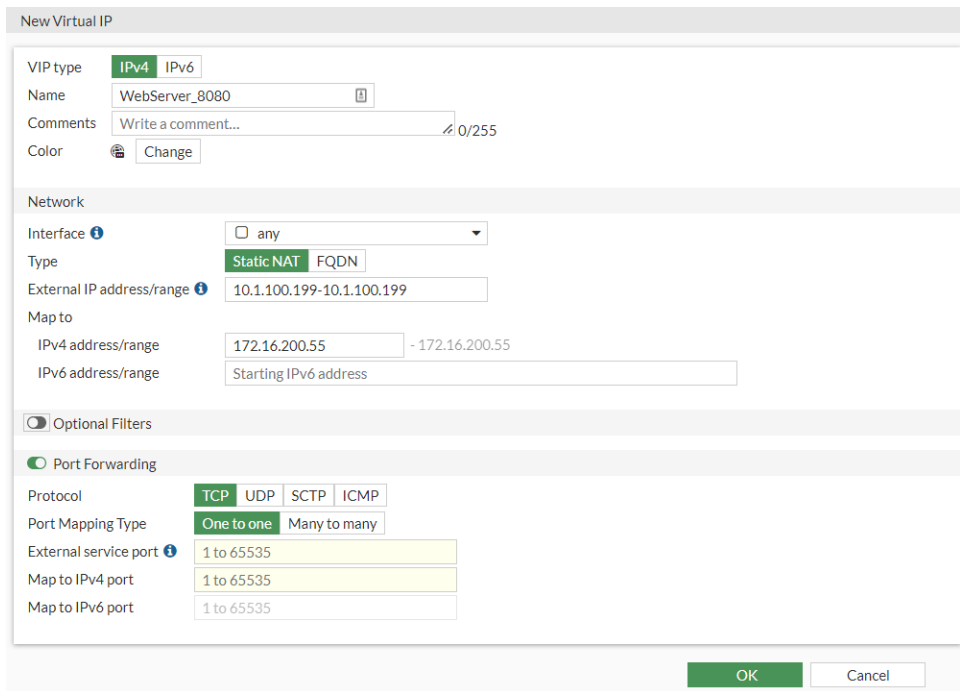

If you need to hide the internal server port number or need to map several internal servers to the same public IP address, enable port-forwarding for Virtual IP.

This topic shows how to use virtual IPs to configure port forwarding on a FortiGate unit. This example has one public external IP address. We map TCP ports 8080, 8081, and 8082 to different internal WebServers' TCP port 80. This allows remote connections to communicate with a server behind the firewall.

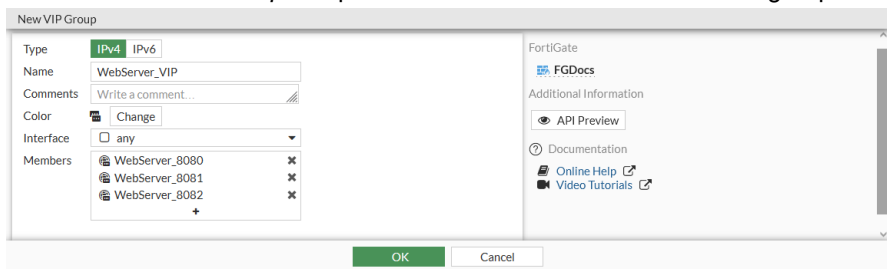

Sample configuration

To create a virtual IP with port forwarding in the GUI:

1. In *Policy & Objects > Virtual IPs*.
2. Click *Create New* and select *Virtual IP*.
3. For *VIP Type*, select *IPv4*.
4. Enter a unique name for the virtual IP and fill in the other fields.
5. Configure the fields in the *Network* section. For example:
 - Set *Interface* to *any*.
 - Set *External IP Address/Range* to *10.1.100.199*.
 - Set *Mapped IP Address/Range* to *172.16.200.55*.
6. Leave *Optional Filters* disabled.
7. Enable *Port Forwarding*.
8. Configure the fields in the *Port Forwarding* section. For example:
 - Set *Protocol* to *TCP*.
 - Set *External Service Port* to *8080*.
 - Set *Map to IPv4 port* to *80*.

9. Click **OK**.
10. Follow the above steps to create two additional virtual IPs.
 - a. For one virtual IP:
 - Use a different *Mapped IP Address/Range*, for example, *172.16.200.56*.
 - Set *External Service Port* to *8081*.
 - Use the same *Map to IPv4 port* number: *80*.
 - b. For the other virtual IP:
 - Use a different *Mapped IP Address/Range*, for example, *172.16.200.57*.
 - Set *External Service Port* to *8082*.
 - Use the same *Map to IPv4 port* number: *80*.
11. Create a *Virtual IP Group* and put the above three virtual IPs into that group.

To see the results:

1. Apply the above virtual IP to the Firewall policy.
2. The results are:
 - Access 10.1.100.199:8080 from external network and FortiGate maps to 172.16.200.55:80 in internal network.
 - Access 10.1.100.199:8081 from external network and FortiGate maps to 172.16.200.56:80 in internal network.
 - Access 10.1.100.199:8082 from external network and FortiGate maps to 172.16.200.57:80 in internal network

Virtual server load balance

This topic shows a special virtual IP type: virtual server. Use this type of VIP to implement server load balancing.

The FortiOS server load balancing contains all the features of a server load balancing solution. You can balance traffic across multiple backend servers based on multiple load balancing schedules including:

- Static (failover)
- Round robin
- Weighted (to account for different sized servers or based on the health and performance of the server including round trip time and number of connections)

The load balancer supports HTTP, HTTPS, IMAPS, POP3S, SMTPS, SSL/TLS, and generic TCP/UDP and IP protocols. Session persistence is supported based on the SSL session ID based on an injected HTTP cookie, or based on the HTTP or HTTPS host. SSL/TLS load balancing includes protection from protocol downgrade attacks. Server load balancing is supported on most FortiGate devices and includes up to 10,000 virtual servers on high-end systems.

FortiOS HTTP and HTTPS server load balancing does not support load balancing based on URL routing. You can use FortiWeb server pools or FortiADC server load balancing to load balance sessions to two or more URL based routes.

Sample topology

SSL/TLS offloading

FortiGate SSL/TLS offloading is designed for the proliferation of SSL/TLS applications. The key exchange and encryption/decryption tasks are offloaded to the FortiGate unit where they are accelerated using FortiASIC technology which provides significantly more performance than a standard server or load balancer. This frees up valuable resources on the server farm to give better response to business operations. Server load balancing offloads most SSL/TLS versions including SSL 3.0, TLS 1.0, and TLS 1.2, and supports full mode or half mode SSL offloading with DH key sizes up to 4096 bits.

FortiGate SSL offloading allows the application payload to be inspected before it reaches your servers. This prevents intrusion attempts, blocks viruses, stops unwanted applications, and prevents data leakage. SSL/TLS content inspection supports TLS versions 1.0, 1.1, and 1.2 and SSL versions 1.0, 1.1, 1.2, and 3.0.

Virtual server requirements

When creating a new virtual server, you must configure the following options:

- Virtual Server Type.
- Load Balancing Methods.
- Health check monitoring (optional).
- Session persistence (optional).
- Virtual Server IP (External IP Address).
- Virtual Server Port (External Port).
- Real Servers (Mapped IP Address & Port).

Virtual server types

Select the protocol to be load balanced by the virtual server. If you select a general protocol such as IP, TCP, or UDP, the virtual server load balances all IP, TCP, or UDP sessions. If you select specific protocols such as HTTP, HTTPS, or SSL, you can apply additional server load balancing features such as *Persistence* and *HTTP Multiplexing*.

HTTP	Select <i>HTTP</i> to load balance only HTTP sessions with the destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced (usually port 80 for HTTP sessions). You can enable <i>HTTP Multiplexing</i> . You can also set <i>Persistence</i> to <i>HTTP Cookie</i> to enable cookie-based persistence.
HTTPS	Select <i>HTTPS</i> to load balance only HTTPS sessions with the destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced (usually port 443 for HTTPS sessions). You can enable <i>HTTP Multiplexing</i> . You can also set <i>Persistence</i> to <i>HTTP Cookie</i> to enable cookie-based persistence, or you can set <i>Persistence</i> to <i>SSL Session ID</i> .
IMAPS	Select <i>IMAPS</i> to load balance only IMAPS sessions with the destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced (usually port 993 for IMAPS sessions). You can also set <i>Persistence</i> to <i>SSL Session ID</i> .
POP3S	Select <i>POP3S</i> to load balance only POP3S sessions with the destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced (usually port 995 for POP3S sessions). You can also set <i>Persistence</i> to <i>SSL Session ID</i> .
SMTPS	Select <i>SMTPS</i> to load balance only SMTPS sessions with the destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced (usually port 465 for SMTPS sessions). You can also set <i>Persistence</i> to <i>SSL Session ID</i> .
SSL	Select <i>SSL</i> to load balance only SSL sessions with the destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced. You can also set <i>Persistence</i> to <i>SSL Session ID</i> .
TCP	Select <i>TCP</i> to load balance only TCP sessions with the destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced.

UDP	Select <i>UDP</i> to load balance only UDP sessions with the destination port number that matches the <i>Virtual Server Port</i> setting. Change <i>Virtual Server Port</i> to match the destination port of the sessions to be load balanced.
IP	Select <i>IP</i> to load balance all sessions accepted by the security policy that contains this virtual server.

Load balancing methods

The load balancing method defines how sessions are load balanced to real servers.

All load balancing methods do not send traffic to real servers that are down or not responding. FortiGate can only determine if a real server is not responding by using a health check monitor. You should always add at least one health check monitor to a virtual server or to real servers; otherwise load balancing might try to distribute sessions to real servers that are not functioning.

Static	The traffic load is statically spread evenly across all real servers. Sessions are not assigned according to how busy individual real servers are. This load balancing method provides some persistence because all sessions from the same source address always go to the same real server. Because the distribution is stateless, so if a real server is added, removed, or goes up or down, the distribution is changed and persistence might be lost.
Round Robin	Directs new requests to the next real server. This method treats all real servers as equals regardless of response time or the number of connections. This method does not direct requests to real servers that down or non responsive.
Weighted	Real servers with a higher weight value receive a larger percentage of connections. Set the real server weight when adding a real server.
Least Session	Directs requests to the real server that has the least number of current connections. This method works best in environments where the real servers or other equipment you are load balancing all have similar capabilities. This load balancing method uses the FortiGate session table to track the number of sessions being processed by each real server. The FortiGate unit cannot detect the number of sessions actually being processed by a real server.
Least RTT	Directs sessions to the real server with the lowest round trip time. The round trip time is determined by a ping health check monitor. The default is 0 if no ping health check monitors are added to the virtual server.
First Alive	Directs sessions to the first live real server. This load balancing schedule provides real server failover protection by sending all sessions to the first live real server. If a real server fails, all sessions are sent to the next live real server. Sessions are not distributed to all real servers so all sessions are processed by the first real server only.
HTTP Host	Load balances HTTP host connections across multiple real servers using the host's HTTP header to guide the connection to the correct real server.

Health check monitoring

In the FortiGate GUI, you can configure health check monitoring so that the FortiGate unit can verify that real servers are able respond to network connection attempts. If a real server responds to connection attempts, the load balancer continues to send sessions to it. If a real server stops responding to connection attempts, the load balancer assumes that the server is down and does not send sessions to it. The health check monitor configuration determines how the

load balancer tests real servers. You can use a single health check monitor for multiple load balancing configurations. You can configure TCP, HTTP, DNS, and ping health check monitors. You usually set the health check monitor to use the same protocol as the traffic being load balanced to it. For example, for an HTTP load balancing configuration, you would normally use an HTTP health check monitor.

Session persistence

Use persistence to ensure a user is connected to the same real server every time the user makes an HTTP, HTTPS, or SSL request that is part of the same user session. For example, if you are load balancing HTTP and HTTPS sessions to a collection of eCommerce web servers, when users make a purchase, they will be starting multiple sessions as they navigate the eCommerce site. In most cases, all the sessions started by this user during one eCommerce session should be processed by the same real server. Typically, the HTTP protocol keeps track of these related sessions using cookies. HTTP cookie persistence ensure all sessions that are part of the same user session are processed by the same real server.

When you configure persistence, the FortiGate unit load balances a new session to a real server according to the load balance method. If the session has an HTTP cookie or an SSL session ID, the FortiGate unit sends all subsequent sessions with the same HTTP cookie or SSL session ID to the same real server.

Real servers

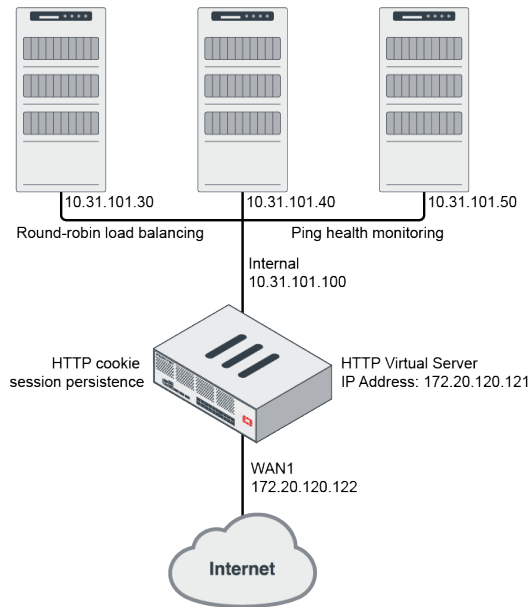

Add real servers to a load balancing virtual server to provide information the virtual server requires to send sessions to the server. A real server configuration includes the IP address of the real server and port number the real server receives sessions on. The FortiGate unit sends sessions to the real server's IP address using the destination port number in the real server configuration.

When configuring a real server, you can also specify the weight (if the load balance method is set to *Weighted*) and you can limit the maximum number of open connections between the FortiGate unit and the real server. If the maximum number of connections is reached for the real server, the FortiGate unit automatically switches all further connection requests to other real servers until the connection number drops below the limit. Setting *Maximum Connections* to 0 means that the FortiGate unit does not limit the number of connections to the real server.

Sample of HTTP load balancing to three real web servers

This example describes the steps to configure the load balancing configuration below. In this configuration, a FortiGate unit is load balancing HTTP traffic from the Internet to three HTTP servers on the internal network. HTTP sessions are accepted at the wan1 interface with destination IP address 172.20.120.121 on TCP port 8080, and forwarded from the internal interface to the web servers. When forwarded, the destination address of the session is translated to the IP address of one of the web servers.

This load balancing configuration also includes session persistence using HTTP cookies, round-robin load balancing, and TCP health monitoring for the real servers. Ping health monitoring consists of the FortiGate unit using ICMP ping to ensure the web servers can respond to network traffic.

General steps:

1. Create a health check monitor.
A ping health check monitor causes the FortiGate to ping the real servers every 10 seconds. If one of the servers does not respond within 2 seconds, the FortiGate unit will retry the ping 3 times before assuming that the HTTP server is not responding.
2. Create a load balance virtual server with three real servers.
3. Add the load balancing virtual server to a policy as the destination address.

To see the virtual servers and health check monitors options in the GUI, *Load Balance* must be selected in *Feature Visibility > Additional Features*. See [Feature visibility on page 2292](#) on page 1 for details.

Configure a load balancing virtual server in the GUI

To create a health check monitor:

1. Go to *Policy & Objects > Health Check*.
2. Click *Create New*.
3. Set the following:
 - *Name* to *Ping-mon-1*
 - *Type* to *Ping*
 - *Interval* to *10* seconds
 - *Timeout* to *2* seconds
 - *Retry* to *3* attempt(s)

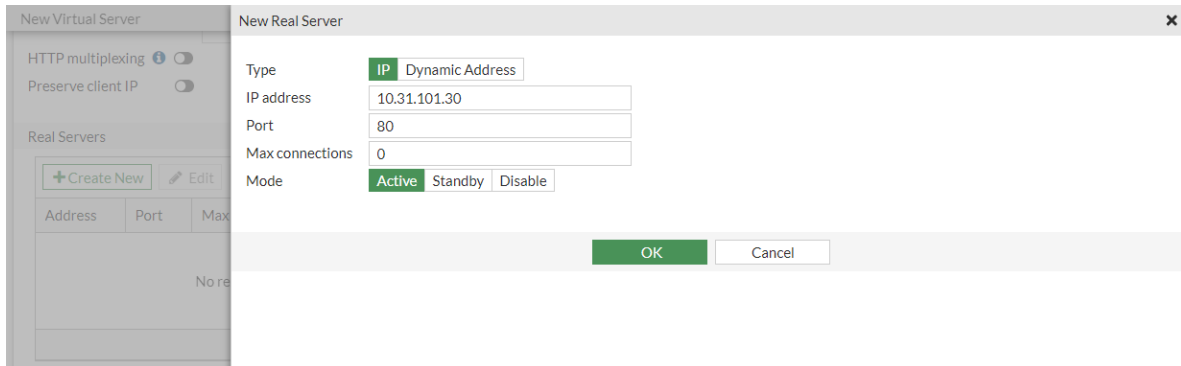

4. Click **OK**.

To create a virtual server:

1. Go to *Policy & Objects > Virtual Servers*.
2. Click *Create New*.
3. Set the following:
 - *Name* to *Vserver-HTTP-1*
 - *Type* to *HTTP*
 - *Interface* to *wan1*
 - *Virtual Server IP* to *172.20.120.121*
 - *Virtual Server Port* to *8080*
 - *Load Balance Method* to *Round Robin*
 - *Persistence* to *HTTP Cookie*
 - *Health Check* to *Ping-mon-1*

4. In the *Real Servers* table, click *Create New*.
5. Set the following for the first real server:
 - *Type* to *IP*
 - *IP Address* to *10.31.101.30*
 - *Port* to *80*
 - *Max Connections* to *0*
 - *Mode* to *Active*

6. Click *OK*. Configure two more real servers with IP addresses 10.31.101.40 and 10.31.101.50, and the same settings as the first real server.
7. Click *OK*.

To create a security policy that includes the load balance virtual server as the destination address:

1. Go to *Policy & Objects > Firewall Policy*.
2. Click *Create New*.
3. Set the *Inspection Mode* to *Proxy-based*. The new virtual server will not be available if the inspection mode is *Flow-based*.
4. Set the following:
 - *Name* to *LB-policy*
 - *Incoming Interface* to *wan1*
 - *Outgoing Interface* to *internal*
 - *Source* to *all*
 - *Destination* to *Vserver-HTTP-1*
 - *Schedule* to *always*
 - *Service* to *ALL*
 - *Action* to *ACCEPT*
5. Enable *NAT* and set *IP Pool Configuration* to *Use Outgoing Interface Address*.

6. Enable *AntiVirus* and select an antivirus profile.

The screenshot shows the 'New Policy' configuration window in FortiGate. The 'AntiVirus' section is enabled, and the 'AV default' profile is selected. Other settings include Name: LB-policy, Incoming Interface: wan1, Outgoing Interface: internal, Source: all, Destination: Vserver-HTTP-1, Schedule: always, Service: ALL, Action: ACCEPT, Inspection Mode: Proxy-based, NAT: NAT, IP Pool Configuration: Use Outgoing Interface Address, Protocol Options: default, and Security Profiles: AV default. The 'OK' button is highlighted in green.

7. Click **OK**.

Configure a load balancing virtual server in the CLI

To configure HTTP load balancing to three real web servers in the CLI:

1. Create a health check monitor:

```
config firewall ldb-monitor
  edit "Ping-mon-1"
    set type ping
    set interval 10
    set timeout 2
    set retry 3
  next
end
```

2. Create a virtual server:

```
config firewall vip
  edit "Vserver-HTTP-1"
    set type server-load-balance
    set extip 172.20.120.121
    set extintf "any"
    set server-type http
    set monitor "Ping-mon-1"
    set ldb-method round-robin
    set persistence http-cookie
```

```
set extport 8080
config realservers
  edit 1
    set type ip
    set ip 10.31.101.30
    set port 80
  next
  edit 2
    set type ip
    set ip 10.31.101.40
    set port 80
  next
  edit 3
    set type ip
    set ip 10.31.101.50
    set port 80
  next
end
next
end
```

3. Add the load balancing virtual server to a policy as the destination address:

```
config firewall policy
  edit 2
    set name "LB-policy"
    set inspection-mode proxy
    set srcintf "wan1"
    set dstintf "internal"
    set srcaddr "all"
    set dstaddr "Vserver-HTTP-1"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set ssl-ssh-profile "certificate-inspection"
    set av-profile "default"
    set fsso disable
    set nat enable
  next
end
```

Results

Traffic accessing 172.20.120.121:8080 is forwarded in turn to the three real servers.

If the access request has an http-cookie, FortiGate forwards the access to the corresponding real server according to the cookie.

Central DNAT

Central NAT allows for the central configuration of SNAT (source NAT) and DNAT (destination NAT).

To enable central NAT in the GUI:

1. Go to *System > Settings*.
2. In the *System Operation Settings*, enable *Central SNAT*.
3. Click *Apply*.

To enable central NAT in the CLI:

```
config system settings
    set central-nat {enable | disable}
end
```

When central NAT is enabled, virtual IPs (VIPs) are not configured in the firewall policy. The VIPs are configured as separate objects where their status must be enabled.

This option is only available for IPv4 VIP and VIP46 objects.

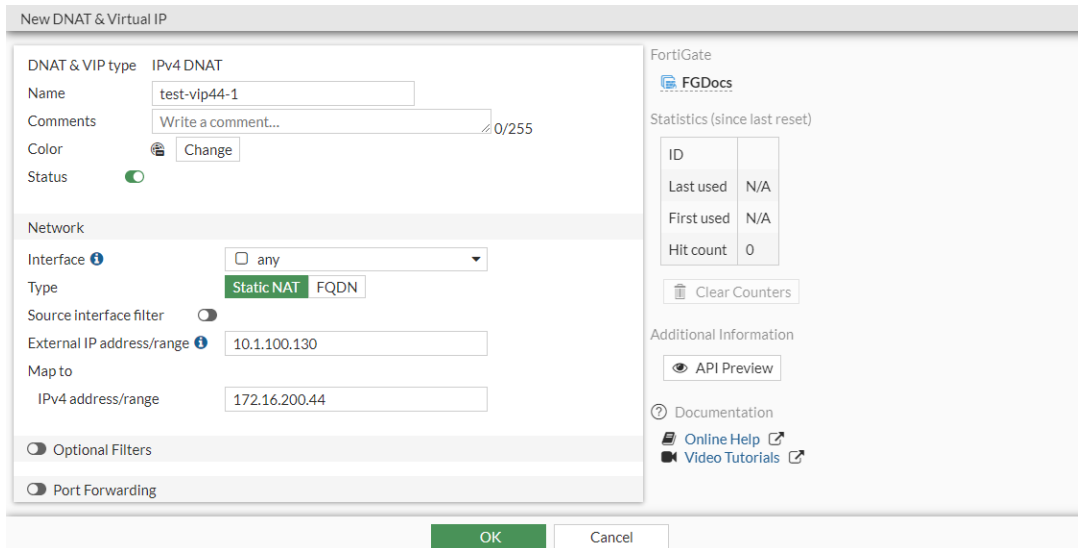

Configuring a DNAT and VIP object in central NAT mode is similar to configuring a VIP when central NAT is disabled. See [Static virtual IPs on page 875](#) for more information on each setting.

VIP objects can carry over when switching from non-central NAT mode to central NAT mode or vice-versa. However, if a VIP is assigned to a firewall policy in non-central NAT mode, it must be unassigned before switching to central NAT mode.

In this example, a DNAT and VIP are configured to forward traffic from 10.1.100.130 to 172.16.200.44. This example assumes that the firewall address, Addr_172.16.200.44/32, has already been configured.

To configure DNAT and a VIP in the GUI:

1. Configure the VIP:
 - a. Go to *Policy & Objects > DNAT & Virtual IPs* and click *Create New > DNAT & Virtual IP*.
 - b. Enter a name (*test-vip44-1*).
 - c. Set the *External IP address/range* to *10.1.100.130*.
 - d. Set the *Map to IPv4 address/range* to *172.16.200.44*.

- e. Click **OK**.
- 2. Configure a firewall policy that allows traffic in the direction of the VIP:
 - a. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
 - b. Configure the following settings:

Name	<i>VIP-port2toport3</i>
Source	<i>all</i>
Destination	<i>Addr_172.16.200.40</i>
Schedule	<i>always</i>
Service	<i>ALL</i>
Action	<i>ACCEPT</i>

- c. Configure the other settings as needed. There is no SNAT configuration section, so central SNAT policies will be applied.

d. Click OK.

To configure DNAT and a VIP in the CLI:

1. Configure the VIP:

```
config firewall vip
  edit "test-vip44-1"
    set extip 10.1.100.130
    set mappedip "172.16.200.44"
    set extintf "any"
    set status enable
  next
end
```

2. Configure a firewall policy that allows traffic in the direction of the VIP:

```
config firewall policy
  edit 3
    set name "VIP-port2toport3"
    set srcintf "port2"
    set dstintf "port3"
    set action accept
    set srcaddr "all"
    set dstaddr "Addr_172.16.200.40"
    set schedule "always"
    set service "ALL"
  next
end
```

To verify the DNAT and VIP:

If the VIP status is enabled, it will appear in the VIP table:

```
# diagnose firewall iprope list 100000
policy index=7 uuid_idx=625 action=accept
flag (8000104): f_p nat pol_stats
cos_fwd=0 cos_rev=0
group=00100000 av=00000000 au=00000000 split=00000000
host=0 chk_client_info=0x0 app_list=0 ips_view=0
misc=0
zone(1): 0 -> zone(1): 0
source(1): 0.0.0.0-255.255.255.255, uuid_idx=0,
dest(1): 10.1.100.130-10.1.100.130, uuid_idx=625,
service(1):
    [0:0x0:0/(0,0)->(0,0)] helper:auto
nat(1): flag=0 base=10.1.100.130:0 172.16.200.44-172.16.200.44(0:0)
```

If the VIP status is disabled, it will not appear in the VIP table.

In this example, a one-to-one static NAT is enabled. Send a ping to 10.1.100.130, and the traffic will be forwarded to the destination 172.16.200.44.

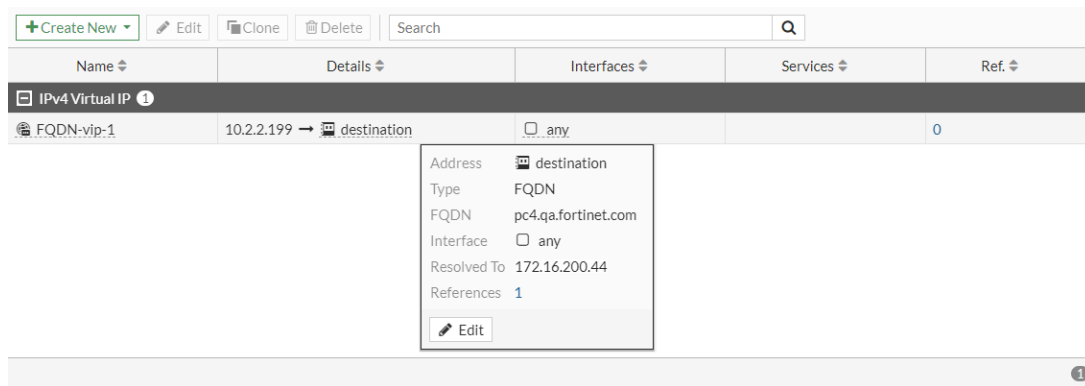

Configure FQDN-based VIPs

In public cloud environments, sometimes it is necessary to map a VIP to an FQDN address.

To configure an FQDN-based VIP in the GUI:

1. Go to *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP*.
2. Enter a name for the VIP.
3. Select an interface.
4. For *Type*, select *FQDN*.
5. For *External*, select *IP* and enter the external IP address.
6. For *Mapped address*, select an FQDN address.

7. Click *OK*.
In the virtual IP list, hover over the address to view more information.

To configure an FQDN-based VIP in the CLI:

```
config firewall vip
  edit "FQDN-vip-1"
    set type fqdn
    set extip 10.2.2.199
    set extintf "any"
    set mapped-addr "destination"
  next
end
```

VIP groups

Virtual IP addresses (VIPs) can be organized into groups. This is useful in scenarios where there are multiple VIPs that are used together in firewall policies. If the VIP group members change, or a group member's settings change (such as the IP address, port, or port mapping type), then those changes are automatically updated in the corresponding firewall policies.

The following table summarizes which VIP types are allowed and not allowed to be members of a VIP group:

Group type	VIP types allowed as members	VIP types not allowed as members
IPv4	<ul style="list-style-type: none"> Static NAT Load balance DNS translation FQDN 	<ul style="list-style-type: none"> Access proxy Server load balance
IPv6	<ul style="list-style-type: none"> Static NAT 	<ul style="list-style-type: none"> Access proxy Server load balance

Different VIP types can be added to the same group.

To configure a VIP group in the GUI:

1. Go to *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP Group*.
2. Set the *Type* to *IPv4* or *IPv6*.
3. Enter a name.
4. Optionally, enter additional information in the *Comments* field.

5. For IPv4 groups, select the *Interface*. Select a specific interface if all of the VIPs are on the same interface; otherwise, select *any*.
6. Click the + in the *Members* field and select the members to add to the group.
7. Click *OK*.

To configure an IPv4 VIP group in the CLI:

```
config firewall vipgrp
  edit <name>
    set interface <name>
    set member <vip1> <vip2> ...
  next
end
```

To configure an IPv6 VIP group in the CLI:

```
config firewall vipgrp6
  edit <name>
    set member <vip1> <vip2> ...
  next
end
```

Local-in policies

While security profiles control traffic flowing through the FortiGate, local-in policies control inbound traffic that is going to a FortiGate interface.

Administrative access traffic (HTTPS, PING, SSH, and others) can be controlled by allowing or denying the service in the interface settings. Trusted hosts can be configured under an administrator to restrict the hosts that can access the administrative service.

Local-in policies allow administrators to granularly define the source and destination addresses, interface, and services. Traffic destined for the FortiGate interface specified in the policy that meets the other criteria is subject to the policies action.

Local-in policies can be used to restrict administrative access or other services, such as VPN, that can be specified as services. You can define source addresses or address groups to restrict access from. For example, by using a geographic type address you can restrict a certain geographic set of IP addresses from accessing the FortiGate.

Local-in policies can only be created or edited in the CLI. You can view the existing local-in policies in the GUI by enabling it in *System > Feature Visibility* under the *Additional Features* section. This page does not list the custom local-in policies.

To configure a local-in policy using the CLI:

```
config firewall {local-in-policy | local-in-policy6}
  edit <policy_number>
    set intf <interface>
    set srcaddr <source_address> [source_address] ...
    set dstaddr <destination_address> [destination_address] ...
    set action {accept | deny}
    set service <service_name> [service_name] ...
```

```
        set schedule <schedule_name>
        set comments <string>
    next
end
```

For example, to prevent the source subnet 10.10.10.0/24 from pinging port1, but allow administrative access for PING on port1:

```
config firewall address
    edit "10.10.10.0"
        set subnet 10.10.10.0 255.255.255.0
    next
end
config firewall local-in-policy
    edit 1
        set intf "port1"
        set srcaddr "10.10.10.0"
        set dstaddr "all"
        set service "PING"
        set schedule "always"
    next
end
```

To test the configuration:

1. From the PC at 10.10.10.12, start a continuous ping to port1:

```
ping 192.168.2.5 -t
```

2. On the FortiGate, enable debug flow:

```
# diagnose debug flow filter addr 10.10.10.12
# diagnose debug flow filter proto 1
# diagnose debug enable
# diagnose debug flow trace start 10
```

3. The output of the debug flow shows that traffic is dropped by local-in policy 1:

```
# id=20085 trace_id=1 func=print_pkt_detail line=5746 msg="vd-root:0 received a packet
(proto=1, 10.10.10.12:1->192.168.2.5:2048) from port1. type=8, code=0, id=1, seq=128."
id=20085 trace_id=1 func=init_ip_session_common line=5918 msg="allocate a new session-
0017c5ad"
id=20085 trace_id=1 func=vf_ip_route_input_common line=2615 msg="find a route:
flag=80000000 gw=192.168.2.5 via root"
id=20085 trace_id=1 func=fw_local_in_handler line=474 msg="iprope_in_check() check
failed on policy 1, drop"
```

Implicit deny rule

If a local-in-policy is not functioning correctly and traffic that should be blocked is being allowed through, the issue may be that the implicit deny local-in-policy has not been created. Unlike IPv4 policies, there is no default implicit deny policy. The implicit deny policy should be placed at the bottom of the list of local-in-policies. Local-in-policies are created for each interface, but if you want to create a general implicit deny rule for all interfaces for a specific service, source, address, or destination address, use the `any` interface.

By default, no local-in policies are defined, so there are no restrictions on local-in traffic. When you define a local-in policy, if no action is set manually, then the action will default to deny.

For example, to allow only the source subnet 172.16.200.0/24 to ping port1:

```
config firewall address
  edit "172.16.200.0"
    set subnet 172.16.200.0 255.255.255.0
  next
end
config firewall local-in-policy
  edit 2
    set intf "port1"
    set srcaddr "172.16.200.0"
    set dstaddr "all"
    set action accept
    set service "PING"
    set schedule "always"
  next
  edit 3
    set intf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "PING"
    set schedule "always"
  next
end
```

To test the configuration:

1. From the PC at 172.16.200.2, start a continuous ping to port1:

```
ping 172.16.200.1 -t
```

2. On the FortiGate, enable debug flow:

```
# diagnose debug flow filter proto 1
# diagnose debug enable
# diagnose debug flow trace start 10
```

3. The output of the debug flow shows that ping traffic coming from the 172.16.200.0 subnet is allowed:

```
# id=65308 trace_id=25 func=print_pkt_detail line=5939 msg="vd-root:0 received a packet
(proto=1, 172.16.200.2:5->172.16.200.1:2048) tun_id=0.0.0.0 from port1. type=8, code=0,
id=5, seq=0."
id=65308 trace_id=25 func=init_ip_session_common line=6121 msg="allocate a new session-
00029409, tun_id=0.0.0.0"
id=65308 trace_id=25 func=_vf_ip_route_input_rcu line=2012 msg="find a route:
flag=80000000 gw=0.0.0.0 via root"
id=65308 trace_id=25 func=ip_session_confirm_final line=3189 msg="npu_state=0x0, hook=1"
id=65308 trace_id=26 func=print_pkt_detail line=5939 msg="vd-root:0 received a packet
(proto=1, 172.16.200.1:5->172.16.200.2:0) tun_id=0.0.0.0 from local. type=0, code=0,
id=5, seq=0."
id=65308 trace_id=26 func=resolve_ip_tuple_fast line=6027 msg="Find an existing session,
id-00029409, reply direction"
```

```

id=65308 trace_id=27 func=print_pkt_detail line=5939 msg="vd-root:0 received a packet
(proto=1, 172.16.200.2:5->172.16.200.1:2048) tun_id=0.0.0.0 from port1. type=8, code=0,
id=5, seq=1."
id=65308 trace_id=27 func=resolve_ip_tuple_fast line=6027 msg="Find an existing session,
id-00029409, original direction"
id=65308 trace_id=28 func=print_pkt_detail line=5939 msg="vd-root:0 received a packet
(proto=1, 172.16.200.1:5->172.16.200.2:0) tun_id=0.0.0.0 from local. type=0, code=0,
id=5, seq=1."

```

- From the PC at 172.20.120.13, start a continuous ping to port1:

```
ping 172.16.200.1 -t
```

- The output of the debug flow shows that ping traffic coming from subnets other than 172.16.200.0 is dropped by local-in policy 3:

```

# id=65308 trace_id=21 func=print_pkt_detail line=5939 msg="vd-root:0 received a packet
(proto=1, 172.20.120.13:1->172.16.200.1:2048) tun_id=0.0.0.0 from port2. type=8, code=0,
id=1, seq=8."
id=65308 trace_id=21 func=init_ip_session_common line=6121 msg="allocate a new session-
0002929d, tun_id=0.0.0.0"
id=65308 trace_id=21 func=__vf_ip_route_input_rcu line=2012 msg="find a route:
flag=80000000 gw=0.0.0.0 via root"
id=65308 trace_id=21 func=__iprope_tree_check line=520 msg="gnum=100004, use int hash,
slot=51, len=2"
id=65308 trace_id=21 func=fw_local_in_handler line=545 msg="iprope_in_check() check
failed on policy 3, drop"

```

Additional options

To disable or re-enable the local-in policy, use the `set status {enable | disable}` command.

To dedicate the interface as an HA management interface, use the `set ha-mgmt-intf-only enable` command.

Example:

```

config firewall local-in-policy
  edit 1
    set ha-mgmt-intf-only enable
    set intf port4
    set srcaddr all
    set dstaddr all
    set service ALL
    set schedule always
    set action accept
    set status enable
  next
end

```

If a user tries to set the HA reserved management interface during the local-in policy an error is generated. Use the `set ha-mgmt-intf-only enable` command to avoid the error.

TTL policies

You can configure a time-to-live (TTL) policy to block attack traffic with high TTLs. This feature only applies to local-in traffic and does not apply to traffic passing through the FortiGate. You can use `srcintf` to set the interface that the local-in traffic hits. See [config firewall ttl-policy](#).

To configure a TTL policy using the CLI:

```
config firewall ttl-policy
  edit <id>
    set status {enable | disable}
    set action {accept | deny}
    set srcintf <interface>
    set srcaddr <source_address> [source_address] ...
    set service <service_name> [service_name] ...
    set schedule <schedule_name>
    set ttl <value/range>
  next
end
```

DoS protection

A Denial of Service (DoS) policy examines network traffic arriving at a FortiGate interface for anomalous patterns, which usually indicates an attack.

A denial of service occurs when an attacking system starts an abnormally large number of sessions with a target system. The large number of sessions slows down or disables the target system, preventing legitimate users from using it.

DoS policies are checked before security policies, preventing attacks from triggering more resource intensive security protection and slowing down the FortiGate.

DoS anomalies

Predefined sensors are setup for specific anomalous traffic patterns. New DoS anomalies cannot be added by the user.

The predefined anomalies that can be used in DoS policies are:

Anomaly	Description	Recommended Threshold
tcp_syn_flood	If the SYN packet rate of new TCP connections, including retransmission, to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
tcp_port_scan	If the SYN packet rate of new TCP connections, including retransmission, from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second.
tcp_src_session	If the number of concurrent TCP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.

Anomaly	Description	Recommended Threshold
tcp_dst_session	If the number of concurrent TCP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
udp_flood	If the UDP traffic to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second.
udp_scan	If the UDP sessions setup rate originating from one source IP address exceeds the configured threshold value, the action is executed.	2000 sessions per second.
udp_src_session	If the number of concurrent UDP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
udp_dst_session	If the number of concurrent UDP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
icmp_flood	If the number of ICMP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	250 packets per second.
icmp_sweep	If the ICMP sessions setup rate originating from one source IP address exceeds the configured threshold value, the action is executed.	100 sessions per second.
icmp_src_session	If the number of concurrent ICMP connections from one source IP address exceeds the configured threshold value, the action is executed.	300 concurrent sessions
icmp_dst_session	If the number of concurrent ICMP connections to one destination IP address exceeds the configured threshold value, the action is executed.	1000 concurrent sessions
ip_src_session	If the number of concurrent IP connections from one source IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
ip_dst_session	If the number of concurrent IP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions.
sctp_flood	If the number of SCTP packets sent to one destination IP address exceeds the configured threshold value, the action is executed.	2000 packets per second
sctp_scan	If the number of SCTP sessions originating from one source IP address exceeds the configured threshold value, the action is executed.	1000 packets per second
sctp_src_session	If the number of concurrent SCTP connections from one source	5000 concurrent sessions

Anomaly	Description	Recommended Threshold
sctp_dst_session	IP address exceeds the configured threshold value, the action is executed. If the number of concurrent SCTP connections to one destination IP address exceeds the configured threshold value, the action is executed.	5000 concurrent sessions

For thresholds based on the number of concurrent sessions, blocking the anomaly will not allow more than the number of concurrent sessions to be set as the threshold.

For example, if the period for a particular anomaly is 60 seconds, such as those where the threshold is measured in concurrent sessions, after the 60 second timer has expired the number of allowed sessions that match the anomaly criteria is reset to zero. This means that, if you allow 10 sessions through before blocking, after the 60 seconds has elapsed, another 10 sessions will be allowed. The attrition of sessions from expiration should keep the allowed sessions from reaching the maximum.

For rate based thresholds, where the threshold is measured in packets per second, the *Block* action prevents anomalous traffic from overwhelming the firewall in two ways:

- continuous: Block packets once an anomaly is detected, and continue to block packets while the rate is above the threshold. This is the default setting.
- periodical: After an anomaly is detected, allow the configured number of packets per second.

For example, if a DoS policy is configured to block icmp_flood with a threshold of 10pps, and a continuous ping is started at a rate of 20pps for 1000 packets:

- In continuous mode, the first 10 packets are passed before the DoS sensor is triggered, and then the remaining 990 packets are blocked.
- In periodical mode, 10 packets are allowed to pass per second, so 500 packets are blocked in the 50 seconds during which the ping is occurring.

The actual numbers of passed and blocked packets may not be exact, as fluctuations in the rates can occur, but the numbers should be close to the defined threshold.

To configure the block action for rate based anomaly sensors:

```
config ips global
    set anomaly-mode {continuous | periodical}
end
```

DoS policies

A DoS policy can be configured to use one or more anomalies.

To configure a DoS policy in the GUI:

1. Go to *Policy & Objects > IPv4 DoS Policy* or *Policy & Objects > IPv6 DoS Policy* and click *Create New*.
If the option is not visible, enable *DoS Policy* in *Feature Visibility*. See [Feature visibility on page 2292](#) for details.

2. Configure the following:

Name	Enter a name for the policy.
Incoming Interface	Enter the interface that the policy applies to.
Source Address	Enter the source address.
Destination Address	Enter the destination address. This is the address that the traffic is addressed to. In this case, it must be an address that is associated with the firewall interface. For example, it could be an interface address, a secondary IP address, or the address assigned to a VIP address.
Service	Select the services or service groups. The ALL service can be used or, to optimize the firewall resources, only the services that will be answered on an interface can be used.
L3 Anomalies L4 Anomalies	Configure the anomalies: <ul style="list-style-type: none"> • Logging: Enable/disable logging for specific anomalies or all of them. Anomalous traffic will be logged when the action is <i>Block</i> or <i>Monitor</i>. • Action: Select the action to take when the threshold is reached: <ul style="list-style-type: none"> • <i>Disable:</i> Do not scan for the anomaly. • <i>Block:</i> Block the anomalous traffic. • <i>Monitor:</i> Allow the anomalous traffic, but record a log message if logging is enabled. • Threshold: The number of detected instances that triggers the anomaly action.
Comments	Optionally, enter a comment.

3. Enable the policy, then click *OK*.

The quarantine option is only available in the CLI. See [Quarantine on page 904](#) for information.

To configure a DoS policy in the GUI:

```
config firewall DoS-policy
edit 1
    set name "Flood"
    set interface "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "ALL"
    config anomaly
        edit "icmp_flood"
            set status enable
            set log enable
            set action block
            set quarantine attacker
            set quarantine-expiry 1dlh1m
```

```

        set quarantine-log enable
        set threshold 100
    next
end
next
end

```

name <string>	Enter a name for the policy.
interface <string>	Enter the interface that the policy applies to.
srcaddr <string>	Enter the source address.
dstaddr <string>	Enter the destination address. This is the address that the traffic is addressed to. In this case, it must be an address that is associated with the firewall interface. For example, it could be an interface address, a secondary IP address, or the address assigned to a VIP address.
service <string>	Enter the services or service groups. The ALL service can used or, to optimize the firewall resources, only the services that will be answered on an interface can be used.
status {enable disable}	Enable/disable this anomaly.
log {enable disable}	Enable/disable anomaly logging. When enabled, a log is generated whenever the anomaly action is triggered, regardless of which action is configured.
action {pass block}	Set the action to take when the threshold is reached: <ul style="list-style-type: none"> pass: Allow traffic, but record a log message if logging is enabled. block: Block traffic if this anomaly is found.
quarantine {none attacker}	Set the quarantine method (see Quarantine on page 904): <ul style="list-style-type: none"> none: Disable quarantine. attacker: Block all traffic from the attacker's IP address, and add the attacker's IP address to the banned user list.
quarantine-expiry <###d##h##m>	Set the duration of the quarantine, in days, hours, and minutes (###d##h##m) (1m - 364d23h59m, default = 5m). This option is available if quarantine is set attacker.
quarantine-log {enable disable}	Enable/disable quarantine logging (default = disable). This option is available if quarantine is set attacker.
threshold <integer>	The number of detected instances - packets per second or concurrent session number - that triggers the anomaly action.

Quarantine

Quarantine is used to block any further traffic from a source IP address that is considered a malicious actor or a source of traffic that is dangerous to the network. Traffic from the source IP address is blocked for the duration of the quarantine, and the source IP address is added to the banned user list.

The banned user list is kept in the kernel, and used by Antivirus, Data Leak Prevention (DLP), DoS, and Intrusion Prevention System (IPS). Any policies that use any of these features will block traffic from the attacker's IP address.

To view the quarantined user list:

```
# diagnose user quarantine list
src-ip-addr      created                expires                cause
192.168.2.205    Wed Nov 25 12:47:54 2020 Wed Nov 25 12:57:54 2020 DOS
```

Troubleshooting DoS attacks

The best way to troubleshoot DoS attacks is with Anomaly logs and IPS anomaly debug messages.

**To test an icmp_flood attack:**

1. From the Attacker, launch an icmp_flood with 50pps lasting for 3000 packets.
2. On the FortiGate, configure continuous mode and create a DoS policy with an icmp_flood threshold of 30pps:

```
config firewall DoS-policy
  edit 1
    set name icmpFlood
    set interface "port1"
    set srcaddr "all"
    set dstaddr "all"
    set service "ALL"
    config anomaly
      edit "icmp_flood"
        set status enable
        set log enable
        set action block
        set threshold 30
      next
    end
  next
end
```

3. Configure the debugging filter:

```
# diagnose ips anomaly config
DoS sensors in kernel vd 0:
DoS id 1 proxy 0
 0 tcp_syn_flood status 0 log 0 nac 0 action 0 threshold 2000
...
 7 udp_dst_session status 0 log 0 nac 0 action 0 threshold 5000
 8 icmp_flood status 1 log 1 nac 0 action 7 threshold 30
 9 icmp_sweep status 0 log 0 nac 0 action 0 threshold 100
...
total # DoS sensors: 1.
```

```
# diagnose ips anomaly filter id 8
```

4. Launch the icmp_flood from a Linux machine. This example uses Nmap:

```
$ sudo nping --icmp --rate 50 -c 3000 192.168.2.50
SENT (0.0522s) ICMP [192.168.2.205 > 192.168.2.50 Echo request (type=8/code=0) id=8597
seq=1] IP [ttl=64 id=47459 iplen=28 ]
...
Max rtt: 11.096ms | Min rtt: 0.028ms | Avg rtt: 1.665ms
Raw packets sent: 3000 (84.000KB) | Rcvd: 30 (840B) | Lost: 2970 (99.00%)
Nping done: 1 IP address pinged in 60.35 seconds
```

5. During the attack, check the anomaly list on the FortiGate:

```
# diagnose ips anomaly list
list nids meter:
id=icmp_flood          ip=192.168.2.50 dos_id=1 exp=998 pps=46 freq=50

total # of nids meters: 1.
```

id=icmp_flood	The anomaly name.
ip=192.168.2.50	The IP address of the host that triggered the anomaly. It can be either the client or the server. For icmp_flood, the IP address is the destination IP address. For icmp_sweep, it would be the source IP address.
dos_id=1	The DoS policy ID.
exp=998	The time to be expired, in jiffies (one jiffy = 0.01 seconds).
pps=46	The number of packets that had been received when the diagnose command was executed.
freq=50	For session based anomalies, freq is the number of sessions. For packet rate based anomalies (flood, scan): <ul style="list-style-type: none"> In continuous mode: freq is the greater of pps, or the number of packets received in the last second. In periodic mode: freq is the pps.

6. Go to *Log & Report > Anomaly* and download the logs:

```
date=2020-11-20 time=14:38:39 eventtime=1605911919824184594 tz="-0800"
logid="0720018433" type="utm" subtype="anomaly" eventtype="anomaly" level="alert"
vd="root" severity="critical" srcip=192.168.2.205 srccountry="Reserved"
dstip=192.168.2.50 srcintf="port1" srcintfrole="undefined" sessionid=0 action="clear_
session" proto=1 service="PING" count=1307 attack="icmp_flood" icmpid="0x2195"
icmptype="0x08" icmpcode="0x00" attackid=16777316 policyid=1 policytype="DoS-policy"
ref="http://www.fortinet.com/ids/VID16777316" msg="anomaly: icmp_flood, 31 > threshold
30, repeats 28 times" crscore=50 craction=4096 crlevel="critical"

date=2020-11-20 time=14:39:09 eventtime=1605911949826224056 tz="-0800"
logid="0720018433" type="utm" subtype="anomaly" eventtype="anomaly" level="alert"
vd="root" severity="critical" srcip=192.168.2.205 srccountry="Reserved"
dstip=192.168.2.50 srcintf="port1" srcintfrole="undefined" sessionid=0 action="clear_
session" proto=1 service="PING" count=1497 attack="icmp_flood" icmpid="0x2195"
icmptype="0x08" icmpcode="0x00" attackid=16777316 policyid=1 policytype="DoS-policy"
```

```
ref="http://www.fortinet.com/ids/VID16777316" msg="anomaly: icmp_flood, 50 > threshold 30, repeats 1497 times" crscore=50 craction=4096 crlevel="critical"
```

Analysis

In the first log message:

msg="anomaly: icmp_flood, 31 > threshold 30	At the beginning of the attack, a log is recorded when the threshold of 30pps is broken.
repeats 28 times	The number of packets that has exceeded the threshold since the last time a log was recorded.
srcip=192.168.2.205 dstip=192.168.2.50	The source and destination IP addresses of the attack.
action="clear_session"	Equivalent to block. If action was set to monitor and logging was enabled, this would be action="detected".

In the second log message:

- Because it is an ongoing attack, the FortiGate generates one log message for multiple packets every 30 seconds..
- It will not generate a log message if:
 - The same attack ID happened more than once in a five second period, or
 - The same attack ID happened more than once in a 30 second period and the actions are the same and have the same source and destination IP addresses.

msg="anomaly: icmp_flood, 50 > threshold 30	In the second before the log was recorded, 50 packets were detected, exceeding the configured threshold.
repeats 1497 times	The number of packets that has exceeded the threshold since the last time a log was recorded

Access control lists

An access control list (ACL) is a granular, targeted blocklist that is used to block IPv4 and IPv6 packets on a specified interface based on the criteria configured in the ACL policy.

On FortiGate models with ports that are connected through an internal switch fabric with TCAM capabilities, ACL processing is offloaded to the switch fabric and does not use CPU resources. VLAN interfaces that are based on physical switch fabric interfaces are also supported. Interfaces that are connected through an internal switch fabric usually have names prefixed with *port* or *lan*, such as *port1* or *lan2*; other interfaces are not supported.

The packets will be processed by the CPU when offloading is disabled or not possible, such as when a port on a supported model does not connect to the internal fabric switch.

ACL is supported on the following FortiGate models:

- 100D, 100E, 100EF, 101E
- 140D, 140D-POE, 140E, 140E-POE
- 1200D, 1500D, 1500DT

- 3000D, 3100D, 3200D, 3700D, 3800D, 3810D, 3815D
- All 300E and larger E-series models
- All 100F and larger F-series models

Example

To block all IPv4 and IPv6 telnet traffic from port2 to Company_Servers:

```
config firewall acl
  edit 1
    set interface "port2"
    set srcaddr "all"
    set dstaddr "Company_Servers"
    set service "TELNET"
  next
end
config firewall acl6
  edit 1
    set interface "port2"
    set srcaddr "all"
    set dstaddr "Company_Servers_v6"
    set service "TELNET"
  next
end
```

Diagnose commands

To check the number of packets dropped by an ACL:

```
# diagnose firewall acl counter
ACL id 1 dropped 0 packets

# diagnose firewall acl counter6
ACL id 2 dropped 0 packets
```

To clear the packet drop counters:

```
# diagnose firewall acl clearcounter
# diagnose firewall acl clearcounter6
```

Mirroring SSL traffic in policies

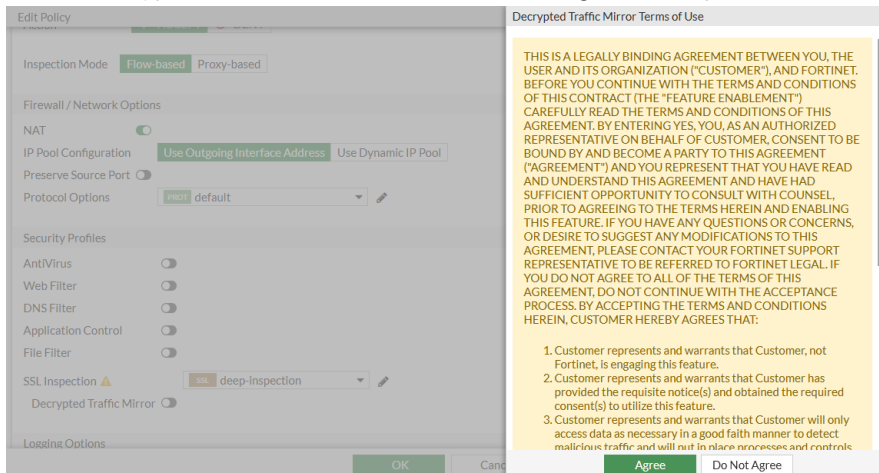

SSL mirroring allows the FortiGate to decrypt and mirror traffic to a designated port. A new decrypted traffic mirror profile can be applied to IPv4, IPv6, and explicit proxy firewall policies in both flow and proxy mode. Full SSL inspection must be used in the policy for the traffic mirroring to occur.

SSL inspection is automatically enabled when you enable a security profile on the policy configuration page.

To configure SSL mirroring in a policy in the GUI:

1. Go to *Policy & Objects > Firewall Policy*.
2. Create a new policy, or edit an existing one.
3. Configure the interfaces, sources, and other required information.
4. In the *Security Profiles* section, for *SSL Inspection*, select *deep-inspection*, or another profile that uses *Full SSL Inspection*.
5. Enable *Decrypted Traffic Mirror*. The terms of use agreement opens.

6. Click *Agree* to accept the terms.
7. In the drop-down list, select a decrypted traffic mirror, or click *Create* to create a new one. In this example, a new decrypted traffic mirror is created using the port3 interface.

8. Click *OK* to save the policy.

To configure SSL mirroring in proxy mode in the CLI:

1. Create the decrypted traffic mirror profile:

```
config firewall decrypted-traffic-mirror
  edit SSL-to-port3
    set dstmac ff:ff:ff:ff:ff:ff
    set traffic-type ssl
    set traffic-source client
    set interface port3
  next
end
```

2. Configure the policy to enable SSL traffic mirroring:

```
config firewall policy
  edit 1
    set name "mirror-policy"
    set srcintf "port1"
    set dstintf "port2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
    set ssl-ssh-profile "deep-inspection"
    set decrypted-traffic-mirror "SSL-to-port3"
```

THIS IS A LEGALLY BINDING AGREEMENT BETWEEN YOU, THE USER AND ITS ORGANIZATION ("CUSTOMER"), AND FORTINET. BEFORE YOU CONTINUE WITH THE TERMS AND CONDITIONS OF THIS CONTRACT (THE "FEATURE ENABLEMENT") CAREFULLY READ THE TERMS AND CONDITIONS OF THIS AGREEMENT. BY ENTERING YES, YOU, AS AN AUTHORIZED REPRESENTATIVE ON BEHALF OF CUSTOMER, CONSENT TO BE BOUND BY AND BECOME A PARTY TO THIS AGREEMENT ("AGREEMENT") AND YOU REPRESENT THAT YOU HAVE READ AND UNDERSTAND THIS AGREEMENT AND HAVE HAD SUFFICIENT OPPORTUNITY TO CONSULT WITH COUNSEL, PRIOR TO AGREEING TO THE TERMS HEREIN AND ENABLING THIS FEATURE. IF YOU HAVE ANY QUESTIONS OR CONCERNS, OR DESIRE TO SUGGEST ANY MODIFICATIONS TO THIS AGREEMENT, PLEASE CONTACT YOUR FORTINET SUPPORT REPRESENTATIVE TO BE REFERRED TO FORTINET LEGAL. IF YOU DO NOT AGREE TO ALL OF THE TERMS OF THIS AGREEMENT, DO NOT CONTINUE WITH THE ACCEPTANCE PROCESS. BY ACCEPTING THE TERMS AND CONDITIONS HEREIN, CUSTOMER HEREBY AGREES THAT:

1. Customer represents and warrants that Customer, not Fortinet, is engaging this feature.
2. Customer represents and warrants that Customer has provided the requisite notice(s) and obtained the required consent(s) to utilize this feature.
3. Customer represents and warrants that Customer will only access data as necessary in a good faith manner to detect malicious traffic and will put in place processes and controls to ensure this occurs.
4. Customer represents and warrants that Customer has the right to enable and utilize this feature, and Customer is fully in compliance with all applicable laws in so doing.

5. Customer shall indemnify Fortinet in full for any of the above certifications being untrue.

6. Customer shall promptly notify Fortinet Legal in writing of any breach of these Terms and Conditions and shall indemnify Fortinet in full for any failure by Customer or any of its employees or representatives to abide in full by the Terms and Conditions above.

7. Customer agrees that these Terms and Conditions shall be governed by the laws of the State of California, without regards to the choice of laws provisions thereof and Customer hereby agrees that any dispute related to these Terms and Conditions shall be resolved in Santa Clara County, California, USA, and Customer hereby consents to personal jurisdiction in Santa Clara County, California, USA.

Inspection mode per policy

Inspection mode is configured on a per-policy basis in NGFW mode. This gives you more flexibility when setting up different policies.

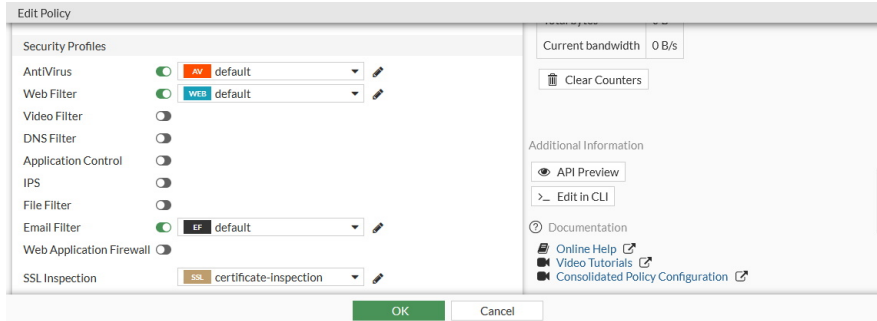

When configuring a firewall policy, you can select a *Flow-based* or *Proxy-based* Inspection Mode. The default setting is *Flow-based*.

To configure inspection mode in a policy:

1. Go to *Policy & Objects > Firewall Policy*.
2. Create a new policy, or edit an existing policy.
3. Configure the policy as needed.
 - a. If you change the *Inspection Mode* to *Proxy-based*, the *Proxy HTTP(S) traffic* option displays.

- b. In the *Security Profiles* section, if no security profiles are enabled, the default *SSL Inspection* is *no-inspection*.
- c. In the *Security Profiles* section, if you enable any security profile, the *SSL Inspection* changes to *certificate-inspection*.

To see the inspection mode changes using the CLI:

```
config firewall policy
  edit 1
    set srcintf "wan2"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set inspection-mode proxy
    set nat enable
  next
end
```

To see the HTTP and SSH policy redirect settings when inspection mode is set to proxy using the CLI:

```
config firewall policy
  edit 1
    set srcintf "wan2"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set inspection-mode proxy
    set http-policy-redirect enable
    set ssh-policy-redirect enable
    set nat enable
  next
end
```

To see the default SSL-SSH policy set to no inspection using the CLI:

```
config firewall policy
  edit 1
    show fu | grep ssl-ssh-profile
    set ssl-ssh-profile "no-inspection"
  next
end
```

OSPFv3 neighbor authentication

OSPFv3 neighbor authentication is available for enhanced IPv6 security.

To configure an OSPF6 interface:

```
config router ospf6
  config ospf6-interface
    edit <name>
      set authentication {none | ah | esp | area}
      set key-rollover-interval <integer>
      set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
      set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
      config ipsec-keys
        edit <spi>
          set auth-key <string>
          set enc-key <string>
        next
      end
    next
  end
end
```

To configure an OSPF6 virtual link:

```
config router ospf6
  config area
    edit <id>
      config virtual-link
        edit <name>
          set authentication {none | ah | esp | area}
          set key-rollover-interval <integer>
          set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
          set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
          config ipsec-keys
            edit <spi>
              set auth-key <string>
              set enc-key <string>
            next
          end
        next
      end
    next
  end
end
```

To configure an OSPF6 area:

```
config router ospf6
  config area
    edit <id>
      set authentication {none | ah | esp}
      set key-rollover-interval <integer>
      set ipsec-auth-alg {md5 | sha1 | sha256 | sha384 | sha512}
      set ipsec-enc-alg {null | des | 3des | aes128 | aes192 | aes256}
    end
  end
end
```

```

        config ipsec-keys
            edit <spi>
                set auth-key <string>
                set enc-key <string>
            next
        end
    next
end
end
end

```

CLI command descriptions

Command	Description
<id>	Area entry IP address.
authentication {none ah esp area}	Authentication mode: <ul style="list-style-type: none"> • none: Disable authentication • ah: Authentication Header • esp: Encapsulating Security Payload • area: Use the routing area authentication configuration
key-rollover-interval <integer>	Enter an integer value (300 - 216000, default = 300).
ipsec-auth-alg {md5 sha1 sha256 sha384 sha512}	Authentication algorithm.
ipsec-enc-alg {null des 3des aes128 aes192 aes256}	Encryption algorithm.
<spi>	Security Parameters Index.
auth-key <string>	Authentication key should be hexadecimal numbers. Key length for each algorithm: <ul style="list-style-type: none"> • MD5: 16 bytes • SHA1: 20 bytes • SHA256: 32 bytes • SHA384: 48 bytes • SHA512: 84 bytes If the key is shorter than the required length, it will be padded with zeroes.
enc-key <string>	Encryption key should be hexadecimal numbers. Key length for each algorithm: <ul style="list-style-type: none"> • DES: 8 bytes • 3DES: 24 bytes • AES128: 16 bytes • AES192: 24 bytes • AES256: 32 bytes If the key is shorter than the required length, it will be padded with zeroes.

Firewall anti-replay option per policy

When the global anti-replay option is disabled, the FortiGate does not check TCP flags in packets. The per policy anti-replay option overrides the global setting. This allows you to control whether or not TCP flags are checked per policy.

To enable the anti-replay option so TCP flags are checked using the CLI:

```
config firewall policy
  edit 1
    set name "policyid-1"
    set srcintf "wan2"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set anti-replay enable
    set logtraffic all
    set nat enable
  next
end
```

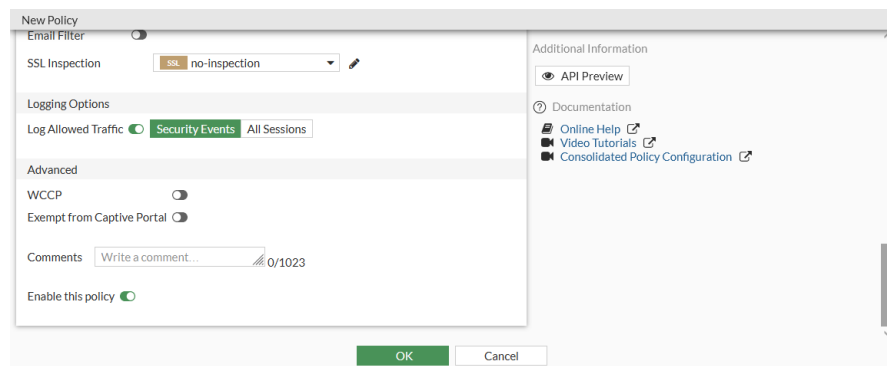

Enabling advanced policy options in the GUI

Advanced policy options can be enabled so that you can configure the options in the GUI.

To enable advanced policy options:

```
config system settings
  set gui-advanced-policy enable
end
```

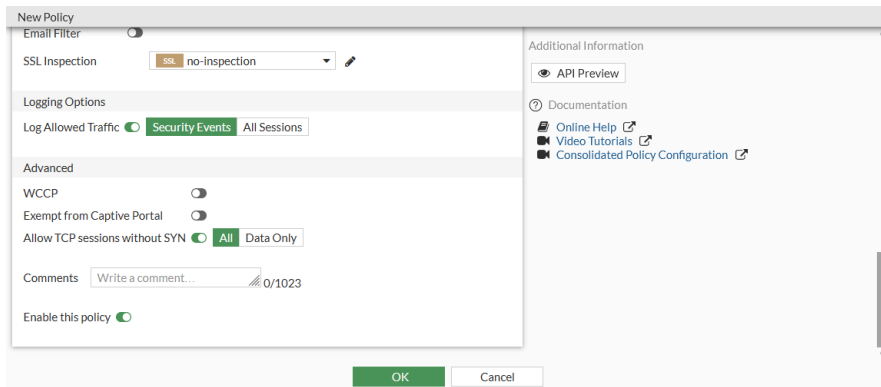

Advanced policy options are now available when creating or editing a policy in the GUI:

To enable configuring TCP sessions without SYN:

```
config system settings
  set tcp-session-without-syn enable
end
```

TCP sessions without SYN can now be configured when creating or editing a policy in the GUI:

Recognize anycast addresses in geo-IP blocking

An anycast IP can be advertised from multiple locations and the router selects a path based on latency, distance, cost, number of hops, and so on. This technique is widely used by providers to route users to the closest server. Since the IP is hosted in multiple geographic locations, there is no way to specify one single location to that IP.

Anycast IP address ranges can be bypassed in geo-IP blocking. The ISDB contains a list of confirmed anycast IP ranges that can be used for this purpose.

When the source or destination is set to `geoip`, you can enable the `geoip-anycast` option. Once enabled, IPs where the anycast option is set to 1 in `geoip_db` are bypassed in country matching and blocking.

You can only use the CLI to configure this feature.

To enable the `geoip-anycast` option using the CLI:

```
config firewall policy
  edit 1
    set name "policyid-1"
    set srcintf "wan2"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "test-geoip-CA_1"
    set action accept
    set schedule "always"
    set service "ALL"
    set geoip-anycast enable
    set logtraffic all
    set nat enable
  next
end
```

To check the `geoip-anycast` option for an IP address using the CLI:

```
diagnose geoip ip2country 1.0.0.1
```

1.0.0.1 - Australia, is anycast ip

The anycast IP is 1.0.0.1.

Matching GeoIP by registered and physical location

IP addresses have both a physical and registered location in the geography IP database. Sometimes these two locations are different. The `geoip-match` command allows users to match an IPv4 address in an firewall policy to its physical or registered location when a GeoIP is used as a source or destination address. IPv6 policies currently support geography address objects but do not support `geoip-match`.

In the following example, the physical location of 220.243.219.10 is CA (Canada), the registered location is CN (China), and it is not an anycast IP.

To configure GeoIP matching based on registered location:

1. Create a firewall policy to match the IP:

```
config firewall policy
  edit 1
    set name "policy_id_1"
    set srcintf "wan2"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "test-geoip-CA"
    set action accept
    set schedule "always"
    set service "ALL"
    set geoip-match registered-location
    set logtraffic all
    set auto-asic-offload disable
    set nat enable
  next
end
```

Since CA is applied as a destination address and registered location IP matching is enabled, if the destination IP of the traffic is 220.243.219.10, then the traffic will be blocked because the registered location is CN.

2. Verify that the policy is blocking traffic from the IP address:

```
# diagnose sniffer packet any icmp 4
interfaces=[any]
filters=[icmp]
5.383798 wan2 in 10.1.100.41 -> 220.243.219.10: icmp: echo request
6.381982 wan2 in 10.1.100.41 -> 220.243.219.10: icmp: echo request
7.382608 wan2 in 10.1.100.41 -> 220.243.219.10: icmp: echo request
^C
3 packets received by filter
0 packets dropped by kernel
```

To configure GeoIP matching based on physical location:

1. Create a firewall policy to match the IP:

```
config firewall policy
  edit 1
```

```

set name "policy_id_1"
set srcintf "wan2"
set dstintf "wan1"
set srcaddr "all"
set dstaddr "test-geosp-CA"
set action accept
set schedule "always"
set service "ALL"
set geosp-match physical-location
set logtraffic all
set auto-asic-offload disable
set nat enable
next
end

```

Since CA is applied as a destination address and physical location IP matching is enabled, if the destination IP of the traffic is 220.243.219.10, then the traffic will pass through.

2. Verify that the policy is allowing traffic from the IP address:

```

# diagnose sniffer packet any icmp 4
interfaces=[any]
filters=[icmp]
5.273985 wan2 in 10.1.100.41 -> 220.243.219.10: icmp: echo request
5.274176 wan1 out 172.16.200.10 -> 220.243.219.10: icmp: echo request

```

Authentication policy extensions

By default, unauthenticated traffic is permitted to fall to the next policy. This means that unauthenticated users are only forced to authenticate against a policy when there are no other matching policies. To avoid this, you can force authentication to always take place.

To set that authentication requirement:

```

config user setting
    set auth-on-demand {always | implicitly}
end

```

Where:

always	Always trigger firewall authentication on demand.
implicitly (default)	Implicitly trigger firewall authentication on demand. This is the default setting (and the behavior in FortiOS 6.0 and earlier).

In the following example, authentication is required; traffic that would otherwise be allowed by the second policy is instead blocked by the first policy.

To use forced authentication:

```
config user setting
    set auth-on-demand always
end

config firewall policy
    edit 1
        set name "QA to Database"
        set srcintf "port10"
        set dstintf "port9"
        set srcaddr "QA_subnet"
        set dstaddr "Database"
        set action accept
        set schedule "always"
        set service "ALL"
        set fsso disable
        set groups "qa_group"
        set nat enable
    next
    edit 2
        set name "QA to Internet"
        set srcintf "port10"
        set dstintf "port9"
        set srcaddr "QA_subnet"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "ALL"
        set fsso disable
        set nat enable
    next
end
```

HTTP to HTTPS redirect for load balancing

You can configure a virtual server with HTTP to HTTPS redirect enabled. When enabled, a virtual server can convert a client's HTTP requests to HTTPS requests. Through this mandatory conversion, HTTP traffic is converted to HTTPS traffic. This conversion improves the security of the user network.

You can only enable this feature by using the CLI. After you enable this feature, traffic flows as follows:

- When FortiGate receives an HTTP request for an external IP, such as 10.1.100.201 in the following example, FortiGate sends an HTTP 303 response back to the original client and redirects HTTP to HTTPS, instead of forwarding the HTTP request to the real backend servers.
- The client browser restarts the TCP session to HTTPS.
- The HTTPS session comes to the FortiGate where a matching firewall policy allows the HTTPS traffic and establishes a secure SSL connection, and then forwards the request to the real backend servers.

To configure virtual server with HTTPS redirect enabled:

1. Create a virtual server with `server-type` set to `http`:

```
config firewall vip
    edit "virtual-server-http"
        set type server-load-balance
```

```
set extip 10.1.100.201
set extintf "wan2"
set server-type http
set ldb-method round-robin
set extport 80
config realservers
  edit 1
    set ip 172.16.200.44
    set port 80
  next
  edit 2
    set ip 172.16.200.55
    set port 80
  next
end
next
end
```

2. Create a virtual server with `server-type` set to `https` and with the same external IP address:

```
config firewall vip
  edit "virtual-server-https"
    set type server-load-balance
    set extip 10.1.100.201
    set extintf "wan2"
    set server-type https
    set ldb-method round-robin
    set extport 443
    config realservers
      edit 1 set ip 172.16.200.44
      set port 443
    next
    edit 2
      set ip 172.16.200.55
      set port 443
    next
  end
  set ssl-certificate "Fortinet_CA_SSL"
next
end
```

3. Enable the `http-redirect` option for the virtual server with `server-type` set to `http`:

```
config firewall vip
  edit "virtual-server-http"
    set http-redirect enable
  next
end
```

4. Add the two virtual servers to a policy:

```
config firewall policy
  edit 9
    set srcintf "wan2"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "virtual-server-http" "virtual-server-https"
    set action accept
    set schedule "always"
    set service "ALL"
    set inspection-mode proxy set logtraffic all
    set auto-asic-offload disable
```

```
set nat enable
next
end
```

Use Active Directory objects directly in policies

Active Directory (AD) groups can be used directly in identity-based firewall policies. You do not need to add remote AD groups to local FSSO groups before using them in policies.

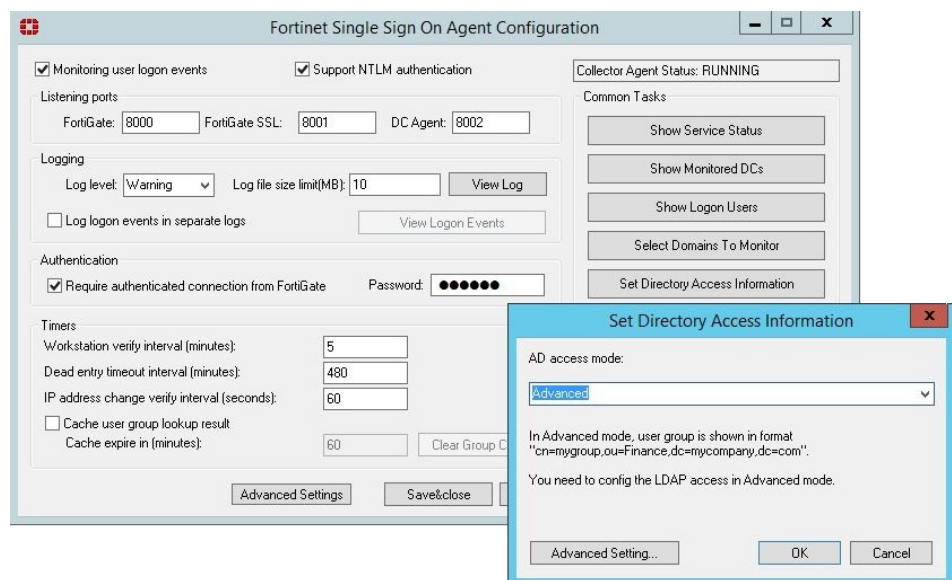

FortiGate administrators can define how often group information is updated from AD LDAP servers.

To retrieve and use AD user groups in policies:

1. [Set the FSSO Collector Agent AD access mode on page 921](#)
2. [Add an LDAP server on page 922](#)
3. [Create the FSSO collector that updates the AD user groups list on page 923](#)
4. [Use the AD user groups in a policy on page 924](#)

Set the FSSO Collector Agent AD access mode

To use this feature, you must set FSSO Collector Agent to *Advanced* AD access mode. If the FSSO Collector Agent is running in the default mode, FortiGate cannot correctly match user group memberships.

Add an LDAP server

When configuring an LDAP connection to an Active Directory server, an administrator must provide Active Directory user credentials.

- To secure this connection, use LDAPS on both the Active Directory server and FortiGate. See [Configuring an LDAP server on page 1923](#).
- Apply the principle of least privilege. For the LDAP regular bind operation, do not use credentials that provide full administrative access to the Windows server when using credentials. See [Configuring least privileges for LDAP admin account authentication in Active Directory on page 1930](#).

To add an LDAP server in the GUI:

1. Go to *User & Authentication > LDAP Servers*.
2. Click *Create New*.
3. Configure the settings as needed.

4. If secure communication over TLS is supported by the remote AD LDAP server:
 - a. Enable *Secure Connection*.
 - b. Select the protocol.
 - c. Select the certificate from the CA that issued the AD LDAP server certificate.
If the protocol is LDAPS, the port will automatically change to 636.
5. Click *OK*.

To add an LDAP server in the CLI:

```
config user ldap
edit "AD-ldap"
set server "10.1.100.131"
set cnid "cn"
set dn "dc=fortinet-fsso,dc=com"
set type regular
set username "cn=Administrator,cn=users,dc=fortinet-fsso,dc=com"
set password XXXXXXXXXXXXXXXXXXXXXXXXXXXX
next
end
```

Create the FSSO collector that updates the AD user groups list

To create an FSSO agent connector in the GUI:

1. Go to *Security Fabric > External Connectors*.
2. Click *Create New*.
3. In the *Endpoint/Identity* section, click *FSSO Agent on Windows AD*.
4. Fill in the *Name*
5. Set the *Primary FSSO Agent* to the IP address of the FSSO Collector Agent, and enter its password.
6. Set the *User Group Source* to *Local*.
7. Set the *LDAP Server* to the just created *AD-Idap* server.
8. Enable *Proactively Retrieve from LDAP Server*.
9. Set the *Search Filter* to *(&(objectClass=group)(cn=group*))*.
The default search filter retrieves all groups, including Microsoft system groups. In this example, the filter is configured to retrieve *group1*, *group2*, etc, and not groups like *grp199*.
The filter syntax is not automatically checked; if it is incorrect, the FortiGate might not retrieve any groups.
10. Set the *Interval (minutes)* to configure how often the FortiGate contacts the remote AD LDAP server to update the group information.

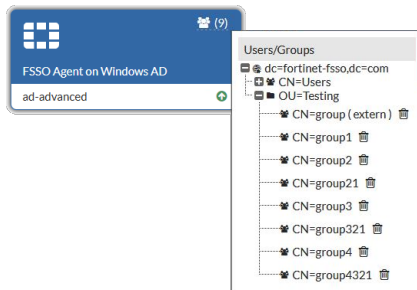

The screenshot shows the 'New External Connector' configuration window. The 'Endpoint/Identity' section is set to 'FSSO Agent on Windows AD'. The 'Connector Settings' section includes the following fields:

- Name: ad-advanced
- Primary FSSO agent: 10.1.100.131
- Trusted SSL certificate: Disabled
- User group source: Collector Agent Local
- LDAP server: AD-Idap
- Proactively retrieve from LDAP server: Enabled
- Search filter: (&(objectClass=group)(cn=group*))
- Interval (minutes): 2

At the bottom, there are three buttons: 'Apply & Refresh', 'OK', and 'Cancel'. A yellow warning message states: 'Currently configured FSSO groups will be removed after changes are applied.' A blue information message states: 'FSSO groups will be populated in the background.'

11. Click *OK*.
12. To view the AD user groups that are retrieved by the FSSO agent, hover the cursor over the group icon on the fabric

connector listing.

To create an FSSO agent connector in the CLI:

```
config user fsso
  edit "ad-advanced"
    set server "10.1.100.131"
    set password XXXXXXXXXXXXXXXX
    set ldap-server "AD-ldap"
    set ldap-poll enable
    set ldap-poll-interval 2
    set ldap-poll-filter "( & (objectClass=group) (cn=group*) )"
  next
end
```

You can view the retrieved AD user groups with the `show user adgrp` command.

Use the AD user groups in a policy

The AD user groups retrieved by the FortiGate can be used directly in firewall policies.

FortiGate Cloud / FDN communication through an explicit proxy

Explicit proxy communication to FortiGate Cloud and FortiGuard servers from FortiGate is enabled. A proxy server can be configured in the FortiGuard settings so that all FortiGuard connections under the `forticldd` process can be established through the proxy server.

Not all FortiGuard services are supported by these proxy settings. For example, web filter service traffic to FortiGuard will not be directed to the configured proxy.

To configure a proxy server and communicate with FortiGate Cloud through it:

1. Configure FortiGate B as a proxy server:

```

config firewall proxy-policy
  edit 1
    set proxy explicit-web
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set service "webproxy"
    set action accept
    set schedule "always"
    set logtraffic all
    set users "guest1"
  next
end
config user local
  edit "guest1"
    set type password
    set passwd 123456
  next
end
config authentication scheme
  edit "local-basic"
    set method basic
    set user-database "local-user-db"
  next
end
config authentication rule
  edit "local-basic-rule"
    set srcaddr "all"
    set ip-based disable
    set active-auth-method "local-basic"
  next
end
  
```

2. Configure a firewall policy on FortiGate B to allow FortiGate A to get DNS resolution:

```
config firewall policy
  edit 1
    set name "dns"
    set srcintf "port18"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "DNS"
    set fsso disable
    set nat enable
  next
end
```

3. Configure the FortiGuard proxy settings on FortiGate A:

```
config system fortiguard
  set proxy-server-ip 10.2.2.2
  set proxy-server-port 8080
  set proxy-username "guest1"
  set proxy-password 123456
end
```

4. On FortiGate A, log in to FortiGate Cloud to activate the logging service:

```
execute fortiguard-log login <username> <password>
```

5. On FortiGate A, view the `forticldd` debug message to see the connection to the log controller through the proxy server:

```
# diagnose test application forticldd 1
```

No session timeout

To allow clients to permanently connect with legacy medical applications and systems that do not have keepalive or auto-reconnect features, the session timeout can be set to never for firewall services, policies, and VDOMs.

The options to disable session timeout are hidden in the CLI.

To set the session TTL value of a custom service to never:

```
config firewall service custom
  edit "tcp_23"
    set tcp-portrange 23
    set session-ttl never
  next
end
```

To set the session TTL value of a policy to never:

```
config firewall policy
  edit 201
    set srcintf "wan1"
    set dstintf "wan2"
```

```
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set service "TCP_8080"
        set logtraffic disable
        set session-ttl never
        set nat enable
    next
end
```

To set the session TTL value of a VDOM to never:

```
config system session-ttl
    set default never
config port
    edit 1
        set protocol 6
        set timeout never
        set start-port 8080
        set end-port 8080
    next
end
end
```

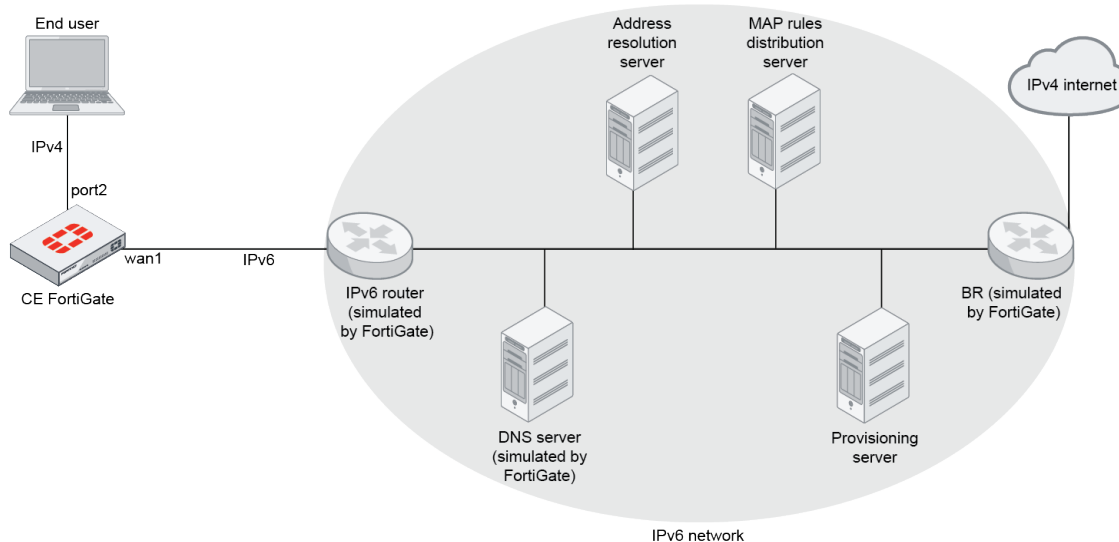

To view a session list with the timeout set to never:

```
# diagnose sys session list

session info: proto=6 proto_state=01 duration=9 expire=never timeout=never flags=00000000
sockflag=00000000 sockport=0 av_idx=0 use=3

npu_state=0x000001 no_offload
no_ofld_reason: disabled-by-policy
total session 1
```

MAP-E support

On a customer edge (CE) FortiGate, an IPv4-over-IPv6 (MAP-E) tunnel can be created between the FortiGate and the border relay (BR) operating in an IPv6 network. A tunnel interface is created between the FortiGate and BR, which can be applied to firewall policies and IPsec VPN.

To configure a MAP-E tunnel between the FortiGate and the BR:

1. Configure fixed IP mode.

a. Configure IPv6 on the interface:

```
config system interface
  edit "wan1"
    config ipv6
      set autoconf enable
      set unique-autoconf-addr enable
      set interface-identifier ::6f:6clf:3400:0
    end
  next
end
```

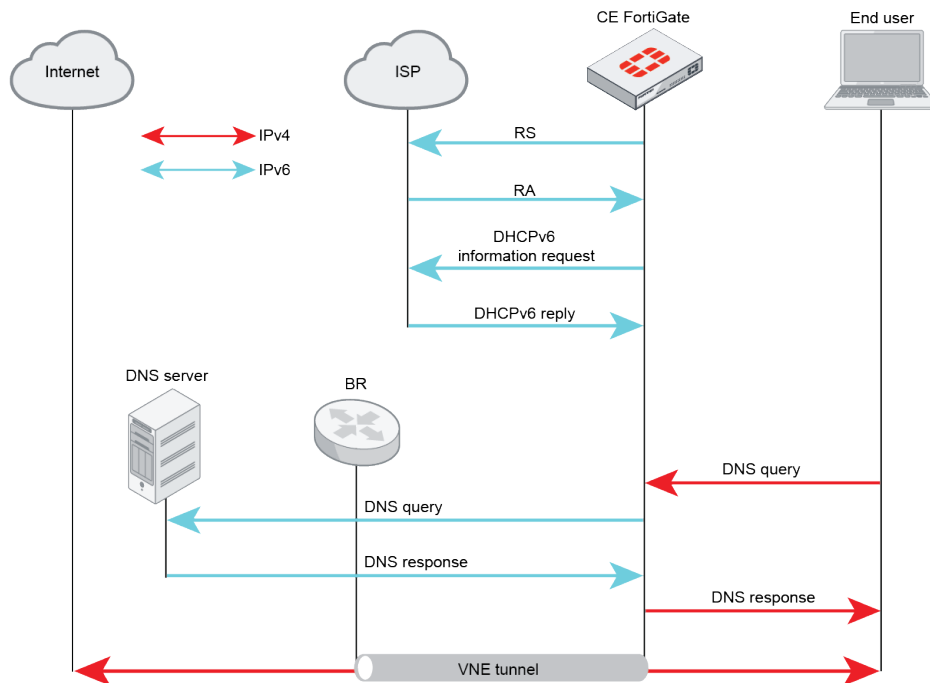

The `interface-identifier` is an IPv6 address. Its last 64-bit will be kept and the rest will be cleared automatically. It will combine with the IPv6 prefix it gets from the IPv6 router to generate the IPv6 address of the interface.

By default, `unique-autoconf-addr` is disabled. It must be enabled so it can handle IPv6 prefix changing.

b. Configure the VNE tunnel:

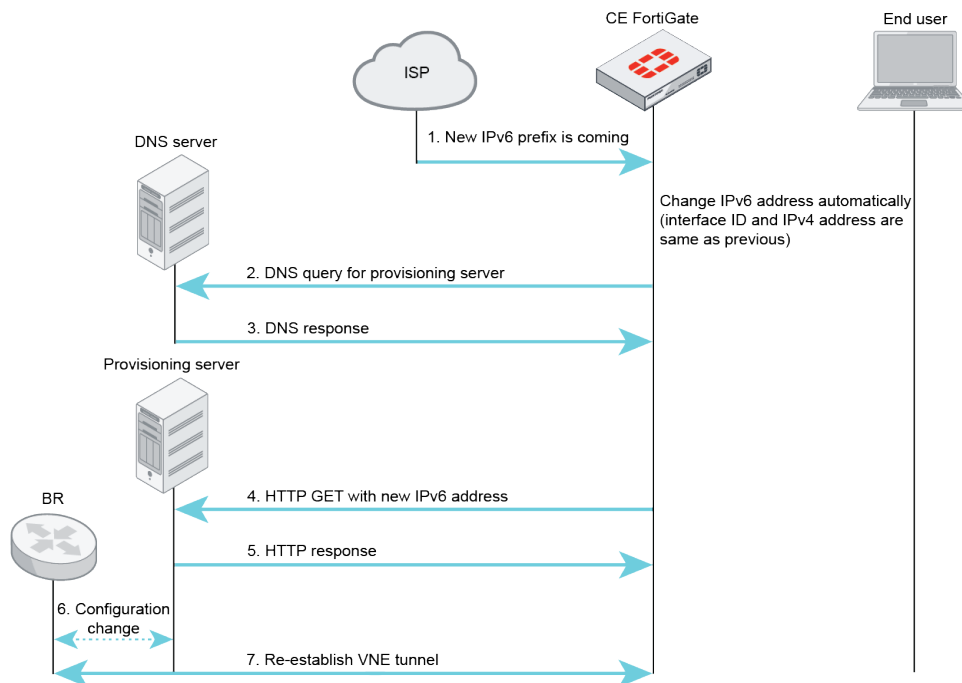

```
config system vne-tunnel
  set status enable
  set interface "wan1"
  set mode fixed-ip
  set ipv4-address 10.10.81.81 255.255.255.0
  set br 2001:160::82
  set update-url "http://qa.forosqa.com/update?user=xxxx&pass=yyyy"
end
```

Initial sequence overview of VNE tunnel under fixed IP mode:

Once the IPv6 address of the FortiGate changes, the tunnel will be down because the BR does not know the FortiGate's new IPv6 address. The FortiGate uses `update-url` to update the new IPv6 address to the provisioning server. The provisioning server updates the FortiGate's IPv6 address to the BR so the VNE tunnel can be re-established.

Communication sequence overview of re-establishing VNE tunnel:

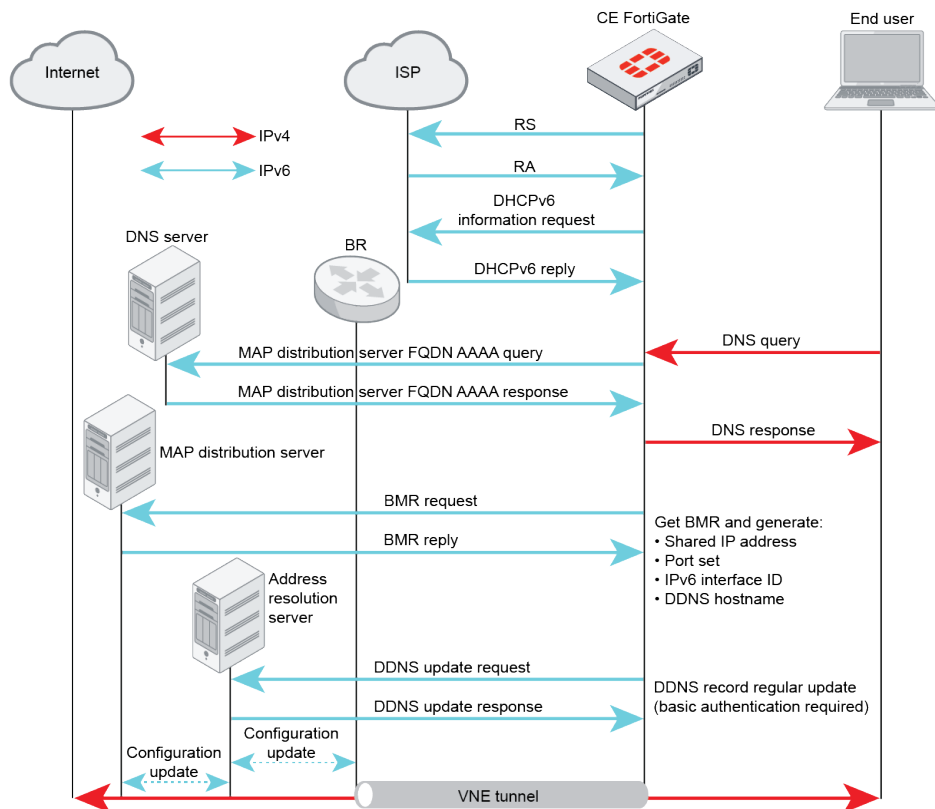

2. Configure the VNE tunnel to use MAP-E mode:

```

config system vne-tunnel
  set status enable
  set interface 'wan1'
  set ssl-certificate "Fortinet_Factory"
  set bmr-hostname *****
  set auto-asic-offload enable
  set mode map-e
end
    
```

Initial sequence overview of VNE tunnel under MAP-E mode:

The FortiGate sends a MAP rule request to the MAP distribution server once the IPv6 address is configured on the FortiGate by RS/RA. Next, the FortiGate will send an AAAA query to get the IPv6 address of the MAP distribution server. After sending the BMR request to the MAP distribution server, the FortiGate will get the IPv4 address, port set, BR IPv6 address, and hostname of the address resolution server from the BMR reply. The VNE tunnel between the FortiGate and BR is now established.

The address resolution server is actually a dynamic DNS. The hostname is used for the FortiGate to maintain an IPv6 address when it changes.

The FortiGate updates the DDNS server with its IPv6 address whenever it updates, which in turn provides the update to the MAP distribution server and BR so they know how to resolve the FortiGate by hostname.

Once the VNE tunnel is established, a tunnel interface is created (`vne.root`), and an IPv4-over-IPv6 tunnel is set up between the FortiGate and BR. The route, firewall policy, and DNS server can now be configured to let the traffic go through the VNE tunnel and then protect the end-user. The VNE tunnel can also be used in IPsec phase 1.

3. Configure the route:

```
config router static
  edit 1
    set device "vne.root"
  next
end
```

4. Configure the firewall policy:

```
config firewall policy
  edit 111
    set name "ff"
    set srcintf "port2"
    set dstintf "vne.root"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set utm-status enable
    set ssl-ssh-profile "certificate-inspection"
    set av-profile "default"
    set nat enable
  next
end
```

5. Configure the DNS server:

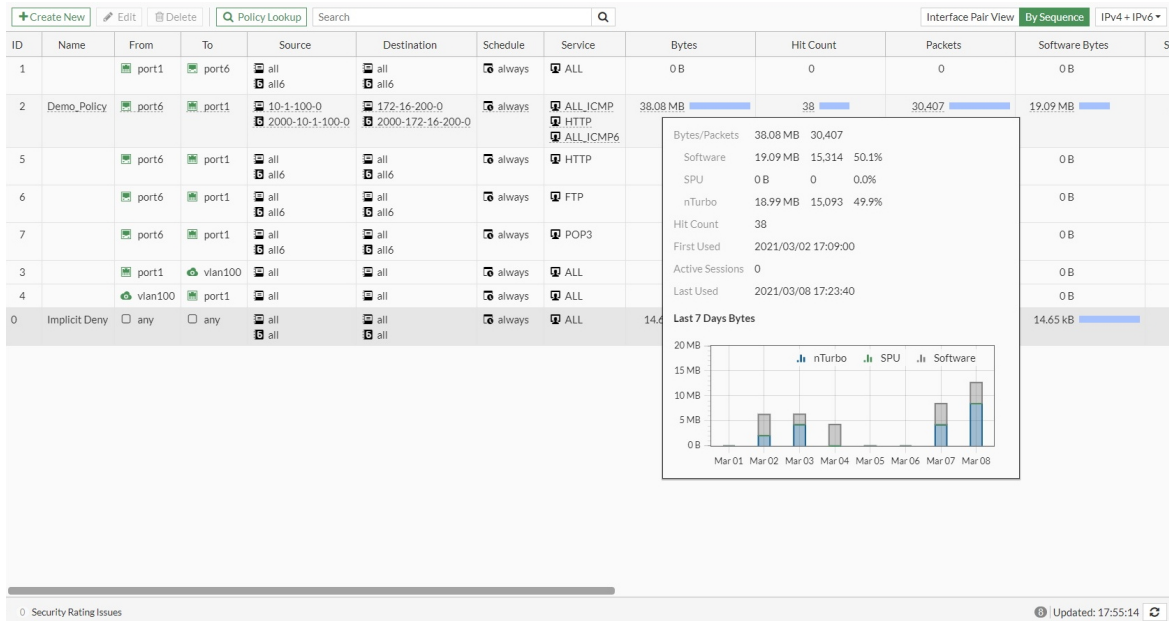

```
config system dns-server
  edit "port2"
  next
end
```

Seven-day rolling counter for policy hit counters

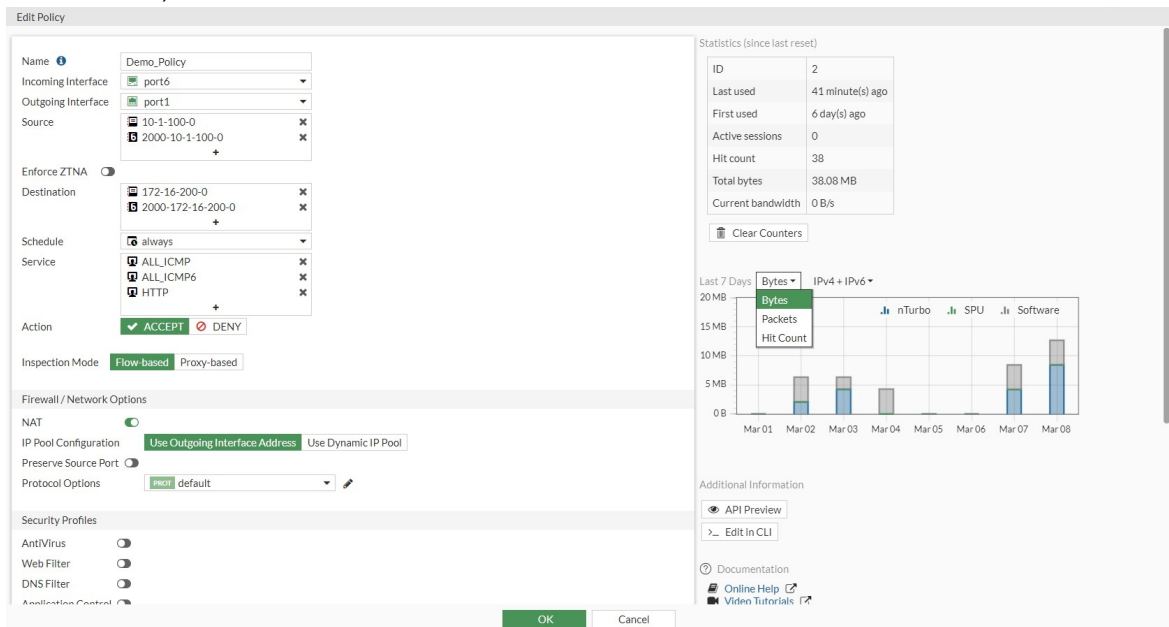

Instead of storing a single number for the hit count and byte count collected since the inception of each policy, seven numbers for the last seven days and an active counter for the current day are stored. The past seven-day hit count is displayed in the policy list and policy pages. A seven-day bar chart shows statistics on each policy page. This feature is currently supported in firewall and multicast policies, but not security policies.

To view the rolling counter information in the GUI:

1. Go to *Policy & Objects > Firewall Policy* or *Policy & Objects > Multicast Policy*.
2. Select a policy and hover over the *Bytes*, *Packets*, or *Hit Count* values to view the tooltip with the corresponding traffic statistics and bar graph (this example uses firewall policies).

- Click *Edit*. The policy traffic statistics appear in the right-hand side of the page.
- Use the dropdowns to filter the bar graph data by counter (*Bytes*, *Packets*, or *Hit Count*) and policy type (*IPv4*, *IPv6*, or *IPv4 + IPv6*).

- Optionally, click *Clear Counters* to delete the traffic statistics for the policy.
- Click *OK*.

To view the rolling counter information in the CLI:

```
# diagnose firewall iprope show 100004 2
idx=2 pkts/bytes=14709/18777329 asic_pkts/asic_bytes=8087/10413737 nturbo_pkts/nturbo_

idx=2 pkts/bytes=15698/19307164 asic_pkts/asic_bytes=7006/8578911 nturbo_pkts/nturbo_
bytes=7006/8578911 flag=0x0 hit count:19 (4 7 0 1 3 2 2 0)
  first:2021-03-02 17:10:32 last:2021-03-08 17:23:33
established session count:0
  first est:2021-03-02 17:11:43 last est:2021-03-08 17:23:33
  
```

Cisco Security Group Tag as policy matching criteria

The FortiGate can read the Cisco Security Group Tag (SGT) in Ethernet frames, and use them as matching criteria in firewall policies. A policy can match based on the presence of an SGT, or the detection of a specific ID or IDs.

When a packet with a SGT passes through and a session is established, the `ext_header_type=0xc5:0xc5` flag is included in the session table.

This feature is available in flow mode policies for virtual wire pair policies or policies in transparent mode VDOMs.

Ethernet frames with both Cisco Security Group Tags and VLAN tags are supported in 7.4.0 and later.

To configure a firewall policy to detect SGTs in Ethernet frames:

```

config firewall policy
  edit 1
    set sgt-check {enable | disable}
    set sgt <ID numbers>
  next
end
  
```

Examples

In these examples, port2 and port5 are in a virtual wire pair. Firewall policies are created that pass traffic with SGTs with a specific ID number, any ID number, or either of two specific ID numbers.

To configure the virtual wire pair:

```

config system virtual-wire-pair
  edit "test-vwp-1"
    set member "port5" "port2"
    set wildcard-vlan enable
  
```

```
    next
end
```

To configure a firewall policy to match frames that have an SGT with ID 20 and allow them through:

```
config firewall policy
  edit 1
    set srcintf "port2"
    set dstintf "port5"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set schedule "always"
    set service "ALL"
    set sgt-check enable
    set sgt 20
  next
end
```

To configure a firewall policy to match frames that have an SGT with any ID:

```
config firewall policy
  edit 1
    set srcintf "port2"
    set dstintf "port5"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set schedule "always"
    set service "ALL"
    set sgt-check enable
  next
end
```

To configure a firewall policy to match frames that have the SGT with IDs 20 or 21:

```
config firewall policy
  edit 1
    set srcintf "port2"
    set dstintf "port5"
    set action accept
    set srcaddr "all"
    set dstaddr "all"
    set schedule "always"
    set service "ALL"
    set sgt-check enable
    set sgt 20 21
  next
end
```

To check the session list:

```
# diagnose sys session list

session info: proto=6 proto_state=01 duration=10 expire=3593 timeout=3600 flags=00000000
```

```

```

NAT46 and NAT64 policy and routing configurations

Multiple NAT46 and NAT64 related objects are consolidated into regular objects. A per-VDOM virtual interface, `naf.<vdom>`, is automatically added to process NAT46/NAT64 traffic. The features include:

- `vip46` and `vip64` settings are consolidated in `vip` and `vip6` configurations.
- `policy46` and `policy64` settings are consolidated in `firewall policy` settings.
- `nat46/nat64` are included in `firewall policy` settings.
- `ippool` and `ippool6` support NAT46 and NAT64 (when enabled, the IP pool should match a subnet).
- Central SNAT supports NAT46 and NAT64.
- `add-nat46-route` in `ippool6` and `add-nat64-route` in `ippool` are enabled by default. The FortiGate generates a static route that matches the IP range in `ippool6` or `ippool` for the `naf` tunnel interface.

Automatic processing of the `naf` tunnel interface is not supported in security policies.

To configure NAT46/NAT64 translation, use the standard `vip/vip6` setting, apply it in a firewall policy, enable NAT46/NAT64, and enter the IP pool to complete the configuration.

The external IP address cannot be the same as the external interface IP address.

Examples

IPv6 must be enabled to configure these examples. In the GUI, so go to *System > Feature Visibility* and enable *IPv6*. In the CLI, enter the following:

```
config system global
    set gui-ipv6 enable
end
```

NAT46 policy

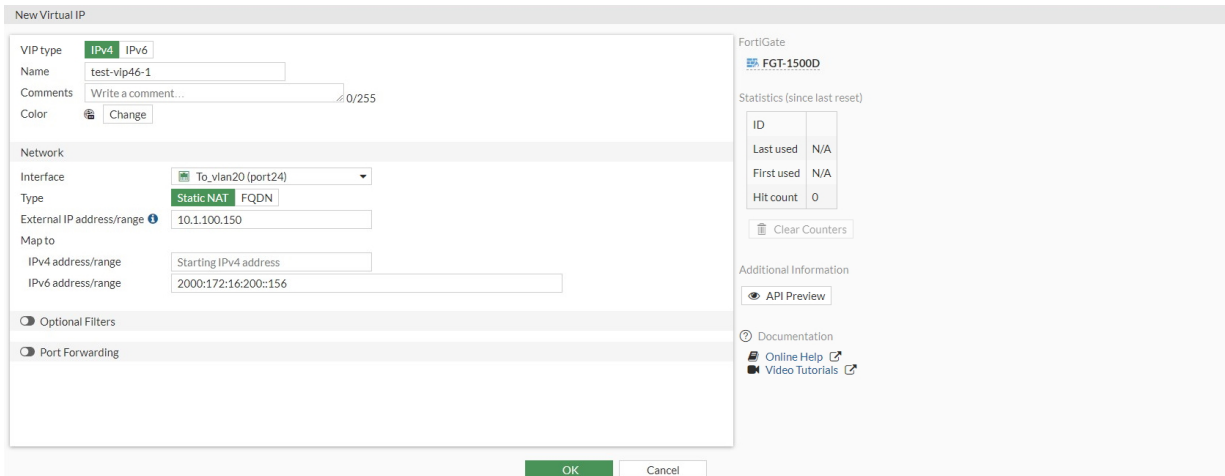

In this example, a client PC is using IPv4 and an IPv4 VIP to access a server that is using IPv6. The FortiGate uses NAT46 to translate the request from IPv4 to IPv6 using the virtual interface `naf.root`. An `ippool6` is applied so that the request is SNATed to the `ippool6` address (2000:172:16:101::1 - 2000:172:16:101::1).

To create a NAT46 policy in the GUI:

1. Configure the VIP:
 - a. Go to *Policy & Objects > Virtual IPs* and click *Create New > VIP*.
 - b. Enter the following:

VIP type	IPv4
Name	test-vip46-1
Interface	To_vlan20
Type	Static NAT
External IP address/range	10.1.100.150
Map to IPv6 address/range	2000:172:16:200::156

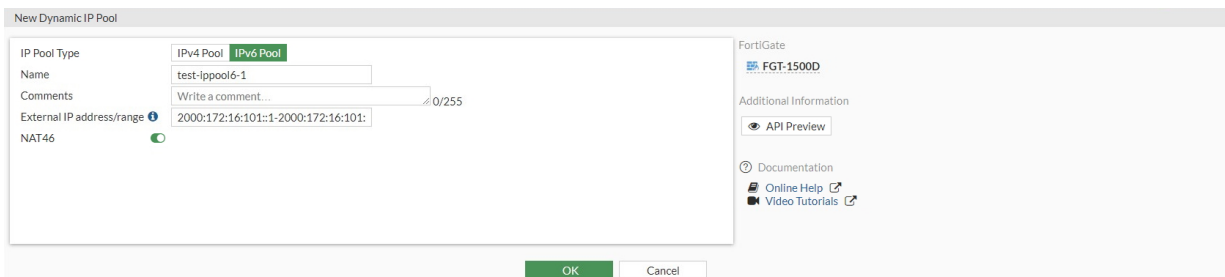

c. Click *OK*.

2. Configure the IPv6 pool:

- a. Go to *Policy & Objects > IP Pools* and click *Create New*.
- b. Enter the following:

IP Pool Type	IPv6 Pool
Name	test-ippool6-1
External IP address/range	2000:172:16:101::1-2000:172:16:101::1
NAT46	Enable

c. Click *OK*.

3. Configure the firewall policy:

- a. Go to *Policy & Objects > Firewall Policy* and click *Create New* or edit an existing policy.
- b. Enter the following:

Name	policy46-1
Incoming Interface	To_vlan20
Outgoing Interface	To_vlan30
Source	all
Destination	test-vip46-1
Schedule	always

Service	ALL
Action	ACCEPT
NAT	NAT46
IP Pool Configuration	test-ippool6-1

- c. Configure the other settings as needed.

- d. Click OK.

To create a NAT46 policy in the CLI:

1. Configure the VIP:

```
config firewall vip
  edit "test-vip46-1"
    set extip 10.1.100.150
    set nat44 disable
    set nat46 enable
    set extintf "port24"
    set arp-reply enable
    set ipv6-mappedip 2000:172:16:200::156
  next
end
```

2. Configure the IPv6 pool:

```
config firewall ippool6
  edit "test-ippool6-1"
    set startip 2000:172:16:101::1
    set endip 2000:172:16:101::1
    set nat46 enable
    set add-nat46-route enable
```

```

    next
end

```

3. Configure the firewall policy:

```

config firewall policy
    edit 2
        set name "policy46-1"
        set srcintf "port24"
        set dstintf "port17"
        set action accept
        set nat46 enable
        set srcaddr "all"
        set dstaddr "test-vip46-1"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set ippool enable
        set poolname6 "test-ippool6-1"
    next
end

```

To verify the traffic and session tables:

1. Verify the traffic by the sniffer packets:

```

(root) # diagnose sniffer packet any 'icmp or icmp6' 4
interfaces=[any]
filters=[icmp or icmp6]
2.593302 port24 in 10.1.100.41 -> 10.1.100.150: icmp: echo request
2.593344 naf.root out 10.1.100.41 -> 10.1.100.150: icmp: echo request
2.593347 naf.root in 2000:172:16:101::1 -> 2000:172:16:200::156: icmp6: echo request seq
1
2.593383 port17 out 2000:172:16:101::1 -> 2000:172:16:200::156: icmp6: echo request seq
1
2.593772 port17 in 2000:172:16:200::156 -> 2000:172:16:101::1: icmp6: echo reply seq 1
2.593788 naf.root out 2000:172:16:200::156 -> 2000:172:16:101::1: icmp6: echo reply seq
1
2.593790 naf.root in 10.1.100.150 -> 10.1.100.41: icmp: echo reply
2.593804 port24 out 10.1.100.150 -> 10.1.100.41: icmp: echo reply
11 packets received by filter
0 packets dropped by kernel

```

2. Verify the session tables for IPv4 and IPv6:

```

(root) # diagnose sys session list
session info: proto=1 proto_state=00 duration=2 expire=59 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=log may_dirty f00 netflow-origin netflow-reply
statistic(bytes/packets/allow_err): org=252/3/1 reply=252/3/1 tuples=2
tx speed(Bps/kbps): 106/0 rx speed(Bps/kbps): 106/0

```

```

total session 1

```

The IPv4 session is between the incoming physical interface port24 and naf.root. The IPv6 session is between the naf.root and the outgoing physical interface port17.

NAT64 policy

In this example, a client PC is using IPv6 and an IPv6 VIP to access a server that is using IPv4. The FortiGate uses NAT64 to translate the request from IPv6 to IPv4 using the virtual interface naf.root. An `ippool` is applied so that the request is SNATed to the `ippool` address (172.16.101.2 - 172.16.101.3).

An embedded VIP64 object is used in this configuration so a specific IPv4 mapped IP does not need to be set. The lower 32 bits of the external IPv6 address are used to map to the IPv4 address. Only an IPv6 prefix is defined. In this example, the IPv6 prefix is 2001:10:1:100::, so the IPv6 address 2001:10:1:100::ac10:c89c will be translated to 172.16.200.156.

To create a NAT64 policy in the GUI:

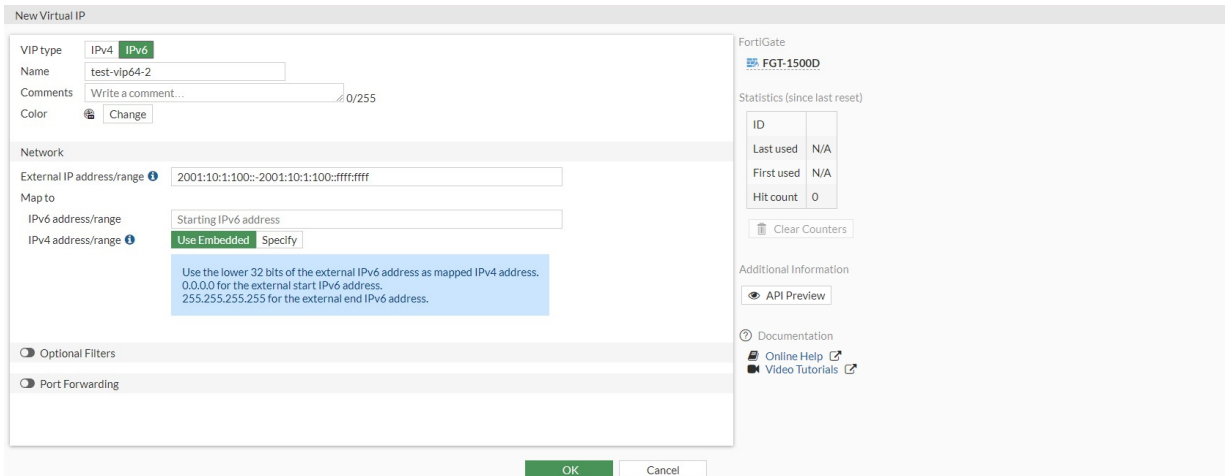

1. Configure the VIP:
 - a. Go to *Policy & Objects > Virtual IPs* and click *Create New > VIP*.
 - b. Enter the following:

VIP type	IPv6
Name	test-vip64-1
External IP address/range	2000:10:1:100::150
Map to IPv4 address/range	Specify: 172.16.200.156

The screenshot shows the 'New Virtual IP' configuration window in the FortiGate GUI. The 'VIP type' is set to IPv6. The 'Name' field contains 'test-vip64-1'. The 'External IP address/range' is '2000:10:1:100::150'. Under the 'Map to' section, the 'IPv4 address/range' is set to 'Specify' with the value '172.16.200.156'. The 'Optional Filters' and 'Port Forwarding' sections are collapsed. The right sidebar shows device information for 'FGT-1500D'.

- c. Click *OK*.
2. Configure the VIP with the embedded IPv4 address enabled:
 - a. Go to *Policy & Objects > Virtual IPs* and click *Create New > VIP*.
 - b. Enter the following:

VIP type	IPv6
Name	test-vip64-2
External IP address/range	2001:10:1:100::-2001:10:1:100::ffff:ffff
Map to IPv4 address/range	Use Embedded

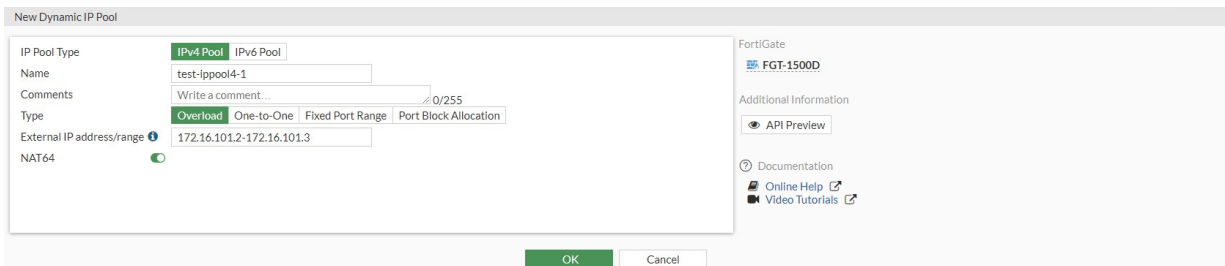

c. Click **OK**.

3. Configure the IP pool:

- a. Go to *Policy & Objects > IP Pools* and click *Create New*.
- b. Enter the following:

IP Pool Type	IPv4 Pool
Name	test-ippool4-1
Type	Overload
External IP address/range	172.16.101.2-172.16.101.3
NAT64	Enable

c. Click **OK**.

4. Configure the firewall policy:

- a. Go to *Policy & Objects > Firewall Policy* and click *Create New* or edit an existing policy.
- b. Enter the following:

Name	policy64-1
Incoming Interface	To_vlan20
Outgoing Interface	To_vlan30
Source	all
Destination	test-vip64-1 test-vip64-2

Schedule	always
Service	ALL
Action	ACCEPT
NAT	NAT64
IP Pool Configuration	test-ippool4-1

c. Configure the other settings as needed.

d. Click OK.

To create a NAT64 policy in the CLI:

1. Configure the VIP:

```
config firewall vip6
  edit "test-vip64-1"
    set extip 2000:10:1:100::150
    set nat66 disable
    set nat64 enable
    set ipv4-mappedip 172.16.200.156
  next
end
```

2. Configure the VIP with the embedded IPv4 address enabled:

```
config firewall vip6
  edit "test-vip64-2"
    set extip 2001:10:1:100::-2001:10:1:100::ffff:ffff
    set nat66 disable
    set nat64 enable
    set embedded-ipv4-address enable
  next
end
```

```

    next
end

```

3. Configure the IP pool:

```

config firewall ippool
    edit "test-ippool4-1"
        set startip 172.16.101.2
        set endip 172.16.101.3
        set nat64 enable
        set add-nat64-route enable
    next
end

```

4. Configure the firewall policy:

```

config firewall policy
    edit 1
        set name "policy64-1"
        set srcintf "port24"
        set dstintf "port17"
        set action accept
        set nat64 enable
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all"
        set dstaddr6 "test-vip64-1" "test-vip64-2"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set ippool enable
        set poolname "test-ippool4-1"
    next
end

```

To verify the traffic and session tables:

1. Verify the VIP64 traffic by the sniffer packets:

```

(root) # diagnose sniffer packet any 'icmp or icmp6' 4
interfaces=[any]
filters=[icmp or icmp6]
20.578417 port24 in 2000:10:1:100::41 -> 2000:10:1:100::150: icmp6: echo request seq 1
20.578495 naf.root out 2000:10:1:100::41 -> 2000:10:1:100::150: icmp6: echo request seq
1
20.578497 naf.root in 172.16.101.2 -> 172.16.200.156: icmp: echo request
20.578854 port17 out 172.16.101.2 -> 172.16.200.156: icmp: echo request
20.579083 port17 in 172.16.200.156 -> 172.16.101.2: icmp: echo reply
20.579093 naf.root out 172.16.200.156 -> 172.16.101.2: icmp: echo reply
20.579095 naf.root in 2000:10:1:100::150 -> 2000:10:1:100::41: icmp6: echo reply seq 1
20.579377 port24 out 2000:10:1:100::150 -> 2000:10:1:100::41: icmp6: echo reply seq 1
11 packets received by filter
0 packets dropped by kernel

```

2. Verify the session tables for IPv6 and IPv4:

```
(root) # diagnose sys session6 list
session6 info: proto=58 proto_state=00 duration=5 expire=56 timeout=0 flags=00000000
sockport=0 socktype=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/0
state=log may_dirty
statistic(bytes/packets/allow_err): org=312/3/0 reply=312/3/0 tuples=2
tx speed(Bps/kbps): 55/0 rx speed(Bps/kbps): 55/0
orgin->sink: org pre->post, reply pre->post dev=24->53/53->24

rpdb_link_id = 00000000 ngfwid=n/a
npu_state=0x040001 no_offload
no_ofld_reason: disabled-by-policy non-npu-intf
total session 1
```

```
(root) # diagnose sys session list
session info: proto=1 proto_state=00 duration=7 expire=54 timeout=0 flags=00000000
socktype=0 sockport=0 av_idx=0 use=3
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=0 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
state=log may_dirty f00
statistic(bytes/packets/allow_err): org=252/3/1 reply=252/3/1 tuples=2
tx speed(Bps/kbps): 0/0 rx speed(Bps/kbps): 0/0
orgin->sink: org pre->post, reply pre->post dev=53->17/17->53
gwy=172.16.200.156/172.16.101.2
hook=pre dir=org act=noop 172.16.101.2:45392->172.16.200.156:8(0.0.0.0:0)
hook=post dir=reply act=noop 172.16.200.156:45392->172.16.101.2:0(0.0.0.0:0)
peer=2000:10:1:100::150:29949->2000:10:1:100::41:129 naf=2
hook=pre dir=org act=noop 2000:10:1:100::41:29949->2000:10:1:100::150:128(:::0)
hook=post dir=reply act=noop 2000:10:1:100::150:29949->2000:10:1:100::41:129(:::0)
misc=0 policy_id=1 auth_info=0 chk_client_info=0 vd=0
serial=0001347f tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a
npu_state=0x000001 no_offload
no_ofld_reason: disabled-by-policy
total session 1
```

The IPv6 session is between the incoming physical interface port24 and naf.root. The IPv4 session is between the naf.root and the outgoing physical interface port17.

3. Verify the embedded VIP64 traffic by the sniffer packets:

```
(root) # diagnose sniffer packet any 'icmp or icmp6' 4
interfaces=[any]
filters=[icmp or icmp6]
```

```

7.696010 port24 in 2000:10:1:100::41 -> 2001:10:1:100::ac10:c89c: icmp6: echo request

1
11 packets received by filter
0 packets dropped by kernel

```

Per-policy disclaimer messages

FortiOS supports a customizable captive portal to direct users to install or enable required software.

Per-policy custom disclaimers in each VDOM are supported. For example, you may want to configure three firewall policies, each of which matches traffic from endpoints with different FortiClient statuses:

Endpoint status	FortiOS behavior
Endpoint does not have FortiClient installed.	Traffic matches a firewall policy that displays an in-browser warning to install FortiClient from the provided link.
Endpoint has FortiClient installed, registered to EMS, and connected to the FortiGate.	Traffic matches a dynamic firewall policy which allows the endpoint to reach its destination via this policy.
Endpoint is deregistered from EMS and disconnected from the FortiGate.	Traffic matches another dynamic firewall policy that displays warning to register FortiClient to EMS.

The [replacement message groups](#) and policy disclaimer settings must be enabled.

To enable per-policy disclaimer messages in the GUI:

1. Go to *System > Feature Visibility*.
2. Enable *Replacement Message Groups* and *Policy Disclaimer*.
3. Click *Apply*.

To enable per-policy disclaimer messages in the CLI:

```

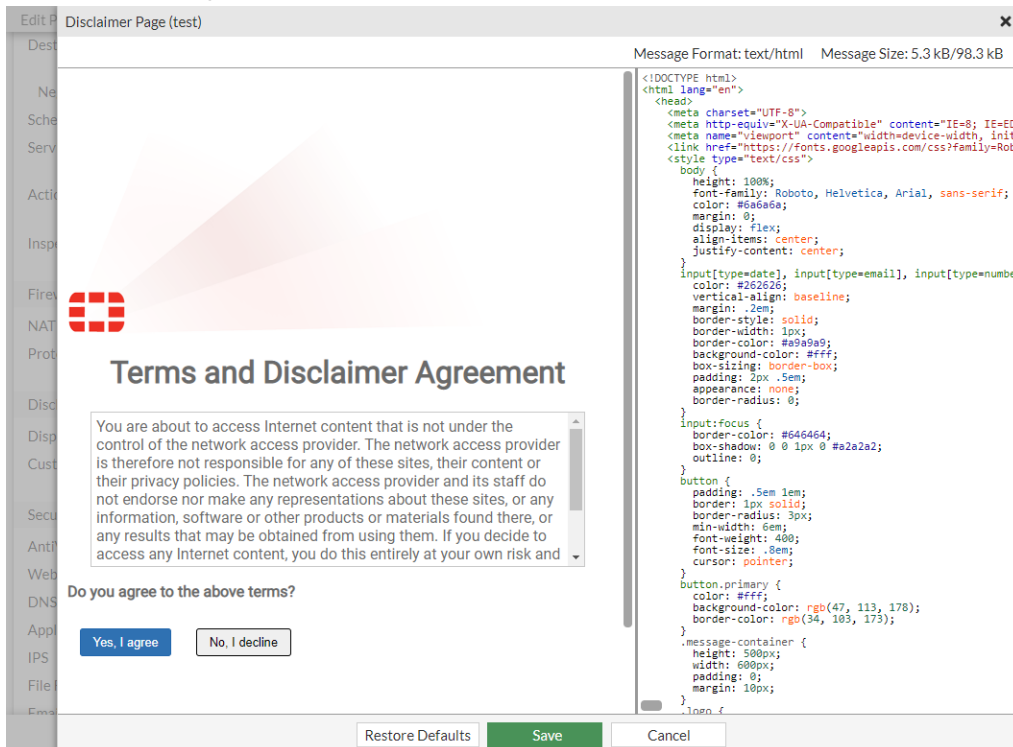

config system global
    set gui-replacement-message-groups enable
end

config system settings
    set gui-policy-disclaimer enable
end

```

To configure per-policy disclaimers in the GUI:

1. Ensure the per-policy disclaimer messages option is enabled.
2. Go to *Policy & Objects > Firewall Policy*.
3. Edit the policy that applies when an endpoint does not have FortiClient installed.
4. Under *Disclaimer Options*, enable *Display Disclaimer* and *Customize Messages*.
5. Add a replacement message group:
 - a. Select an existing replacement message group from the dropdown and click *Edit Disclaimer Message*.
 - b. Click *Create*, enter a name, and click *OK*. Select the replacement message group and click *Edit Disclaimer Message*.

6. Edit the message to warn users to install FortiClient, and provide the FortiClient download link.
7. Click *Save*.
8. Repeat the above steps for each policy that requires a custom disclaimer message.

To configure per-policy disclaimers in the CLI:

```
config firewall policy
  edit 1
    set name "l11"
    set srcintf "port12"
    set dstintf "port11"
    set srcaddr "all"
    set dstaddr "pc155_address"
    set action accept
    set schedule "always"
    set service "ALL"
    set wso disable
    set groups "ems_03_group"
```

```
    set disclaimer enable
    set replacemsg-override-group "test"
    set nat enable
next
edit 4
    set name "44"
    set srcintf "port12"
    set dstintf "port11"
    set srcaddr "all"

end
```

Address objects

Addresses define sources and destinations of network traffic and can be used in many functions such as firewall policies, ZTNA, etc.

To view the possible uses list of address object usage:

1. Go to *Policy & Objects > Addresses*.
2. Click the number under *Ref. The Usage of Address:<Predefined address>* pane opens, where *<Predefined address>* is one of the predefined addresses, such as *SSLVPN_TUNNEL_ADDR1*.
3. In the *Usage of Address:<Predefined address>* pane, click *Possible Uses* to view the list.

When properly set up, these address objects can be used with great flexibility to make the configuration of different functions simpler and more intuitive. When used in a firewall policy, the FortiGate compares the IP addresses contained in packet headers with a policy's source and destination addresses to determine if the policy matches the traffic. The matching of IP addresses in packet headers is also performed for other FortiGate functions configured with address objects.

Address Types

When creating an IPv4 address, there are several different types of addresses that can be specified. Which one is chosen will depend on which method most easily yet accurately describes the addresses that you are trying to include with as few entries as possible based on the information that you have. For instance, if you are trying to describe the addresses of a specific company's web server but do not know how extensive their web server farm is, you would be more likely to use a Fully Qualified Domain Name (FQDN) rather than a specific IP address. On the other hand, some computers do not have FQDNs and a specific IP address must be used.

The following table provides a short description of the different types of addresses:

Address type	Description
Subnet	<p>The subnet type of address is expressed using a host address and a subnet mask. This is the most flexible of the address types because the address can refer to as little as one individual address (x.x.x.x/32) or as many as all of the available addresses (0.0.0.0/0).</p> <p>See Subnet on page 950 and Dynamic policy — fabric devices on page 951 for more information.</p>
IP range	<p>The IP range type can be used to define a continuous set of IP addresses between one specific IP address and another (inclusive). It is a flexible way to describe a continuous set of addresses while being specific and granular, without needing to fall within the boundaries of standard subnets.</p> <p>See IP range on page 953 for more information.</p>
FQDN	<p>The Fully Qualified Domain Name (FQDN) address type accepts an address string and resolves it to one or more IP addresses. It relies on DNS to keep up with address changes without having to manually change the IP addresses on the FortiGate.</p> <p>See FQDN addresses on page 954 for more information.</p> <p>FQDN can also be specified as wildcard addresses such as *.example.com. See Using wildcard FQDN addresses in firewall policies on page 955 for more information.</p>
Geography	<p>Geography addresses are those determined by the country/region of origin. The IPs for the country/region is automatically determined from the Geography IP database.</p> <p>See Geography based addresses on page 957 and IPv6 geography-based addresses on page 960 for more information.</p>
Dynamic	<p>Dynamic address object can be used in the policies that support dynamic address type and comes in different subtypes such as FSSO and SDN connector dynamic addresses.</p> <p>See FSSO dynamic address subtype on page 967, ClearPass integration for dynamic address objects on page 971, FortiNAC tag dynamic address on page 974, and Getting started with public and private SDN connectors on page 2594 for more information.</p>

Address type	Description
Device (Mac address)	A MAC address is a link layer-based address type and it cannot be forwarded across different IP segments. In FortiOS, you can configure a firewall address object with a singular MAC, wildcard MAC, multiple MACs, or a MAC range. See MAC addressed-based policies on page 977 , Adding MAC-based addresses to devices on page 105 , ISDB well-known MAC address list on page 978 , and IPv6 MAC addresses and usage in firewall policies on page 980 for more information.
Wildcard (CLI only)	Wildcard addresses are addresses that identify ranges of IP addresses, reducing the amount of firewall addresses and security policies required to match some of the traffic on your network. See Wildcard addressing on page 962 for more information.
Interface subnet (CLI only)	For all interfaces set to a LAN or DMZ role, an option is available to automatically create an address object for the connected network. If the interface's subnet changes the address object subnet changes too. See Interface subnet on page 963 for more information.

Address Group

Address groups are designed for ease of use in the administration of the device. If you have several addresses or address ranges that will commonly be treated the same or require the same security policies, you can put them into address groups, rather than entering multiple individual addresses in each policy that refers to them.

There are two different types of address groups and the following table provides a short description of each type:

Address group type	Description
Group	Members of an address group type group can belong to multiple address groups. See Address group on page 964 and Address group exclusions on page 966 for more information.
Folder	Members or an address group type folder can only belong to a single address folder. See Address folder on page 965 for more information.

Subnet

A subnet address object is usually used to refer internal networks or addresses which are defined by the network administrator.

A subnet address usually consists of a network address and a netmask, for example, 192.168.1.0 255.255.255.0. In this example, the network address is 192.168.1.0 and the netmask is 255.255.255.0. The network address defines the network to match and the netmask specify the IP address to match on the network.

In the above example, the subnet address 192.168.1.0 255.255.255.0 would match the following IP addresses:

192.168.1.1
192.168.1.2
192.168.1.3
...
192.168.1.255

For defining a subnet address object the valid format of IP address and netmask could be either:

x.x.x.x/x.x.x.x, such as 192.168.1.0/255.255.255.0

or

x.x.x.x/x, such as 192.168.1.0/24

To define a single address using subnet, use the netmask 255.255.255.255 or /32. A warning message will be shown if any other netmask is used and will not let the user save the address object.

To create a subnet address:

1. Go to *Policy & Objects > Addresses*.
2. Select *Create New > Address*.
3. In the *Category* field, select *Address*.
4. Enter a *Name* for the address object.
5. In the *Type* field, select *Subnet* from the dropdown menu.
6. In the *IP/Netmask* field, enter the address and subnet mask according to the format x.x.x.x/x.x.x.x or the short hand format of x.x.x.x/x
7. In the *Interface* field, leave as the default *any* or select a specific interface from the dropdown menu.
8. Enable/disable *Static route configuration*.
9. Enter any additional information in the *Comments* field.
10. Click *OK*.

Dynamic policy — fabric devices

The dynamic address group represents the configured IP addresses of all Fortinet devices connected to the Security Fabric. It currently includes FortiManager, FortiAnalyzer, FortiClient EMS, FortiMail, FortiAP(s), and FortiSwitch(es). Like other dynamic address groups for fabric connectors, it can be used as an IPv4 address in firewall policies and objects.

The list of firewall addresses includes a default address object called `FABRIC_DEVICE`. You can apply the `FABRIC_DEVICE` object to the following types of policies:

- Firewall policy, including virtual wire pairs, NAT 46, and NAT 64 (IPv4 only)
- IPv4 shaping policy
- IPv4 ACL policy

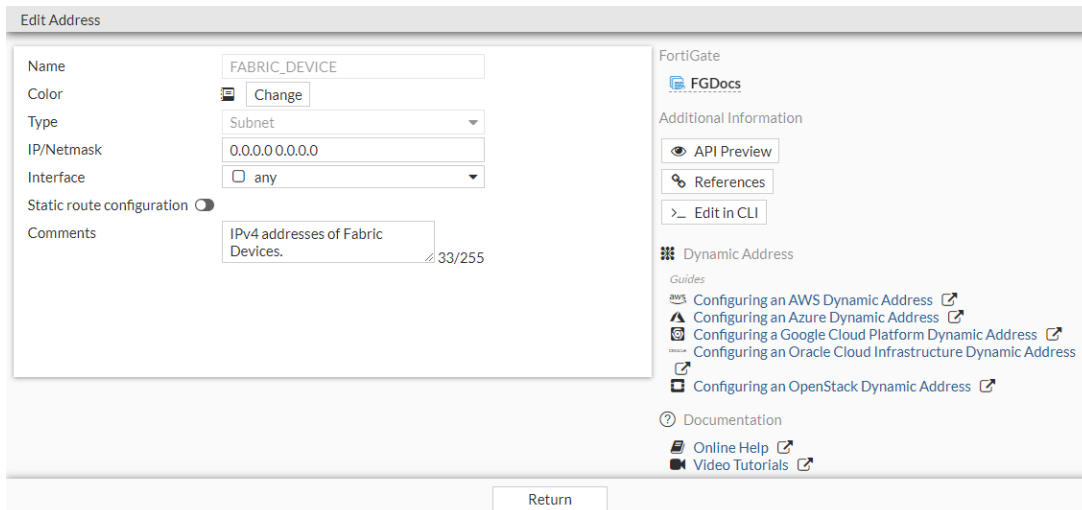

You cannot apply the `FABRIC_DEVICE` object to the following types of policies:

- IPv4 explicit proxy policy

You also cannot use the `FABRIC_DEVICE` object with the following settings:

- Custom extension on `internet-service`
- Exclusion of `addrgrp`

Initially the `FABRIC_DEVICE` object does not have an address value. The address value is populated dynamically as things change. As a result, you cannot edit the `FABRIC_DEVICE` object, add any addresses to the object, or remove any addresses from the object. The *Edit Address* pane in the GUI only has a *Return* button because the object is read-only:

The `FABRIC_DEVICE` object address values are populated based on:

- FortiAnalyzer IP (from the *Fabric Settings* pane)
- FortiManager IP (from the *Fabric Settings* pane)
- FortiMail IP (from the *Fabric Settings* pane)
- FortiClient EMS IP (from the *Fabric Settings* pane)
- FortiAP IPs (from the *FortiAP Setup* pane or DHCP)
- FortiSwitch IPs (from the *FortiSwitch Setup* page or DHCP)

To apply the `FABRIC_DEVICE` object to a firewall policy using the GUI:

1. Go to *Policy & Objects > Firewall Policy*.
2. Create a new policy or edit an existing policy.
3. For the *Destination* field, select `FABRIC_DEVICE` from the list of address entries.
4. Configure the rest of the policy as needed.
5. Click *OK*.

To apply the `FABRIC_DEVICE` object to a firewall policy using the CLI:

```
config firewall address
  edit "FABRIC_DEVICE"
    set type ipmask
    set comment "IPv4 addresses of Fabric Devices."
    set visibility enable
    set associated-interface ''
    set color 0
    set allow-routing disable
    set subnet 0.0.0.0 0.0.0.0
```

```
    next
end
config firewall policy
    edit 1
        set srcintf "port2"
        set dstintf "port1"
        set srcaddr "all"
        set dstaddr "FABRIC_DEVICE"
        set action accept
        set schedule "always"
        set service "ALL"
        set utm-status enable
        set fsso disable
        set nat enable
    next
end
```

Diagnose command

You can use the diagnose command to list IP addresses of Fortinet devices that are configured in the Security Fabric.

To run the diagnose command using the CLI:

```
(root) # diagnose firewall sf-addresses list
```

```
FabricDevices: 172.18.64.48
FortiAnalyzer: 172.18.60.25
FortiSandbox: 172.18.52.154
FortiManager: 172.18.28.31
FortiClientEMS: 172.18.62.6
FortiAP:
FortiSwitch:
FortiAP/SW-DHCP:
```

IP range

The IP range type of address can describe a group of addresses while being specific and granular. It does this by specifying a continuous set of IP addresses between one specific IP address and another.

The format would be:

`x.x.x.x-x.x.x.x`, such as `192.168.110.100-192.168.110.120`

To create an IP range address:

1. Go to *Policy & Objects > Addresses*.
2. Select *Create New > Address*.
3. In the *Category* field, select *Address*.
4. Enter a *Name* for the address object.
5. In the *Type* field, select *IP Range* from the dropdown menu.
6. In the *IP Range* field, enter the range of addresses in the following format: `x.x.x.x-x.x.x.x` (no spaces)
7. In the *Interface* field, leave as the default any or select a specific interface from the drop down menu.

8. Enter any additional information in the *Comments* field.
9. Click *OK*.

FQDN addresses

By using Fully Qualified Domain Name (FQDN) addressing you can take advantage of the dynamic ability of DNS to keep up with address changes without having to manually change the addresses on the FortiGate. FQDN addresses are most often used with external web sites but they can be used for internal web sites as well if there is a trusted DNS server that can be accessed. FQDN addressing also comes in handy for large web sites that may use multiple addresses and load balancers for their web sites. The FortiGate firewall automatically maintains a cached record of all the addresses resolved by the DNS for the FQDN addresses used.

For example, if you were doing this manually and you wanted to have a security policy that involved Google, you could track down all of the IP addresses that they use across multiple countries. Using the FQDN address is simpler and more convenient.

When representing hosts by an FQDN, the domain name can also be a subdomain, such as mail.example.com.

Valid FQDN formats include:

- <host_name>.<top_level_domain_name>, such as example.com
- <host_name>.<second_level_domain_name>.<top_level_domain_name>, such as mail.example.com.

The FortiGate firewall keeps track of the DNS TTLs so as the entries change on the DNS servers the IP address will effectively be updated for the FortiGate. As long as the FQDN address is used in a security policy, it stores the address in the DNS cache.

There is a possible security downside to using FQDN addresses. Using a fully qualified domain name in a security policy means that your policies are relying on the DNS server to be accurate and correct. Should the DNS server be compromised, security policies requiring domain name resolution may no longer function properly.

To create a Fully Qualified Domain Name address:

1. Go to *Policy & Objects > Addresses*.
2. Select *Create New > Address*.
3. In the *Category* field, choose *Address*.
4. Enter a *Name* for the address object.
5. In the *Type* field, select *FQDN* from the dropdown menu.
6. Enter the domain name in the *FQDN* field.
7. In the *Interface* field, leave as the default *any* or select a specific interface from the dropdown menu.
8. Enable/disable *Static route configuration*.
9. Enter any additional information in the *Comments* field.
10. Click *OK*.

Using wildcard FQDN addresses in firewall policies

You can use wildcard FQDN addresses in firewall policies. IPv4, IPv6, ACL, local, shaping, NAT64, NAT46, and NGFW policy types support wildcard FQDN addresses.

For wildcard FQDN addresses to work, the FortiGate should allow DNS traffic to pass through.

Initially, the wildcard FQDN object is empty and contains no addresses. When the client tries to resolve a FQDN address, the FortiGate will analyze the DNS response. The IP address(es) contained in the answer section of the DNS response will be added to the corresponding wildcard FQDN object. It is therefore necessary to have the DNS session-helpers defined in the `config system session-helper` setting.

Since FortiGate must analyze the DNS response, it does not work with DNS over HTTPS.

In FortiOS 7.0 and later, FortiGate supports DNS over TLS. It is possible to analyze DNS responses sent over DoT, as long as there is a firewall policy that allows the DNS traffic from the client and is configured with a DNS filter that supports DoT. For information on configuring this, see [DNS inspection with DoT and DoH on page 1283](#).

When the wildcard FQDN gets the resolved IP addresses, FortiOS loads the addresses into the firewall policy for traffic matching.

The FortiGate will keep the IP addresses in the FQDN object table as long as the DNS entry itself has not expired. Once it expires, the IP address is removed from the wildcard FQDN object until another query is made. At any given time, a single wildcard FQDN object may have up to 1000 IP addresses.

The DNS expiry TTL value is set by the authoritative name server for that DNS record. If the TTL for a specific DNS record is very short and you would like to cache the IP address longer, then you can extend it with the CLI. See [To extend the TTL for a DNS record in the CLI: on page 957](#)

Wildcard FQDN IPs are synchronized to other autoscale members whenever a peer learns of a wildcard FQDN address.

To create a wildcard FQDN using the GUI:

1. Go to *Policy & Objects > Addresses* and click *Create New > Address*.
2. Specify a *Name*.
3. For *Type*, select *FQDN*.

4. For *FQDN*, enter a wildcard FQDN address, for example, *.fortinet.com.

5. Click *OK*.

To use a wildcard FQDN in a firewall policy using the GUI:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. For *Destination*, select the wildcard FQDN.
3. Configure the rest of the policy as needed.
4. Click *OK*.

To create a wildcard FQDN using the CLI:

```
config firewall address
  edit "test-wildcardfqdn-1"
    set type fqdn
    set fqdn "*.fortinet.com"
  next
end
```

To use wildcard FQDN in a firewall policy using the CLI:

```
config firewall policy
  edit 2
    set srcintf "port3"
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "test-wildcardfqdn-1"
    set action accept
    set schedule "always"
    set service "ALL"
    set auto-asic-offload disable
    set nat enable
  next
end
```

To use the diagnose command to list resolved IP addresses of wildcard FQDN objects:

```
# diagnose firewall fqdn list

List all FQDN:
```

```
*.fortinet.com: ID(48) ADDR(96.45.36.159) ADDR(192.168.100.161) ADDR(65.39.139.161)
```

Alternatively:

```
# diagnose test application dnsproxy 6

worker idx: 0

vfid=0 name=*.fortinet.com ver=IPv4 min_ttl=3266:0, cache_ttl=0 , slot=-1, num=3,
wildcard=1

    96.45.36.159 (ttl=68862:68311:68311) 192.168.100.161 (ttl=3600:3146:3146)
65.39.139.161

(ttl=3600:3481:3481)
```

To use the diagnose command for firewall policies which use wildcard FQDN:

```
# diagnose firewall iprule list 100004
...
destination fqdn or dynamic address (1):*.fortinet.com ID(48) uuid_idx=57 ADDR
(208.91.114.104) ADDR(208.91.114.142) ADDR(173.243.137.143) ADDR(65.104.9.196) ADDR
(96.45.36.210)
...
```

To extend the TTL for a DNS record in the CLI:

In this the example the `set cache-ttl` value has been extended to 3600 seconds.

```
config firewall address
  edit "fortinet.com"
    set type fqdn
    set fqdn "www.fortinet.com"
    set cache-ttl 3600
  next
end
```

Geography based addresses

Geography addresses are those determined by country of origin. The IP for the country or region is automatically determined from the Geography IP database.

To view IP Geography database:

```
#diagnose autoupdate versions | grep -A 6 "IP Geography DB"
IP Geography DB
-----
Version: 3.00152
Contract Expiry Date: n/a
Last Updated using manual update on Thu Nov 17 17:52:00 2022
Last Update Attempt: Wed Nov 23 10:56:46 2022
Result: No Updates
```

Without a valid license, local IP geography database will continue to work. However the FortiGate will stop receiving geography IP updates from the FortiGuard servers and the geography IP database will no longer be updated. IP geolocation service is part of base services included with all FortiCare support contracts. See [FortiGuard Security Services](#) for more information.

To create a geography address:

1. Go to *Policy & Objects > Addresses*.
2. Select *Create New > Address*.
3. In the *Category* field, choose *Address*.
4. Enter a *Name* for the address object.
5. In the *Type* field, select *Geography* from the dropdown menu.
6. In the *Country/Region* field, select a single country from the dropdown menu.
7. In the *Interface* field, leave as the default *any* or select a specific interface from the dropdown menu.
8. Enter any additional information in the *Comments* field.
9. Click *OK*.

Overrides

It is possible to assign a specific IP address range to a customized country ID. Generally, geographic addressing is done at the VDOM level; it could be considered global if you are using the root VDOM, but the `geoip-override` setting is a global setting.

To configure a geography IP override:

1. Assign a specific IP address range to a customized country ID:

```
config system geoip-override
  edit "MyCustomCountry"
    config ip-range
      edit 1
        set start-ip 1.1.1.1
        set end-ip 1.1.1.2
      next
    end
  next
end
```

2. Use `get sys geoip-country XX` to determine the name corresponding to the custom 2-digit country code A0:

```
# get sys geoip-country A0
id          : A0
name       : MyCustomCountry
```

3. Show the full configuration of the geography IP override just created to show that it corresponds to country code A0:

```
# show full sys geoip-override
config system geoip-override
  edit "MyCustomCountry"
    set description ''
```

```

set country-id "A0"
config ip-range
  edit 1
    set start-ip 1.1.1.1
    set end-ip 1.1.1.2
  next
end
next
end

```

To configure a geography address:

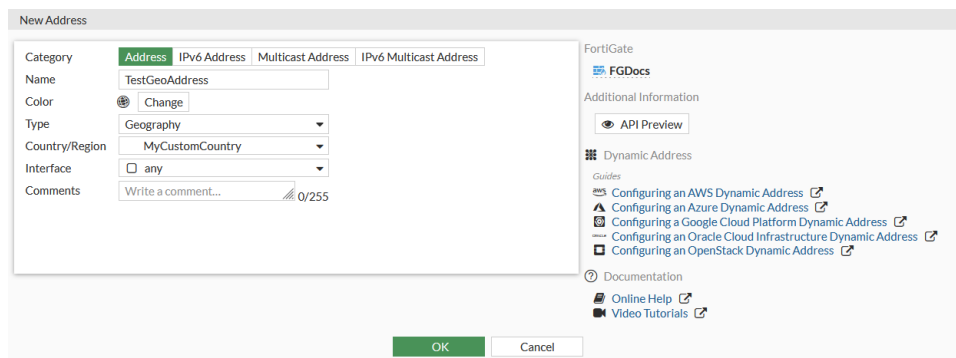

1. Enable debug to display the CLI commands running on the backend in response to certain GUI configuration:

```

# diagnose debug enable
# diagnose debug cli 7
Debug messages will be on for 30 minutes.

```

2. Go to *Policy & Objects > Addresses* and create a geography address using the previously created custom country code:

3. Observe the corresponding CLI commands run on the backend:

```

FGT # 0: config firewall address
0: edit "TestGeoAddress"
0: set type geography
0: set country "A0"
0: end

```

Diagnose commands

There are a few diagnose commands used with geographic addresses:

```
diagnose firewall ipgeo [country-list | ip-list | ip2country | override | copyright-notice]
```

Diagnose command	Description
country-list	List of all countries.
ip-list	List of the IP addresses associated with the country.
ip2country	Used to determine the physical and registered locations of the IP address as well and if the type is anycast.

Diagnose command	Description
override	List of user defined geography data; items configured with the <code>config system geoip-override</code> command.
copyright-notice	Shows the copyright notice.

```
diagnose geoip [geoip-query | ip2country | iprange]
```

Diagnose command	Description
geoip-query	Used to determine the complete geolocation of a specific IP address from the FortiGuard IP Geography DB.
ip2country	Used to determine which country a specific IP address is assigned to.
iprange	List the IP addresses or IP ranges associated with the country.

For more details and examples using these diagnose commands, see the Fortinet Community article [Technical Tip: Commands to verify GeolIP information and troubleshoot GeolIP database](#).

IPv6 geography-based addresses

Geography-based IPv6 addresses can be created and applied to IPv6 firewall policies.

IPv6 geography-based addresses do not support `geoip-override` or `geoip-anycast`.

To create an IPv6 geography-based address in the GUI:

1. Go to *Policy and Objects > Addresses*.
2. Click *Create New > Address*.
3. Set *Category* to *IPv6 Address*.
4. Enter a name for the address.
5. Set *Type* to *IPv6 Geography*.
6. Select the *Country/Region* from the list.

7. Optionally, enter comments.

8. Click OK.

To use the IPv6 geography address in a policy:

1. Go to *Policy & Objects > Firewall Policy*.
2. Edit an existing policy, or create a new one, using the IPv6 geography address as the *Source* or *Destination Address*.

3. In the policy list, hover over the address to view details.

Name	From	To	Source	Dest	Action
DMZ to WAN	port2	wan1 (port5)	all	all	ACC
Internet Service in Policy	wan2 (port6)	wan1 (port5)	all	Google	ACC
LB-policy	wan1 (port5)	port2	all	Vserver	ACC
test-policy6-1	wan2 (port6)	wan1 (port5)	all	test-ipv6-geoip	ACC
Implicit Deny	any	any	all	all	DEN

IPv6 Address: test-ipv6-geoip

Type: IPv6 Geography

Country/Region: Canada

Comments: IPv6 Geography address

References: 1

[Edit](#)

To configure an IPv6 geography-based address in the CLI:

1. Create an IPv6 geography-based address:

```
config firewall address6
  edit "test-ipv6-geoip"
    set type geography
    set color 6
    set comment "IPv6 Geography address"
    set country "CA"
  next
end
```

2. Use the IPv6 geography-based address in a policy:

```
config firewall policy
  edit 1
    set name "test-policy6-1"
    set srcintf "port6"
    set dstintf "port5"
    set srcaddr6 "all"
    set dstaddr6 "test-ipv6-geoip"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
  next
end
```

Wildcard addressing

Wildcard addresses are addresses that identify ranges of IP addresses, reducing the amount of firewall addresses and security policies required to match some of the traffic on your network. Wildcard addresses are an advanced feature, usually required only for complex networks with complex firewall filtering requirements. By using these wildcard addresses in the firewall configuration, administrators can eliminate creating multiple, separate IP based address objects and then grouping them to then apply to multiple security policies.

A wildcard address consists of an IP address and a wildcard netmask, for example, 192.168.0.56 255.255.0.255. In this example, the IP address is 192.168.0.56 and the wildcard netmask is 255.255.0.255. The IP address defines the networks to match and the wildcard netmask defines the specific addresses to match on these networks.

In a wildcard netmask, zero denotes ignoring the value of the octet in the IP address. This means the wildcard firewall address matches any number in this address octet. This also means that the number included in this octet of IP address is ignored and can be any number. Usually, if the octet in the wildcard netmask is zero, the corresponding octet in the IP address is also zero.

In a wildcard netmask, a number denotes matching addresses according to how the numbers translate into binary addresses. For example, the wildcard netmask is 255; the wildcard address will only match addresses with the value for this octet that is in the IP address part of the wildcard address. So, if the first octet of the IP address is 192 and the first octet of the wildcard netmask is 255, the wildcard address will only match addresses with 192 in the first octet.

In the above example, the wildcard address 192.168.0.56 255.255.0.255 would match the following IP addresses:

```
192.168.0.56
192.168.1.56
192.168.2.56
```

```
...  
192.168.255.56
```

The wildcard addresses 192.168.0.56 255.255.0.255 and 192.168.1.56 255.255.0.255 define the same thing since the 0 in the wildcard mask means to match any address in the third octet.

The following is an example of how to configure a wildcard firewall address.

```
config firewall address  
  edit example_wildcard_address  
    set type wildcard  
    set wildcard 192.168.0.56 255.255.0.255  
  next  
end
```

Wildcard firewall addresses are initially configured in the CLI. You cannot choose wildcard in the GUI when creating the address, but after the address is created in the CLI, it will show up in the GUI. The *Type* field shows a grayed-out value of *Wildcard* and the settings, other than the *Type*, can be edited.

Interface subnet

Interface subnet address type enables automatic address creation for attached networks.

The *Create address object matching subnet* option is displayed in the GUI when *Role* is set to *LAN* or *DMZ*.

To create an interface subnet:

1. Go to *Network > Interfaces*.
2. Select *Create New > Interface* or select existing interface and *Edit*.
3. Enable *Create address object matching subnet* and configure the settings.
4. Click *OK*.

The following is an example of how to configure an interface subnet firewall address on the CLI:

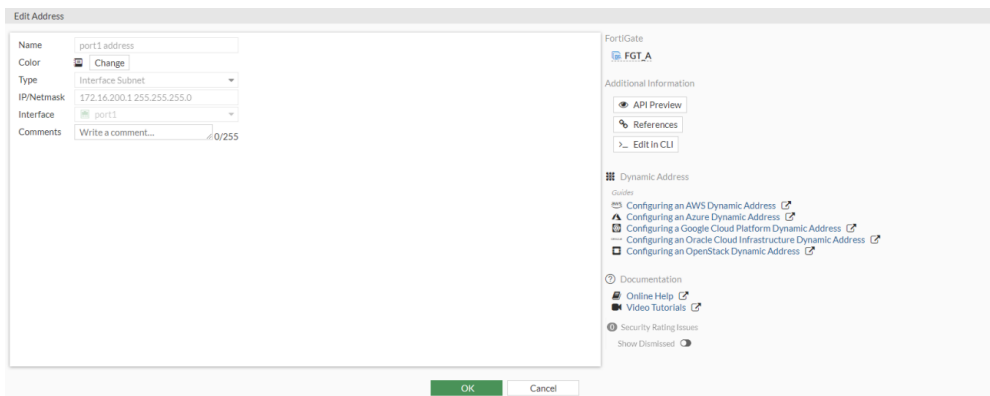

```
config firewall address  
  edit "port1 address"  
    set type interface-subnet  
    set interface "port1"  
  next  
end
```

Interface subnet addresses are automatically created after enabling the *Create address object matching subnet* option in the interface page or they can be manually configured in the CLI. You cannot choose *Interface Subnet* in the GUI when creating the address, but after the address is created, it will show up in the GUI. However, all the settings are grayed other than the comments, which can be edited.

When the *Create address object matching subnet* option is enabled, the new address object displays on the *Policy & Objects > Address > Interface Subnet*.

Name	Details	Interface	Type	Ref.
IP Range/Subnet				
FABRIC_DEVICE	0.0.0.0/0		Address	0
FIREWALL_AUTH_PORTAL_ADDRESS	0.0.0.0/0		Address	0
SSLVPN_TUNNEL_ADDR1	10.212.134.200 - 10.212.134.210		Address	2
all	0.0.0.0/0		Address	4
none	0.0.0.0/32		Address	0
FQDN				
gmail.com	gmail.com		Address	1
login.microsoft.com	login.microsoft.com		Address	1
login.microsoftonline.com	login.microsoftonline.com		Address	1
login.windows.net	login.windows.net		Address	1
wildcard.dropbox.com	*dropbox.com		Address	0
wildcard.google.com	*google.com		Address	1
Interface Subnet				
port1 address	172.16.200.0/24	port1	Address	0
Address Group				
G Suite	gmail.com wildcard.google.com		Address Group	0
Microsoft Office 365	login.microsoftonline.com login.microsoft.com login.windows.net		Address Group	0

After the address is created, the subnet is dynamically assigned to the address object which can be seen on both GUI and CLI:

```

config firewall address
  edit "port1 address"
    set type interface-subnet
    set subnet 172.16.200.1 255.255.255.0
    set interface "port1"
  next
end
  
```

Address group

The use of groups is not mandatory. However, adding individual addresses to a policy sometimes become tedious. If you use several different addresses with a given policy, these address objects can be grouped into an address group as it is much easier to add or subtract addresses from the group.

Security policies require addresses with homogenous network interfaces. Therefore, address groups should contain only addresses bound to the same network interface or Any.

For example, if address 1.1.1.1 is associated with port1, and address 2.2.2.2 is associated with port2, they cannot be in the same group. However, if 1.1.1.1 and 2.2.2.2 are configured with an interface of Any, they can be grouped, even if the addresses involve different networks.

To create an address group:

1. Go to *Policy & Objects > Addresses*.
2. Go to *Create New > Address Group*.
3. In the *Category* field, select *IPv4 Group*.
4. Enter a *Group name* for the address object.
5. In the *Type* field, select *Group*.
6. Select the + in the *Members* field. The *Select Entries* pane opens.
7. Select members of the group. It is possible to select more than one entry. Select the x icon in the field to remove an entry.
8. Enable/disable *Static route configuration*.
9. Enter any additional information in the *Comments* field.
10. Click *OK*.

Address folder

Some address objects logically belong to the same device, such as two IPs from the same computer. These address objects can be grouped into an address folder, which is an exclusive list of address objects that do not appear in other address groups or folders.

In the CLI, the folder type can be set after the member list is already populated. If the member list contains an incompatible entry, then the setting will be discarded when the `next/end` command is issued. If the folder type is set before the member list is populated, then the possible member entry list will be filtered according to the selected type.

To create an address folder in the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Click *Create New > Address Group* and enter a name.
3. For *Type*, select *Folder*.
4. For *Members*, click the + to add the addresses. Address folders and groups are exclusive, so the *Select Entries* window filters out address objects that are a member of an existing group or folder.

The screenshot shows the 'New Address Group' configuration window. The 'Group name' is 'dev1-addr-comb'. The 'Type' is set to 'Folder'. The 'Members' list includes 'dev1-IP-nic1', 'dev1-IP-nic2', and 'dev1-mac'. A tooltip message states: 'Members of address folders can only belong to a single address folder.' The 'Static route configuration' is disabled. The 'Comments' field is empty.

5. Click *OK*.
6. In the address table, expand the *Address Group* section to view the folder (*dev1-addr-comb*). The expandable

folder view shows the address folder's child objects:

	 safe-network1-devices	Address Group (Folder)	2 entries		0
	 dev1-addr-comb	Address Group (Folder)	3 entries		1
	 dev1-IP-nic1	Subnet	192.168.1.25/32		1
	 dev1-IP-nic2	Subnet	192.168.1.22/32		1
	 dev1-mac	Device (MAC Address)	00:0a:95:9d:68:16		1
	 dev2-addr-comb	Address Group (Folder)	4 entries		1
	 dev2-IP-nic1	Subnet	192.168.1.101/32		1
	 dev2-IP-nic2	Subnet	192.168.1.102/32		1
	 dev2-IP-nic3	Subnet	192.168.1.103/32		1
	 dev2-mac	Device (MAC Address)	11:5b:12:2c:87:02		1

To configure an address folder in the CLI:

```
config firewall addrgrp
  edit "safe-network1-devices"
    set type folder
    set member "dev1-addr-comb" "dev2-addr-comb"
    set comment ''
    set exclude disable
    set color 13
  next
end

config firewall addrgrp
  edit "dev1-addr-comb"
    set type folder
    set member "dev1-IP-nic1" "dev1-IP-nic2" "dev1-mac"
    set comment ''
    set exclude disable
    set color 18
  next
end

config firewall addrgrp
  edit "dev2-addr-comb"
    set type folder
    set member "dev2-IP-nic1" "dev2-IP-nic2" "dev2-IP-nic3" "dev2-mac"
    set comment ''
    set exclude disable
    set color 5
  next
end
```

Address group exclusions

Specific IP addresses or ranges can be subtracted from the address group with the *Exclude Members* setting in IPv4 address groups.

This feature is only supported for IPv4 address groups, and only for addresses with a *Type* of *IP Range* or *Subnet*.

To exclude addresses from an address group using the GUI:

1. Go to *Policy & Objects > Addresses*.
2. Create a new address group, or edit an existing address group.
3. Enable *Exclude Members* and click the + to add entries.
4. Configure the other settings as needed.
5. Click *OK*.

The excluded members are listed in the *Exclude Members* column.

Name	Details	Interface	Type	Ref.	Exclude Members
Address Group					
Cosignees	all		Address Group	0	Marketing Network Marketing-DB
FinanceServersDMZ	Finance-Server1 Finance-Server2		Address Group	1	
FortiDEMO_local	FortiDEMO_local_...		Address Group	3	
FortiDEMO_remote	FortiDEMO_remot...		Address Group	3	
G Suite	gmail.com wildcard.google.co...		Address Group	0	

To exclude addresses from an address group using the CLI:

```
config firewall addrgrp
  edit <address group>
    set exclude enable
    set exclude-member <address> <address> ... <address>
  next
end
```

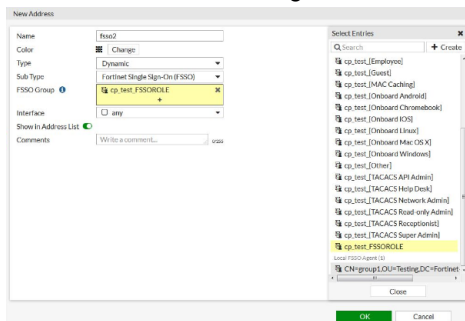

FSSO dynamic address subtype

The Fortinet Single Sign-ON (FSSO) dynamic firewall address subtype can be used in policies that support dynamic address types. The FortiGate will update the dynamic address used in firewall policies based on the source IP information for the authenticated FSSO users.

It can also be used with FSSO group information that is forwarded by ClearPass Policy Manager (CPPM) via FortiManager, and other FSSO groups provided by the FSSO collector agent or FortiNAC.

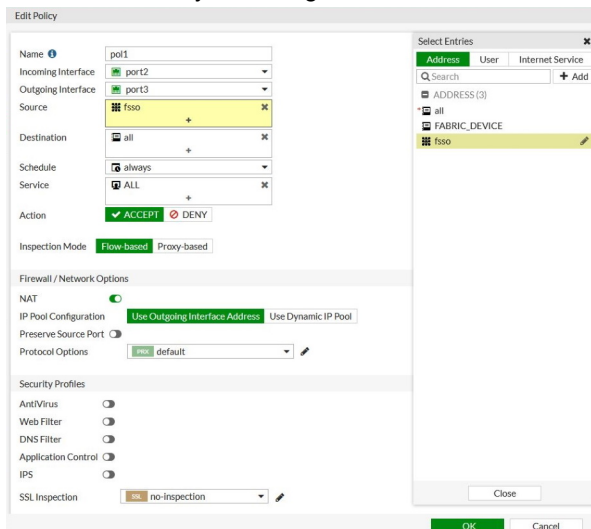

To configure FSSO dynamic addresses with CPPM and FortiManager in the GUI:

1. Create the dynamic address object:
 - a. Go to *Policy & Objects > Addresses*, and click *Create New > Address*.
 - b. For *Type*, select *Dynamic*.
 - c. For *Sub Type*, select *Fortinet Single Sign-On (FSSO)*. The *Select Entries* pane opens and displays all available FSSO groups.
 - d. Select one or more groups.
 - e. Click *OK* to save the configuration.

In the address table, there will be an error message for the address you just created (*Unresolved dynamic address: fss0*). This is expected because there are currently no authenticated FSSO users (based on source IP) in the local FSSO user list.

2. Add the dynamic address object to a firewall policy:
 - a. Go to *Policy & Objects > Firewall Policy*.
 - b. Create a new policy or edit an existing policy.
 - c. For *Source*, add the dynamic FSSO address object you just created.
 - d. Configure the rest of the policy as needed.
 - e. Click *OK* to save your changes.

3. Test the authentication to add a source IP address to the FSSO user list:
 - a. Log in as user and use CPPM for user authentication to connect to an external web server. After successful authentication, CPPM forwards the user name, source IP address, and group membership to the FortiGate via FortiManager.

b. Go to **Monitor > Firewall User Monitor** to view the user name (*fss01*) and IP address.

User Name	User Group	Duration	IP Address	Traffic Volume	Method
fss01	FSSO-CPPM cp_test_FSSOROLE	44 minute(s) and 36 second(s)	10.1.100.185	0B	Fortinet Single Sign-On

c. Go to **Policy & Objects > Addresses** to view the updated address table. The error message no longer appears.

d. Hover over the dynamic FSSO address to view the IP address (*fss0 resolves to: 10.1.100.185*).

Name	Type	Details	Interface	Visibility	Ref.
FABRIC_DEVICE	Subnet	0.0.0.0/0		Visible	0
FIREWALL_AUTH_PORTAL_ADDRESS	Subnet	0.0.0.0/0		Hidden	0
SSL	IP Range	10.212.134.200 - 10.212.134.210	SSL-VPN tunnel interface (ssl.root)	Visible	0
fss0 resolves to:					
all	Subnet	0.0.0.0/0		Visible	1
fss0	Dynamic (FSSO)	cp_test_FSSOROLE		Visible	1

To verify user traffic in the GUI:

1. Go to **Log & Report > Forward Traffic**.

Details for the user *fss01* are visible in the traffic log:

Date/Time	Source	Device	Destination	Application	Log Details
2019/08/29 11:23:06	fss01 (10.1.100.185)		13.56.33.144 (ec2-13-56-33-144us-west-1.compute.amazonaws.com)		General Date: 2019/08/29 Time: 11:22:42 Duration: 2s Session ID: 1360230 Virtual Domain: root NAT Translation Source: Source IP: 10.1.100.185 NAT IP: 172.16.200.199 Source Port: 61820 Country/Region: Reserved Source Interface: port2 User: fss01 Destination IP: 13.56.33.144 Port: 80 Country/Region: United States Destination Interface: port3 Application Control Application Name: Category Name: unscanned Risk: undefined Protocol: 6 Service: HTTP Data Received Bytes: 394 B Received Packets: 4 Sent Bytes: 504 B Sent Packets: 6 Action Action: Accept: session close Policy: pol1 (1) Policy ID: 2b88ed8a-c906-51e9-

2019/08/28 15:24:51	fss02 (10.1.100.188)		173.243.138.99		
2019/08/28 15:10:06	fss02 (10.1.100.188)		72.21.91.29		
2019/08/28 15:10:00	fss02 (10.1.100.188)		72.21.91.29		
2019/08/28 15:09:19	fss02 (10.1.100.188)		72.21.81.200		
2019/08/28 15:09:18	fss02 (10.1.100.188)		72.21.81.200		
2019/08/28 15:09:17	fss02 (10.1.100.188)		72.21.81.200		
2019/08/28 14:32:02	fss02 (10.1.100.188)		20.189.79.72		
2019/08/28 14:24:53	fss02 (10.1.100.188)		173.243.138.99		
2019/08/28 14:24:48	fss02 (10.1.100.188)		173.243.138.99		
2019/08/28 14:14:06	fss02 (10.1.100.188)		104.80.88.122 (a104-80-88-122.deploy.static.akamaitechnologies.com)		
2019/08/28 14:14:00	fss02 (10.1.100.188)		104.80.88.122 (a104-80-88-122.deploy.static.akamaitechnologies.com)		
2019/08/28 14:12:56	fss02 (10.1.100.188)		72.21.81.200		
2019/08/28 14:12:56	fss02 (10.1.100.188)		72.21.81.200		
2019/08/28 14:12:44	fss02 (10.1.100.188)		151.139.128.14		
2019/08/28 14:12:38	fss02 (10.1.100.188)		151.139.128.14		
2019/08/28 13:32:02	fss02 (10.1.100.188)		20.189.79.72		
2019/08/28 12:32:02	fss02 (10.1.100.188)		20.189.79.72		
2019/08/28 12:24:53	fss02 (10.1.100.188)		173.243.138.100		
2019/08/28 12:24:49	fss02 (10.1.100.188)		173.243.138.100		

- If another user is authenticated by CPPM, then the dynamic address *fss0* entry in the address table will be updated. The IP address for user *fss02* (*10.1.100.188*) is now visible:

Name	Type	Details	Interface	Visibility	Ref.
FABRIC_DEVICE	Subnet	0.0.0.0/0		Visible	0
FIREWALL_AUTH_PORTAL_ADDRESS	Subnet	0.0.0.0/0		Hidden	0
SSL	IP Range	10.212.134.200 - 10.212.134.210	SSL-VPN tunnel interface (ssl.root)	Visible	0
fss0 resolves to:					
all	Subnet	0.0.0.0/0		Visible	1
fss0	Dynamic (FSSO)	cp_test_FSSOROLE		Visible	1

2. Go to **FortiView > Sources** to verify that the users were able to successfully pass the firewall policy.

Source	Device	Bytes	Sessions	Bandwidth
fss02 10.1.100.188		12.07 MB	173	10.32 Mbps
fss01 10.1.100.185		4.42 MB	148	5.62 Mbps

If a user logs off and CPPM receives log off confirmation, then CPPS updates the FortiGate FSSO user list via FortiManager. The user IP address is deleted from the dynamic FSSO address, and the user is no longer be able to pass the firewall policy.

To configure FSSO dynamic addresses with CPPM and FortiManager in the CLI:**1. Create the dynamic address object:**

```
config firewall address
  edit "fsso"
    set type dynamic
    set sub-type fsso
    set fsso-group "cp_test_FSSOROLE"
  next
end
```

2. Add the dynamic address object to a policy:

```
config firewall policy
  edit 1
    set name "pol1"
    set srcintf "port2"
    set dstintf "port3"
    set srcaddr "fsso"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
    set fsso disable
    set nat enable
  next
end
```

To verify user traffic in the CLI:**1. Check the FSSO user list:**

```
diagnose debug authd fsso list
----FSSO logons----
IP: 10.1.100.185  User: fssol  Groups: cp_test_FSSOROLE  Workstation:  MemberOf: FSSO-
CPPM cp_test_FSSOROLE
Total number of logons listed: 1, filtered: 0
----end of FSSO logons----
```

2. Check the authenticated firewall users list:

```
diagnose firewall auth list
10.1.100.185, fssol
type: fsso, id: 0, duration: 2928, idled: 2928
server: FortiManager
packets: in 0 out 0, bytes: in 0 out 0
group_id: 2 33554433
group_name: FSSO-CPPM cp_test_FSSOROLE
----- 1 listed, 0 filtered -----
```

After user traffic passes through the firewall, the nu

```
diagnose firewall auth list
10.1.100.185, fssol
type: fsso, id: 0, duration: 3802, idled: 143
server: FortiManager
packets: in 1629 out 1817, bytes: in 2203319 out 133312
```

```
group_id: 2 33554433
group_name: FSSO-CPPM cp_test_FSSOROLE
----- 1 listed, 0 filtered -----
```

ClearPass integration for dynamic address objects

ClearPass Policy Manager (CPPM) can gather information about the statuses of network hosts, for example, the latest patches or virus infections. Based on this information, CPPM send the IP addresses and current states, such as Healthy or Infected, to the FortiGate.

On the FortiGate, the IP addresses received from CPPM are added to a dynamic firewall address with the *clearpass-spt* subtype. This address can be used in any policy that supports dynamic addresses, such as Firewall or SSL-VPN policies.

In this example, you create two dynamic IP addresses that are used in two firewall policies (deny and allow). One policy allows traffic (host state = Healthy), and the other denies traffic (host state = Infected). When CPPM sends the information, the IP addresses are assigned according to their host state: Healthy or Infected.

You can then verify that traffic from the Infected host is denied access by the deny policy, and traffic from the Healthy host is allowed access by the allow policy.

Create a REST API administrator

A REST API administrator is required to generate an authorization token for REST API messages, and to limit hosts that can send REST API messages to the FortiGate.

To create a REST API administrator in the GUI:

1. Go to *System > Administrators*.
2. Click *Create New > REST API Admin*.
3. Configure the *Username* and other information as needed.
4. Disable *PKI Group*.
5. In the *Trusted Hosts* field, enter *10.1.100.0/24*.

New REST API Admin

Username

Comments 0/255

Administrator profile

PKI Group

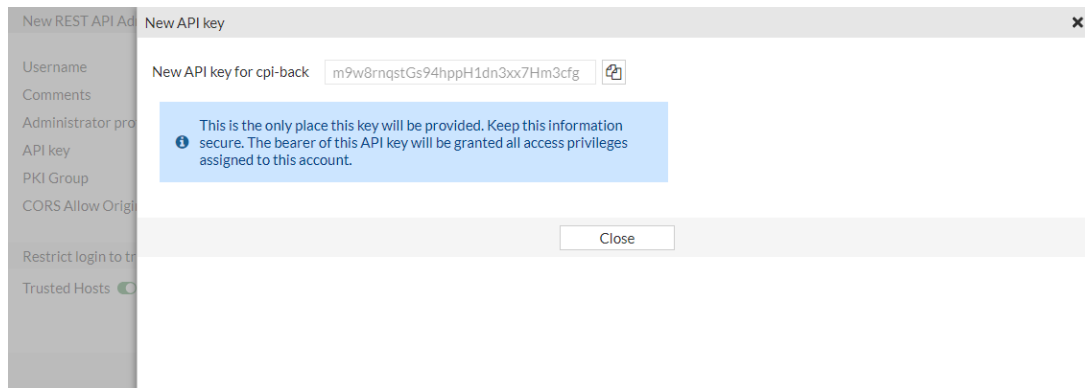

CORS Allow Origin

Restrict login to trusted hosts

Trusted Hosts

For this example, an administrator profile called *clearpass* was created with full read/write access. See [Administrator profiles on page 2049](#) for details.

6. Click *OK*.
The *New API key* pane opens.

The API key is the REST API authorization token that is used in REST API messages sent by CPPM to the FortiGate.

7. Copy the API key to a secure location. A new key can be generated if this one is lost or compromised.
8. Click *Close*.

To create a REST API administrator in the CLI:

```
config system api-user
  edit "cpi-back"
    set accprofile "clearpass"
    config trusthost
      edit 1
        set ipv4-trusthost 10.1.100.0 255.255.255.0
      next
    end
  next
end

execute api-user generate-key cp-api
New API key: 0f1HxGHh9r9p74k7qgfHNNH40p51bjs
NOTE: The bearer of this API key will be granted all access privileges assigned to the
api-user cp-api.
```

Create dynamic IP addresses with the clearpass subtype

Two dynamic IP addresses are required, one for the allow policy, and the other for the deny policy.

To create the dynamic IP addresses:

```
config firewall address
  edit "cppm"
    set type dynamic
    set sub-type clearpass-spt
    set clearpass-spt healthy
    set comment ''
    set visibility enable
    set associated-interface ''
    set color 0
  next
  edit "cppm-deny"
    set type dynamic
```

```
        set sub-type clearpass-spt
        set clearpass-spt infected
        set comment ''
        set visibility enable
        set associated-interface ''
        set color 0
    next
end
```

Create firewall policies

Two firewall policies are required, one to accept traffic (*cppm-allow*), and the other to deny traffic (*cppm-deny*).

To create the firewall policies in the GUI:

1. Go to *Policy & Objects > Firewall Policy*.
2. Configure the allow policy:
 - a. Click *Create New*.
 - b. Enter a name for the policy.
 - c. Set *Source* set to *cppm*.
 - d. Set *Action* to *ACCEPT*.
 - e. Configure the remaining settings as needed.
 - f. Click *OK*.
3. Configure the deny policy:
 - a. Click *Create New*.
 - b. Enter a name for the policy.
 - c. Set *Source* set to *cppm-deny*.
 - d. Set *Action* to *DENY*.
 - e. Configure the remaining settings as needed.
 - f. Click *OK*.

To create the firewall policies in the CLI:

```
config firewall address
  edit "cppm"
    set type dynamic
    set sub-type clearpass-spt
    set clearpass-spt healthy
    set comment ''
    set visibility enable
    set associated-interface ''
    set color 0
  next
  edit "cppm-deny"
    set type dynamic
    set sub-type clearpass-spt
    set clearpass-spt infected
    set comment ''
    set visibility enable
    set associated-interface ''
    set color 0
```

```

next
end

```

Verification

Go to *Log & Report > Forward Traffic* to review traffic logs and ensure that traffic is allowed or denied as expected.

To verify that FortiGate addresses are assigned correctly, enter the following:

```

# diagnose firewall dynamic list
List all dynamic addresses:
cppm-deny: ID(141)
            ADDR(10.1.100.188)

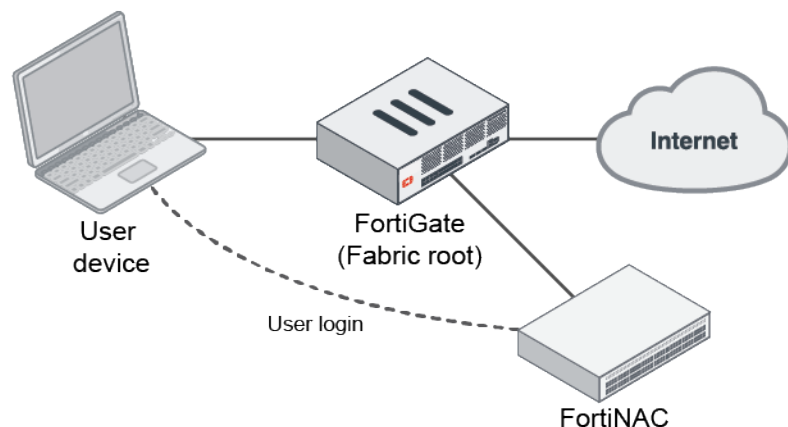

cppm: ID(176)
      ADDR(10.1.100.185)
      ADDR(10.1.100.186)

```

FortiNAC tag dynamic address

The FortiNAC tag dynamic firewall address type is used to store the device IP, FortiNAC firewall tags, and FortiNAC group information sent from FortiNAC by the REST API when user logon and logoff events are registered.

In the following example, the user connecting to the network will be required to first log on to the FortiNAC. When the login succeeds, the logon information is synchronized to the FortiGate using the REST API. The FortiGate updates the dynamic firewall address object with the user and IP information of the user device. This firewall address is used in firewall policies to dynamically allow network access for authenticated users, thereby allowing SSO for the end user.

This example assumes the following:

- The FortiGate is the Security Fabric root device (refer to [Configuring the root FortiGate and downstream FortiGates on page 2364](#) for more information).
- The FortiNAC is running version 9.2.2 (or later), and it is connected to the Security Fabric (refer to [Configuring FortiNAC on page 2408](#) for more information).
- Firewall tags and groups have been assigned in FortiNAC to the registered FortiGate (refer to [Virtualized Devices](#) for more information). Unlike firewall tags, which are simple labels that can be configured on FortiNAC, firewall groups can be local, built-in, user-defined, or remote user groups imported from a remote server used for user authentication. Only groups that the user of the current logon event belongs to are sent to the FortiGate. Firewall tags are sent for all user authentication.

To use a FortiNAC tag dynamic firewall address in a policy:

1. Trigger two user logon events on the FortiNAC.
2. In FortiOS, go to *Policy & Objects > Addresses*, and expand the *FortiNAC Tag (IP Address)* section to view the newly created dynamic firewall address objects. The dynamic firewall addresses matching the current user logon status on FortiNAC have the current IP address of user devices. The addresses without matching user logons are marked with a red exclamation mark (!).

Name	Details	Interface	Fabric Sync	Type	Ref.
IP Range/Subnet					
FABRIC_DEVICE	0.0.0.0/0		Disable	Address	0
FIREWALL_AUTH_PORTAL_ADDRESS	0.0.0.0/0		Disable	Address	0
SSLVPN_TUNNEL_ADDR1	10.212.134.200 - 10.212.134.210		Disable	Address	3
all	0.0.0.0/0		Disable	Address	12
ipsec_range	10.1.10.1 - 10.1.10.24		Disable	Address	0
van_vpn_range	1.1.1.1 - 1.1.1.5		Disable	Address	0
FortiNAC Tag (IP Address)					
!! FNVMCATM..._Forced User Authentication Ex...			Disable	Address	0
FNVMCATM..._QA-group1	10.1.100.184-10.1.100.185		Disable	Address	1
FNVMCATM..._QA-group2	10.1.100.184-10.1.100.185		Disable	Address	1
FNVMCATM..._Registered Hosts	10.1.100.184-10.1.100.185		Disable	Address	1
!! FNVMCATM..._g1			Disable	Address	0
FNVMCATM..._g2	10.1.100.184-10.1.100.185		Disable	Address	0
!! FNVMCATM..._group1			Disable	Address	0
FNVMCATM..._group2	10.1.100.184-10.1.100.185		Disable	Address	0
Dynamic (ClearPass)					
!! cp-healthy			Disable	Address	0

3. Go to *Policy & Objects > Firewall Policy* and click *Create New* or edit an existing policy. FortiNAC tag dynamic firewall address can be used as source or destination addresses.

Edit Policy

- Configure the settings as needed, then click **OK**. In this policy, traffic can only pass if it originates from any of the mapped IP addresses (10.1.100.184 and 10.1.100.185); other traffic cannot pass.
- Hover over the address in the policy, then in the tooltip, click **View Matched Addresses**.

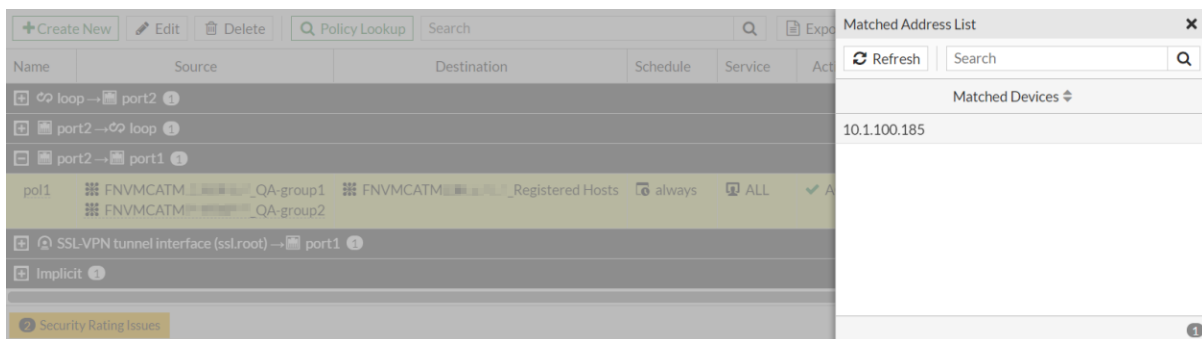

- Have one of the users log off from the FortiNAC.
- In FortiOS, go to **Policy & Objects > Addresses** and verify the **FortiNAC Tag** addresses. A user logged off from 10.1.100.184, so now only 10.1.100.185 is mapped to the dynamic firewall objects.

All firewall policies using those objects are automatically updated.

- Go to **Policy & Objects > Firewall Policy**. Hover over the address in the policy, then in the tooltip, click **View Matched Addresses**.

The firewall policy was automatically updated so that traffic from 10.1.100.184 can no longer pass, and only traffic from 10.1.100.185 can pass.

MAC addressed-based policies

MAC addresses can be added to the following IPv4 policies:

- Firewall
- Virtual wire pair
- ACL
- Central SNAT
- DoS

A MAC address is a link layer-based address type and it cannot be forwarded across different IP segments. In FortiOS, you can configure a firewall address object with a singular MAC, wildcard MAC, multiple MACs, or a MAC range.

FortiOS only supports the MAC address type as source address for policies in NAT mode VDOM. When you use the MAC address type in a policy as source address in NAT mode VDOM, IP address translation (NAT) is still performed according to the rules defined in the policy. The MAC address type only works for source address matching. It does not have any association with NAT actions.

For policies in transparent mode or the virtual wire pair interface, you can use the MAC address type as source or destination address.

To configure a MAC address using the GUI:

1. Go to *Policy & Objects > Addresses* and click *Create New > Address*.
2. Enter a name.
3. For *Category*, select *Address*.
4. For *Type*, select *Device (MAC Address)*.
5. Enter the MAC address.

The screenshot shows the 'New Address' configuration window in FortiOS. The 'Category' is set to 'Address'. The 'Name' field contains 'test-mac-addr1'. The 'Type' is set to 'Device (MAC Address)'. The 'MAC address' field contains '00:0c:29:41:98:88'. The 'Interface' is set to 'any'. The 'Comments' field is empty. The right sidebar shows 'FortiGate-VM64' and 'Additional Information' with links to 'API Preview', 'Dynamic Address', and 'Documentation'.

6. Click **OK**.

7. Go to *Policy & Objects > Firewall Policy* to apply the address type to a policy in NAT mode VDOM:
 - a. For *Source*, select the MAC address you just configured.
 - b. For *Destination*, select an address.

In NAT mode VDOM, this address type cannot be used as destination address.

- c. Configure the other settings as needed.
- d. Click OK.

To configure a MAC address using the CLI:

1. Create a new MAC address:

```
config firewall address
  edit "test-mac-addr1"
    set type mac
    set macaddr 00:0c:29:41:98:88
  next
end
```

2. Apply the address type to a policy. In transparent mode or the virtual wire pair interface, this address type can be mixed with other address types in the policy:

```
config firewall policy
  edit 1
    set srcintf "port2"
    set dstintf "port1"
    set srcaddr "test-mac-addr1" "10-1-100-42"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
    set nat enable
  next
end
```

ISDB well-known MAC address list

The Internet Service Database (ISDB) includes well-known vendor MAC address range lists. The lists can only be used for source MAC addresses in IPv4 policies, and include the vendor name and the MAC address ranges that the vendor belongs to.

To view the vendor list:

```
# diagnose vendor-mac id
Please input Vendor MAC ID.
ID: 1 name: "Asus"
ID: 2 name: "Acer"
ID: 3 name: "Amazon"
ID: 4 name: "Apple"
```

```
ID: 5 name: "Xiaomi"
ID: 6 name: "BlackBerry"
ID: 7 name: "Canon"
ID: 8 name: "Cisco"
ID: 9 name: "Linksys"
ID: 10 name: "D-Link"
ID: 11 name: "Dell"
ID: 12 name: "Ericsson"
ID: 13 name: "LG"
ID: 14 name: "Fujitsu"
ID: 15 name: "Fitbit"
ID: 16 name: "Fortinet"
ID: 17 name: "OPPO"
ID: 18 name: "Hitachi"
ID: 19 name: "HTC"
ID: 20 name: "Huawei"
ID: 21 name: "HP"
ID: 22 name: "IBM"
ID: 23 name: "Juniper"
ID: 24 name: "Lenovo"
ID: 25 name: "Microsoft"
ID: 26 name: "Motorola"
ID: 27 name: "Netgear"
ID: 28 name: "Nokia"
ID: 29 name: "Nintendo"
ID: 30 name: "PaloAltoNetworks"
ID: 31 name: "Polycom"
ID: 32 name: "Samsung"
ID: 33 name: "Sharp"
ID: 34 name: "Sony"
ID: 35 name: "Toshiba"
ID: 36 name: "VMware"
ID: 37 name: "Vivo"
ID: 38 name: "Zyxel"
ID: 39 name: "ZTE"
```

To view the MAC address ranges for a vendor:

```
# diagnose vendor-mac id 16
Vendor MAC: 16(Fortinet)
Version: 0000700021
Timestamp: 201908081432
Number of MAC ranges: 6
00:09:0f:00:00:00 - 00:09:0f:ff:ff:ff
04:d5:90:00:00:00 - 04:d5:90:ff:ff:ff
08:5b:0e:00:00:00 - 08:5b:0e:ff:ff:ff
70:4c:a5:00:00:00 - 70:4c:a5:ff:ff:ff
90:6c:ac:00:00:00 - 90:6c:ac:ff:ff:ff
e8:1c:ba:00:00:00 - e8:1c:ba:ff:ff:ff
```

To query the vendor of a specific MAC address or range:

```
# diagnose vendor-mac match 00:09:0f:ff:ff:ff 48
Vendor MAC: 16(Fortinet), matched num: 1
```

To use the vendor ID in a firewall policy:

```
config firewall policy
  edit 9
    set name "policy_id_9"
    set uuid 6150cf30-308d-51e9-a7a3-bcbd05d61f93
    set srcintf "wan2"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set vendor-mac 36 16
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
    set auto-asic-offload disable
    set nat enable
  next
end
```

Only packets whose source MAC address belong to Fortinet or VMware are passed by the policy.

IPv6 MAC addresses and usage in firewall policies

Users can define IPv6 MAC addresses that can be applied to the following policies:

- Firewall
- Virtual wire pair
- ACL/DoS
- Central NAT
- NAT64
- Local-in

In FortiOS, you can configure a firewall address object with a singular MAC, wildcard MAC, multiple MACs, or a MAC range. In this example, a firewall policy is configured in a NAT mode VDOM with the IPv6 MAC address as a source address.

IPv6 MAC addresses cannot be used as destination addresses in VDOMs when in NAT operation mode.

To configure IPv6 MAC addresses in a policy in the GUI:

1. Create the MAC address:
 - a. Go to *Policy & Objects > Addresses* and click *Create New > Address*.
 - b. For *Category*, select *IPv6 Address*.
 - c. Enter an address name.
 - d. For *Type*, select *Device (MAC Address)*.

e. Enter the the MAC address.

The screenshot shows the 'New Address' configuration window in FortiGate. The 'IPv6 Address' tab is active. The 'Name' field is 'test-ipv6-mac-addr-1', 'Type' is 'Device (MAC Address)', and 'MAC address' is '00:0c:29:b5:92:8d'. The right sidebar shows 'FortiGate-VM64' and 'Dynamic Address' guides.

f. Click OK.

2. Configure the policy:

- a. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
- b. For *Source*, select the IPv6 MAC address object.
- c. Configure the other settings as needed.
- d. Click OK.

To configure IPv6 MAC addresses in a policy in the CLI:

1. Create the MAC address:

```
config firewall address6
  edit "test-ipv6-mac-addr-1"
    set type mac
    set macaddr 00:0c:29:b5:92:8d
  next
end
```

2. Configure the policy:

```
config firewall policy
  edit 2
    set srcintf "wan2"
    set dstintf "wan1"
    set srcaddr "all"
    set dstaddr "all"
    set srcaddr6 "test-ipv6-mac-addr-1" "2000-10-1-100-0"
    set dstaddr6 "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
    set auto-asic-offload disable
    set nat enable
  next
end
```

Protocol options

Firewall policies contain a *Protocol Options* field that defines the parameters for handling protocol-specific traffic. Multiple protocol options profiles can be configured in FortiOS since the requirements may differ between policies. A single protocol options profile is applied per policy, but the profile can be used in multiple policies.

To create a protocol options profile, go to *Policy & Objects > Protocol Options*. The following settings can be configured.

Log oversized files

Enable this option to log the occurrence of oversized files being processed. This does not change how they are processed. It only allows the FortiGate to log that they were either blocked or allowed through.

It is common practice to allow larger files through without antivirus processing. Monitor the logs for the frequency of oversized file processing to determine whether or not to alter the settings for treating oversized files. The threshold setting for oversized files and emails is located in the *Common Options* section.

RPC over HTTP

This protocol is used by Microsoft Exchange Servers to perform virus scanning on emails that use RPC over HTTP.

Protocol port mapping

To optimize the FortiGate's resources, the mapping and inspection of the following protocols can be enabled or disabled:

- HTTP
- SMTP
- POP3
- IMAP
- FTP
- NNTP
- MAPI
- DNS
- CIFS

Each protocol has a default TCP port. The ports can be modified to inspect any port with flowing traffic. The packet headers indicate which protocol generated the packet.

Protocol port mapping only works with proxy-based inspection. Flow-based inspection inspects all ports regardless of the protocol port mapping configuration.

Common options

The *Comfort Clients* and *Block Oversized File/Email* options apply to multiple protocols.

Comfort clients

When proxy-based antivirus scanning is enabled, the FortiGate buffers files as they are downloaded. Once the entire file is captured, the FortiGate begins scanning the file. The user must wait during the buffering and scanning procedure.

After the scan is completed and if no infection is found, the file is sent to the next step in the process flow. If the file is large, this part of the process can take some time. In some cases, enough time that some users may get impatient and cancel the download.

The *Comfort Clients* option mitigates this potential issue by feeding a trickle of data while waiting for the scan to complete. The user is aware that processing is taking place, and that there has not been a failure in the transmission. The slow transfer rate continues until the antivirus scan is complete. The transfer will proceed at full speed once the file is scanned successfully and does not contain any viruses.

If there is evidence of an infection, the FortiGate caches the URL and drops the connection. The client does not receive any notification of what happened because the download to the client has already started. Instead, the download stops and the user is left with a partially downloaded file. If the user tries to download the same file again within a short period of time, the cached URL is matched and the download is blocked. A notification is displayed that the download was blocked. The number of URLs in the cache is limited by the size of the cache.

Client comforting is available for HTTP and FTP traffic. If the FortiGate supports SSL content scanning and inspection, client comforting can be configured for HTTPS and FTPS traffic.

Buffering the entire file allows the FortiGate to eliminate the danger of missing an infection due to fragmentation because the file is reassembled before examination. This buffering is performed whenever the *Comfort Clients* option is disabled.

Client comforting can send unscanned and potentially infected content to the client, so only enable this option if you are prepared to accept this risk. Keeping the client comforting interval high and the amount low will reduce the amount of potentially infected data that is downloaded.

Block oversized files and emails

This option is related to antivirus scanning. The FortiGate has a finite amount of resources to buffer and scan a file. If a large file (such as an ISO image or video file) is downloaded, this could overwhelm or exceed the FortiGate's memory, especially if other large files are being downloaded at the same time.

A threshold is assigned to identify an oversize file or email. The default is 10 MB. The range varies per model, and the minimum is 1 MB. Any file or email over this threshold will not be processed by policies applying the antivirus security profile.

If the FortiGate enters conserve mode on a regular basis, lowering the threshold can lessen the impact of processing the files on memory. This can increase risk, even though malware is more likely to be in smaller files.

Web options

The *Chunked Bypass* option applies to traffic containing web protocols.

Chunked bypass

Chunked bypass is a mechanism in HTTP 1.1 that allows a web server to start sending chunks of dynamically generated output in response to a request before actually knowing the actual size of the content. For dynamically generated

content, enabling chunked bypass speeds up the initial response to HTTP requests, but the content is not held in the proxy as an entire file before proceeding.

Email options

The *Allow Fragmented Messages* and *Append Signature (SMTP)* options apply to email protocols.

Allow fragmented messages

The specifications of RFC 2046 allow for the breaking up of emails and sending the fragments in parallel to be rebuilt and read at the other end by the mail server. It was originally designed to increase the performance over slower connections where larger email messages were involved. Feasibility of using this function depends on the mail configuration. Outside of Microsoft Outlook, not many email clients are set up to break up messages like this. The drawback of this feature is that if malware is broken up between multiple fragments of the message, there is a risk that it will not be detected by some antivirus configurations because all the code may not be present at the same time to identify the malware.

Append signature

This option adds a plain text email signature to SMTP email messages as they pass through the FortiGate. The message maximum is 1023 characters.

This feature works best in an environment where there is some standardization of what goes into the senders' personal signatures so that there is no duplication or contradiction of information. For example:

- *This email should not be forwarded without prior approval.*
- *Please consider the environment before printing this email.*
- *For questions regarding purchasing our products, please call ...*

Traffic shaping

A FortiGate provides quality of service (QoS) by applying bandwidth limits and prioritization to network traffic. Traffic shaping is one technique used by the FortiGate to provide QoS. A basic approach to traffic shaping is to prioritize higher priority traffic over lower priority traffic during periods of traffic congestion. This provides a stabilizing effect for important traffic while throttling less important traffic.

The FortiGate can be configured to deliver traffic shaping with policing or traffic shaping with queuing. The general difference between the two is as follows:

Technique	Description
Traffic shaping with policing	When traffic exceeds the configured bandwidth limits, traffic is dropped.
Traffic shaping with queuing	When traffic exceeds the configured bandwidth limits, traffic is delayed for transport until bandwidth frees up. Traffic may be dropped if the queues are full.

Policing and queuing can both prioritize traffic and deliver guaranteed bandwidth and maximum bandwidth by setting bandwidth limits. The implementation differs though, since queuing uses queues, and policing does not. In queuing,

before a packet egresses an interface, it is first enqueued to a queue using an algorithm such as RED or FIFO. The kernel dequeues the packet based on the HTB algorithm before sending it out. In policing, traffic simply drops if it is over the allocated bandwidth.

The following topics provide information about configuring traffic shaping:

- [Traffic shaping policies on page 987](#)
- [Traffic shaping profiles on page 990](#)
- [Traffic shapers on page 1000](#)
- [Global traffic prioritization on page 1010](#)
- [DSCP matching and DSCP marking on page 1013](#)
- [Examples on page 1017](#)

Configuration methods

There are different methods to configure traffic shaping on the FortiGate. The following table lists the methods and their capabilities in order of preference. If all three methods are configured, the first will be preferred over the second, which is preferred over the third.

Method	Policing		Queuing
	Traffic prioritization	Guaranteed and maximum bandwidth limits	Traffic queuing
Traffic shaping profile *	Yes	Yes, based on percentage of outbandwidth	Yes
Traffic shaper	Yes	Yes, based on rate	No
Global traffic prioritization	Yes	No	No

* Traffic shaping profiles are configured as either policing or queuing types. Queuing allows for additional options when configuring a shaping class entry.

The features of each method's implementation are slightly different. The following is a brief summary of the traffic policing features and the approach each method takes.

Traffic prioritization

The FortiGate can place packets into different priority levels in order to prioritize certain traffic over others.

Method	Description
Traffic shaping profile	Traffic is placed into classes. A total of 30 classes are available. For each class, traffic can be configured into five priority levels.
Traffic shaper	Traffic can be prioritized into the high (2), medium (3), or low (4) levels. When traffic is below the guaranteed bandwidth of the shaper, the traffic is automatically applied the critical level (1).

Method	Description
Global traffic prioritization	Traffic is prioritized into high (2), medium (3), or low (4) based on ToS (type of service) or DSCP.

Guaranteed and maximum bandwidth limits

The general purpose for configuring guaranteed bandwidth is to allocate a certain proportion of the total outbandwidth to guarantee transport for a certain type of traffic. This is configured and handled differently in each method.

A traffic shaping profile, when applied to an interface's egress shaping profile, can be configured to use up to 100% of the interface's configured bandwidth between all the classes. It does not matter what priority is configured in each class. The guaranteed bandwidth is always honored.

Traffic shapers, however, do not have a hard limit on the guaranteed bandwidth. Administrators need to be aware how much guaranteed bandwidth has been allocated to all their traffic shapers, so that they do not exceed the total outbandwidth of an interface. Traffic under the guaranteed bandwidth of a traffic shaper is given a priority of one. If the total traffic with priority one exceeds the total outbandwidth, traffic can be dropped.

The maximum bandwidth limit caps the maximum bandwidth that can be used. This is configured as a percentage of the outbandwidth in a traffic shaping profile. It is configured as a rate for traffic shapers.

Configuring outbandwidth

Traffic shaping is generally configured for egress traffic leaving the FortiGate. Therefore, it is necessary for the interface outbandwidth to be defined for traffic prioritization to take place in all of the traffic shaping configuration methods. Interface outbandwidth is also needed when defining the guaranteed and maximum bandwidth in a traffic shaping profile.

For traffic shapers, configuring outbandwidth is not necessary to apply maximum bandwidth limits; however, outbandwidth is necessary for guaranteed bandwidth. Traffic under the guaranteed bandwidth limit on a traffic shaper is given priority 1. If outbandwidth is not configured, traffic prioritization does not take place and the priority is meaningless.

Traffic shaping policy

Traffic shaping profiles and traffic shapers are methods of policing traffic. Traffic shaping policies are used to map traffic to a traffic shaper or assign them to a class.

A traffic shaping policy is a rule that matches traffic based on certain IP header fields and/or upper layer criteria. For example, it can match traffic based on source and destination IP, service, application, and URL category. One common use case is to match traffic based on the ToS or DS (differentiated services) field in the IP header. This allows Type of Service or Differentiated Services (DiffServ) tags to be read from traffic from a downstream device and prioritized accordingly on the FortiGate.

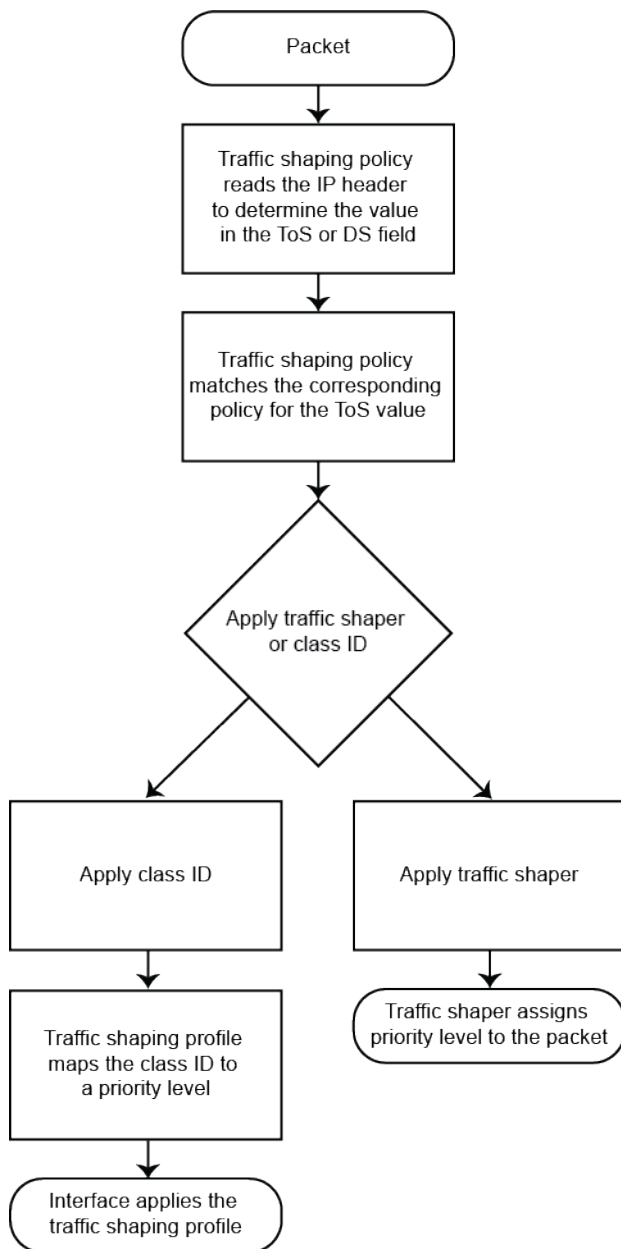

DSCP matching and DSCP marking

DSCP matching and DSCP marking can be performed on a firewall shaping policy and a regular firewall policy. DSCP matching is used to match DSCP tags from ingress traffic, and DSCP marking is used to change the DSCP tag on egress traffic.

In a firewall shaping policy and regular firewall policy, use the `tos` and `tos-mask` fields to perform DSCP matching. Use the `diffserv-forward` and `diffserv-reverse` fields to perform DSCP marking.

Traffic shaping policies

As mentioned in [Traffic shaping on page 984](#), traffic shaping starts with the traffic shaping policy. Traffic shaping policies are used to map traffic to a traffic shaper or assign them to a class. Traffic is then shaped by the shaper or the shaping profile that is applied on an interface.

Traffic can also be shaped by applying traffic shapers directly on a firewall policy. However, this legacy approach can only be configured from the CLI, and is not a preferred method for applying traffic shaping. As the number of firewall

policies increases, managing shaping on each individual policy becomes increasingly difficult. For the same reason, it is also not recommended to mix the legacy approach with traffic shaping policies to avoid the added complexity.

Overview

A traffic shaping policy is a rule that matches traffic based on certain IP header fields and/or upper layer criteria. When traffic hits the firewall, the FortiGate will first look up a firewall policy, and then match a shaping policy. The matching traffic will apply a traffic shaper, class ID, or assign a DSCP DiffServ tag to the outgoing traffic.

The traffic shaping policies must be placed in the correct order in the traffic shaping policy list page to obtain the desired results. Policies are matched from top-down, so the traffic shaping policies should be arranged in a sequence that places the more granular policies above general policies.

The policy can be configured by going to *Policy & Objects > Traffic Shaping* and selecting the *Traffic Shaping Policies* tab. If the menu does not display the traffic shaping settings, go to *System > Feature Visibility* and enable *Traffic Shaping*.

Configuring traffic shaping policies

A traffic shaping policy can be split into two parts:

- Options used to match the traffic
- Options used to apply actions to the matched traffic

In the GUI, the options are configured in the *If Traffic Matches* and *Then* sections. In the CLI, all options are configured under `config firewall shaping-policy`. Some options can only be configured from the CLI.

The following options can be configured for traffic matching criteria:

GUI option	CLI option	Description
<i>Source</i>		
<i>Address</i>	<code>set srcaddr <address_object></code>	Select the address object to match the source IP.
<i>User</i>	<code>set users <user_object></code>	Select the user object to match the user authenticated for the session.
<i>Internet Service</i>	<pre>set internet-service-src enable set internet-service-src-name <name> set internet-service-src-group <group> set internet-service-src-custom <custom> set internet-service-src-custom-group <custom_group></pre>	Select the internet service to match the source of the incoming traffic. Internet service currently cannot be used with source address.
<i>Destination</i>		

GUI option	CLI option	Description
<i>Address</i>	<code>set dstaddr <address_
object></code>	Select the address object to match the destination IP.
<i>Internet Service</i>	<code>set internet-service
enable
set internet-service-name
<name>
set internet-service-
group <group>
set internet-service-
custom <custom>
set internet-service-
custom-group
<custom_group></code>	Select the internet service to match the destination of the incoming traffic. Internet service currently cannot be used with destination address and service.
<i>Schedule</i>	<code>set schedule <schedule></code>	Enable to select a schedule (one-time, recurring, or group).
<i>Service</i>	<code>set service <service></code>	Select the service or service group for the traffic.
<i>Application</i>		Application control must be enabled in the related firewall policy to learn the application of the traffic.
<i>Application</i>	<code>set application
<application></code>	Select the application to match the application of the traffic.
<i>Category</i>	<code>set app-category
<category></code>	Select the application category to match the application of the traffic.
<i>Group</i>	<code>set app-group <groups></code>	Select the application group to match the application of the traffic.
<i>URL Category</i>	<code>set url-category
<category></code>	Select the URL category to match the URL of the traffic. A web filter profile must be enabled in the related firewall policy to know the URL of the traffic (see Web filter on page 1217).
n/a	<code>set tos-mask
<hexadecimal_mask>
set tos <value>
set tos-negate {enable
disable}</code>	Specify the type of service (ToS) and mask to match. These options can only be configured in the CLI.

The following options can be configured for actions to apply to the matched traffic:

GUI option	CLI option	Description
<i>Outgoing interface</i>	<code>set dstintf <interface></code>	Select the destination interface that the traffic shaping applies to (required).
<i>Apply shaper</i>		

GUI option	CLI option	Description
<i>Shared shaper</i>	<code>set traffic-shaper <shaper></code>	Select the shared shaper to be applied to traffic in the ingress-to-egress direction. For example, on traffic that egresses on the wan interface, the shaper is applied to upload or outbound traffic.
<i>Reverse shaper</i>	<code>set traffic-shaper-reverse <shaper></code>	Select the reverse shaper to be applied to traffic in the egress-to-ingress direction. For example, on traffic that egresses on the wan interface, the shaper is applied to download or inbound traffic.
<i>Per-IP shaper</i>	<code>set per-ip-shaper <shaper></code>	Select the per-IP shaper. Per-IP shapers affect downloads and uploads. The allotted bandwidth applies to each individual IP. In a shared shaper, the allotted bandwidth applies to all IPs.
<i>Assign shaping class ID</i>		
<i>Traffic shaping class ID</i>	<code>set class-id <class></code>	Set the class ID to apply the matching traffic. Class IDs are further prioritized within a traffic shaping profile and applied to an interface.
n/a	<code>set diffserv-forward {enable disable}</code> <code>set diffservcode-forward <code></code> <code>set diffserv-reverse {enable disable}</code> <code>set diffservcode-reverse <code></code>	Specify the settings to apply a DSCP tag to the forward or reverse traffic. The DiffServ code is in 6-bit binary format. These options can only be configured in the CLI.

Traffic shapers and class IDs can be applied at the same time when configuring traffic shaping policies. However, to reduce the complexity, it is recommended to use one method over the other.

The following topics include examples with traffic shaping policies:

- [Interface-based traffic shaping profile on page 1017](#)
- [Shared traffic shaper on page 1000](#)
- [Per-IP traffic shaper on page 1005](#)

Traffic shaping profiles

As mentioned in [Traffic shaping on page 984](#), the three main methods of configuring traffic shaping are:

- Traffic shaping profiles
- Traffic shapers
- Global traffic prioritization

A traffic shaping profile allows traffic shaping to be configured with policing or queuing. Up to 30 classes can be defined, with prioritization and bandwidth limits configured for each class. When queuing is enabled, metrics can be configured for traffic queuing in each class.

Traffic shaping with policing

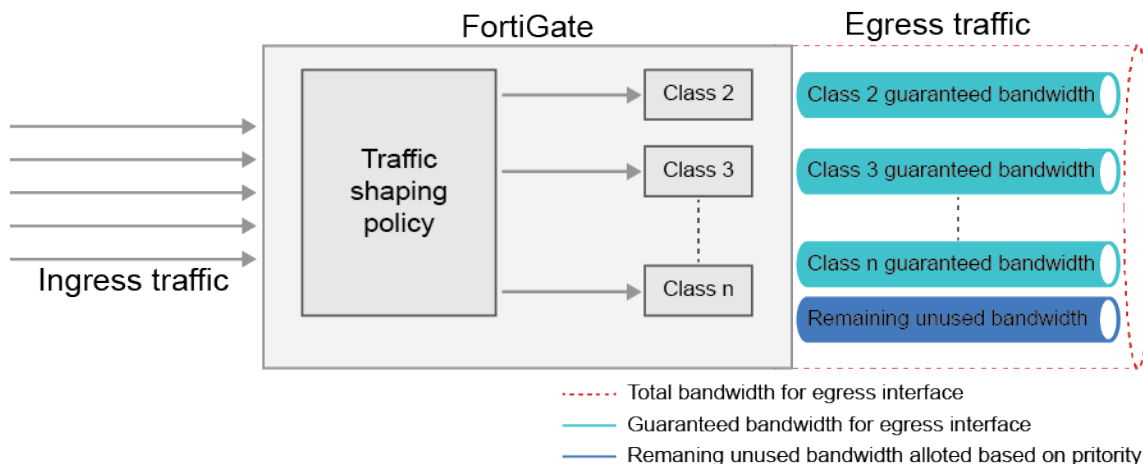

At the most basic level, policing involves traffic prioritization and bandwidth limits. Traffic prioritization helps categorize traffic into different priority levels: low, medium, high, critical, and top. When bandwidth is limited, traffic with higher priority levels will take precedence over lower priority traffic. Traffic with lower priority levels that exceeds available bandwidth will be dropped. These levels are only applicable in the context of traffic shaping profiles and should not be confused with global traffic prioritization levels.

Bandwidth limits define the guaranteed and maximum bandwidth allotted to each traffic class. These limits are configured as a percentage of the outbandwidth, which is the outbound bandwidth configured on an interface.

Guaranteed bandwidth limits guarantee the minimum bandwidth that is allotted to a given class of traffic. The sum of all guaranteed bandwidth of all classes within a traffic shaping profile cannot exceed 100%. However, the sum of all guaranteed bandwidth does not need to add up to 100%. The guaranteed bandwidth is always respected, even if one class has lower priority than another.

Maximum bandwidth limits define the maximum percentage of the outbandwidth that a traffic class can use up. This value often will be 100%, given that when there is no other traffic going through other classes, you would want to fully utilize the bandwidth of the outbound link. Traffic throughput exceeding the maximum bandwidth will be dropped.

The following diagram illustrates ingress traffic and how the FortiGate assigns classes and bandwidth to each class.

When comparing traffic shaping profiles and traffic shapers, it is important to remember that guaranteed and maximum bandwidth in a traffic shaping profile is a percentage of the outbandwidth, while guaranteed and maximum bandwidth in a traffic shaper is a rate (Kbps, Mbps, and so on). As long as the outbandwidth is true to its measurement, the bandwidth usage should not exceed the available bandwidth of a link when using a traffic shaping profile.

Congestion occurs when actual traffic surpasses the outbandwidth limit. At this point, traffic prioritization helps determine which traffic will be prioritized over others. First, the guaranteed bandwidth limit is allocated for each class. The left over bandwidth is allocated to traffic classes based on priority. The traffic classes with the highest priority can use as much of the remaining bandwidth as needed. Then, the remaining bandwidth can be allocated to classes at the next priority level, and so forth.

To see examples of applied traffic prioritization and bandwidth limits, see the debugs in [Verifying that the traffic is being shaped on page 995](#).

Traffic shaping with queuing

When traffic congestion occurs and if there is no queuing, then the excess packets are dropped. With queuing, when traffic exceeds the configured bandwidth limits, the traffic is delayed for transport until bandwidth frees up. Traffic may still be dropped if the queues are full.

In queuing, before a packet egresses an interface, it is first enqueued using an algorithm, such as random early detection (RED) or first in, first out (FIFO). The kernel then dequeues the packet based on the HTB algorithm before sending it out. Queuing can be configured per shaping profile, and it can be customized per class.

The following diagram shows how traffic policing differs from traffic queuing by comparing the bandwidth limit, projected bandwidth utilization, and actual bandwidth utilization.

For more information about traffic shaping with queuing, see [Traffic shaping with queuing using a traffic shaping profile on page 996](#).

Configuring traffic shaping profiles

The main steps to configure traffic shaping are:

1. Configure the traffic shaping policy, and assign matched traffic to a class (see [Traffic shaping policies on page 987](#)).
2. Configure the traffic shaping profile and apply traffic bandwidth, prioritization and/or queuing per class.
3. Configure the interface outbandwidth and apply an egress shaping profile to the interface.

Configuring the traffic shaping profile

A traffic shaping profile consists of the class ID and the settings per class ID. It also defines the type of traffic shaping to apply (policing or queuing) and the default class ID for traffic that does not match any traffic shaping policies.

A class can be configured in the GUI as part of a traffic shaping profile or policy. In the CLI, a traffic class must be defined before it can be assigned within a traffic shaping profile. Class IDs range from 2 - 31, and they can be reused between different traffic shaping profiles.

When NPU offloading is enabled on the NP6, SoC3, or SoC4 platforms, the class ID limit for egress traffic is 2 - 15. Setting the egress traffic class ID outside of these limits can result in unexpected behavior.

If NPU offloading is disabled, or enabled on the NP7 platform, the class ID limit for egress traffic is 2 - 31.

When configuring a traffic shaping profile, the settings can be defined per class.

The following options can be configured for traffic shaping classes:

GUI option	CLI option	Description
<i>Default</i>	set default-class-id <class-id>	Set the default class ID. Each profile must have one default class ID. The default class ID can be changed at any time.
<i>Traffic shaping class ID</i>	set class-id <integer>	Set the class ID (2 - 31).
<i>Guaranteed bandwidth</i>	set guaranteed-bandwidth- percentage <integer>	Set the percentage of the outbandwidth that will be guaranteed for the class ID.
<i>Maximum bandwidth</i>	set maximum-bandwidth- percentage <integer>	Set the percentage of the outbandwidth that will be the maximum bandwidth for the class ID.
<i>Priority</i>	set priority {top critical high medium low}	Select the priority level for the class ID.

To configure a traffic shaping profile in the GUI:

1. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shaping Profiles* tab, and click *Create New*.
2. Enter the profile name, and optionally enter a comment.
3. In the *Traffic Shaping Classes* section, click *Create New*.
4. Configure the traffic shaping class ID settings (*Traffic shaping class ID*, *Guaranteed bandwidth*, *Maximum bandwidth*, and *Priority*).
5. Click *OK*.
6. Create more shaping classes as needed (the total guaranteed bandwidth of all classes cannot exceed 100%).
7. Click *OK*.

To configure a traffic shaping profile in the CLI:

1. Configure the shaping class:

```
config firewall traffic-class
  edit <integer>
    set class-name <string>
  next
end
```

2. Configure the shaping profile:

```
config firewall shaping-profile
  edit <name>
    set type {policing | queuing}
    set default-class-id <class-id>
    config shaping-entries
      edit <id>
        set class-id <integer>
        set priority {top | critical | high | medium | low}
```

```

        set guaranteed-bandwidth-percentage <integer>
        set maximum-bandwidth-percentage <integer>
    next
end
next
end

```

Configuring the interface outbandwidth

There are two settings that must be configured on an interface that has traffic shaping applied to egressing traffic: a traffic shaping profile must be assigned, and the outbound bandwidth must be configured.

Since traffic shaping is often configured on the WAN interface for egressing traffic, the outbound bandwidth is effectively the upstream bandwidth allowed by your ISP. On the FortiGate, it is possible to perform a speed test on interfaces are assigned a WAN role assigned (see [Manual interface speedtest on page 674](#)). The speed test performs measurements against public cloud servers, and provides an accurate measurement of the upstream bandwidth. After the test is complete, the results can be used to populate the *Outbound bandwidth* field.

To configure traffic shaping on an interface:

1. Go to *Network > Interfaces* and double-click an interface to edit it.
2. For interfaces assigned a WAN role, in the right-side of the screen, click *Execute speed test*.
3. When the test completes, click *OK* in the *Confirm* pane to apply the results to the estimated bandwidth. The speed test results are populated in the *Estimated bandwidth* fields for *kbps Upstream* and *kbps Downstream*.

4. In the *Traffic Shaping* section, enable *Outbound shaping profile* and select a profile.

5. Enable *Outbound bandwidth* and copy the *kbps Upstream* value from the speed test, or enter a custom value.
6. Click **OK**.

Verifying that the traffic is being shaped

In this example, three traffic classes are defined in the traffic shaping profile assigned to port1. The outbound bandwidth configured on port1 is 1000 Kbps. Each class has an `allocated-bandwidth`, `guaranteed-bandwidth`, `max-bandwidth`, and `current-bandwidth` value.

- The `guaranteed-bandwidth` and `max-bandwidth` are rates that are converted from the percentage of outbound bandwidth configured for each class. For example, `class-id 2` has 10% `guaranteed-bandwidth`, equivalent to 100 Kbps, and 100% `max-bandwidth` equivalent to 1000 Kbps.
- The `allocated-bandwidth` displays the real-time bandwidth allocation for the traffic class based on all available factors. This value changes as traffic demand changes.
- The `current-bandwidth` displays the real-time bandwidth usage detected for the traffic class.

To verify that traffic is being shaped by the traffic shaping profile:

1. Enable debug flow to view the live traffic as it matches a traffic shaping policy:

```
# diagnose debug flow show function-name enable
# diagnose debug flow show iprope enable
# diagnose debug flow filter <filters>
# diagnose debug flow trace start <repeat_number>
# diagnose debug enable
```

The `iprope_shaping_check` function outputs the shaping policy matched for any given traffic:

```
...
id=20085 trace_id=21 func=iprope_shaping_check line=934 msg="in-[port3], out-[port1],
skb_flags-02000000, vid-0"
id=20085 trace_id=21 func=__iprope_check line=2277 msg="gnum-100015, check-
fffffffffa002a8fe"
id=20085 trace_id=21 func=__iprope_check_one_policy line=2029 msg="checked gnum-100015
policy-3, ret-matched, act-accept"
id=20085 trace_id=21 func=__iprope_check_one_policy line=2247 msg="policy-3 is matched,
act-accept"
id=20085 trace_id=21 func=__iprope_check line=2294 msg="gnum-100015 check result: ret-
matched, act-accept, flag-00000000, flag2-00000000"
```

2. Display the session list:

```
# diagnose sys session filter <filters>
# diagnose sys session list
```

Sessions that match a shaping policy will display `class_id` and `shaping_policy_id` fields:

```
...
session info: proto=6 proto_state=05 duration=32 expire=0 timeout=3600 flags=00000000
socktype=0 sockport=0 av_idx=0 use=4
origin-shaper=
reply-shaper=
per_ip_shaper=
class_id=4 shaping_policy_id=3 ha_id=0 policy_dir=0 tunnel=/ vlan_cos=0/255
```

3. Display the interface statistics:

```
# diagnose netlink interface list port1
if=port1 family=00 type=1 index=3 mtu=1500 link=0 master=0
ref=95 state=start present fw_flags=2001b800 flags=up broadcast run allmulti multicast
Qdisc=pfifo_fast hw_addr=52:54:00:7e:af:a6 broadcast_addr=ff:ff:ff:ff:ff:ff
inbandwidth=10000 (kbps)          total_bytes=2098887K    drop_bytes=7854K
egress traffic control:
  bandwidth=1000 (kbps) lock_hit=241 default_class=3 n_active_class=3
  class-id=2    allocated-bandwidth=140 (kbps)  guaranteed-bandwidth=100 (kbps)
                max-bandwidth=1000 (kbps)    current-bandwidth=147 (kbps)
                priority=low    forwarded_bytes=8161K
                dropped_packets=2032  dropped_bytes=3074K
  class-id=3    allocated-bandwidth=30 (kbps)  guaranteed-bandwidth=300 (kbps)
                max-bandwidth=1000 (kbps)    current-bandwidth=10 (kbps)
                priority=medium  forwarded_bytes=501K
                dropped_packets=1    dropped_bytes=1195
  class-id=4    allocated-bandwidth=830 (kbps)  guaranteed-bandwidth=500 (kbps)
                max-bandwidth=1000 (kbps)    current-bandwidth=810 (kbps)
                priority=high  forwarded_bytes=1393K
                dropped_packets=379  dropped_bytes=572K
stat: rxp=8349728 txp=11101735 rxb=2216101183 txb=1394077978 rx=0 txe=0 rxd=0 txd=0
mc=0 collision=0 @ time=1654202868
re: rxl=0 rxo=0 rxc=0 rxf=0 rxfi=0 rxm=0
te: txa=0 txc=0 txfi=0 txh=0 txw=0
misc rxc=0 txc=0
input_type=0 state=3 arp_entry=0 refcnt=95
```

If the debug output does not display egress traffic control by class and displays them by priority, it is likely that global traffic prioritization is configured. The global traffic prioritization settings must be disabled to view the preceding debug output (see [Global traffic prioritization on page 1010](#)).

Traffic shaping with queuing using a traffic shaping profile

You can use the weighted random early detection (WRED) queuing function within traffic shaping.

This topic includes two parts:

- [Traffic shaping with queuing on page 996](#)
- [Burst control in queuing mode on page 998](#)

You cannot configure or view WRED in the GUI; you must use the CLI.

WRED is not supported when traffic is offloaded to an NPU.

Traffic shaping with queuing

Traffic shaping has a queuing option. Use this option to fine-tune the queue by setting the profile queue size or performing random early drop (RED) according to queue usage.

This example shows setting the profile queue size limit to 5 so that the queue can contain a maximum of five packets and more packets are dropped.

To set the profile queue size limit:

```
config firewall shaping-profile
  edit "profile"
    set type queuing
    set default-class-id 31
    config shaping-entries
      edit 31
        set class-id 31
        set guaranteed-bandwidth-percentage 5
        set maximum-bandwidth-percentage 10
        set limit 5 <range from 5 to 10000; default: 1000>
      next
    end
  next
end
```

This example shows performing RED according to queue usage by setting `red-probability`, `min`, and `max`. Setting `red-probability` to 10 means start to drop packets when queue usage reaches the `min` setting. When queue usage reaches the `max` setting, drop 10% of the packets.

- Level 1: when queue is less than `min` packets, drop 0% of packets.
- Level 2: when queue reaches `min` packets, start to drop packets.
- Level 3: when queue usage is between `min` and `max` packets, drop 0–10% of packets by proportion.
- Level 4: when queue (average queue size) is more than `max` packets, drop 100% of packets.

To set RED according to queue usage:

```
config firewall shaping-profile
  edit "profile"
    set type queuing
    set default-class-id 31
    config shaping-entries
      edit 31
        set class-id 31
        set guaranteed-bandwidth-percentage 5
        set maximum-bandwidth-percentage 10
        set red-probability 10 <range from 0 to 20; default: 0 no drop>
        set min 100 <range from 3 to 3000>
        set max 300 <range from 3 to 3000>
      next
    end
  next
end
```

To troubleshoot this function, use the following diagnose commands:

```
diagnose netlink intf-class list <intf>
diagnose netlink intf-qdisc list <intf>
```

Burst control in queuing mode

In a hierarchical token bucket (HTB) algorithm, each traffic class has buckets to allow a burst of traffic. The maximum burst is determined by the bucket size `burst` (for guaranteed bandwidth) and `cburst` (for maximum bandwidth). The shaping profile has `burst-in-msec` and `cburst-in-msec` parameters for each shaping entry (`class id`) to control the bucket size.

This example uses the outbandwidth of the interface as 1 Mbps and the maximum bandwidth of class is 50%.

$burst = burst\text{-in-msec} * \text{guaranteed bandwidth} = 100\text{ ms} * 1\text{ Mbps} * 50\% = 50000\text{ b} = 6250\text{ B}$

$cburst = cburst\text{-in-msec} * \text{maximum bandwidth} = 200\text{ ms} * 1\text{ Mbps} * 50\% = 100000\text{ b} = 12500\text{ B}$

The following example sets `burst-in-msec` to 100 and `cburst-in-msec` to 200.

To set burst control in queuing mode:

```
config firewall shaping-profile
  edit "profile"
    set type queuing
    set default-class-id 31
    config shaping-entries
      edit 31
        set class-id 31
        set guaranteed-bandwidth-percentage 5
        set maximum-bandwidth-percentage 50
        set burst-in-msec 100 <range from 0 to 2000>
        set cburst-in-msec 200 <range from 0 to 2000>
      next
    end
  next
end
```

Example

Enabling RED for FTP traffic from QA

This example shows how to enable RED for FTP traffic from QA. This example sets a maximum of 10% of the packets to be dropped when queue usage reaches the maximum value.

To configure the firewall address:

```
config firewall address
  edit QA_team
    set subnet 10.1.100.0/24
  next
end
```

To set the shaping policy to classify traffic into different class IDs:

```
config firewall shaping-policy
  edit 1
    set service HTTPS HTTP
    set dstintf port1
    set srcaddr QA_team
```

```
        set dstaddr all
        set class-id 10
    next
    edit 2
        set service FTP
        set dstintf port1
        set srcaddr QA_team
        set dstaddr all
        set class-id 20
    next
end
```

To set the shaping policy to define the speed of each class ID:

```
config firewall shaping-profile
    edit QA_team_profile
        set type queuing
        set default-class-id 30
        config shaping-entries
            edit 1
                set class-id 10
                set guaranteed-bandwidth-percentage 50
                set maximum-bandwidth-percentage 100
            next
            edit 2
                set class-id 20
                set guaranteed-bandwidth-percentage 30
                set maximum-bandwidth-percentage 60
                set red-probability 10
            next
            edit 3
                set class-id 30
                set guaranteed-bandwidth-percentage 20
                set maximum-bandwidth-percentage 50
            next
        end
    next
end
```

To apply the shaping policy to the interface:

```
config sys interface
    edit port1
        set outbandwidth 10000
        set egress-shaping-profile QA_team_profile
    next
end
```

To use diagnose commands to troubleshoot:

```
# diagnose netlink intf-class list port1

Traffic shapers

The following topics provide more information about traffic shapers:

- [Shared traffic shaper on page 1000](#)
- [Per-IP traffic shaper on page 1005](#)
- [Changing traffic shaper bandwidth unit of measurement on page 1008](#)
- [Multi-stage DSCP marking and class ID in traffic shapers on page 1008](#)

Shared traffic shaper

Shared traffic shaper is used in a firewall shaping policy to indicate the priority and guaranteed and maximum bandwidth for a specified type of traffic use.

The maximum bandwidth indicates the largest amount of traffic allowed when using the policy. You can set the maximum bandwidth to a value between 1 and 16776000 Kbps. The GUI displays an error if any value outside this range is used. If you want to allow unlimited bandwidth, use the CLI to enter a value of 0.

The guaranteed bandwidth ensures that there is a consistent reserved bandwidth available. When setting the guaranteed bandwidth, ensure that the value is significantly less than the interface's bandwidth capacity. Otherwise, the interface will allow very little or no other traffic to pass through, potentially causing unwanted latency.

In a shared traffic shaper, the administrator can prioritize certain traffic as high, medium, or low. FortiOS provides bandwidth to low priority connections only when high priority connections do not need the bandwidth. For example, you should assign a high traffic priority to a policy for connecting a secure web server that needs to support e-commerce traffic. You should assign less important services a low priority.

When you configure a shared traffic shaper, you can apply bandwidth shaping per policy or for all policies. By default, a shared traffic shaper applies traffic shaping evenly to all policies that use the shared traffic shaper.

When configuring a per-policy traffic shaper, FortiOS applies the traffic shaping rules defined for each security policy individually. For example, if a per-policy traffic shaper is configured with a maximum bandwidth of 1000 Kbps, any security policies that have that traffic shaper enabled get 1000 Kbps of bandwidth each.

If a traffic shaper for all policies is configured with a maximum bandwidth of 1000 Kbps, all policies share the 1000 Kbps on a first-come, first-served basis.

The configuration is as follows:

```
config firewall shaper traffic-shaper
  edit "traffic_shaper_name"
    set per-policy enable
  next
end
```

The shared traffic shaper selected in the traffic shaping policy affects traffic in the direction defined in the policy. For example, if the source port is LAN and the destination is WAN1, the traffic shaping affects the flow in this direction only, affecting the outbound traffic's upload speed. You can define the traffic shaper for the policy in the opposite direction (reverse shaper) to affect the inbound traffic's download speed. In this example, that would be from WAN1 to LAN.

Only traffic through forward traffic shapers will be included in FortiView; reverse and per-IP shapers are not included.

The following example shows how to apply different speeds to different types of service. The example configures two shared traffic shapers to use in two firewall shaping policies. One policy guarantees a speed of 10 Mbps for VoIP traffic. The other policy guarantees a speed of 1 Mbps for other traffic. In the example, FortiOS communicates with a PC using port10 and the Internet using port9.

To configure shared traffic shapers in the GUI:

1. Create a firewall policy:
 - a. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
 - b. Set the *Name* to *Internet Access*.
 - c. Set the *Incoming Interface* to *port10*.
 - d. Set the *Outgoing Interface* to *port9*.
 - e. Set the *Source and Destination* to *all*.
 - f. Set the *Schedule* to *always*.
 - g. Set the *Service* to *ALL*.
 - h. Click *OK*.

2. Create the shared traffic shapers:

- a. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shapers* tab, and click *Create New*.
- b. Set the *Name* to *10Mbps*. This shaper is for VoIP traffic.
- c. Set the *Traffic Priority* to *High*.
- d. Enable *Max Bandwidth* and enter *20000*.
- e. Enable *Guaranteed Bandwidth* and enter *10000*.

- f. Click *OK*.
 - g. Repeat the above steps to create another traffic shaper named *1Mbps* with the *Traffic Priority* set to *Low*, the *Max Bandwidth* set to *10000*, and the *Guaranteed Bandwidth* set to *1000*.
- ## 3. Create a firewall shaping policy:
- a. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shaping Policies* tab, and click *Create New*.
 - b. Set the *Name* to *VoIP_10Mbps_High*. This policy is for VoIP traffic.
 - c. Set the *Source* and *Destination* to *all*.
 - d. Set the *Service* to all VoIP services.
 - e. Set the *Outgoing Interface* to *port9*.
 - f. Enable *Shared shaper* and select *10Mbps*.
 - g. Enable *Reverse shaper* and select *10Mbps*.
 - h. Click *OK*.
 - i. Repeat the above steps to create another firewall shaping policy named *Other_1Mbps_Low* for other traffic, with the *Source* and *Destination* set to *all*, *Service* set to *ALL*, *Outgoing Interface* set to *port9*, and *Shared shaper* and *Reverse shaper* set to *1Mbps*.

To configure shared traffic shapers in the CLI:

1. Create a firewall policy:

```
config firewall policy
  edit 1
    set name "Internet Access"
    set srcintf "port10"
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
```

```

        set fssso disable
        set nat enable
    next
end

```

2. Create the shared traffic shapers:

```

config firewall shaper traffic-shaper
    edit "10Mbps"
        set guaranteed-bandwidth 10000
        set maximum-bandwidth 20000
    next
    edit "1Mbps"
        set guaranteed-bandwidth 1000
        set maximum-bandwidth 10000
        set priority low
    next
end

```

3. Create a firewall shaping policy:

```

config firewall shaping-policy
    edit 1
        set name "VOIP_10Mbps_High"
        set service "H323" "IRC" "MS-SQL" "MYSQL" "RTSP" "SCCP" "SIP" "SIP-MSNmessenger"
        set dstintf "port9"
        set traffic-shaper "10Mbps"
        set traffic-shaper-reverse "10Mbps"
        set srcaddr "all"
        set dstaddr "all"
    next
    edit 2
        set name "Other_1Mbps_Low"
        set service "ALL"
        set dstintf "port9"
        set traffic-shaper "1Mbps"
        set traffic-shaper-reverse "1Mbps"
        set srcaddr "all"
        set dstaddr "all"
    next
end

```

To troubleshoot shared traffic shapers:

1. Check if specific traffic is attached to the correct traffic shaper. The example output shows the traffic attached to the 10Mbps and 1Mbps shapers:

```

# diagnose firewall iprope list 100015
policy index=1 uuid_idx=0 action=accept
flag (0):
shapers: orig=10Mbps (2/1280000/2560000)
cos_fwd=0 cos_rev=0
group=00100015 av=00000000 au=00000000 split=00000000
host=4 chk_client_info=0x0 app_list=0 ips_view=0
misc=0 dd_type=0 dd_mode=0
zone(1): 0 -> zone(1): 38
source(1): 0.0.0.0-255.255.255.255, uuid_idx=0,
dest(1): 0.0.0.0-255.255.255.255, uuid_idx=0,
service(15):
    [6:0x0:0/(1,65535)->(1720,1720)] helper:auto
    [6:0x0:0/(1,65535)->(1503,1503)] helper:auto

```

```

[17:0x0:0/(1,65535)->(1719,1719)] helper:auto
[6:0x0:0/(1,65535)->(6660,6669)] helper:auto
[6:0x0:0/(1,65535)->(1433,1433)] helper:auto
[6:0x0:0/(1,65535)->(1434,1434)] helper:auto
[6:0x0:0/(1,65535)->(3306,3306)] helper:auto
[6:0x0:0/(1,65535)->(554,554)] helper:auto
[6:0x0:0/(1,65535)->(7070,7070)] helper:auto
[6:0x0:0/(1,65535)->(8554,8554)] helper:auto
[17:0x0:0/(1,65535)->(554,554)] helper:auto
[6:0x0:0/(1,65535)->(2000,2000)] helper:auto
[6:0x0:0/(1,65535)->(5060,5060)] helper:auto
[17:0x0:0/(1,65535)->(5060,5060)] helper:auto
[6:0x0:0/(1,65535)->(1863,1863)] helper:auto

```

```

policy index=2 uuid_idx=0 action=accept
flag (0):
shapers: orig=1Mbps(4/128000/1280000)

no_ofld_reason: offload-denied helper
total session 1

```

3. Check the statuses of shared traffic shapers:

```

# diagnose firewall shaper traffic-shaper list
name 10Mbps

```

```
maximum-bandwidth 2500 KB/sec
guaranteed-bandwidth 1250 KB/sec
current-bandwidth 0 B/sec
priority 2
tos ff
packets dropped 0
bytes dropped 0

name 1Mbps
maximum-bandwidth 1250 KB/sec
guaranteed-bandwidth 125 KB/sec
current-bandwidth 0 B/sec
priority 4
tos ff
packets dropped 0
bytes dropped 0
```

Per-IP traffic shaper

With per-IP traffic shaping, you can limit each IP address's behavior to avoid a situation where one user uses all of the available bandwidth. In addition to controlling the maximum bandwidth used per IP address, you can also define the maximum number of concurrent sessions for an IP address. For example, if you apply a per-IP shaper of 1 Mbps to your entire network, FortiOS allocates each user/IP address 1 Mbps of bandwidth. Even if the network consists of a single user, FortiOS allocates them 1 Mbps. If there are ten users, each user gets 1 Mbps of bandwidth, totaling 10 Mbps of outgoing traffic.

For shared shapers, all users share the set guaranteed and maximum bandwidths. For example, if you set a shared shaper for all PCs using an FTP service to 10 Mbps, all users uploading to the FTP server share the 10 Mbps.

Shared shapers affect upload speed. If you want to limit the download speed from the FTP server in the example, you must configure the shared shaper as a reverse shaper. Per-IP shapers apply the speed limit on both upload and download operations. Only traffic through forward traffic shapers will be included in FortiView; reverse and per-IP shapers are not included.

The following example shows how to apply a per-IP shaper to a traffic shaping policy. This shaper assigns each user a maximum bandwidth of 1 Mbps and allows each user to have a maximum of ten concurrent connections to the FTP server. In the example, FortiOS communicates with users using port10 and the FTP server using port9.

To configure a per-IP traffic shaper in the GUI:

1. Create a firewall policy:
 - a. Go to *Policy & Objects > IPv4 Policy* and click *Create New*.
 - b. Set the *Name* to *FTP Access*.
 - c. Set the *Incoming Interface* to *port10*.
 - d. Set the *Outgoing Interface* to *port9*.
 - e. Set the *Source* to *all*.
 - f. Set the *Destination* to *FTP_Server*.
 - g. Set the *Schedule* to *always*.
 - h. Set the *Service* to *ALL*.
 - i. Click *OK*.

2. Create the per-IP traffic shaper:
 - a. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shapers* tab, and click *Create New*.
 - b. Set *Type* to *Per IP Shaper*.
 - c. Enter the *Name* (*FTP_Max_1M*). This shaper is for VoIP traffic.
 - d. Enable *Max Bandwidth* and enter *1000*.
 - e. Enable *Max Concurrent Connections* and enter *10*. This means that each user can have up to ten concurrent connections to the FTP server.

- f. Click *OK*.
3. Create a firewall shaping policy:
 - a. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shaping Policies* tab, and click *Create New*.
 - b. Enter the *Name* (*FTP speed 1M*).
 - c. Set the *Source* to the addresses and users that require access to the FTP server.
 - d. Set the *Destination* to *FTP_Server*.
 - e. Set the *Service* to *ALL*.
 - f. Set the *Outgoing Interface* to *port9*.
 - g. Enable *Per-IP shaper* and select *FTP_Max_1M*.
 - h. Click *OK*.

To configure a per-IP traffic shaper in the CLI:

1. Create a firewall policy:

```
config firewall policy
  edit 1
    set name "FTP Access"
    set srcintf "port10"
    set dstintf "port9"
    set srcaddr "all"
    set dstaddr "FTP_Server"
    set action accept
    set schedule "always"
    set service "ALL"
    set fssso disable
    set nat enable
  next
end
```

2. Create the per-IP traffic shaper:

```
config firewall shaper per-ip-shaper
```

```

edit "FTP_Max_1M"
  set max-bandwidth 1000
  set max-concurrent-session 10
next
end

```

3. Create a firewall shaping policy:

```

config firewall shaping-policy
  edit 1
    set name "FTP speed 1M"
    set service "ALL"
    set dstintf "port9"
    set per-ip-shaper "FTP_Max_1M"
    set srcaddr "PC1" "WinPC" "PC2"
    set dstaddr "FTP_Server"
  next
end

```

To troubleshoot per-IP traffic shapers:

1. Check if specific traffic is attached to the correct traffic shaper. The example output shows the traffic attached to the FTP_Max_1M shaper:

```

# diagnose firewall iprope list 100015
policy index=3 uuid_idx=0 action=accept
flag (0):
shapers: per-ip=FTP_Max_1M
cos_fwd=0 cos_rev=0
group=00100015 av=00000000 au=00000000 split=00000000
host=2 chk_client_info=0x0 app_list=0 ips_view=0
misc=0 dd_type=0 dd_mode=0
zone(1): 0 -> zone(1): 38
source(3): 10.1.100.11-10.1.100.11, uuid_idx=30, 10.1.100.143-10.1.100.143, uuid_idx=32,
          10.1.100.22-10.1.100.22, uuid_idx=31,
dest(1): 172.16.200.55-172.16.200.55, uuid_idx=89,
service(1):
  [0:0x0:0/(0,65535)->(0,65535)] helper:auto

```

2. Check if the correct traffic shaper is applied to the session. The example output shows that the FTP_Max_1M shaper is applied to the session:

```

# diagnose sys session list
session info: proto=6 proto_state=01 duration=36 expire=3567 timeout=3600 flags=00000000
  sockflag=00000000 sockport=0 av_idx=0 use=4
origin-shaper=
reply-shaper=
per_ip_shaper=FTP_Max_1M
class_id=0 shaping_policy_id=3 ha_id=0 policy_dir=0 tunnel=/ helper=ftp vlan_cos=0/255
state=may_dirty per_ip npu npd mif route_preserve
statistic(bytes/packets/allow_err): org=506/9/1 reply=416/6/1 tuples=2
tx speed(Bps/kbps): 0/0 rx speed(Bps/kbps): 0/0
origin->sink: org pre->post, reply pre->post dev=39->38/38->39 gwy=172.16.200.55/0.0.0.0
hook=post dir=org act=snat 10.1.100.11:58275->172.16.200.55:21(172.16.200.1:58275)
hook=pre dir=reply act=dnat 172.16.200.55:21->172.16.200.1:58275(10.1.100.11:58275)
pos/(before,after) 0/(0,0), 0/(0,0)
misc=0 policy_id=1 auth_info=0 chk_client_info=0 vd=2
serial=0000211a tos=ff/ff app_list=0 app=0 url_cat=0
sdwan_mbr_seq=0 sdwan_service_id=0
rpd_b_link_id = 00000000
dd_type=0 dd_mode=0

```

```
npu_state=0x100000
npu info: flag=0x00/0x00, offload=0/0, ips_offload=0/0, epid=0/0, ipid=0/0,
          vlan=0x0000/0x0000
vlifid=0/0, vtag_in=0x0000/0x0000 in_npu=0/0, out_npu=0/0, fwd_en=0/0, qid=0/0
no_ofld_reason: offload-denied helper
```

3. Check the statuses of per-IP traffic shapers. The output should resemble the following:

```
# diagnose firewall shaper per-ip-shaper list
name FTP_Max_1M
maximum-bandwidth 125 KB/sec
maximum-concurrent-session 10
tos ff/ff
packets dropped 0
bytes dropped 0
addr=10.1.100.11 status: bps=0 ses=3
```

Changing traffic shaper bandwidth unit of measurement

Bandwidth speeds are measured in kilobits per second (Kbps), and bytes that are sent and received are measured in megabytes (MB). In some cases, this can cause confusion depending on whether your ISP uses kilobits per second (Kbps), kilobytes per second (KBps), megabits per second (Mbps), or gigabits per second (Gbps).

You can change the unit of measurement for traffic shapers in the CLI.

To change the bandwidth unit of measurement for a shared traffic shaper:

```
config firewall shaper traffic-shaper
  edit <traffic_shaper_name>
    set bandwidth-unit {kbps | mbps | gbps}
  next
end
```

To change the bandwidth unit of measurement for a per-IP traffic shaper:

```
config firewall shaper per-ip-shaper
  edit <traffic_shaper_name>
    set bandwidth-unit {kbps | mbps | gbps}
  next
end
```

Multi-stage DSCP marking and class ID in traffic shapers

Traffic shapers have a multi-stage method so that packets are marked with a different differentiated services code point (DSCP) and `class id` at different traffic speeds. Marking packets with a different DSCP code is for the next hop to classify the packets. The FortiGate benefits by marking packets with a different `class id`. Combined with the egress interface shaping profile, the FortiGate can handle the traffic differently according to its `class id`.

Rule	DSCP code	Class ID
speed < guarantee bandwidth	diffservcode	class id in shaping policy
guarantee bandwidth < speed < exceed bandwidth	exceed-dscp	exceed-class-id
exceed bandwidth < speed	maximum-dscp	exceed-class-id

This example sets the following parameters:

- When the current bandwidth is less than 50 Kbps, mark packets with `diffservcode 100000` and set `class id` to 10.
- When the current bandwidth is between 50 Kbps and 100 Kbps, mark packets with `exceed-dscp 111000` and set `exceed-class-id` to 20.
- When the current bandwidth is more than 100 Kbps, mark packets with `maximum-dscp 111111` and set `exceed-class-id` to 20.

To set multi-stage DSCP marking and class ID in a traffic shaper:

```
config firewall shaper traffic-shaper
  edit "50k-100k-150k"
    set guaranteed-bandwidth 50
    set maximum-bandwidth 150
    set diffserv enable
    set dscp-marking-method multi-stage
    set exceed-bandwidth 100
    set exceed-dscp 111000
    set exceed-class-id 20
    set maximum-dscp 111111
    set diffservcode 100000
  next
end

config firewall shaping-policy
  edit 1
    set service "ALL"
    set dstintf PORT2
    set srcaddr "all"
    set dstaddr "all"
    set class-id 10
  next
end
```

Traffic shapers also have an `overhead` option that defines the per-packet size overhead used in rate computation.

To set the traffic shaper overhead option:

```
config firewall shaper traffic-shaper
  edit "testing"
    set guaranteed-bandwidth 50
    set maximum-bandwidth 150
    set overhead 14 <range from 0 to 100>
  next
end
```

Example

This example shows how to mark QA traffic with a different DSCP according to real-time traffic speed.

To configure the firewall address:

```
config firewall address
  edit QA_team
```

```

        set subnet 10.1.100.0/24
    next
end

```

To configure the firewall shaper traffic shaper:

```

config firewall shaper traffic-shaper
    edit "500k-1000k-1500k"
        set guaranteed-bandwidth 500
        set maximum-bandwidth 1500
        set diffserv enable
        set dscp-marking-method multi-stage
        set exceed-bandwidth 1000
        set exceed-dscp 111000
        set maximum-dscp 111111
        set diffservcode 100000
    next
end

config firewall shaping-policy
    edit QA_team
        set service "ALL"
        set dstintf port1
        set traffic-shaper "500k-1000k-1500k"
        set traffic-shaper-reverse "500k-1000k-1500k"
        set srcaddr "QA_team"
        set dstaddr "all"
    next
end

```

Global traffic prioritization

Global traffic prioritization allows your traffic to be prioritized as high (2), medium (3), or low (4) based on ToS (type of service) or DSCP. When using ToS-based priority, integers 0 to 15 can be used, which correspond to the definitions of the ToS field values in RFC 1349. When using DSCP, values 0 to 63 can be used, which correspond to the six bits in the DSCP value.

The outbandwidth must be defined in order for global prioritization to take effect. When the outbandwidth is defined on an interface without an applied `egress-shaping-profile`, the interface has a total of five priority levels:

Priority level	Description
0	Top
1	Critical
2	High
3	Medium
4	Low

Priority level 0 is reserved for administrative and local out traffic. Priority level 1 is used for traffic that is below guaranteed bandwidth when using a traffic shaper.

Traffic shaper and traffic shaping profile configurations take precedence over global traffic prioritization.

CLI commands

The following commands are used to configure the prioritization either by ToS or DSCP.

To configure the traffic prioritization type and level:

```
config system global
    set traffic-priority {tos | dscp}
    set traffic-priority-level {high | medium | low}
end
```

To configure the ToS-based priority table:

```
config system tos-based-priority
    edit <id>
        set tos <0-15>
        set priority (high | medium | low)
    next
end
```

To configure the DSCP-based priority table:

```
config system dscp-based-priority
    edit <id>
        set ds <0-63>
        set priority (high | medium | low)
    next
end
```

To configure the interface outbandwidth:

```
config system interface
    edit <name>
        set outbandwidth <bandwidth in kbps>
    next
end
```

Example

In the following configuration, packets with DSCP markings of 1 are prioritized as high, and packets with DSCP markings of 2 are prioritized as medium. All the other traffic is prioritized as low. The outbandwidth on interface port3 is set to 1000 kbps.

To configure DSCP-based traffic prioritization:**1. Configure DSCP-based prioritization in the global settings:**

```
config system global
    set traffic-priority dscp
    set traffic-priority-level low
end
```

2. Configure the DSCP-based priority table:

```
config system dscp-based-priority
    edit 1
        set ds 1
        set priority high
    next
    edit 2
        set ds 2
        set priority medium
    next
end
```

3. Configure the outbandwidth on port3:

```
config system interface
    edit "port3"
        set outbandwidth 1000
    next
end
```

Verifying the traffic prioritization

When traffic exceeds the outbandwidth of 1000 kbps, traffic prioritization will take effect. Since the form of traffic shaping applied here is policing, excess packets above the outbandwidth are dropped.

In scenario 1, approximately 300 kbps of high priority traffic and 300 kbps of medium priority traffic passes through the FortiGate on port3.

To debug the bandwidth allocation:

```
# diagnose netlink interface list port3
if=port3 family=00 type=1 index=5 mtu=1500 link=0 master=0
ref=35 state=start present fw_flags=3800 flags=up broadcast run allmulti multicast
Qdisc=pfifo_fast hw_addr=52:54:00:fb:81:0c broadcast_addr=ff:ff:ff:ff:ff:ff
outbandwidth=1000 (kbps)

bytes=197K
    priority=1    allocated-bandwidth=0 (kbps)    total_bytes=0    drop_bytes=0
priority=2    allocated-bandwidth=354 (kbps)    total_bytes=20407K    drop_
bytes=48K
priority=3    allocated-bandwidth=354 (kbps)    total_bytes=7093K    drop_
bytes=1262K
    priority=4    allocated-bandwidth=290 (kbps)    total_bytes=266018K    drop_
bytes=7743K
stat: rxp=15450901 txp=25933756 rxb=5456860515 txb=17257309292 rxe=0 txe=0 rxd=0 txd=0 mc=0
collision=0 @ time=1629439926
re: rxl=0 rxo=0 rxc=0 rxf=0 rxfi=0 rxm=0
```

```
te: txa=0 txc=0 txfi=0 txh=0 txw=0
misc rxc=0 txc=0
input_type=0 state=3 arp_entry=0 refcnt=35
```

High priority (2) traffic is allocated 354 kbps of bandwidth. Medium priority (3) traffic is also allocated 354 kbps of bandwidth. The remaining bandwidth is allocated to low priority (4) traffic.

In scenario 2, approximately 400 kbps of high priority traffic and 800 kbps of medium priority traffic passes through the FortiGate on port3.

To debug the bandwidth allocation:

```
# diagnose netlink interface list port3
if=port3 family=00 type=1 index=5 mtu=1500 link=0 master=0
ref=36 state=start present fw_flags=3800 flags=up broadcast run allmulti multicast
Qdisc=pfifo_fast hw_addr=52:54:00:fb:81:0c broadcast_addr=ff:ff:ff:ff:ff:ff
outbandwidth=1000 (kbps)
    priority=0      allocated-bandwidth=7 (kbps)      total_bytes=9981K      drop_
bytes=240K
    priority=1      allocated-bandwidth=0 (kbps)      total_bytes=0      drop_bytes=0
    priority=2      allocated-bandwidth=425 (kbps)    total_bytes=31478K    drop_
bytes=101K
    priority=3      allocated-bandwidth=567 (kbps)    total_bytes=12056K    drop_
bytes=1984K
    priority=4      allocated-bandwidth=0 (kbps)      total_bytes=266795K    drop_
bytes=7771K
stat: rxp=15461740 txp=25950805 rxb=5459688950 txb=17273940560 rxe=0 txe=0 rxd=0 txd=0 mc=0
collision=0 @ time=1629440553
re: rxl=0 rxo=0 rxc=0 rxf=0 rxfi=0 rxm=0
te: txa=0 txc=0 txfi=0 txh=0 txw=0
misc rxc=0 txc=0
input_type=0 state=3 arp_entry=0 refcnt=36
```

High priority (2) traffic is allocated 425 kbps of bandwidth. Medium priority (3) traffic is allocated 567 kbps of bandwidth. Since the total bandwidth required exceeds 1000 kbps, the remaining medium priority (3) traffic is dropped. In comparing the successive debug outputs, the `drop_bytes` counter for medium priority (3) traffic gets bigger.

DSCP matching and DSCP marking

This feature has three parts:

- [DSCP matching in firewall policies](#)
- [DSCP matching in firewall shaping policies](#)
- [DSCP marking in firewall shaping policies](#)

DSCP matching in firewall policies

Traffic is allowed or blocked according to the Differentiated Services Code Point (DSCP) values in the incoming packets.

The following CLI variables are available in the `config firewall policy` command:

```
tos-mask <mask_value>      Non-zero bit positions are used for comparison. Zero bit positions are ignored
                             (default = 0x00).
```

	This variable replaces the <code>dscp-match</code> variable.
<code>tos <tos_value></code>	Type of Service (ToC) value that is used for comparison (default = 0x00). This variable is only available when <code>tos-mask</code> is not zero. This variable replaces the <code>dscp-value</code> variable.
<code>tos-negate {enable disable}</code>	Enable/disable negated ToS match (default = disable). This variable is only available when <code>tos-mask</code> is not zero. This variable replaces the <code>dscp-negate</code> variable.

DSCP matching in firewall shaping policies

Shaping is applied to the session or not according to the DSCP values in the incoming packets. The same logic and commands as in firewall policies are used.

DSCP marking in firewall shaping policies

Traffic is allowed or blocked according to the DSCP values in the incoming packets. DSCP marking in firewall shaping policies uses the same logic and commands as in firewall policy and traffic-shaper.

When DSCP marking on `firewall shaper traffic-shaper`, `firewall shaping-policy`, and `firewall policy` all apply to the same session, `shaping-policy` overrides `policy`, and `shaper traffic-shaper` overrides both `shaping-policy` and `policy`.

The following CLI variables in `config firewall policy` are used to mark the packets:

<code>diffserv-forward {enable disable}</code>	Enable/disable changing a packet's DiffServ values to the value specified in <code>diffservcode-forward</code> (default = disable).
<code>diffservcode-forward <dscp_value></code>	The value that packet's DiffServ is set to (default = 000000). This variable is only available when <code>diffserv-forward</code> is enabled.
<code>diffserv-reverse {enable disable}</code>	Enable/disable changing a packet's reverse (reply) DiffServ values to the value specified in <code>diffservcode-rev</code> (default = disable).
<code>diffservcode-rev <dscp_value></code>	The value that packet's reverse (reply) DiffServ is set to (default = 000000). This variable is only available when <code>diffserv-rev</code> is enabled.

Examples

Example 1

FortiGate A marks traffic from the sales and QA teams with different DSCP values. FortiGate B does DSCP matching, allowing only the sales team to access the database.

1. Configure FortiGate A:

```
config firewall policy
  edit 1
    set srcintf "port2"
    set dstintf "port3"
    set srcaddr "QA"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set diffserv-forward enable
    set diffservcode-forward 110000
    set nat enable
  next
  edit 5
    set srcintf "port2"
    set dstintf "port3"
    set srcaddr "Sales"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set diffserv-forward enable
    set diffservcode-forward 111011
    set nat enable
  next
end
```

2. Configure FortiGate B:

```
config firewall policy
  edit 2
    set srcintf "port3"
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "Database"
    set action accept
    set schedule "always"
    set service "ALL"
    set tos-mask 0xf0
    set tos 0xe0
    set fsso disable
    set nat enable
  next
end
```

Example 2

FortiGate A marks traffic from the sales and QA teams with different DSCP values. FortiGate B uses a firewall shaping policy to do the DSCP matching, limiting the connection speed of the sales team to the database to 10MB/s.

1. Configure FortiGate A:

```
config firewall policy
  edit 1
    set srcintf "port2"
    set dstintf "port3"
    set srcaddr "QA"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set diffserv-forward enable
    set diffservcode-forward 110000
    set nat enable
  next
  edit 5
    set srcintf "port2"
    set dstintf "port3"
    set srcaddr "Sales"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set diffserv-forward enable
    set diffservcode-forward 111011
    set nat enable
  next
end
```

2. Configure FortiGate B:

```
config firewall policy
  edit 2
    set srcintf "port3"
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set nat enable
  next
end
config firewall shaper traffic-shaper
  edit "10MB/s"
    set guaranteed-bandwidth 60000
    set maximum-bandwidth 80000
  next
end
config firewall shaping-policy
  edit 1
    set service "ALL"
    set dstintf "port1"
    set tos-mask 0xf0
    set tos 0xe0
    set traffic-shaper "10MB/s"
    set srcaddr "all"
```

```

        set dstaddr "all"
    next
end

```

Example 3

FortiGate A has a traffic shaping policy to mark traffic from the QA team with a DSCP value of 100000, while reverse traffic is marked with 000011.

1. Configure FortiGate A:

```

config firewall shaping-policy
    edit 1
        set name "QA Team 50MB"
        set service "ALL"
        set dstintf "port3"
        set traffic-shaper "50MB/s"
        set traffic-shaper-reverse "50MB/s"
        set diffserv-forward enable
        set diffserv-reverse enable
        set srcaddr "QA"
        set dstaddr "all"
        set diffservcode-forward 100000
        set diffservcode-rev 000011
    next
end

```

Examples

This section includes the following traffic shaping configuration examples:

- [Interface-based traffic shaping profile on page 1017](#)
- [Interface-based traffic shaping with NP acceleration on page 1026](#)
- [QoS assignment and rate limiting for FortiSwitch quarantined VLANs on page 1027](#)
- [Ingress traffic shaping profile on page 1028](#)

Interface-based traffic shaping profile

A traffic shaping policy can be used for interface-based traffic shaping by organizing traffic into 30 class IDs. The shaping profile defines the percentage of the interface bandwidth that is allocated to each class. Each traffic class ID is shaped to the assigned speed according to the outgoing bandwidth limit configured to the interface.

Traffic classification

A shaping policy classifies traffic and organizes it into different class IDs, based on matching criteria. For traffic matching a criteria, you can choose to put it into 30 different shaping classes, identified by class ID 2 - 31.

When NPU offloading is enabled on the NP6, SoC3, or SoC4 platforms, the class ID limit for egress traffic is 2 - 15. Setting the egress traffic class ID outside of these limits can result in unexpected behavior.

If NPU offloading is disabled, or enabled on the NP7 platform, the class ID limit for egress traffic is 2 - 31.

You must select an outgoing interface for the traffic. The shaping policy is only applied when the traffic goes to one of the selected outgoing interfaces.

Criterion	Description
Source	<ul style="list-style-type: none"> Address: match the source address of the traffic to the selected address or address group. User: use the user credentials of the traffic to match the selected user or user group. At least one address, address group, or internet service must also be selected. Internet service: match the traffic to the selected internet service. Internet services cannot be used if addresses or address or groups are used.
Destination	<ul style="list-style-type: none"> Address: match the destination address of the traffic to the selected address or address group. Internet service: match the traffic to the selected internet service. Internet services cannot be used if addresses or address or groups are used.
Schedule	Match the current date and time to the selected schedule. You can select a one-time schedule, recurring schedule, or schedule group. This setting is optional.
Service	Match the service of the traffic to the selected service or service group.
Application	Match the application of the traffic to the selected application, application category, or application group. Application control must be enabled in the related firewall policy to know the application of the traffic. See Application control on page 1289 for more information.
URL category	Match the URL of the traffic to the selected URL category. Web filter must be enabled in the related firewall policy to know the URL of the traffic. See Web filter on page 1217 for more information.

When multiple items are selected in one criterion, it is considered a match when traffic matches any one of them.

Traffic prioritization

Shaping profiles define how different shaping classes of traffic are prioritized. For each class, you can define three prioritization strategies: guaranteed bandwidth, maximum bandwidth, and priority.

For each shaping profile, a default shaping class must be defined. Traffic is prioritized based on the default shaping group in the following two circumstances:

- All traffic to the outgoing interface that does not match to any shaping policy
- Traffic with a shaping group that is not defined in a shaping profile

Prioritization strategy	Description
Guaranteed bandwidth	The percentage of the link speed that is reserved for the shaping group. The total guaranteed bandwidth for all shaping groups cannot exceed 100%.

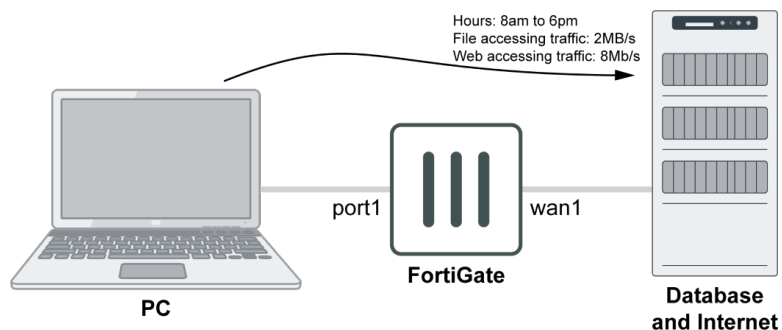

Prioritization strategy	Description
Maximum bandwidth	The maximum percentage of the link speed that the shaping group can use.
Priority	The shaping class priority: top, critical, high, medium, or low. When groups are competing for bandwidth on the interface, the group with the higher priority wins.

Applying a shaping profile to an interface

Traffic shaping is accomplished by configuring the outgoing bandwidth and outgoing shaping profile on an interface. The shaping profile uses the outgoing bandwidth of the interface as the maximum link speed, and it only works when the outgoing bandwidth is configured.

This example shows how to apply interface-based traffic shaping to web and file accessing traffic according to a schedule:

- The link speed of the wan1 interface is 10 Mb/s.
- File access can use up to 2 Mb/s from 8:00 AM to 6:00 PM.
- Web access can use 8 Mb/s from 8:00 AM to 6:00 PM.

Putting the traffic into shaping classes

To create a recurring schedule in the GUI:

1. Go to *Policy & Objects > Schedules*.
2. Click *Create New > Schedule*.
3. Configure a recurring schedule called *Day_Hours* for everyday from 8:00 AM to 6:00 PM.
4. Click *OK*.

To create a traffic shaping policy and class ID for the web accessing traffic in the GUI:

1. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shaping Policies* tab, and click *Create New*.
2. Enter a name for the policy, such as *web_access_day_hours*.
3. Enable *Schedule* and select the schedule you just created.
4. Set *Service* to web accessing services, such as *HTTP* and *HTTPS*.
5. Set *Action* to *Assign Shaping Class ID*, and *Outgoing interface* to *wan1*.
6. Click the *Traffic shaping class ID* drop down then click *Create*.
7. Enter an integer value for the *ID* (3) and a description for the *Name*, such as *Web Access*.
8. Click *OK*.

9. Select the class ID you just created for *Traffic shaping class ID*.

10. Configure the remaining settings as required.

11. Click **OK**.

To create a traffic shaping policy and class ID for the file accessing traffic in the GUI:

1. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shaping Policies* tab, and click *Create New*.
2. Enter a name for the policy, such as *file_access_day_hours*.
3. Enable *Schedule* and select the schedule you just created.
4. Set *Service* to file accessing services, such as *ASF3*, *FTP* and *SMB*.
5. Set *Action* to *Assign Shaping Class ID*, and *Outgoing interface* to *wan1*.
6. Click the *Traffic shaping class ID* drop down then click *Create*.
7. Enter an integer value for the *ID* (4) and a description for the *Name*, such as *File Access*.
8. Click **OK**.

9. Select the class ID you just created for *Traffic shaping class ID*.

10. Configure the remaining settings as required.

11. Click **OK**.

To put the traffic into shaping classes in the CLI:

1. Create a recurring schedule:

```
config firewall schedule recurring
    edit "Day_Hours"
        set start 08:00
        set end 18:00
        set day sunday monday tuesday wednesday thursday friday saturday
    next
end
```

2. Create the traffic class IDs:

```
config firewall traffic-class
    edit 3
        set class-name "Web Access"
    next
    edit 4
        set class-name "File Access"
    next
end
```

3. Create the web and file accessing traffic shaping policies:

```
config firewall shaping-policy
edit 2
    set name "web_access_day_hours"
    set comment "Limit web accessing traffic to 8Mb/s in day time"
    set service "HTTP" "HTTPS"
    set schedule "Day_Hours"
    set dstintf "wan1"
    set class-id 3
    set srcaddr "all"
    set dstaddr "all"
next
edit 3
    set name "file_access_day_hours"
    set comment "Limit file accessing traffic to 2Mb/s during the day"
    set service "AFS3" "FTP" "FTP_GET" "FTP_PUT" "NFS" "SAMBA" "SMB" "TFTP"
    set schedule "Day_Hours"
    set dstintf "wan1"
    set class-id 4
    set srcaddr "all"
    set dstaddr "all"
next
end
```

Allocating bandwidth to the shaping classes

A traffic shaping profile defines the guaranteed and maximum bandwidths each class receives. In this example, file access can use up to 2 Mb/s and web access can use 8 Mb/s from 8:00 AM to 6:00 PM.

To create a traffic shaping profile using the GUI:

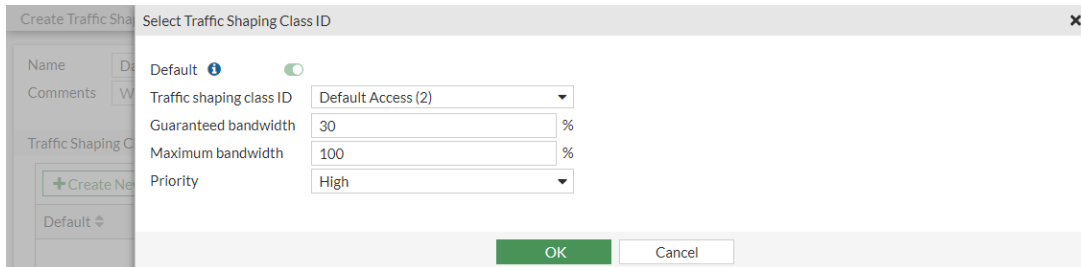

1. Go to *Policy & Objects > Traffic Shaping*, select the *Traffic Shaping Profiles* tab, and click *Create New*.
2. Enter a name for the profile, such as *Day_Hours_Profile*.
3. Configure a default traffic shaping class:

This class has a high priority, meaning that when the other classes have reached their guaranteed bandwidths, this default class will use the rest of the available bandwidth.

 - a. In the *Traffic Shaping Classes* table click *Create New*.
 - b. Click the *Traffic shaping class ID* drop down then click *Create*.
 - c. Enter a name for the class, such as *Default Access*.
 - d. Click *OK*.
 - e. Select the class ID you just created for *Traffic shaping class ID*.

- f. Configure the following settings, then click *OK*:

Guaranteed bandwidth	30
Maximum bandwidth	100
Priority	High

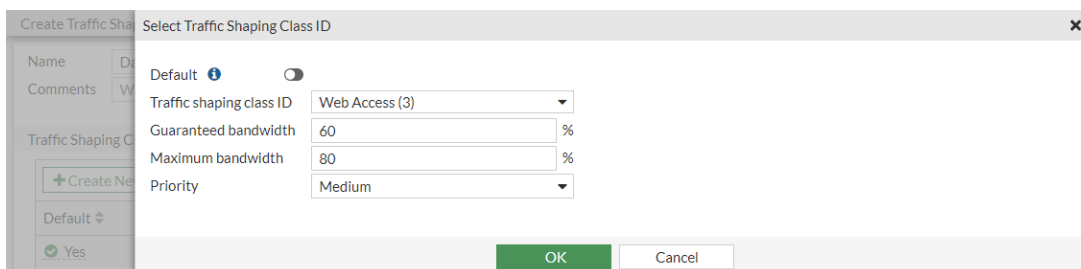

4. Configure a web accessing traffic shaping class:

When other types of traffic are competing for bandwidth, this class is guaranteed to 6 Mb/s, or 60% of the bandwidth.

- a. In the *Traffic Shaping Classes* table click *Create New*.
- b. Configure the following settings, then click *OK*:

Traffic shaping class ID	Web Access
Guaranteed bandwidth	60
Maximum bandwidth	80
Priority	Medium

5. Configure a file accessing traffic shaping class:

When other types of traffic are competing for bandwidth, this group is guaranteed to 1 Mb/s, or 10% of the bandwidth.

- a. In the *Traffic Shaping Classes* table click *Create New*.
- b. Configure the following settings, then click *OK*:

Traffic shaping class ID	File Access
Guaranteed bandwidth	10
Maximum bandwidth	20
Priority	Medium

The screenshot shows the 'Create Traffic Shaping Profile' dialog in the FortiGate GUI. The profile name is 'Day_Hours_Profile'. The 'Traffic Shaping Classes' table is as follows:

Default	Class ID	Guaranteed Bandwidth	Maximum Bandwidth	Priority
Yes	Default Access (2)	30%	100%	High
	Web Access (3)	60%	80%	Medium
	File Access (4)	10%	20%	Medium

Below the table is a donut chart titled 'Guaranteed Bandwidth Usage' showing the distribution of bandwidth for the three classes: Default Access (2) (orange), Web Access (3) (purple), and File Access (4) (red). The chart is labeled 'Total' in the center.

6. Click OK.

To create a traffic shaping profile using the CLI:

```
config firewall shaping-profile
  edit "Day_Hours_Profile"
    set default-class-id 2
    config shaping-entries
      edit 1
        set class-id 2
        set guaranteed-bandwidth-percentage 30
        set maximum-bandwidth-percentage 100
      next
      edit 2
        set class-id 3
        set priority medium
        set guaranteed-bandwidth-percentage 60
        set maximum-bandwidth-percentage 80
      next
      edit 3
        set class-id 4
```

```

        set priority medium
        set guaranteed-bandwidth-percentage 10
        set maximum-bandwidth-percentage 20
    next
end
next
end

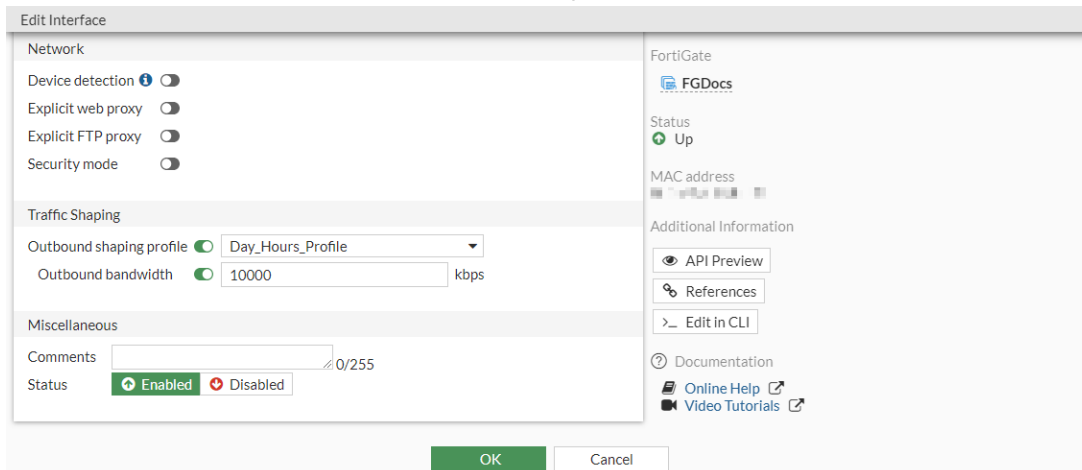

```

Defining the available bandwidth on an interface

In this example, the link speed of the wan1 interface is 10 Mb/s.

To set the bandwidth of the wan1 interface in the GUI:

1. Go to *Network > Interfaces*.
2. Edit the wan1 interface.
3. Under Traffic Shaping, enable *Outbound shaping profile* and select the profile that you just created, *Day_Hours_Profile*.
4. Enable *Outbound Bandwidth* and set it to *10000 Kbps*.

5. Click **OK**.

To set the bandwidth of the wan1 interface in the CLI:

```

config system interface
    edit "wan1"
        set egress-shaping-profile "Day_Hours_Profile"
        set outbandwidth 10000
    next
end

```

Diagnose commands

To check that the specific traffic is put into the correct shaping group or class ID:

```
# diagnose firewall iprope list 100015
```

To check the speed limit for each class ID on an interface:

```
# diagnose netlink interface list wan1
```

Interface-based traffic shaping with NP acceleration

Interface-based traffic shaping with NP acceleration is supported on some devices.

An administrator configures the WAN interface's maximum outbound bandwidth and, based on that, creates a traffic shaping profile with a percentage based shaper. This allows for proper QoS and traffic shaping. VLAN interfaces are not supported.

This feature is supported on FortiGate 600E, 500E, 400E, and 300E models.

To configure interface-based traffic shaping:

1. Enable NPU offloading when doing interface-based traffic shaping according to the egress-shaping-profile:

```
config system npu
    set intf-shaping-offload enable
end
```

2. Configure shaping profiles:

```
config firewall shaping-profile
    edit "sdwan"
        set default-class-id 4
        config shaping-entries
            edit 1
                set class-id 4
                set guaranteed-bandwidth-percentage 3
                set maximum-bandwidth-percentage 5
            next
            edit 2
                set class-id 3
                set priority medium
                set guaranteed-bandwidth-percentage 50
                set maximum-bandwidth-percentage 100
            next
            edit 3
                set class-id 2
                set priority low
                set guaranteed-bandwidth-percentage 1
                set maximum-bandwidth-percentage 5
            next
        end
    next
end
```

The class number is limited to 16.

3. Configure a traffic shaper and shaping policy:

```
config firewall shaper traffic-shaper
  edit "Transactional"
    set priority medium
  next
end

config firewall shaping-policy
  edit 1
    set service "ALL"
    set dstintf "any"
    set traffic-shaper "Transactional"
    set class-id 3
    set srcaddr "all"
    set dstaddr "all"
  next
end
```

4. Apply the egress shaping profile on the interface:

```
config system interface
  edit "port2"
    set vdom "root"
    set ip 10.1.100.23 255.255.255.0
    set allowaccess ping
    set type physical
    set outbandwidth 500
    set egress-shaping-profile "sdwan"
    set snmp-index 4
  next
end
```

5. Configure a firewall policy:

```
config firewall policy
  edit 3
    set srcintf "port2"
    set dstintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set service "ALL"
    set logtraffic all
    set nat enable
  next
end
```

QoS assignment and rate limiting for FortiSwitch quarantined VLANs

When devices are quarantined, they are isolated from the rest of the network. However, they can still impact the network if not controlled beyond isolation. A quarantined host, which offers heavy traffic, could congest the network and create a DOS-style reduction in service to authorized hosts.

Within the quarantined VLAN, two restrictions are available within the network:

- Traffic policing (also known as rate limiting)
- QoS (Quality of Service) assignment (also known as priority assignment)

Each quarantined host's traffic can be subject to rate limiting and priority adjustment. This reduces the impact that any quarantined host can have on authorized traffic on the network.

To configure QoS assignment and rate limiting for quarantined VLANs:

1. Configure a traffic policy, or use the default "quarantine" policy:

```
config switch-controller traffic-policy
  edit "quarantine"
    set description "Rate control for quarantined traffic"
    set guaranteed-bandwidth 163840
    set guaranteed-burst 8192
    set maximum-burst 163840
    set cos-queue 0
  next
end
```

2. Configure an interface:

```
config system interface
  edit "qtn.aggr1"
    set vdom "root"
    set ip 10.254.254.254 255.255.255.0
    set description "Quarantine VLAN"
    set security-mode captive-portal
    set replacemsg-override-group "auth-intf-qtn.aggr1"
    set device-identification enable
    set snmp-index 30
    set switch-controller-access-vlan enable
    set switch-controller-traffic-policy "quarantine"
    set color 6
    set interface "aggr1"
    set vlanid 4093
  next
end
```

By default, `switch-controller-traffic-policy` is empty. You need to apply the necessary traffic policy (not only limited to "quarantine").

Ingress traffic shaping profile

A traffic shaping profile can be applied to an interface for traffic in the ingress direction. Similar to an egress traffic shaping profile, the guaranteed bandwidth and priority of the profile will be respected when an interface receives inbound traffic. When congestion occurs, any remaining bandwidth will be allotted to classes based on priority.

Ingress traffic shaping does not support NPU offloading.

Example

In this example, the port2 interface has a total inbound bandwidth of 100 Mbps. Traffic from certain clients to certain servers are assigned different classes.

IPv6 traffic from any client PCs to server PCs is assigned class 5.

For each class, the priority, guaranteed bandwidth, and maximum bandwidth are as follows:

Class	Priority	Guaranteed bandwidth	Maximum bandwidth
2	Low	10%	60%
3	High	20%	100%
4	High	30%	100%
5	Medium	10%	50%

Bandwidth will first be allotted to each class according to its guaranteed bandwidth. Then remaining available bandwidth will be allotted to class 3 and 4 first based on their priority. The allocation will be proportional to their guaranteed bandwidth ratio.

To configure ingress traffic shaping:

1. Configure the client and server addresses:

```
config firewall address
  edit "pc1"
    set subnet 10.1.100.11 255.255.255.255
  next
  edit "pc2"
    set subnet 10.1.100.22 255.255.255.255
  next
  edit "pc4"
    set subnet 172.16.200.44 255.255.255.255
  next
  edit "pc5"
    set subnet 172.16.200.55 255.255.255.255
  next
end
```

2. Configure the class IDs:

```
config firewall traffic-class
  edit 2
    set class-name "class2"
  next
  edit 3
    set class-name "class3"
  next
  edit 4
    set class-name "class4"
  next
  edit 4
    set class-name "class5"
  next
end
```

3. Configure traffic shaping policies to assign classes to each group of traffic.**a. Configure a policy to assign traffic from PC1 to PC4 in class 2:**

```
config firewall shaping-policy
  edit 1
    set name "shaping policy 1"
    set service "ALL"
    set dstintf "wan1"
    set class-id 2
    set srcaddr "pc1"
    set dstaddr "pc4"
  next
end
```

b. Configure a policy to assign traffic from PC2 to PC4 in class 3:

```
config firewall shaping-policy
  edit 2
    set name "shaping policy 2"
    set service "ALL"
    set dstintf "wan1"
    set class-id 3
    set srcaddr "pc2"
    set dstaddr "pc4"
  next
end
```

c. Configure a policy to assign traffic from PC2 to PC5 in class 4:

```
config firewall shaping-policy
  edit 3
    set name "shaping policy 3"
    set service "ALL"
    set dstintf "wan1"
    set class-id 4
    set srcaddr "pc2"
    set dstaddr "pc5"
  next
end
```

d. Configure a policy to assign all IPv6 traffic to class 5:

```
config firewall shaping-policy
  edit 4
    set name "shaping policy 4"
    set ip-version 6
    set service "ALL"
    set dstintf "wan1"
    set class-id 5
    set srcaddr6 "all"
    set dstaddr6 "all"
  next
end
```

4. Configure a shaping profile to set the priority, and the guaranteed and maximum bandwidth percentages for each class:

```
config firewall shaping-profile
  edit "ingShapeProfile"
    set default-class-id 2
    config shaping-entries
      edit 2
        set class-id 2
        set priority low
        set guaranteed-bandwidth-percentage 10
        set maximum-bandwidth-percentage 60
      next
      edit 3
        set class-id 3
        set guaranteed-bandwidth-percentage 20
        set maximum-bandwidth-percentage 100
      next
      edit 4
        set class-id 4
        set guaranteed-bandwidth-percentage 30
        set maximum-bandwidth-percentage 100
      next
      edit 5
        set class-id 5
        set priority medium
        set guaranteed-bandwidth-percentage 10
        set maximum-bandwidth-percentage 50
      next
    end
  next
end
```

5. Configure the inbandwidth and apply the ingress shaping profile on port2:

```
config system interface
  edit "port2"
    set ip 10.1.100.1 255.255.255.0
    set inbandwidth 100000
    set ingress-shaping-profile "ingShapeProfile"
    config ipv6
      set ip6-address 2000:10:1:100::1/64
    end
  end
```

```

    next
end

```

Inbandwidth must be configured for traffic shaping to take effect.

6. Configure a firewall policy to allow traffic to go through. Since traffic shaping is for inbound traffic on port2, the policy is defined from port2 to wan1:

```

config firewall policy
    edit 2
        set srcintf "port2"
        set dstintf "wan1"
        set action accept
        set srcaddr "all"
        set dstaddr "all"
        set srcaddr6 "all"
        set dstaddr6 "all"
        set schedule "always"
        set service "ALL"
        set logtraffic all
        set auto-asic-offload disable
        set nat enable
    next
end

```

NPU must be disabled by configuring `set auto-asic-offload disable`.

Verifying that the traffic is being shaped

In each of the following cases, the server PCs (PC4 and PC5) are configured as iPerf servers. The client PCs (PC1 and PC2) are configured as iPerf clients. The client sends traffic to the server from the client to server direction, triggering inbound traffic shaping on the port2 interface. The inbound bandwidth on port2 is 100 Mbps.

Case 1: single stream, PC1 to PC4

Traffic is sent from PC1 to PC4. There is no other traffic. Traffic is marked with class ID 2 and allocated the maximum bandwidth 60 Mbps (60%).

```

# diagnose netlink interface list port2
if=port2 family=00 type=1 index=20 mtu=1500 link=0 master=0
ref=25 state=start present fw_flags=3800 flags=up broadcast run multicast

```

Case 2: dual stream, PC1 to PC4, PC2 to PC4

Traffic is sent from both PC1 and PC2 to PC4. PC1 to PC4 traffic is marked with class ID 2 and low priority, and PC2 to PC4 traffic is marked with class ID 3 and high priority. Both class 2 and 3 will be allocated their guaranteed bandwidth first, using up 10% and 20% respectively. The remaining available bandwidth is used by class 3 since it has a higher priority. Class 2 uses around 10 Mbps, and class 3 uses around 90 Mbps.

```

# diagnose netlink interface list port2
if=port2 family=00 type=1 index=20 mtu=1500 link=0 master=0
ref=36 state=start present fw_flags=3800 flags=up broadcast run multicast

misc rxc=0 txc=0
input_type=0 state=3 arp_entry=0 refcnt=36

```

Case 3: multiple streams

Multiple streams of traffic are sent at the same time:

- PC1 to PC4 traffic is assigned class 2 with low priority, and a guaranteed bandwidth of 10 Mbps.
- PC2 to PC4 traffic is assigned class 3 with high priority, and a guaranteed bandwidth of 20 Mbps.
- PC2 to PC5 traffic is assigned class 4 with high priority, and a guaranteed bandwidth of 30 Mbps.

All classes will be allocated their guaranteed bandwidth first, using up 10 Mbps, 20 Mbps, and 30 Mbps respectively. The remaining available bandwidth (40 Mbps) is shared by class 3 and class 4 based on their guaranteed bandwidth ratio of 20:30.

- Class 3's share of the remaining 40 Mbps traffic = $40 \times 20 / (20 + 30) = 16$ Mbps
- Class 4's share of the remaining 40 Mbps traffic = $40 \times 30 / (20 + 30) = 24$ Mbps

Each class is allocated roughly the following bandwidth:

- Class 2: 10 Mbps
- Class 3: 20 Mbps + 16 Mbps = 36 Mbps
- Class 4: 30 Mbps + 24 Mbps = 54 Mbps

```
# diagnose netlink interface list port2
if=port2 family=00 type=1 index=20 mtu=1500 link=0 master=0
ref=27 state=start present fw_flags=3800 flags=up broadcast run multicast

Zero Trust Network Access introduction

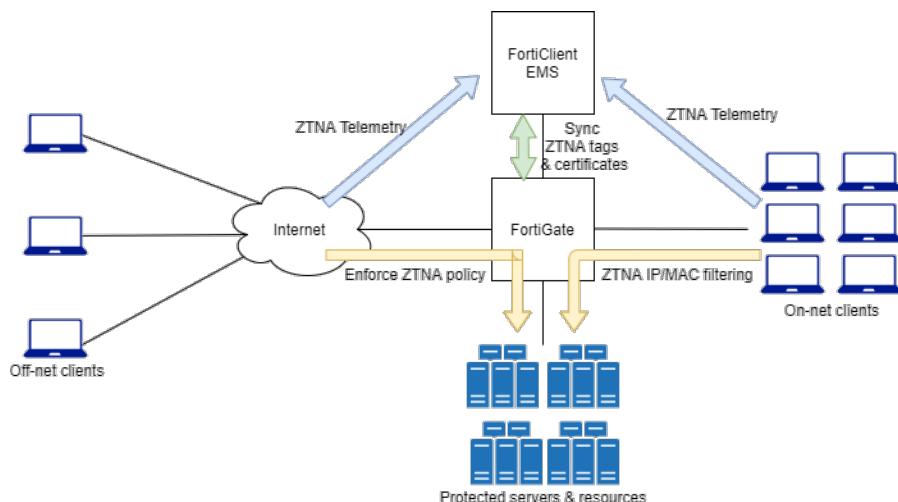

Zero Trust Network Access (ZTNA) is an access control method that uses client device identification, authentication, and Zero Trust tags to provide role-based application access. It gives administrators the flexibility to manage network access for On-net local users and Off-net remote users. Access to applications is granted only after device verification, authenticating the user's identity, authorizing the user, and then performing context based posture checks using Zero Trust tags.

Traditionally, a user and a device have different sets of rules for on-net access and off-net VPN access to company resources. With a distributed workforce and access that spans company networks, data centers, and cloud, managing the rules can become complex. User experience is also affected when multiple VPNs are needed to get to various resources. ZTNA can improve this experience.

ZTNA access proxy and IP/MAC based access control

- ZTNA access proxy allows users to securely access resources through an SSL encrypted access proxy. This simplifies remote access by eliminating the use of VPNs.
- IP/MAC based access control combines IP/MAC with uses ZTNA tags for identification and security posture check to implement role-based zero trust access.

ZTNA telemetry, tags, and policy enforcement

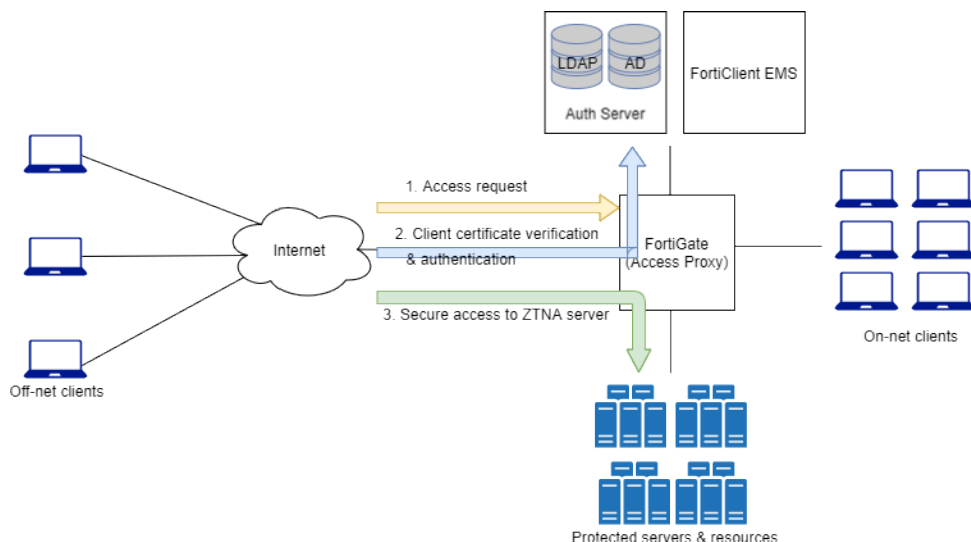

When On-net and Off-net FortiClient endpoints register to FortiClient EMS, device information, log on user information, and security posture are all shared over ZTNA telemetry with the EMS server. Clients also make a certificate signing request to obtain a client certificate from the EMS that is acting as the ZTNA Certificate Authority (CA).

Based on the client information, EMS applies matching Zero Trust tagging rules to tag the clients. These tags, and the client certificate information, are synchronized with the FortiGate in real-time. This allows the FortiGate to verify the client's identity using the client certificate, and grant access based on the ZTNA tags applied in the ZTNA rule.

For more information, see [Establish device identity and trust context with FortiClient EMS on page 1046](#).

Access proxy

The FortiGate access proxy can proxy HTTP, SSH, RDP, SMB, FTP, and other TCP traffic over secure connections with the client. This enables seamless access from the client to the protected servers, without needing to form IPsec or SSL VPN tunnels.

HTTPS access proxy

The FortiGate HTTPS access proxy works as a reverse proxy for the HTTP server. When a client connects to a webpage hosted by the protected server, the address resolves to the FortiGate's access proxy VIP. The FortiGate proxies the connection and takes steps to authenticate the user. It prompts the user for their certificate on the browser, and verifies this against the ZTNA endpoint record that is synchronized from the EMS. If an authentication scheme, such as SAML authentication, is configured, the client is redirected to a captive portal for sign-on. If this passes, traffic is allowed based on the ZTNA rules, and the FortiGate returns the webpage to the client.

For example configurations, see [ZTNA HTTPS access proxy example on page 1053](#), [ZTNA HTTPS access proxy with basic authentication example on page 1060](#), and [ZTNA proxy access with SAML authentication example on page 1078](#).

TCP forwarding access proxy (TFAP)

The TCP forwarding access proxy works as a special type of HTTPS reverse proxy. Instead of proxying traffic to a web server, TCP traffic is tunneled between the client and the access proxy over HTTPS, and forwarded to the protected resource. The FortiClient endpoint configures the ZTNA connection by pointing to the proxy gateway, and then specifying the destination host that it wants to reach. An HTTPS connection is made to the FortiGate's access proxy VIP, where the client certificate is verified and access is granted based on the ZTNA rules. TCP traffic is forwarded from the FortiGate to the protected resource, and an end to end connection is established. To reduce overhead, you can disable access proxy encryption on the client, as some TCP protocols, like RDP, are already secure. The TCP forwarding access proxy supports UTM scanning and deep inspection for HTTP, HTTPS, SMTP, SMTPS, IMAP, IMAPS, POP3, POP3S, SMB, and CIFS.

For an example configuration, see [ZTNA TCP forwarding access proxy example on page 1067](#).

SSH access proxy

The SSH access proxy provides some benefits to proxying SSH connections over TFAP, including allowing SSH deep inspection, performing optional SSH host-key validation, and allowing one time user authentication to authenticate the ZTNA SSH access proxy connection and SSH server connection.

For an example configuration, see [ZTNA SSH access proxy example on page 1095](#).

Basic ZTNA configuration components

The basic components that are required to configure ZTNA access proxy on the FortiGate are:

1. FortiClient EMS fabric connector and ZTNA tags.
2. FortiClient EMS running version 7.0.0 or later or FortiClient EMS Cloud.
3. FortiClient running 7.0.0 or later.
4. ZTNA server
5. ZTNA rule

For configuration details, see [Basic ZTNA configuration on page 1037](#).

Basic ZTNA configuration

To deploy a ZTNA access proxy, configure the following components on the FortiGate:

1. [Configure a FortiClient EMS connector on page 1038](#)
2. [Configure a ZTNA server on page 1040](#)
3. [Configure a ZTNA rule on page 1043](#)
4. [Optional authentication on page 1044](#)

To configure ZTNA in the GUI, go to *System > Feature Visibility* and enable *Zero Trust Network Access*.

Configure a FortiClient EMS connector

To add an on-premise FortiClient EMS server in the GUI:

1. Go to *Security Fabric > Fabric Connectors*.
2. Click *Create New* and click *FortiClient EMS*.
3. Enter a name for the connector and the IP address or FQDN of the EMS.
4. Click *OK*.
5. A window appears to verify the EMS server certificate. Click *Accept*.
See [FortiClient EMS](#) for more information.

To add an on-premise FortiClient EMS server in the CLI:

```
config endpoint-control fctems
  edit <name>
    set server <server IP or domain>
  next
end
```

To add FortiClient EMS Cloud in the GUI:

1. Go to *Security Fabric > Fabric Connectors*.
2. Double-click *FortiClient EMS* to open it for editing.
3. Set *Type* to *FortiClient EMS Cloud*.
4. Enter a name for the connector.
5. Click *OK*. A window appears to verify the EMS server certificate.
6. Click *Accept*.
See [FortiClient EMS](#) for more information.

To add FortiClient EMS Cloud in the CLI:

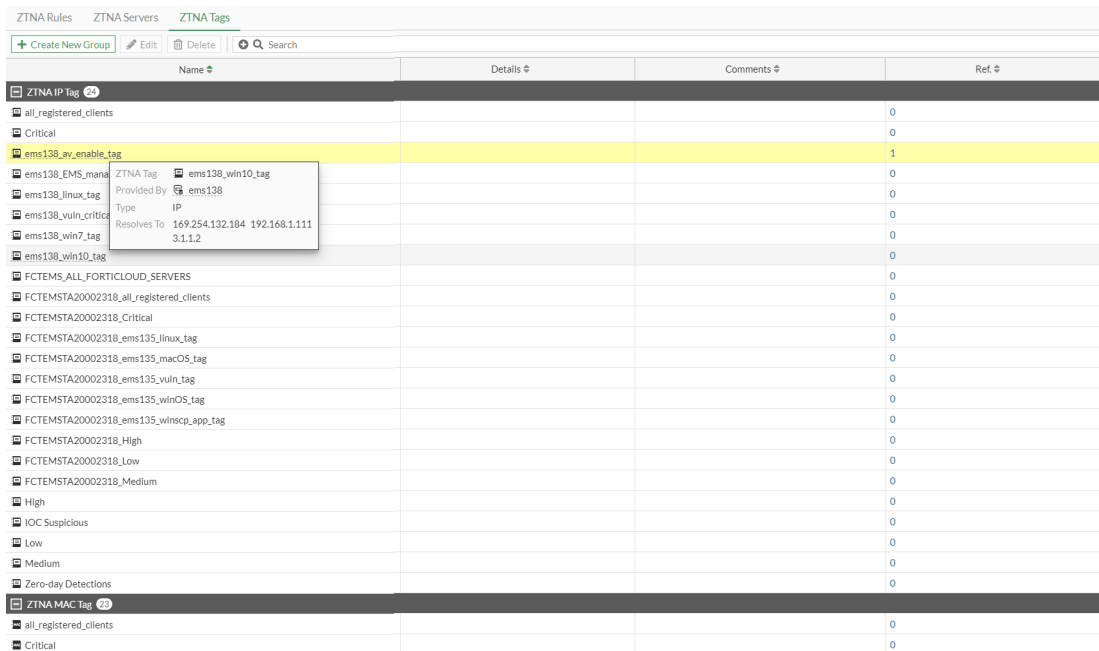

```
config endpoint-control fctems
  edit <name>
    set fortinetone-cloud-authentication enable
    set certificate <string>
  next
end
```

ZTNA tags

After the FortiGate connects to the FortiClient EMS, it automatically synchronizes ZTNA tags. ZTNA tags are generated from tagging rules configured on the FortiClient EMS. These tagging rules are based on various posture checks that can be applied on the endpoints. See [Endpoint Posture Check Reference](#).

To view the synchronized ZTNA tags in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Tags* tab.
2. Hover the cursor over a tag name to view more information about the tag, such as its resolved addresses.

To create a ZTNA tag group in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Tags* tab.
2. Click *Create New Group*.
3. Enter a name for the group and select the group members.

4. Click **OK**.

To view the synchronized ZTNA tags in the CLI:

```
# diagnose firewall dynamic address
# diagnose firewall dynamic list
```

To create a ZTNA tag group in the CLI:

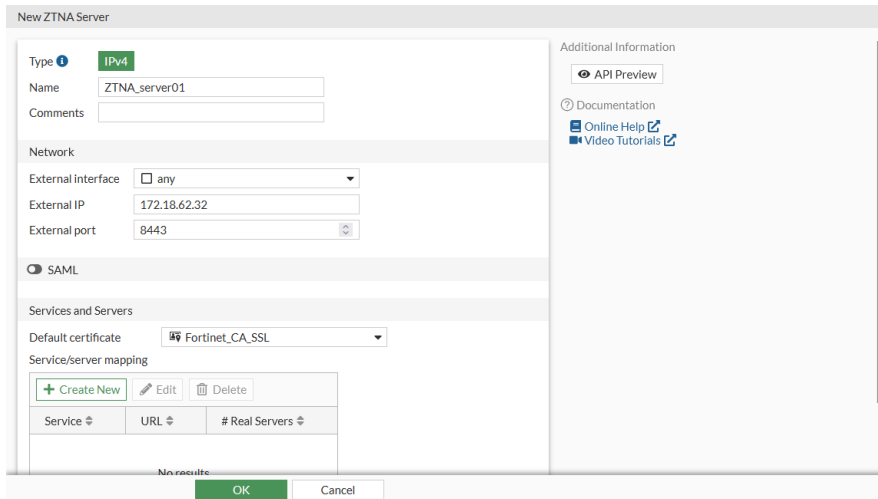

```
config firewall addrgrp
  edit <group name>
    set category ztna-ems-tag
    set member <members>
  next
end
```

Configure a ZTNA server

To configure a ZTNA server, define the access proxy VIP and the real servers that clients will connect to. The access proxy VIP is the FortiGate ZTNA gateway that clients make HTTPS connections to. The service/server mappings define the virtual host matching rules and the real server mappings of the HTTPS requests.

To create a ZTNA server for HTTPS access proxy in the GUI:

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Enter a name for the server.
4. Select an external interface, enter the external IP address, and select the external port that the clients will connect to.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.

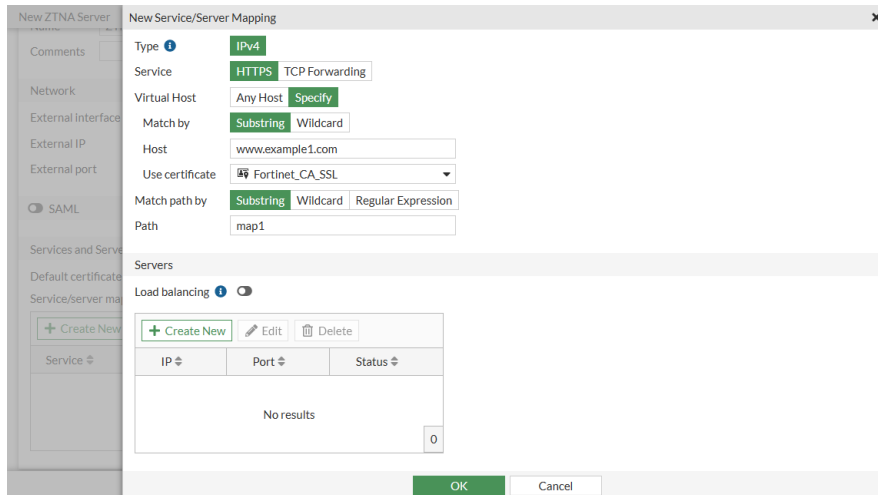

6. Add server mapping:

- a. In the *Service/server mapping* table, click *Create New*.
- b. Set *Service* to *HTTPS*.
- c. Set *Virtual Host* to *Any Host* or *Specify*.

- *Any Host*: Any request that resolves to the access proxy VIP will be mapped to your real servers. For example, if both `www.example1.com` and `www.example2.com` resolve to the VIP, then both requests are mapped to your real servers.
- *Specify*: Enter the name or IP address of the host that the request must match. For example, if `www.example1.com` is entered as the host, then only requests to `www.example1.com` will match.

d. Configure the path as needed.

The path can be matched by substring, wildcard, or regular expression. For example, if the virtual host is specified as `www.example1.com`, and the path substring is `map1`, then `www.example1.com/map1` will be matched.

- e. If multiple servers will be configured, enable *Load balancing* and select an algorithm.
- f. Add a server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Enter the server IP address and port number.
 - iii. Set the server status.

- iv. Click OK.
 - v. Add more servers as needed.
 - g. Click OK.
 - h. Add more server mappings as needed.
7. Click OK.

To create a ZTNA server and access proxy VIP in the CLI:

1. Configure an access proxy VIP:

```
config firewall vip
  edit <name>
    set type access-proxy
    set extip <external IP>
    set extintf <external interface>
    set server-type { https | ssh }
    set extport <external port>
    set ssl-certificate <certificate>
  next
end
```

2. If the virtual host is specified, configure the virtual host:

```
config firewall access-proxy-virtual-host
  edit <auto generated when configured from GUI>
    set ssl-certificate <certificate>
    set host <host name or IP>
    set host-type { sub-string | wildcard }
  next
end
```

3. Configure the server and path mapping:

```
config firewall access-proxy
  edit <name>
    set vip <vip name>
    set client-cert { enable | disable }
    set empty-cert-action { accept | block }
    set log-blocked-traffic {enable | disable}
    config api-gateway
      edit 1
        set url-map <mapped path>
        set service { http | https | tcp-forwarding | samlsp }
        set virtual-host <name of virtual-host if specified>
        set url-map-type { sub-string | wildcard | regex }
        config realservers
          edit 1
            set addr-type ip
            set ip <ip of real server>
            set port <port>
            set status { active | standby | disable }
            set health-check { enable | disable }
          next
        end
        set ldb-method static
        set persistence none
      end
    end
```

```

        set ssl-dh-bits 2048
        set ssl-algorithm high
        set ssl-min-version tls-1.1
        set ssl-max-version tls-1.3
    next
end
next
end

```

Configure a ZTNA rule

A ZTNA rule is a proxy policy used to enforce access control. ZTNA tags or tag groups can be defined to enforce zero trust role based access. Security profiles can be configured to protect this traffic.

To configure a ZTNA rule in the GUI:

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Rules* tab.
2. Click *Create New*.
3. Enter a name for the rule.
4. Select an *Incoming Interface* and *Source*.
5. Add the ZTNA tags or tag groups that are allowed access. If multiple tags are included, select the *Match ZTNA Tags* method, *Any* or *All*.
6. Select the *ZTNA Server*.
7. Select the *Destination*.

8. Configure the remaining options as needed.
9. Click *OK*.

To configure a ZTNA rule in the CLI:

```

config firewall proxy-policy
  edit 1
    set name <ZTNA rule name>
    set proxy access-proxy
    set access-proxy <access proxy>
  end
end

```

```

    set srcintf <interface>
    set srcaddr "all"
    set transparent {enable | disable}
    set dstaddr "all"
    set ztna-ems-tag <ZTNA tag(s)>
    set ztna-tags-match-logic {or | and}
    set action accept
    set schedule "always"
    set logtraffic all
    set poolname <ip_pool>
    set utm-status enable
    set ssl-ssh-profile <inspection profile>
next
end

```

The `transparent` and `poolname` settings cannot be enabled at the same time. Use one setting at a time when configuring ZTNA rules.

Optional authentication

To configure authentication to the access proxy, you must configure an authentication scheme and authentication rule in the GUI or CLI. They are used to authenticate proxy-based policies, similar to configuring authentication for explicit and transparent proxy.

The authentication scheme defines the method of authentication that is applied. For ZTNA, basic HTTP and SAML methods are supported. Each method has additional settings to define the data source to check against. For example, with basic HTTP authentication, a user database can reference an LDAP server, RADIUS server, local database, or other supported authentication servers that the user is authenticated against.

The authentication rule defines the proxy sources and destinations that require authentication, and which authentication scheme to apply. For ZTNA, active authentication method is supported. The active authentication method references a scheme where users are actively prompted for authentication, like with basic authentication.

After the authentication rule triggers the method to authenticate the user, a successful authentication returns the groups that the user belongs to. In the ZTNA rule and proxy policy you can define a user or user group as the allowed source. Only users that match that user or group are allowed through the proxy policy.

To configure a basic authentication scheme:

```

config authentication scheme
    edit <name>
        set method basic
        set user-database <auth server>
    next
end

```

To configure an authentication rule:

```

config authentication rule
    edit <name>
        set status enable
        set protocol http
    next
end

```

```
        set srcintf <interface>
        set srcaddr <address>
        set dstaddr <address>
        set ip-based enable
        set active-auth-method <active auth scheme>
    next
end
```

To apply a user group to a ZTNA rule in the GUI:

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Rules* tab.
2. Edit an existing rule, or click *Create New* to create a new rule.
3. Click in the *Source* field, select the *User* tab, and select the users and user groups that will be allowed access.
4. Configure the remaining settings as required.
5. Click *OK*.

To apply a user group to a ZTNA rule in the CLI:

```
config firewall proxy-policy
  edit <policy ID>
    set name <ZTNA rule name>
    set proxy access-proxy
    set access-proxy <access proxy>
    set srcintf <interface>
    set srcaddr "all"
    set dstaddr "all"
    set ztna-ems-tag <ZTNA tags>
    set ztna-tags-match-logic {or | and}
    set action accept
    set schedule "always"
    set logtraffic all
    set groups <user group>
    set utm-status enable
    set ssl-ssh-profile <inspection profile>
  next
end
```

The authentication rule and scheme defines the method used to authenticate users. With basic HTTP authentication, a sign in prompt is shown after the client certificate prompt. After the authentication passes, the returned groups that the user is a member of are checked against the user groups that are defined in the ZTNA rule. If a group matches, then the user is allowed access after passing a posture check.

For basic setup information, see [ZTNA HTTPS access proxy with basic authentication example on page 1060](#).

For advanced setup information, see [ZTNA proxy access with SAML authentication example on page 1078](#) and [ZTNA access proxy with SAML and MFA using FortiAuthenticator example on page 1102](#).

HTTP access proxy vs TCP forwarding access proxy

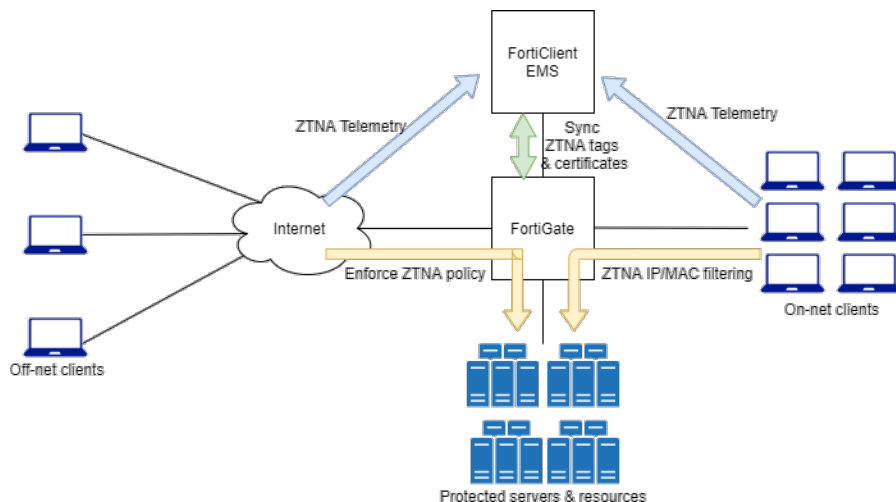

In an HTTP access proxy connection, there is no configurations needed on the client endpoint. Users can simply access the HTTP website on a browser by entering its URL. For TCP forwarding access proxy, a ZTNA rule must be configured on the FortiClient endpoint. This rule instructs the FortiClient to listen to traffic to the destination address and port, and redirects the traffic to the FortiGate access proxy over HTTPS.

For more information, see:

- [ZTNA TCP forwarding access proxy example on page 1067](#)
- [ZTNA TCP forwarding access proxy without encryption example on page 1073](#)

Establish device identity and trust context with FortiClient EMS

How device identity is established through client certificates, and how device trust context is established between FortiClient, FortiClient EMS, and the FortiGate, are integral to ZTNA.

Device roles

FortiClient

FortiClient endpoints provide the following information to FortiClient EMS when they register to the EMS:

- Device information (network details, operating system, model, and others)
- Logged on user information
- Security posture (On-net/Off-net, antivirus software, vulnerability status, and others)

It also requests and obtains a client device certificate from the EMS ZTNA Certificate Authority (CA) when it registers to FortiClient EMS. The client uses this certificate to identify itself to the FortiGate.

FortiClient EMS

FortiClient EMS issues and signs the client certificate with the FortiClient UID, certificate serial number, and EMS serial number. The certificate is then synchronized to the FortiGate. EMS also shares its EMS ZTNA CA certificate with the FortiGate, so that the FortiGate can use it to authenticate the clients.

FortiClient EMS uses zero trust tagging rules to tag endpoints based on the information that it has on each endpoint. The tags are also shared with the FortiGate. See [Endpoint Posture Check Reference](#) for a list of the endpoint posture checks that EMS can perform.

Each ZTNA tag creates two firewall addresses in all VDOMs on a FortiGate. One firewall address is the IP address, and the other firewall address is the MAC address. Because each FortiGate model has a global limit and a per-VDOM limit for the maximum number of supported firewall addresses, the FortiGate model determines the maximum number of ZTNA tags allowable by that unit, which is the maximum number of firewall address divided by two. For each FortiGate model's limit, see the Maximum Values table.

FortiGate

The FortiGate maintains a continuous connection to the EMS server to synchronize endpoint device information, including primarily:

- FortiClient UID
- Client certificate SN
- EMS SN
- Device credentials (user/domain)
- Network details (IP and MAC address and routing to the FortiGate)

When a device's information changes, such as when a client moves from on-net to off-net, or their security posture changes, EMS is updated with the new device information and then updates the FortiGate. The FortiGate's WAD daemon can use this information when processing ZTNA traffic. If an endpoint's security posture change causes it to no longer match the ZTNA rule criteria on an existing session, then the session is terminated.

Certificate management on FortiClient EMS

FortiClient EMS has a *default_ZTNARootCA* certificate generated by default that the ZTNA CA uses to sign CSRs from the FortiClient endpoints. Clicking the refresh button revokes and updates the root CA, forcing updates to the FortiGate and FortiClient endpoints by generating new certificates for each client.

The screenshot displays the 'EMS Settings' page in the FortiClient Endpoint Management Server interface. The left sidebar contains a navigation menu with options like Dashboard, Endpoints, Deployment & Installers, and System Settings. The main content area is titled 'EMS Settings' and includes several configuration sections:

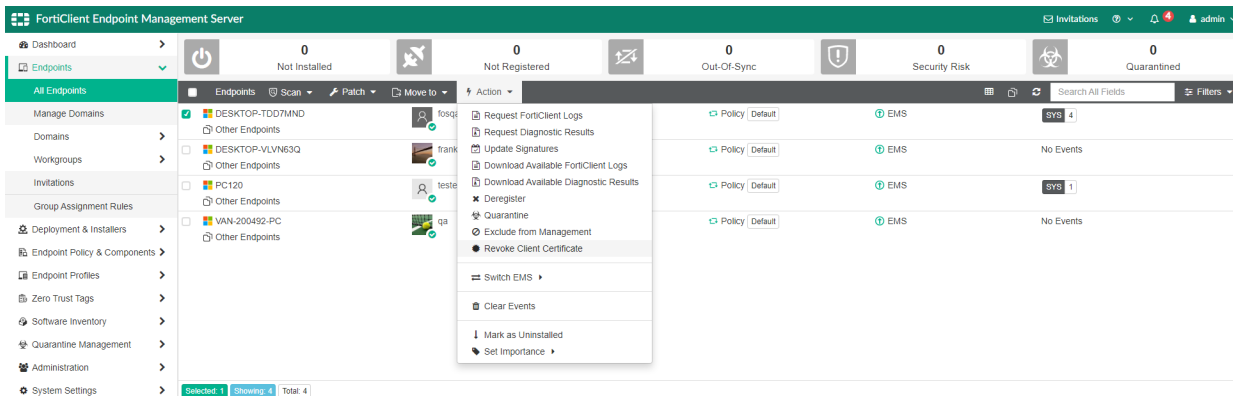

- Custom hostname:** Optional text input field.
- Management IP and Port:** Optional text input field with a dropdown menu showing 'e.g. 443'.
- Redirect HTTP request to HTTPS:** A checked checkbox.
- SSL certificate:** A dropdown menu showing 'FCTEHS8821R01322.1' with a date '2028-01-19' and a refresh icon.
- Show FortiGate Server List:** An unchecked checkbox.
- EMS CA certificate (ZTNA):** A dropdown menu showing 'default_ZTNARootCA.pem' with a date '2046-03-17' and a refresh icon. Below it, a note states: 'Certificate was created on 2021-03-23T20:25:36.480'.
- Reset Stalled Deployment Interval:** A text input field with '12' and a unit dropdown set to 'hours'.

Below these settings are sections for 'EMS Settings' (with a toggle for 'EMS for Chromebooks Settings'), 'Endpoints Settings', and 'FortiClient telemetry connection key'. At the bottom, there are fields for 'Keep alive interval' (60 seconds), 'License timeout' (45 days), and checkboxes for 'Automatically upload avatars' (checked) and 'Enable endpoint snapshot reports' (unchecked). A 'Save' button is located at the bottom right.

Do not confuse the EMS CA certificate (ZTNA) with the SSL certificate. The latter is the server certificate that is used by EMS for HTTPS access and fabric connectivity to the EMS server.

EMS can also manage individual client certificates. To revoke the current client certificate that is used by the endpoint: go to *Endpoint > All Endpoints*, select the client, and click *Action > Revoke Client Certificate*.

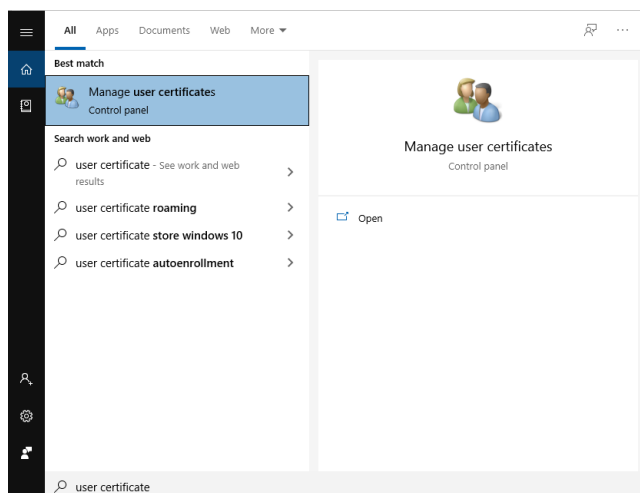

Locating and viewing the client certificate on an endpoint

In Windows, FortiClient automatically installs certificates into the certificate store. The certificate information in the store, such as certificate UID and SN, should match the information on EMS and the FortiGate.

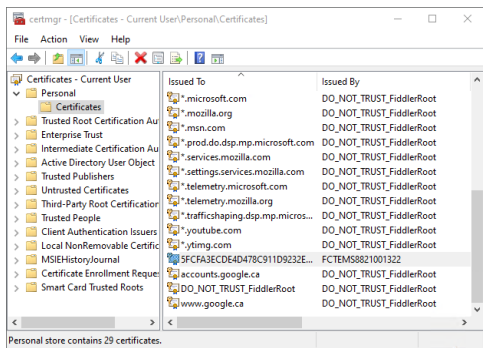

To locate certificates on other operating systems, consult the vendor documentation.

To locate the client certificate and EMS ZTNA CA certificate on a Windows PC:

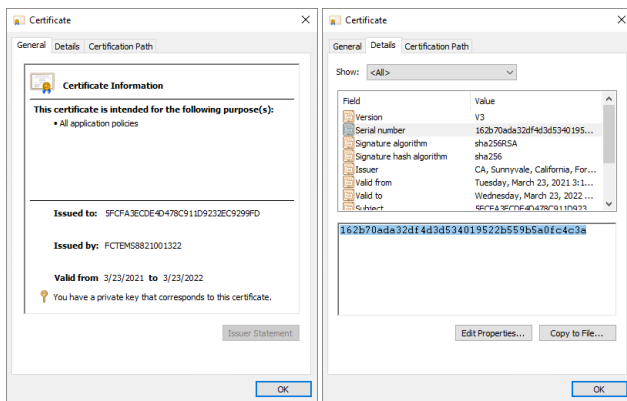

1. In the Windows search box, enter *user certificate* and click *Manage user certificates* from the results.

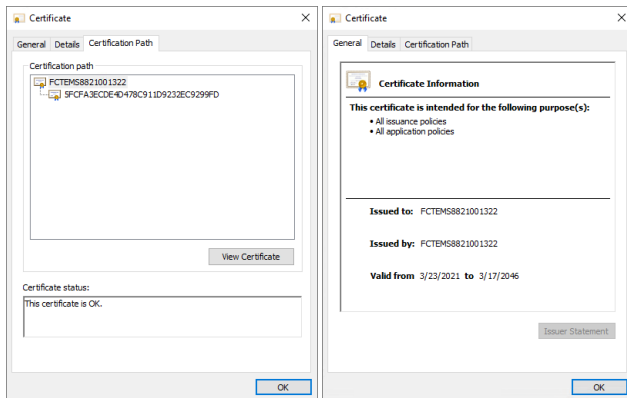

2. In the certificate manager, go to *Certificates - Current User > Personal > Certificates* and find the certificate that is issued by the FortiClient EMS.

3. Right-click on it and select Properties.
4. The *General* tab shows the client certificate UID and the issue and expiry dates. The *Details* tab show the certificate SN.

5. Go to the *Certificate Path* tab to see the full certificate chain.
6. Select the root CA and click *View Certificate* to view the details about the EMS ZTNA CA certificate.

Verifying that the client information is synchronized to the FortiGate

The following diagnose commands help to verify the presence of matching endpoint record, and information such as the client UID, client certificate SN, and EMS certificate SN on the FortiGate. If any of the information is missing or incomplete, client certificate authentication might fail because the corresponding endpoint entry is not found. More in-depth diagnosis would be needed to determine the reason for the missing records.

Command	Description
# diagnose endpoint record list <ip>	Show the endpoint record list. Optionally, filter by the endpoint IP address.
# diagnose endpoint lls-comm send ztna find-uid <uid>	Query endpoints by client UID.
# diagnose endpoint lls-comm send ztna find-ip-vdom <ip> <vdom>	Query endpoints by the client IP-VDOM pair.
# diagnose wad dev query-by uid <uid>	Query from WAD diagnose command by UID.
# diagnose wad dev query-by ipv4 <ip>	Query from WAD diagnose command by IP address.
# diagnose test application fcnacd 7 # diagnose test application fcnacd 8	Check the FortiClient NAC daemon ZTNA and route cache.

To check the endpoint record list for IP address 10.6.30.214:

```
# diagnose endpoint record list 10.6.30.214
```

```
Record #1:
```

```

IP Address = 10.6.30.214
MAC Address = 00:0c:29:ba:1e:61
MAC list = 00:0c:29:ba:1e:61;00:0c:29:ba:1e:6b;
VDOM = root (0)

SSL certificate based authentication

A client certificate is obtained when an endpoint registers to EMS. FortiClient automatically submits a CSR request and the FortiClient EMS signs and returns the client certificate. This certificate is stored in the operating system's certificate store for subsequent connections. The endpoint information is synchronized between the FortiGate and FortiClient EMS.

When an endpoint disconnects or is unregistered from EMS, its certificate is removed from the certificate store and revoked on EMS. The endpoint obtains a certificate again when it reconnected the EMS.

By default, client certificate authentication is enabled on the access proxy, so when the HTTPS request is received the FortiGate's WAD process challenges the client to identify itself with its certificate. The FortiGate makes a decision based on the following possibilities:

1. If the client responds with the correct certificate that the client UID and certificate SN can be extracted from:
 - If the client UID and certificate SN match the record on the FortiGate, the client is allowed to continue with the ZTNA proxy rule processing.
 - If the client UID and certificate SN do not match the record on the FortiGate, the client is blocked from further ZTNA proxy rule processing.
2. If the client cancels and responds with an empty client certificate:
 - If `empty-cert-action` is set to `accept`, the client is allowed to continue with ZTNA proxy rule processing.
 - If `empty-cert-action` is set to `block`, the client is blocked from further ZTNA proxy rule processing.

To configure the client certificate actions:

```
config firewall access-proxy
  edit <name>
    set client-cert {enable | disable}
    set empty-cert-action {accept | block}
  next
end
```

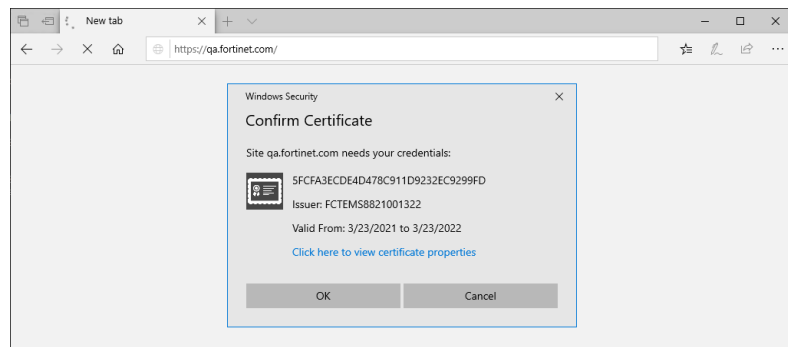

Example

In this example, a client connects to *qa.fortinet.com* and is prompted for a client certificate.

- `client-cert` is set to `enable`, and `empty-cert-action` is set to `block`.
- The ZTNA server is configured, and a ZTNA rule is set to allow this client.
- The domain resolves to the FortiGate access proxy VIP.

Scenario 1:

When prompted for the client certificate, the client clicks *OK* and provides a valid certificate that is verified by the FortiGate.

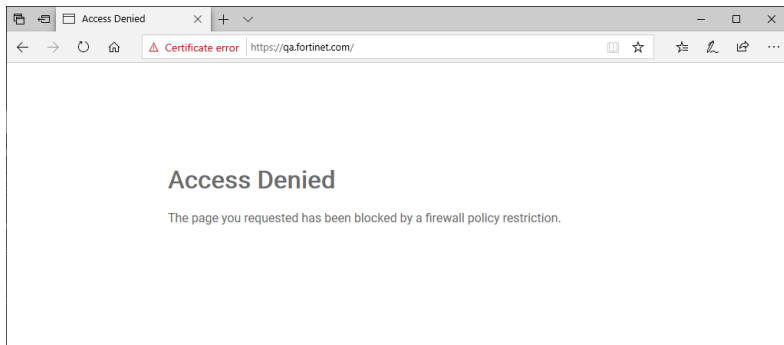

Result:

The client passes SSL certificate authentication and is allowed to access the website.

Scenario 2:

When prompted for the client certificate, the client clicks *Cancel*, resulting in an empty certificate response to the access proxy.

Result:

Because the certificate response is empty and `empty-cert-action` is set to `block`, the WAD daemon blocks the connection.

Currently, the Microsoft Edge, Google Chrome, and Safari browsers are supported by ZTNA.

ZTNA configuration examples

This section includes the following ZTNA configuration examples:

- [ZTNA HTTPS access proxy example on page 1053](#)
- [ZTNA HTTPS access proxy with basic authentication example on page 1060](#)
- [ZTNA TCP forwarding access proxy example on page 1067](#)
- [ZTNA TCP forwarding access proxy without encryption example on page 1073](#)
- [ZTNA proxy access with SAML authentication example on page 1078](#)
- [ZTNA IP MAC based access control example on page 1083](#)
- [ZTNA IPv6 examples on page 1089](#)
- [ZTNA SSH access proxy example on page 1095](#)
- [ZTNA access proxy with SAML and MFA using FortiAuthenticator example on page 1102](#)
- [ZTNA access proxy with SSL VPN web portal example on page 1114](#)
- [Posture check verification for active ZTNA proxy session examples on page 1118](#)
- [ZTNA TCP forwarding access proxy with FQDN example on page 1124](#)
- [ZTNA session-based form authentication on page 1128](#)

ZTNA HTTPS access proxy example

In this example, an HTTPS access proxy is configured to demonstrate its function as a reverse proxy on behalf of the web server it is protecting. It verifies user identity, device identity, and trust context, before granting access to the protected source.

This example shows access control that allows or denies traffic based on ZTNA tags. Traffic is allowed when the FortiClient endpoint is tagged as *Low* risk, and denied when the endpoint is tagged with *Malicious-File-Detected*.

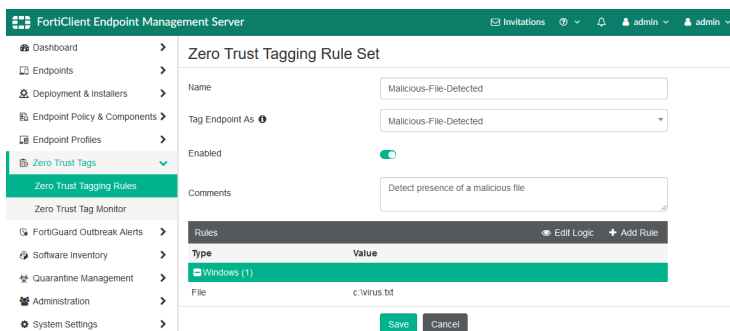

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

To configure ZTNA in the GUI, go to *System > Feature Visibility* and enable *Zero Trust Network Access*.

To configure a Zero Trust tagging rule on the FortiClient EMS:

1. Log in to the FortiClient EMS.
2. Go to *Zero Trust Tags > Zero Trust Tagging Rules*, and click *Add*.
3. In the *Name* field, enter *Malicious-File-Detected*.
4. In the *Tag Endpoint As* dropdown list, select *Malicious-File-Detected*.
EMS uses this tag to dynamically group together endpoints that satisfy the rule, as well as any other rules that are configured to use this tag.
5. Click *Add Rule* then configure the rule:
 - a. For *OS*, select *Windows*.
 - b. From the *Rule Type* dropdown list, select *File* and click the + button.
 - c. Enter a file name, such as *C:\virus.txt*.
 - d. Click *Save*.

6. Click *Save*.

To configure a ZTNA server for HTTPS access proxy in the GUI:

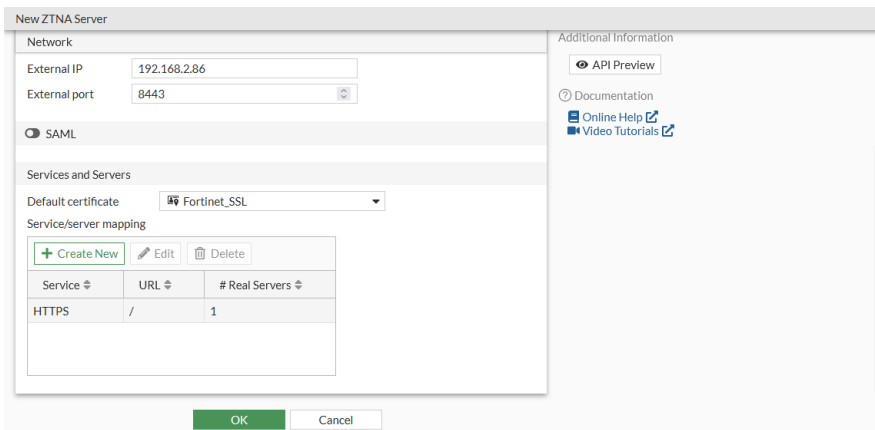

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Set *Name* to *WIN2K16-P1*.
4. Configure the network settings:
 - a. Set *External interface* to *port1*.
 - b. Set *External IP* to *192.168.2.86*.
 - c. Set *External port* to *8443*.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.
6. Add server mapping:
 - a. In the *Service/server mapping* table, click *Create New*.
 - b. Set *Service* to *HTTPS*.
 - c. Set *Virtual Host* to *Any Host*.
 - d. Configure the path as needed. For example, to map to *winserver.fgdocs.com/fortigate*, enter */fortigate*.
 - e. Add a server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Set *IP* to *192.168.20.6*.
 - iii. Set *Port* to *443*.
 - iv. Click *OK*.

The screenshot shows the 'New Service/Server Mapping' dialog in the FortiOS GUI. The dialog is divided into several sections:

- Network:** Type is set to 'IPv4', Service is 'HTTPS', and TCP Forwarding is checked.
- Virtual Host:** Set to 'Any Host'.
- Match path by:** Set to 'Substring'.
- Path:** Set to '/'. There are also options for 'Wildcard' and 'Regular Expression'.
- Servers:** A table with columns for IP, Port, and Status. One server is listed with IP 192.168.20.6, Port 443, and Status Active.

At the bottom of the dialog, there are 'OK' and 'Cancel' buttons.

f. Click **OK**.

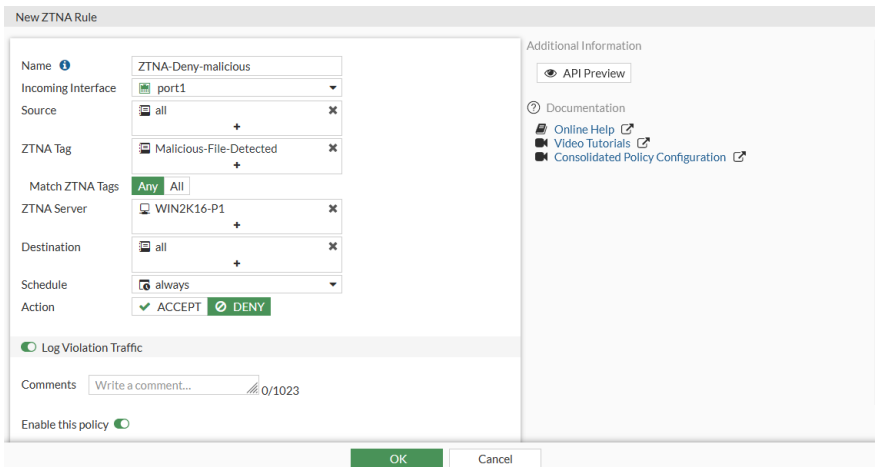

7. Click **OK**.

To configure ZTNA rules to allow and deny traffic based on ZTNA tags in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Rules* tab.
2. Create a rule to deny traffic:
 - a. Click *Create New*.
 - b. Set *Name* to *ZTNA-Deny-malicious*.
 - c. Set *Incoming Interface* to *port1*.
 - d. Set *Source* to *all*.
 - e. Add the ZTNA tag *Malicious-File-Detected*.

This tag is dynamically retrieved from EMS when you first created the Zero Trust Tagging Rule.

- f. Select the ZTNA server *WIN2K16-P1*.
- g. Set *Action* to *DENY*.
- h. Enable *Log Violation Traffic*.

i. Click **OK**.

3. Create a rule to allow traffic:
 - a. Click *Create New*.
 - b. Set *Name* to *proxy-WIN2K16-P1*.

- c. Set *Incoming Interface* to *port1*.
 - d. Set *Source* to *all*. This can also be set to specific IP addresses to only allow those addresses to connect to this HTTPS access proxy.
 - e. Add the ZTNA tag *Low*.
 - f. Select the ZTNA server *WIN2K16-P1*.
 - g. Configure the remaining options as needed.
 - h. Click *OK*.
4. On the ZTNA rules list, make sure that the deny rule (*ZTNA-Deny-malicious*) is above the allow rule (*proxy-WIN2K16-P1*).

To configure HTTPS access in the CLI:

1. Configure the access proxy VIP:

```
config firewall vip
  edit "WIN2K16-P1"
    set type access-proxy
    set extip 192.168.2.86
    set extintf "port1"
    set server-type https
    set extport 8443
    set ssl-certificate "Fortinet_SSL"
  next
end
```

2. Configure the server and path mapping:

```
config firewall access-proxy
  edit "WIN2K16-P1"
    set vip "WIN2K16-P1"
    set client-cert enable
    set log-blocked-traffic enable
    config api-gateway
      edit 1
        config realservers
          edit 1
            set ip 192.168.20.6
          next
        end
      next
    end
  next
end
```

3. Configure ZTNA rules:

```
config firewall proxy-policy
  edit 3
    set name "ZTNA-Deny-malicious"
    set proxy access-proxy
    set access-proxy "WIN2K16-P1"
    set srcintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set ztna-ems-tag "FCTEMS0000109188_Malicious-File-Detected"
```

```

set schedule "always"
set logtraffic all
next
edit 2
set name "proxy-WIN2K16-P1"
set proxy access-proxy
set access-proxy "WIN2K16-P1"
set srcintf "port1"
set srcaddr "all"
set dstaddr "all"
set ztna-ems-tag "FCTEMS0000109188_Low"
set action accept
set schedule "always"
set logtraffic all
next
end

```

Testing the remote access to the HTTPS access proxy

After FortiClient EMS and FortiGate are configured, the HTTPS access proxy remote connection can be tested.

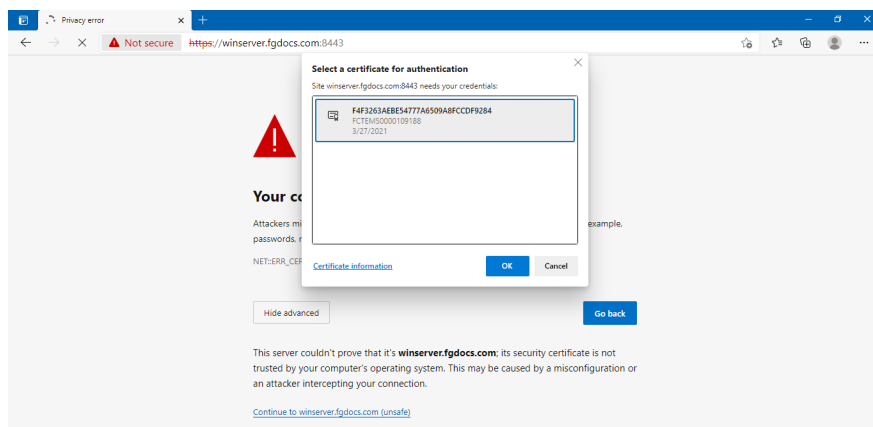

Access allowed:

1. On the remote Windows PC, open FortiClient.
2. On the *Zero Trust Telemetry* tab, make sure that you are connected to the EMS server.

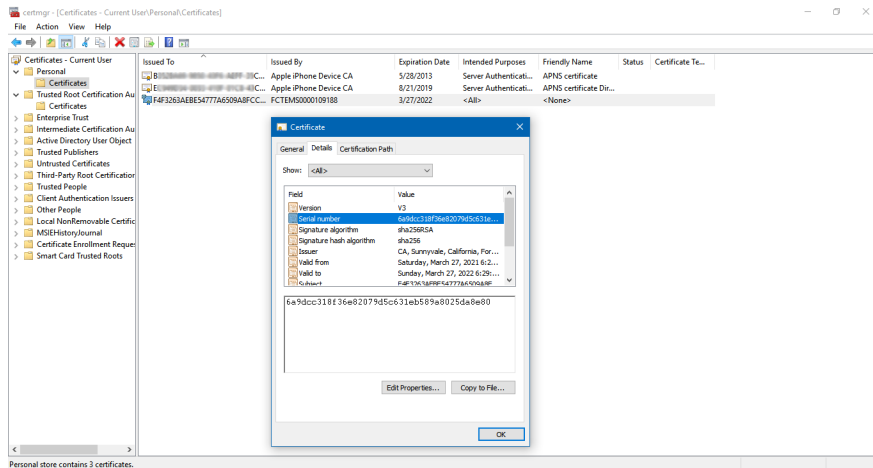

It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.

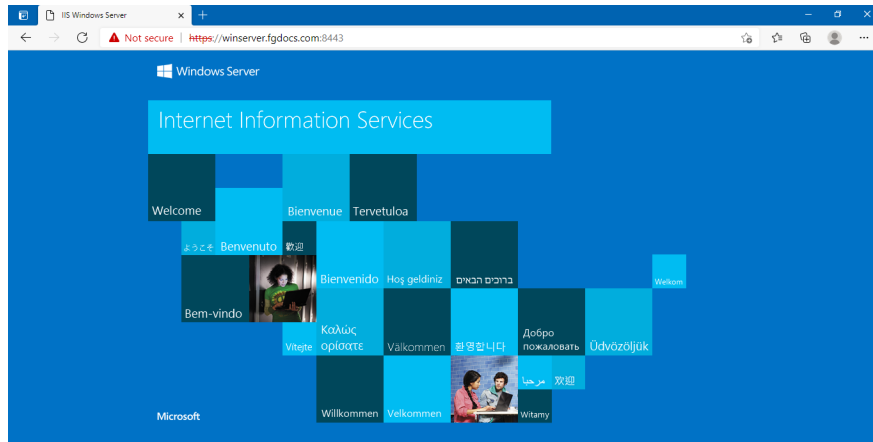

3. Open a browser and enter the address of the server and the access port. When entering the FQDN, make sure that the DNS can resolve the address to the IP address of the FortiGate. In this example, `winserver.fgdocs.com` resolves to `192.168.2.86`.
4. The browser prompts for the client certificate to use. Select the EMS signed certificate, then click **OK**.

The certificate is in the *User Configuration* store, under *Personal > Certificates*. The details show the SN of the certificate, which matches the record on the FortiClient EMS and the FortiGate.

5. The client is verified by the FortiGate to authenticate your identity.
6. The FortiGate matches your security posture by verifying your ZTNA tag and matching the corresponding ZTNA rule, and you are allowed access to the web server.

Access denied:

1. On the remote Windows PC, trigger the Zero Trust Tagging Rule by creating the file in C:\virus.txt.
2. Open a browser and enter the address <http://winserver.fgdocs.com:8443>.
3. The client is verified by the FortiGate to authenticate your identity.
4. FortiGate checks your security posture. Because EMS has tagged the PC with the *Malicious-File-Detected* tag, it matches the *ZTNA-Deny-malicious* rule.
5. You are denied access to the web server.

Access Denied
 The page you requested has been blocked by a firewall policy restriction.

Logs and debugs**Access allowed:**

```
# diagnose endpoint record list
Record #1:
    IP Address = 10.10.10.20
    MAC Address = 9c:b7:0d:2d:5c:d1
    MAC list = 24:b6:fd:fa:54:c1;06:15:cd:45:f1:2e;9c:b7:0d:2d:5c:d1;

ZTNA HTTPS access proxy with basic authentication example

This example expands on the previous example ([ZTNA HTTPS access proxy example on page 1053](#)), adding LDAP authentication to the ZTNA rule. Users are allowed based on passing the client certificate authentication check, user authentication, and security posture check.

Users that are in the AD security group *ALLOWED-VPN* are allowed access to the access proxy. Users that are not part of this security group are not allowed access.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

LDAP/Active Directory Users and Groups:

- Domain: KLHOME.local
- Users (Groups):
 - radCurtis (Domain Users, ALLOWED-VPN)
 - radKeith (Domain Users)

To configure a secure connection to the LDAP server in the GUI:

1. Go to *User & Authentication > LDAP Servers* and click *Create New*.
2. Configure the following settings:

Name	WIN2K16-KLHOME-LDAPS
Server IP/Name	192.168.20.6
Server Port	636
Common Name Identifier	sAMAccountName
Distinguished Name	dc=KLHOME,dc=local
Exchange server	Disabled
Bind Type	Regular Enter the <i>Username</i> and <i>Password</i> for LDAP binding and lookup.
Secure Connection	Enabled <ul style="list-style-type: none"> • Set <i>Protocol</i> to <i>LDAPS</i> • Enable <i>Certificate</i> and select the CA certificate to validate the server certificate.
Server identity check	Optionally, enable to verify the domain name or IP address against the server certificate.

3. Click *Test Connectivity* to verify the connection to the server.
4. Click *OK*.

To configure a secure connection to the LDAP server in the CLI:

```
config user ldap
  edit "WIN2K16-KLHOME-LDAPS"
    set server "192.168.20.6"
    set cnid "sAMAccountName"
    set dn "dc=KLHOME,dc=local"
    set type regular
    set username "KLHOME\Administrator"
    set password <password>
    set secure ldaps
    set ca-cert "CA_Cert_1"
    set port 636
  next
end
```

To configure a remote user group from the LDAP server in the GUI:

1. Go to *User & Authentication > User Groups* and click *Create New*.
2. Set the name to *KLHOME-ALLOWED-VPN*.
3. Set *Type* to *Firewall*.
4. In the *Remote Groups* table click *Add*:
 - a. Set *Remote Server* to *WIN2K16-KLHOME-LDAPS*.
 - b. Locate the *ALLOWED-VPN* group, right-click on it, and click *Add Selected*.
 - c. Click *OK*.

The screenshot shows the 'New User Group' configuration window in FortiGate. The 'Name' field contains 'KLHOME-ALLOWED-VPN'. Under 'Type', 'Firewall' is selected. The 'Members' field has a plus sign. The 'Remote Groups' section contains a table with one entry: Remote Server 'WIN2K16-KLHOME-LDAPS' and Group Name 'CN=ALLOWED-VPN,DC=KLHOME,DC=local'. On the right, there are links for 'API Preview', 'Documentation', 'Online Help', and 'Video Tutorials'. At the bottom, the 'OK' button is highlighted in green.

5. Click **OK**.

To configure a remote user group from the LDAP server in the CLI:

```
config user group
  edit "KLHOME-ALLOWED-VPN"
    set member "WIN2K16-KLHOME-LDAPS"
    config match
      edit 1
        set server-name "WIN2K16-KLHOME-LDAPS"
        set group-name "CN=ALLOWED-VPN,DC=KLHOME,DC=local"
      next
    end
  next
end
```

Authentication scheme and rules

After the LDAP server and user group have been configured, an authentication scheme and rule must be configured.

To configure authentication schemes and rules in the GUI, go to *System > Feature Visibility* and enable *Explicit Proxy*.

Authentication scheme

The authentication scheme defines the method of authentication that is applied. In this example, basic HTTP authentication is used so that users are prompted for a username and password the first time that they connect to a website through the HTTPS access proxy.

To configure an authentication scheme in the GUI:

1. Go to *Policy & Objects > Authentication Rules* and click *Create New > Authentication Scheme*.
2. Set the name to *ZTNA-Auth-scheme*.
3. Set *Method* to *Basic*.
4. Set *User database* to *Other* and select *WIN2K16-KLHOME-LDAPS* as the LDAP server.
5. Click **OK**.

To configure an authentication scheme in the CLI:

```
config authentication scheme
  edit "ZTNA-Auth-scheme"
    set method basic
    set user-database "WIN2K16-KLHOME-LDAPS"
  next
end
```

Authentication rule

The authentication rule defines the proxy sources and destination that require authentication, and what authentication scheme is applied. In this example, active authentication through the basic HTTP prompt is used and applied to all sources.

To configure an authentication rule in the GUI:

1. Go to *Policy & Objects > Authentication Rules* and click *Create New > Authentication Rule*.
2. Set the name to *ZTNA-Auth-rule*.
3. Set *Source Address* to *all*.
4. Set *Protocol* to *HTTP*.
5. Enable *Authentication Scheme* and select *ZTNA-Auth-scheme*.
6. Click *OK*.

To configure an authentication rule in the CLI:

```
config authentication rule
  edit "ZTNA-Auth-rule"
    set srcaddr "all"
    set active-auth-method "ZTNA-Auth-scheme"
  next
end
```

Applying the user group to a ZTNA rule

A user or user group must be applied to the ZTNA rule that you need to control user access to. The authenticated user from the authentication scheme and rule must match the user or user group in the ZTNA rule.

In this example, the user group is applied to the two ZTNA rules that were configured in [ZTNA HTTPS access proxy example on page 1053](#).

To apply a user group to the ZTNA rules in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Rules* tab.
2. Edit the *ZTNA-Deny-malicious* rule.
3. Click in the *Source* field, select the *User* tab, select the *KLHOME-ALLOWED-VPN* group, then click *Close*.
4. Click *OK*.
5. Edit the *proxy-WIN2K16-P1* rule.
6. Click in the *Source* field, select the *User* tab, select the *KLHOME-ALLOWED-VPN* group, then click *Close*.
7. Click *OK*.

To apply a user group to the ZTNA rules in the CLI:

```

config firewall proxy-policy
  edit 3
    set name "ZTNA-Deny-malicious"
    set proxy access-proxy
    set access-proxy "WIN2K16-P1"
    set srcintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set ztna-ems-tag "FCTEMS0000109188_Malicious-File-Detected"
    set schedule "always"
    set logtraffic all
    set groups "KLHOME-ALLOWED-VPN"
  next
  edit 2
    set name "proxy-WIN2K16-P1"
    set proxy access-proxy
    set access-proxy "WIN2K16-P1"
    set srcintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set ztna-ems-tag "FCTEMS0000109188_Low"
    set action accept
    set schedule "always"
    set logtraffic all
    set groups "KLHOME-ALLOWED-VPN"
  next
end

```

Testing remote access to the HTTPS access proxy with user authentication**Scenario 1: access allowed - user radCurtis**

1. On a remote Windows PC, open the FortiClient app, select the *Zero Trust Telemetry* tab, and confirm that you are connected to the EMS server.

It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.

2. In a browser, enter the address of the server and the access port.
If entering an FQDN, make sure that DNS can resolve the address to the IP address of the FortiGate. In this example, *winserver.fgdocs.com* resolves to 192.168.2.86.
3. When the browser asks for the client certificate to use, select the EMS signed certificate, then click *OK*.
The client certificate is verified by the FortiGate to authenticate your identity.
4. When prompted, enter the username *radCurtis* and the password, and click *Sign in*.
As *radCurtis* is a member of the *ALLOWED-VPN* group in Active Directory, it will match the *KLHOME-ALLOWED-VPN* user group. After the user authentication passes, the FortiGate performs a posture check on the ZTNA group. When that passes, you are allowed access to the website.

Verifying the results

```
# diagnose firewall auth list

10.10.10.20, radCurtis
  type: fw, id: 0, duration: 13, idled: 13
  expire: 587, allow-idle: 600
  packets: in 0 out 0, bytes: in 0 out 0
  group_id: 8 16777220
  group_name: KLHOME-ALLOWED-VPN grp_16777220

# diagnose test application fcnacd 7
ZTNA Cache:
-uid F4F3263AEBE54777A6509A8FCCDF9284: { "tags": [ "all_registered_clients", "Low" ], "user_
name": "keith", "client_cert_sn": "6C7433E8E2CEDEB49B6C3C3C03677A3521EA4486", "ems_sn":
"FCTEMS0000109188" }
```

The `user_name` is the windows log in username learned by FortiClient. It might not match the username used in firewall user authentication.

```
# execute log display

1: date=2021-04-13 time=00:11:56 eventtime=1618297916023667886 tz="-0700" logid="0000000010"
type="traffic" subtype="forward" level="notice" vd="root" srcip=10.10.10.20 srcport=51513
srcintf="port1" srcintfrole="wan" dstcountry="Reserved" srccountry="Reserved"

```

Scenario 2: access denied – user radKeith

1. If scenario 1 has just been tested, log in to the FortiGate and deauthenticate the user:
 - a. Go to *Dashboard > Users & Devices* and expand the *Firewall Users* widget.
 - b. Right-click on the user *radCurtis* and select deauthenticate.
2. On a remote Windows PC, open the FortiClient app, select the *Zero Trust Telemetry* tab, and confirm that you are connected to the EMS server.
3. In a browser, enter the address *winserver.fgdocs.com*.
4. When the browser asks for the client certificate to use, select the EMS signed certificate, then click *OK*. This option might not appear if you have already selected the certificate when testing scenario 1.
The client certificate is verified by the FortiGate to authenticate your identity.
5. When prompted, enter the username *radKeith* and the password, and click *Sign in*.
As *radKeith* is not a member of the *ALLOWED-VPN* group in Active Directory, it will not match the *KLHOME-ALLOWED-VPN* user group. Because no other policies are matched, this user is implicitly denied

Verifying the results

Go to *Dashboard > Users & Devices*, expand the *Firewall Users* widget, and confirm that user *radKeith* is listed, but no applicable user group is returned.

```
# execute log display
```

```
1: date=2021-04-13 time=12:29:21 eventtime=1618342161821542277 tz="-0700" logid="0000000013"

ZTNA TCP forwarding access proxy example

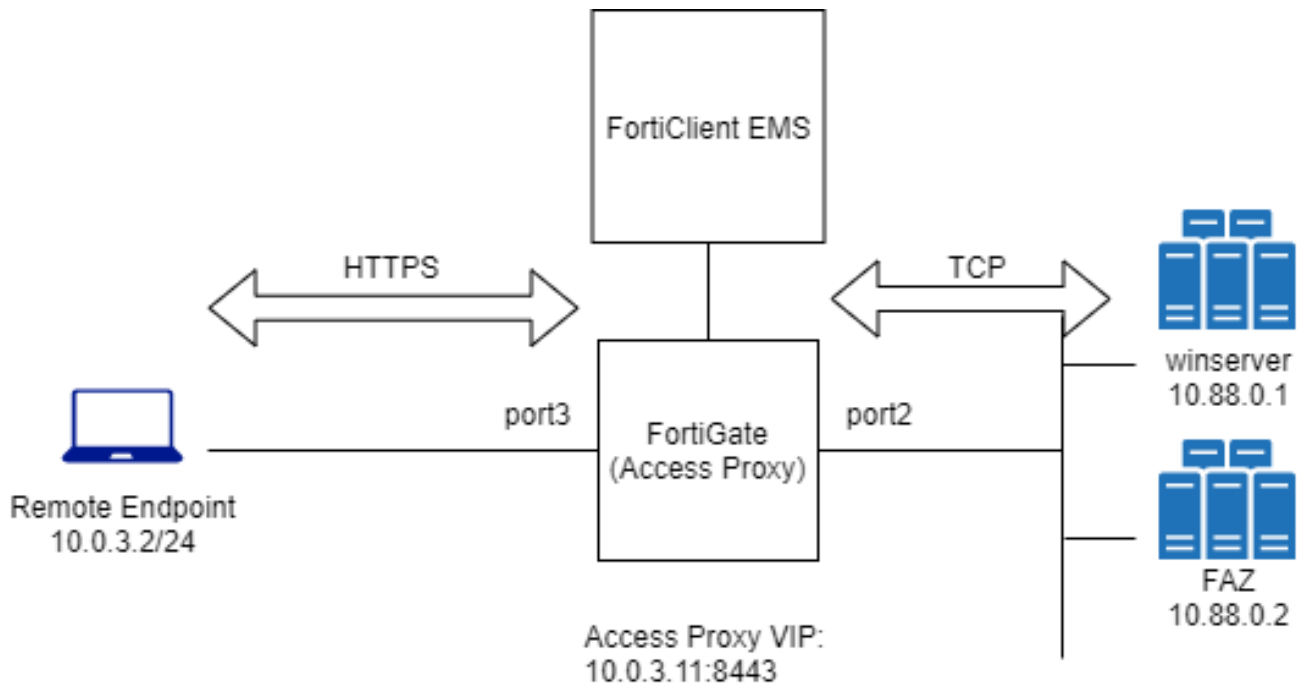

In this example, a TCP forwarding access proxy (TFAP) is configured to demonstrate an HTTPS reverse proxy that forwards TCP traffic to the designated resource. The access proxy tunnels TCP traffic between the client and the FortiGate over HTTPS, and forwards the TCP traffic to the protected resource. It verifies user identity, device identity, and trust context, before granting access to the protected source.

By default, encryption is disabled on FortiClient ZTNA rules, as this reduces overhead for end to end protocols that are already secure. For insecure end to end protocols, enable encryption.

RDP (Remote Desktop Protocol) and SMB (Server Message Block) protocol access are configured to one server, and SSH access to the other server.

FortiClient (Windows) must be running 7.0.3 or later to detect SMB.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

To configure the ZTNA server for TCP access proxy in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Set *Name* to *ZTNA-tcp-server*.
4. Configure the network settings:
 - a. Set *External interface* to *port3*.
 - b. Set *External IP* to *10.0.3.11*.
 - c. Set *External port* to *8443*.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.
6. Add server mapping:
 - a. In the *Service/server mapping* table, click *Create New*.
 - b. Set *Service* to *TCP Forwarding*.
 - c. Add a server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Create a new address for the FortiAnalyzer server at 10.88.0.2 and use it as the address.
 - iii. Set *Port* to 22.
 - iv. Click *OK*.
 - d. Add another server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Create a new address for the winserver at 10.88.0.1 and use it as the address.

- iii. Set *Port* to 445, 3389 to correspond to SMB and RDP.
 - iv. Click *OK*.
 - e. Click *OK*.
7. Click *OK*.

To configure the ZTNA rule to allow traffic to the TCP access proxy in the GUI:

1. Go to *Policy & Objects > ZTNA*, select the *ZTNA Rules* tab, and click *Create New*.
2. Set *Name* to *ZTNA_remote*.
3. Set *Incoming Interface* to *port3*.
4. Set *Source* to *all*.
5. Select the ZTNA server *ZTNA-tcp-server*.
6. Configure the remaining options as needed.
7. Click *OK*.

To configure the access proxy VIP in the CLI:

```
config firewall vip
  edit "ZTNA-tcp-server"
    set type access-proxy
    set extip 10.0.3.11
    set extintf "port3"
    set server-type https
    set extport 8443
    set ssl-certificate "Fortinet_SSI"
  next
end
```

To configure the server addresses in the CLI:

```
config firewall address
  edit "FAZ"
    set subnet 10.88.0.2 255.255.255.255
  next
  edit "winserver"
    set subnet 10.88.0.1 255.255.255.255
  next
end
```

To configure access proxy server mappings in the CLI:

```
config firewall access-proxy
  edit "ZTNA-tcp-server"
    set vip "ZTNA-tcp-server"
    set client-cert enable
    config api-gateway
      edit 1
        set service tcp-forwarding
        config realservers
          edit 1
            set address "FAZ"
            set mappedport 22
```

```

        next
        edit 2
            set address "winserver"
            set mappedport 445 3389
        next
    end
next
end
next
end
end

```

The mapped port (`mappedport`) restricts the mapping to the specified port or port range. If `mappedport` is not specified, then any port will be matched.

To configure a ZTNA rule (proxy policy) in the CLI:

```

config firewall proxy-policy
    edit 0
        set name "ZTNA_remote"
        set proxy access-proxy
        set access-proxy "ZTNA-tcp-server"
        set srcintf "port3"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
        set logtraffic all
    next
end

```

Test the connection to the access proxy

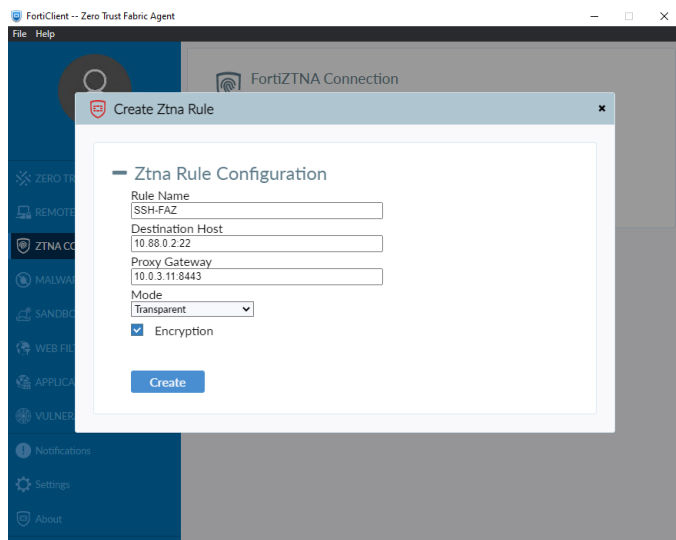

Before connecting, users must have a ZTNA connection rule in FortiClient.

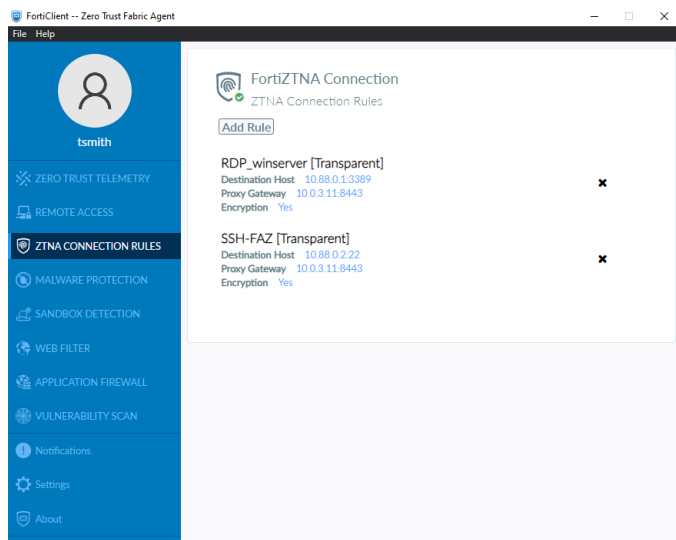

ZTNA TCP forwarding rules can be provisioned from the EMS server. See [Provisioning ZTNA TCP forwarding rules via EMS](#) for details.

To create a ZTNA rule in FortiClient:

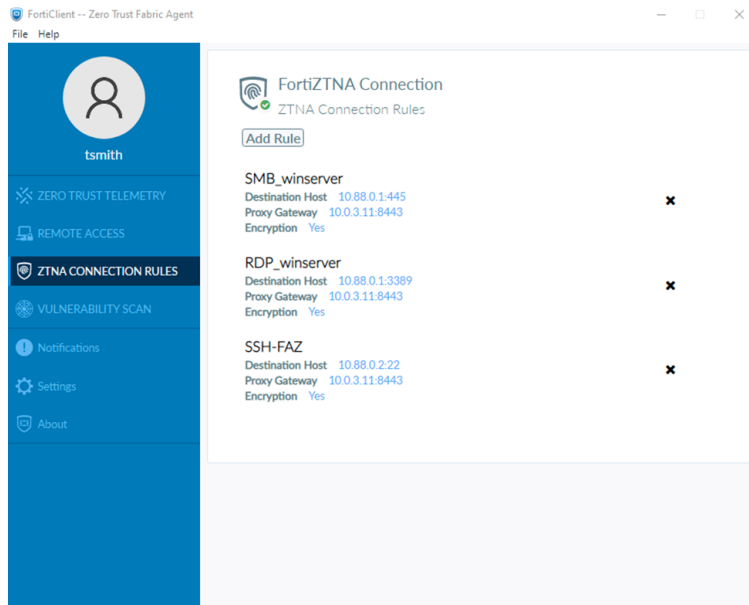

1. On the *ZTNA Connection Rules* tab, click *Add Rule*.
2. Set *Rule Name* to *SSH-FAZ*.
3. Set *Destination Host* to *10.88.0.2:22*. This is the real IP address and port of the server.
4. Set *Proxy Gateway* to *10.0.3.11:8443*. This is the access proxy address and port that are configured on the FortiGate.
5. Enable *Encryption*. This option determines whether or not the Client to FortiGate access proxy connection is encrypted in HTTPS.

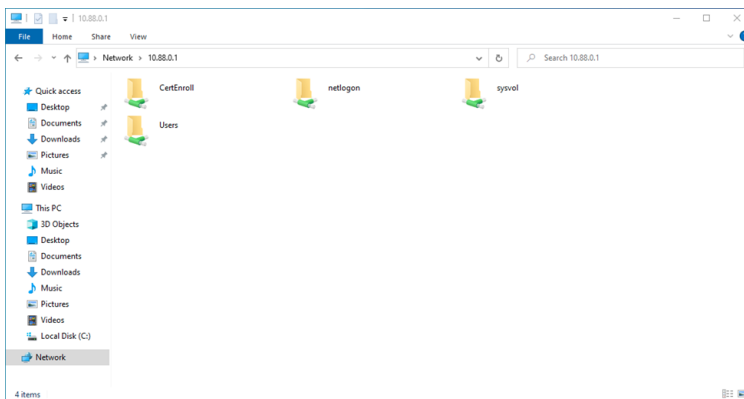

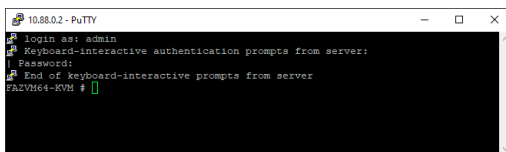

6. Click **Create**.
7. Create a second rule with the following settings:
 - **Rule Name:** *RDP_winserver*
 - **Destination Host:** *10.88.0.1:3389*
 - **Proxy Gateway:** *10.0.3.11:8443*
 - **Encryption:** Enabled

8. Create a third rule with the following settings:
 - **Rule Name:** *SMB_winserver*
 - **Destination Host:** *10.88.0.1:445*
 - **Proxy Gateway:** *10.0.3.11:8443*
 - **Encryption:** Enabled

After creating the ZTNA connection rules, you can SSH, RDP, and SMB directly to the server IP address and port.

ZTNA TCP forwarding access proxy without encryption example

TCP forwarding access proxy supports communication between the client and the access proxy without SSL/TLS encryption. The connection still begins with a TLS handshake. The client uses the HTTP 101 response to switch protocols and remove the HTTPS stack. Further end to end communication between the client and server are encapsulated in the specified TCP port, but not encrypted by the access proxy. This improves performance by reducing the overhead of encrypting an already secured underlying protocol, such as RDP, SSH, or FTPS. Users should still enable the encryption option for end to end protocols that are insecure.

In this example, the encryption option to access the web server on HTTP/8080 is disabled to show that traffic for an insecure connection protocol can be viewed in plain text in a protocol analyzer (such as Wireshark). In a real life application, the encryption option should be used for an insecure protocol.

To configure the ZTNA server for TCP access proxy in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Set *Name* to *ZTNA-tcp-server*.
4. Configure the network settings:
 - a. Set *External interface* to *port3*.
 - b. Set *External IP* to *10.0.3.11*.
 - c. Set *External port* to *8443*.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.
6. Add server mapping:
 - a. In the *Service/server mapping* table, click *Create New*.
 - b. Set *Service* to *TCP Forwarding*.
 - c. Add a server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Create a new address for the winserver at 10.88.0.1 and use it as the address.
 - iii. Click *OK*.
 - d. Click *OK*.
7. Click *OK*.

To configure the ZTNA rule to allow traffic to the TCP access proxy in the GUI:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Rules* tab.
2. Click *Create New*.
3. Set *Name* to *ZTNA-TCP*.
4. Set *Incoming Interface* to *port3*.
5. Set *Source* to *all*.
6. Select the ZTNA server *ZTNA-tcp-server*.
7. Configure the remaining options as needed.
8. Click *OK*.

To configure the access proxy VIP in the CLI:

```
config firewall vip
  edit "ZTNA-tcp-server"
    set type access-proxy
    set extip 10.0.3.11
    set extintf "port3"
    set server-type https
    set extport 443
    set ssl-certificate "Fortinet_SSL"
  next
end
```

To configure the server addresses in the CLI:

```
config firewall address
  edit "winserver"
    set subnet 10.88.0.1 255.255.255.255
  next
end
```

To configure access proxy server mappings in the CLI:

```
config firewall access-proxy
  edit "ZTNA-tcp-server"
    set vip "ZTNA-tcp-server"
    set client-cert enable
    config api-gateway
      edit 1
        set service tcp-forwarding
        config realservers
          edit 2
            set address "winserver"
          next
        end
      next
    end
  next
end
```

The mapped port (`mappedport`) is not specified so that it will map any ports that are defined in FortiClient's ZTNA connection rule.

To configure a ZTNA rule (proxy policy in the CLI):

```
config firewall proxy-policy
  edit 0
    set name "ZTNA-TCP"
    set proxy access-proxy
    set access-proxy "ZTNA-tcp-server"
    set srcintf "port3"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set logtraffic all
```

next
end

Test the connection to the access proxy

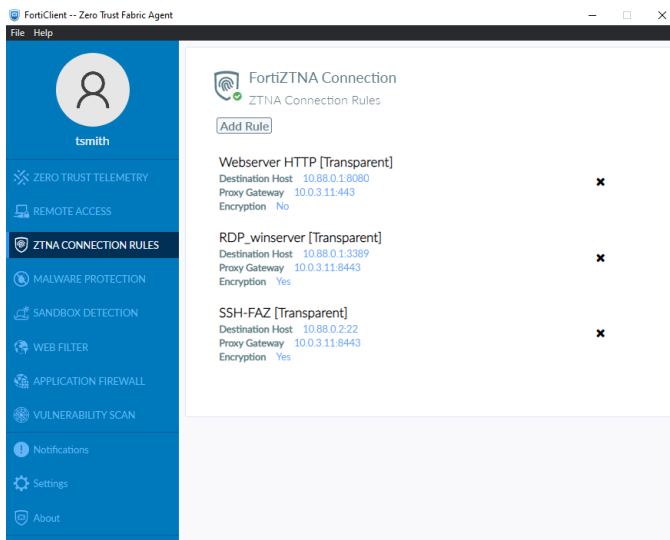

Before connecting, users must have a ZTNA connection rule in FortiClient.

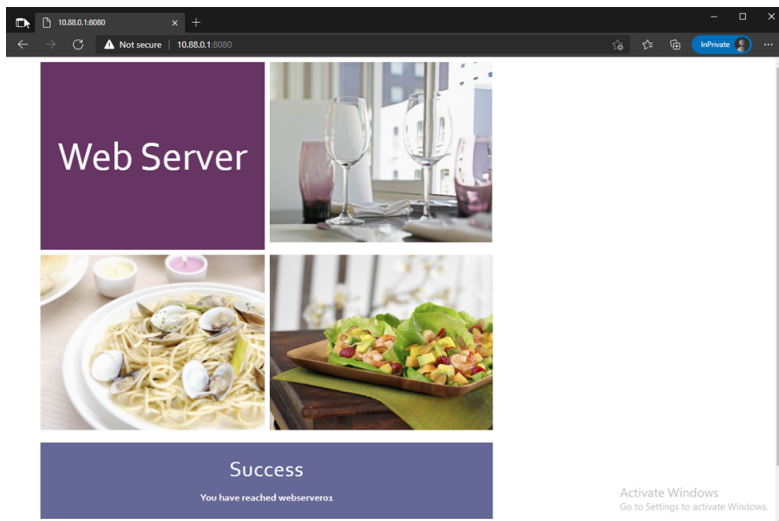

ZTNA TCP forwarding rules can be provisioned from the EMS server. See [Provisioning ZTNA TCP forwarding rules via EMS](#) for details.

To create a ZTNA rule in FortiClient:

1. Go to the *ZTNA Connection Rules* tab and click *Add Rule*.
2. Set *Rule Name* to *Webserver HTTP*.
3. Set *Destination Host* to *10.88.0.1:8080*. This is the real IP address and port of the server.
4. Set *Proxy Gateway* to *10.0.3.11:443*. This is the access proxy address and port that are configured on the FortiGate.
5. Disable *Encryption*. This option determines whether or not the Client to FortiGate access proxy connection is encrypted in HTTPS.
6. Click *Create*.

After creating the ZTNA connection rule, open a browser and access the web page at <http://10.88.0.1:8080>.

Logs and debugs

1. The forward traffic log will show a log similar to this:

```
27: date=2021-07-13 time=13:05:00 eventtime=1626206700290129558 tz="-0700"
logid="0000000024" type="traffic" subtype="forward" level="notice" vd="root"
srcip=10.0.3.2 srcport=61409 srcintf="port3" srcintfrole="wan" dstcountry="Reserved"
srccountry="Reserved" dstip=10.88.0.1 dstport=8080 dstintf="root"
dstintfrole="undefined" sessionid=46959 service="tcp/8080" proto=6 action="accept"
policyid=3 policytype="proxy-policy" poluid="fe0e1ae8-bdf9-51eb-b86f-c5e2adb934b3"
policyname="ZTNA-TCP" duration=114 wanin=38471 rcvdbyte=38471 wanout=775 lanin=2450
sentbyte=2450 lanout=40643 appcat="unscanned"
```

2. Use the following WAD debugs to capture the details about the connection as seen by the FortiGate WAD daemon. Notice that the HTTP request has `tls=0`, indicating that the proxy connection between the client and access proxy is not encrypted.

```
# diagnose wad debug enable category all
# diagnose wad debug enable level verbose
# diagnose debug enable

[I][p:224][s:46086][r:16777237] wad_dump_http_request :2542
hreq=0x7f20bdaf5950 Received request from client: 10.0.3.2:62067

GET /tcp?address=10.88.0.1&port=8080&tls=0 HTTP/1.1
Host: 10.0.3.11:443
User-Agent: Forticlient
Accept: */*
Cookie:
Authorization: Basic
...
```

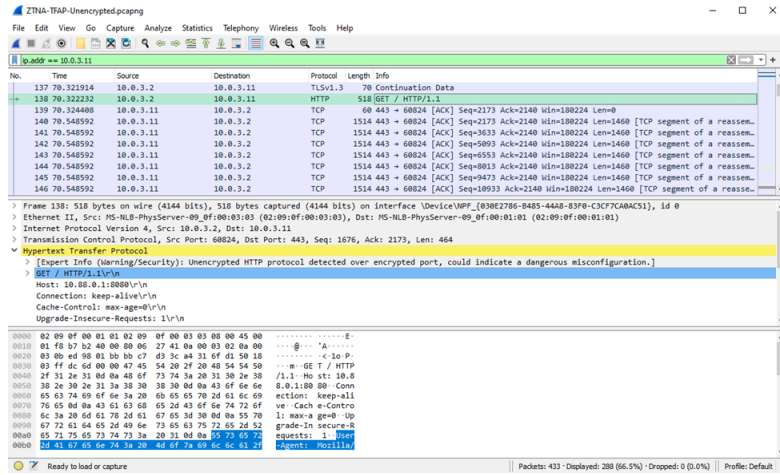

After reviewing the details, disable or reset the debugs:

```
# diagnose debug reset
```

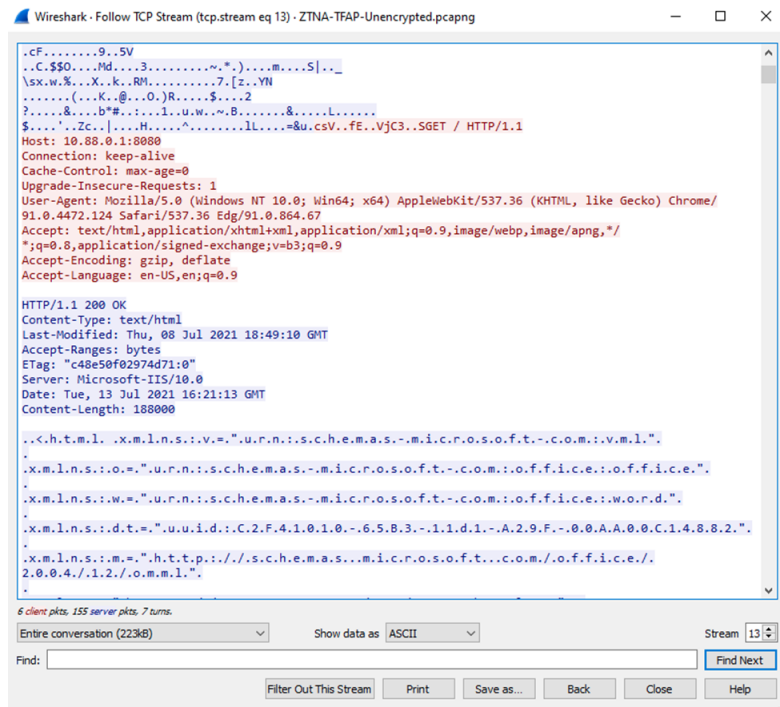

3. On the client PC, perform a packet capture to review the traffic flow between the client (10.0.3.2) and the access proxy (10.0.3.11) in detail. While the traffic is encapsulated in port 443, the underlying HTTP/8080 requests and

traffic are decoded as clear text.

Packet capture of traffic between 10.0.3.2:60824->10.0.3.11:443:

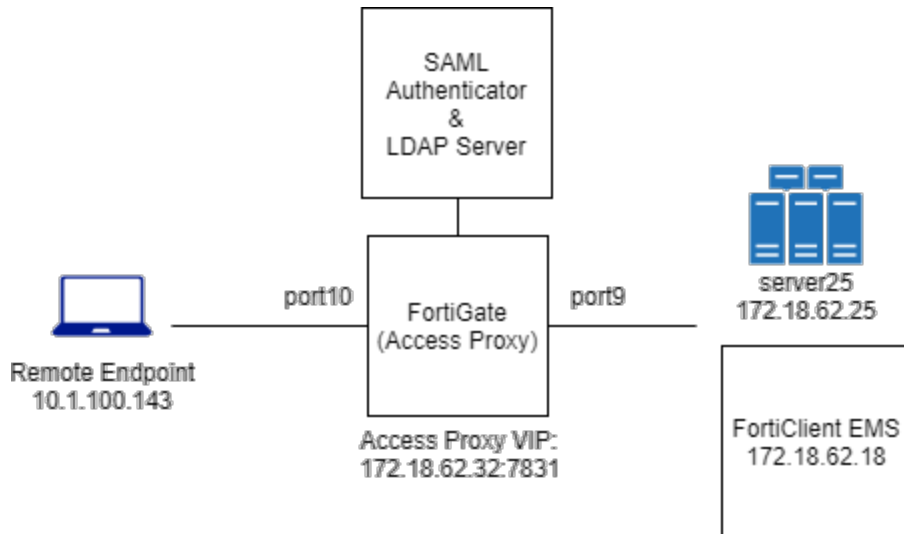

Traffic stream:

ZTNA proxy access with SAML authentication example

In this example, an HTTPS access proxy is configured, and SAML authentication is applied to authenticate the client. The FortiGate acts as the SAML SP and a SAML authenticator serves as the IdP. In addition to verifying the user and device identity with the client certificate, the user is also authorized based on user credentials to establish a trust context before granting access to the protected resource.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

To configure the access proxy VIP:

```
config firewall vip
  edit "ZTNA_server01"
    set type access-proxy
    set extip 172.18.62.32
    set extintf "any"
    set server-type https
    set extport 7831
    set ssl-certificate "Fortinet_CA_SSL"
  next
end
```

To configure access proxy server mappings:

```
config firewall access-proxy
  edit "ZTNA_server01"
    set vip "ZTNA_server01"
    set client-cert enable
    config api-gateway
      edit 1
        set service https
        config realservers
          edit 1
            set ip 172.18.62.25
            set port 443
          next
        end
      next
    end
  next
end
next
end
next
end
```

To configure a SAML server:

```
config user saml
  edit "saml_ztna"
    set cert "Fortinet_CA_SSL"
    set entity-id "https://fgt9.myqalab.local:7831/samlap"
    set single-sign-on-url "https://fgt9.myqalab.local:7831/XX/YY/ZZ/saml/login/"
    set single-logout-url "https://fgt9.myqalab.local:7831/XX/YY/ZZ/saml/logout/"
    set idp-entity-id "http://MYQALAB.LOCAL/adfs/services/trust"
    set idp-single-sign-on-url "https://myqalab.local/adfs/ls"
    set idp-single-logout-url "https://myqalab.local/adfs/ls"
    set idp-cert "REMOTE_Cert_4"
    set digest-method sha256
    set adfs-claim enable
    set user-claim-type upn
    set group-claim-type group-sid
  next
end
```

To map the SAML server into an access proxy configuration:

```
config firewall access-proxy
  edit "ZTNA_server01"
    config api-gateway
      edit 3
        set service samlsp
        set saml-server "saml_ztna"
      next
    end
  next
end
```

To configure an LDAP server and an LDAP server group to verify user groups:

```
config user ldap
  edit "ldap-10.1.100.198"
    set server "10.1.100.198"
    set cnid "cn"
    set dn "dc=myqalab,dc=local"
    set type regular
    set username "cn=fosqal,cn=users,dc=myqalab,dc=local"
    set password *****
    set group-search-base "dc=myqalab,dc=local"
  next
end

config user group
  edit "ldap-group-saml"
    set member "ldap-10.1.100.198"
  next
end
```

To configure the authentication rule and scheme to match the new SAML server:

```
config authentication rule
  edit "saml_ztna"
```

```
        set srcintf "port10"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "saml_ztna"
        set web-auth-cookie enable
    next
end

config authentication scheme
    edit "saml_ztna"
        set method saml
        set saml-server "saml_ztna"
        set saml-timeout 30
        set user-database "ldap-10.1.100.198"
    next
end
```

To enable user group authentication in an access-proxy type firewall proxy-policy:

```
config firewall proxy-policy
    edit 6
        set name "ZTNA_remote"
        set proxy access-proxy
        set access-proxy "ZTNA_server01"
        set srcintf "any"
        set srcaddr "all"
        set dstaddr "all"
        set action accept
        set schedule "always"
        set groups "ldap-group-saml"
        set utm-status enable
        set ssl-ssh-profile "certificate-inspection"
    next
end
```

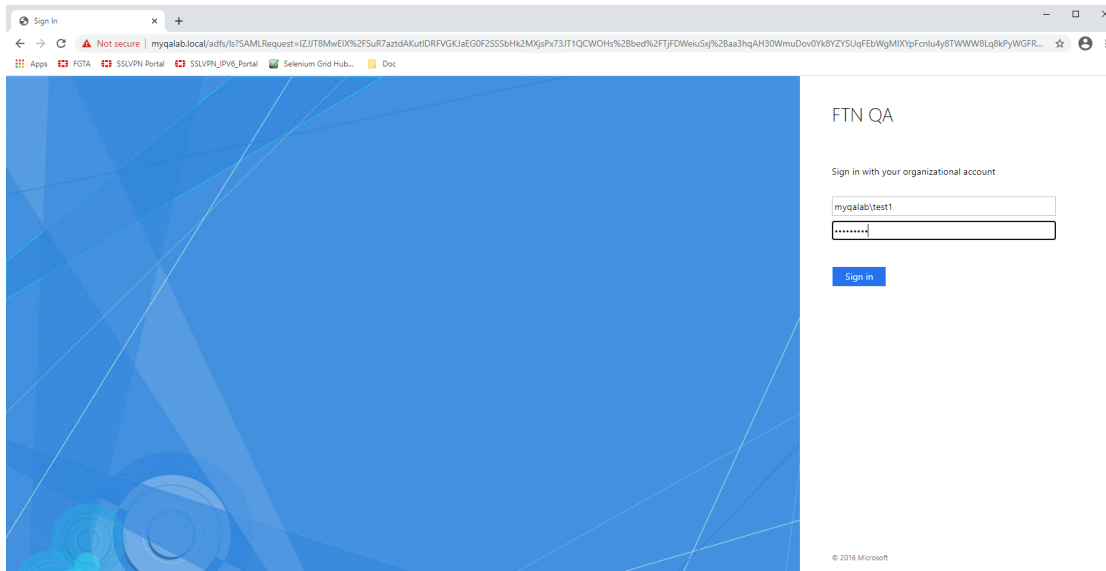

Testing the connection

To test the connection:

It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.

1. On a client PC, try to access the webpage through the HTTPS access proxy. For example, go to `http://172.18.62.32:7831` in a browser.
2. The client PC is prompted for a client certificate. After the certificate is validated, you are redirected to a SAML log in portal.

3. Enter your user credentials. The SAML server authenticates and sends a SAML assertion response message to the FortiGate.
4. The FortiGate queries the LDAP server for the user group, and then verifies the user group against the groups or groups defined in the proxy policy.
5. The user is proxied to the webpage on the real web server.

Logs and debugs

Use the following command to check the user information after the user has been authenticated:

```
# diagnose wad user list
ID: 7, VDOM: vdom1, IPv4: 10.1.100.143
  user name   : test1@MYQALAB.local
  worker      : 0
  duration    : 124
  auth_type   : Session
  auth_method : SAML
  pol_id      : 6
  g_id        : 13
  user_based  : 0
  expire      : no
LAN:
  bytes_in=25953 bytes_out=14158
WAN:
  bytes_in=8828 bytes_out=6830
```

Event log:

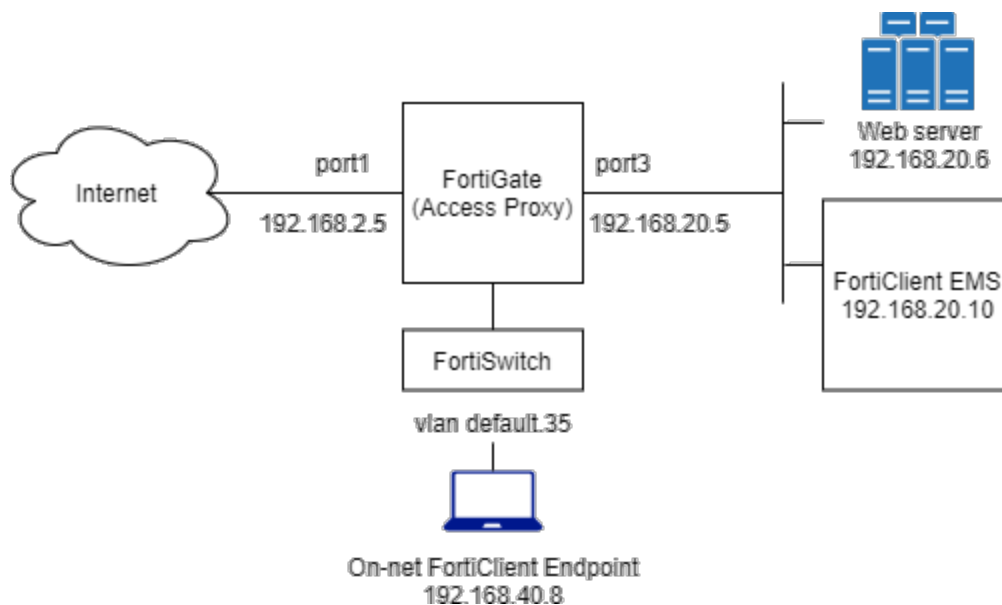

```

```

ZTNA IP MAC based access control example

In this example, firewall policies are configured that use ZTNA tags to control access between on-net devices and an internal web server. This mode does not require the use of the access proxy, and only uses ZTNA tags for access control. Traffic is passed when the FortiClient endpoint is tagged as *Low* risk only. Traffic is denied when the FortiClient endpoint is tagged with *Malicious-File-Detected*.

This example assumes that the FortiGate EMS fabric connector is already successfully connected.

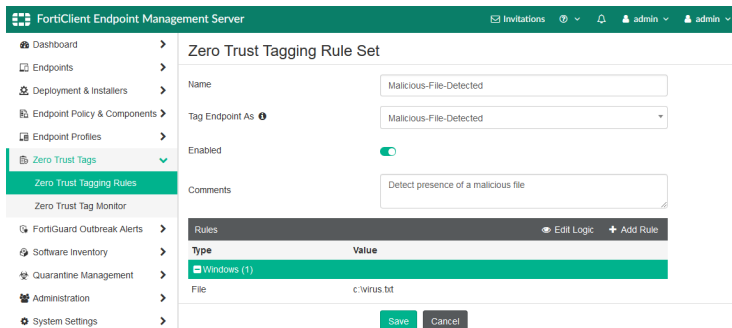

To configure ZTNA in the GUI, go to *System > Feature Visibility* and enable *Zero Trust Network Access*.

To configure a Zero Trust tagging rule on the FortiClient EMS:

1. Log in to the FortiClient EMS.
2. Go to *Zero Trust Tags > Zero Trust Tagging Rules*, and click *Add*.
3. In the *Name* field, enter *Malicious-File-Detected*.
4. In the *Tag Endpoint As* dropdown list, select *Malicious-File-Detected*.

EMS uses this tag to dynamically group together endpoints that satisfy the rule, as well as any other rules that are configured to use this tag.

5. Click *Add Rule* then configure the rule:
 - a. For OS, select *Windows*.
 - b. From the *Rule Type* dropdown list, select *File* and click the + button.
 - c. Enter a file name, such as *C:\virus.txt*.
 - d. Click *Save*.

6. Click *Save*.

To configure a firewall policy with IP/MAC based access control to deny traffic in the GUI:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Set *Name* to *block-internal-malicious-access*.
3. Set *Incoming Interface* to *default.35*.
4. Set *Outgoing Interface* to *port3*.
5. Set *Source* to *all*.
6. Set *IP/MAC Based Access Control* to the *Malicious-File-Detected* tag.
7. Set *Destination* to *all*.
8. Set *Service* to *ALL*.
9. Set *Action* to *DENY*.
10. Enable *Log Violation Traffic*.
11. Configuring the remaining settings as needed.
12. Click *OK*.

To configure a firewall policy with IP/MAC based access control to allow access in the GUI:

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Set *Name* to *allow-internal-access*.
3. Set *Incoming Interface* to *default.35*.
4. Set *Outgoing Interface* to *port3*.
5. Set *Source* to *all*.
6. Set *IP/MAC Based Access Control* to the *Low* tag.
7. Set *Destination* to *all*.
8. Set *Service* to *ALL*.
9. Set *Action* to *ACCEPT*.
10. Enable *Log Allowed Traffic* and set it to *All Sessions*.

11. Configuring the remaining settings as needed.
12. Click OK.

To configure firewall policies with IP/MAC based access control to block and allow access in the CLI:

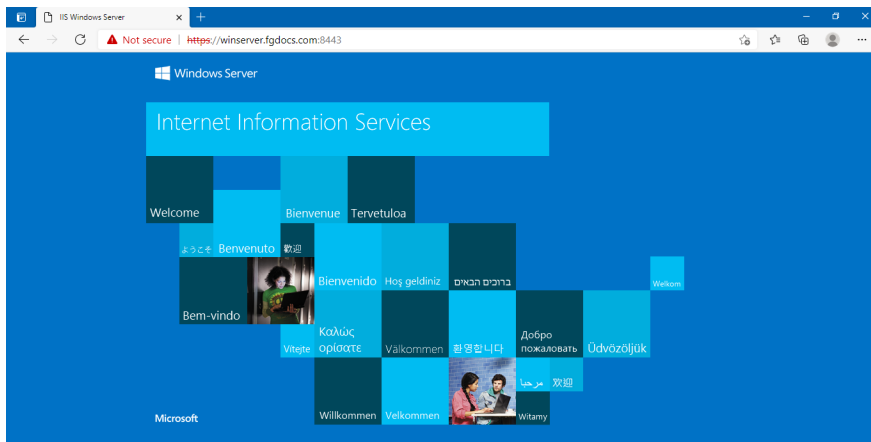

```
config firewall policy
  edit 29
    set name "block-internal-malicious-access"
    set srcintf "default.35"
    set dstintf "port3"
    set srcaddr "all"
    set dstaddr "all"
    set ztna-status enable
    set ztna-ems-tag "FCTEMS0000109188_Malicious-File-Detected"
    set schedule "always"
    set service "ALL"
    set logtraffic all
  next
  edit 30
    set name "allow-internal-access"
    set srcintf "default.35"
    set dstintf "port3"
    set srcaddr "all"
    set dstaddr "all"
    set ztna-status enable
    set ztna-ems-tag "FCTEMS0000109188_Low"
    set action accept
    set schedule "always"
    set service "ALL"
    set inspection-mode proxy
    set logtraffic all
    set nat enable
  next
end
```

Testing the access to the web server from the on-net client endpoint

Access allowed:

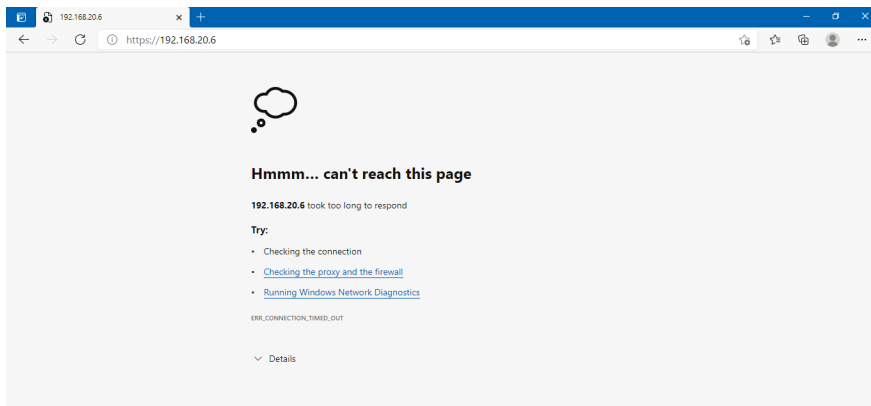

1. On the remote Windows PC, open FortiClient.
2. On the *Zero Trust Telemetry* tab, make sure that you are connected to the EMS server.
3. Open a browser and enter the address of the server.
4. The FortiGate matches your security posture by verifying your ZTNA tag and matching the corresponding allow-

internal-access firewall policy, and you are allowed access to the web server.

Access denied:

1. On the remote Windows PC, trigger the Zero Trust Tagging Rule by creating the file in C:\virus.txt.
2. Open a browser and enter the address of the server.
3. FortiGate checks your security posture. Because EMS has tagged the PC with the *Malicious-File-Detected* tag, it matches the *block-internal-malicious-access* firewall policy.
4. You are denied access to the web server.

Logs and debugs

Access allowed:

```

ZTNA IPv6 examples

IPv6 can be configured in ZTNA in several scenarios:

- IPv6 Client — IPv6 Access Proxy — IPv6 Server
- IPv6 Client — IPv6 Access Proxy — IPv4 Server
- IPv4 Client — IPv4 Access Proxy — IPv6 Server

These examples show the basic configuration for each scenario. It is assumed that the EMS fabric connector is already successfully connected.

Example 1: IPv6 Client — IPv6 Access Proxy — IPv6 Server

To configure the FortiGate:

1. Configure the IPv6 access proxy VIP:

```
config firewall vip6
  edit "zv6"
    set type access-proxy
    set extip 2000:172:18:62::66
    set server-type https
    set extport 6443
    set ssl-certificate "cert"
```

```
    next
end
```

2. Configure a virtual host:

```
config firewall access-proxy-virtual-host
    edit "vhost_ipv6"
        set ssl-certificate "cert"
        set host "qa6.test.com"
    next
end
```

The client uses this address to connect to the access proxy.

3. Configure an IPv6 access proxy and IPv6 api-gateway, apply the VIP6 and virtual host to it, and assign an IPv6 address to the realserver:

```
config firewall access-proxy6
    edit "zs6"
        set vip "zv6"
        config api-gateway6
            edit 1
                set virtual-host "vhost_ipv6"
                config realservers
                    edit 1
                        set ip 2000:172:16:200::209
                    next
                end
            next
        end
    next
end
next
end
```

4. Apply the IPv6 access proxy to a proxy policy:

```
config firewall proxy-policy
    edit 1
        set name "ztna_rule"
        set proxy access-proxy
        set access-proxy6 "zs6"
        set srcintf "port2"
        set action accept
        set schedule "always"
        set logtraffic all
        set srcaddr6 "all"
        set dstaddr6 "all"
        set utm-status enable
        set ssl-ssh-profile "custom-deep-inspection"
        set webfilter-profile "monitor-all"
    next
end
```

5. Apply the IPv6 VIP to a firewall policy:

```
config firewall policy
    edit 4
        set name "ZTNA"
        set srcintf "port2"
        set dstintf "any"
```

```

        set action accept
        set srcaddr6 "all"
        set dstaddr6 "zv6"
        set schedule "always"
        set service "ALL"
        set inspection-mode proxy
        set logtraffic all
        set nat enable
    next
end

```

To test the configuration:

1. On an IPv6 client, ensure that the address qa6.test.com resolves to the IPv6 VIP address of 2000:172:18:62::66.
2. In a browser, connect to <https://qa6.test.com:6443>.
3. After device certificate verification, the browser will open up the webpage on the IPv6 real server.
4. In the Forward Traffic Log, the following log is available:

```

3: date=2021-06-25 time=13:38:18 eventtime=1624653498459580215 tz="-0700"
logid="0000000024" type="traffic" subtype="forward" level="notice" vd="root"
srcip=2000:10:1:100::214 srcport=55957 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=2000:172:16:200::209 dstport=443
dstintf="root" dstintfrole="undefined" sessionid=92406 service="HTTPS" proto=6
action="accept" policyid=1 policytype="proxy-policy" poluid="7afdac8c-d5db-51eb-dfc6-
67bb86e4bdcf" policyname="ztna_rule" duration=5 wanin=2031 rcvbyte=2031 wanout=1332
lanin=1247 sentbyte=1247 lanout=950 appcat="unscanned" utmaction="allow" countweb=1
utmref=65445-0

```

Example 2: IPv6 Client — IPv6 Access Proxy — IPv4 Server

To configure the FortiGate:

1. Configure the IPv6 access proxy VIP:

```

config firewall vip6
    edit "zv6"
        set type access-proxy
        set extip 2000:172:18:62::66
        set server-type https
        set extport 6443
        set ssl-certificate "cert"
    next
end

```

2. Configure a virtual host:

```

config firewall access-proxy-virtual-host
    edit "vhost_ipv6"
        set ssl-certificate "cert"
        set host "qa6.test.com"
    next
end

```

The client uses this address to connect to the access proxy.

3. Configure an IPv6 access proxy and IPv6 api-gateway, apply the VIP6 and virtual host to it, and assign an IPv4 address to the realserver:

```
config firewall access-proxy6
  edit "zs6"
    set vip "zv6"
    config api-gateway6
      edit 1
        set virtual-host "vhost_ipv6"
        config realservers
          edit 1
            set ip 172.16.200.209
          next
        end
      end
    next
  end
end
```

4. Apply the IPv6 access proxy to a proxy policy:

```
config firewall proxy-policy
  edit 1
    set name "ztna_rule"
    set proxy access-proxy
    set access-proxy6 "zs6"
    set srcintf "port2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set logtraffic all
    set srcaddr6 "all"
    set dstaddr6 "all"
    set utm-status enable
    set ssl-ssh-profile "custom-deep-inspection"
    set webfilter-profile "monitor-all"
  next
end
```

5. Apply the IPv6 VIP to a firewall policy:

```
config firewall policy
  edit 4
    set name "ZTNA"
    set srcintf "port2"
    set dstintf "any"
    set action accept
    set srcaddr6 "all"
    set dstaddr6 "zv6"
    set schedule "always"
    set service "ALL"
    set inspection-mode proxy
    set logtraffic all
    set nat enable
  next
end
```

To test the configuration:

1. On an IPv6 client, ensure that the address qa6.test.com resolves to the IPv6 VIP address of 2000:172:18:62::66.
2. In a browser, connect to <https://qa6.test.com:6443>.
3. After device certificate verification, the browser will open up the webpage on the IPv4 real server.
4. In the Forward Traffic Log, the following log is available:

```
2: date=2021-06-25 time=13:46:54 eventtime=1624654014129553521 tz="-0700"
logid="0000000024" type="traffic" subtype="forward" level="notice" vd="root"
srcip=2000:10:1:100::214 srcport=60530 srcintf="port2" srcintfrole="undefined"
dstcountry="Reserved" srccountry="Reserved" dstip=172.16.200.209 dstport=443
dstintf="root" dstintfrole="undefined" sessionid=219 service="HTTPS" proto=6
action="accept" policyid=1 policytype="proxy-policy" poluid="7afdac8c-d5db-51eb-dfc6-
67bb86e4bdcf" policyname="ztna_rule" duration=5 wanin=2028 rcvdbyte=2028 wanout=1321
lanin=1236 sentbyte=1236 lanout=947 appcat="unscanned" utmaction="allow" countweb=1
utmref=65443-14
```

Example 3: IPv4 Client — IPv4 Access Proxy — IPv6 Server**To configure the FortiGate:**

1. Configure the IPv4 access proxy VIP:

```
config firewall vip
  edit "zv4"
    set type access-proxy
    set extip 172.18.62.66
    set extintf "any"
    set server-type https
    set extport 4443
    set ssl-certificate "cert"
  next
end
```

2. Configure a virtual host:

```
config firewall access-proxy-virtual-host
  edit "vhost_ipv4"
    set ssl-certificate "cert"
    set host "qa.test.com"
  next
end
```

The client uses this address to connect to the access proxy.

3. Configure an IPv4 access proxy and IPv6 api-gateway, apply the VIP and virtual host to it, and assign an IPv6 address to the realserver:

```
config firewall access-proxy
  edit "zs4"
    set vip "zv4"
    config api-gateway6
      edit 1
        set virtual-host "vhost_ipv4"
        config realservers
          edit 1
            set ip 2000:172:16:200::209
          next
        next
      next
    next
  next
end
```

```

        next
      end
    next
  end
next
end

```

4. Apply the IPv4 access proxy to a proxy policy:

```

config firewall proxy-policy
  edit 1
    set name "ztna_rule"
    set proxy access-proxy
    set access-proxy "zs4"
    set srcintf "port2"
    set srcaddr "all"
    set dstaddr "all"
    set action accept
    set schedule "always"
    set logtraffic all
    set srcaddr6 "all"
    set dstaddr6 "all"
    set utm-status enable
    set ssl-ssh-profile "custom-deep-inspection"
    set webfilter-profile "monitor-all"
  next
end

```

5. Apply the IPv4 VIP to a firewall policy:

```

config firewall policy
  edit 4
    set name "ZTNA"
    set srcintf "port2"
    set dstintf "any"
    set action accept
    set srcaddr "all"
    set dstaddr "zv4"
    set schedule "always"
    set service "ALL"
    set inspection-mode proxy
    set logtraffic all
    set nat enable
  next
end

```

To test the configuration:

1. On an IPv4 client, ensure that the address qa6.test.com resolves to the IPv4 VIP address of 172.18.62.66.
2. In a browser, connect to <https://qa6.test.com:6443>.
3. After device certificate verification, the browser will open up the webpage on the IPv6 real server.
4. In the Forward Traffic Log, the following log is available:

```

1: date=2021-06-25 time=13:52:30 eventtime=1624654350689576485 tz="-0700"

```

ZTNA SSH access proxy example

ZTNA can be configured with SSH access proxy to provide a seamless SSH connection to the server.

Advantages of using an SSH access proxy instead of a TCP forwarding access proxy include:

- Establishing device trust context with user identity and device identity checks.
- Applying SSH deep inspection to the traffic through the SSH related profile.
- Performing optional SSH host-key validation of the server.
- Using one-time user authentication to authenticate the ZTNA SSH access proxy connection and the SSH server connection.

Perform SSH host-key validation of the server

To act as a reverse proxy for the SSH server, the FortiGate must perform SSH host-key validation to verify the identity of the SSH server. The FortiGate does this by storing the public key of the SSH server in its SSH host-key configurations. When a connection is made to the SSH server, if the public key matches one that is used by the server, then the connection is established. If there is no match, then the connection fails.

One-time user authentication

SSH access proxy allows user authentication to occur between the client and the access proxy, while using the same user credentials to authenticate with the SSH server. The following illustrates how this works:

1. The remote endpoint registers to FortiClient EMS and receives the client certificate.
2. The remote endpoint tries to connect to the SSH access proxy. It must use the same username that is later used for access proxy authentication.
3. The FortiGate challenges the endpoint with device identity validation.
4. The remote endpoint provides the EMS issued certificate for device identification.
5. The FortiGate challenges the endpoint with user authentication. For example, this could be done with basic or SAML authentication.
6. The users enters their credentials on the remote endpoint.
7. The FortiGate authenticates the user and collects the username.
8. Using the FortiGate's CA or the customer's CA certificate, the FortiGate signs an SSH certificate and embeds the username in its principal.
9. The FortiGate attempts to connect to the SSH server using the certificate authentication.
10. The SSH server verifies the authenticity of the certificate, and matches the username principal against its `authorized_keys` file.
11. If the username matches a record in the file, then the SSH connection is established. If no match is found, then the SSH connection fails.

Example

In this example, an SSH connection is established using SSH access proxy with host-key validation and one-time authentication.

- The SSH server is a Linux based server that uses `sshd` to provide remote access
- For SSH host-key validation, the public key of the SSH server has been imported into the FortiGate.
- For one-time authentication using certificate authentication:
 - The SSH server must allow certificate authentication.
 - The SSH server must have the proper entry in its `authorized_keys` file that contains the user principal and the FortiGate CA's public key.
 - The entry is present in the user directory corresponding to the user that is trying to log in.

To pre-configure the Linux SSH server:

1. Retrieve the public key used for host-key validation:

- a. Locate the public key files in the SSH server:

```
$ ls -la /etc/ssh/*.pub
-rw-r--r-- 1 root root 186 Mar 29 2020 /etc/ssh/ssh_host_ecdsa_key.pub
-rw-r--r-- 1 root root 106 Mar 29 2020 /etc/ssh/ssh_host_ed25519_key.pub
-rw-r--r-- 1 root root 406 Mar 29 2020 /etc/ssh/ssh_host_rsa_key.pub2
```

- b. Choose the public key file based on the hash type (in this case, ECDSA), and show it's content:

```
$ cat /etc/ssh/ssh_host_ecdsa_key.pub
ecdsa-sha2-nistp256 AAAAE2*****IpEik=
```

This key will be used when configuring the FortiGate.

2. Retrieve the FortiGate CA's public key from the FortiGate:

```
# show full firewall ssh local-ca Fortinet_SSH_CA
config firewall ssh local-ca
  edit "Fortinet_SSH_CA"
```

```

        set password ENC <hidden password>
        set private-key "-----BEGIN OPENSSSH PRIVATE KEY-----
<hidden private key>
-----END OPENSSSH PRIVATE KEY-----"
        set public-key "ssh-rsa AAAAB3*****JLXlxj3"
        set source built-in
    next
end

```

3. On the Linux server, enable the SSH service to use the `authorized_keys` file:

- a. Locate and edit the `/etc/ssh/sshd_config` file.
- b. Ensure that the `AuthorizedKeysFile` line is uncommented, for example:

```
AuthorizedKeysFile      .ssh/authorized_keys .ssh/authorized_keys2
```

4. Allow remote SSH log in with certificate authentication and principal name:

- a. Log in to the SSH server using the account that will be granted remote SSH access (in this example: `radCurtis`):
- b. Locate the account's `authorized_keys` file in the `~/.ssh` directory:

```

$ ls -la ~/.ssh
total 12
drwxrwxr-x 2 radCurtis radCurtis 4096 Aug 10 19:14 .
drwxr-xr-x 5 radCurtis radCurtis 4096 Aug 10 19:13 ..
-rw-rw-r-- 1 radCurtis radCurtis  419 Aug 10 19:14 authorized_keys

```

- c. If the directory and file do not exist, create the directory:

```
$ mkdir ~/.ssh
```

- d. Create an entry containing the following keywords and add them to the `authorized_keys` file:

```
echo 'cert-authority,principals="radCurtis" ssh-rsa AAAAB3*****JLXlxj3' >>
authorized_keys
```

Where:

- `cert-authority` - indicates that this entry is used in certificate authentication by validating the certificate using the public key provided in this entry.
- `principals="radCurtis"` - indicates the user that must match with the username embedded in the SSH certificate.
- `ssh-rsa AAAAB3*****JLXlxj3` - indicates the FortiGate CA's public key that is used to validate the SSH certificate.

5. Restart the `sshd` service:

```

$ sudo systemctl stop sshd
$ sudo systemctl start sshd

```

The SSH server can now accept SSH connection from `radCurtis@<server IP>`, where the SSH certificate used by the FortiGate to log in contains `radCurtis` embedded as a principal.

When a user connects from a SSH client using `<username>@<server IP>`, sshd will locate the `authorized_keys` file in the directory `/home/<username>/.ssh/authorized_keys`. If the `authorized_keys` is not in that directory, authentication will fail on the SSH server side.

If you suspect that authentication is failing on the SSH server, use the following commands to manually start sshd in debug mode to troubleshoot:

```
$ sudo systemctl stop sshd
$ /usr/sbin/sshd -ddd -p 22
```

To configure the FortiGate :

1. Configure a new VIP to allow access to the SSH access proxy over 192.168.2.87:443:

```
config firewall vip
  edit "ZTNA_SSH"
    set type access-proxy
    set extip 192.168.2.87
    set extintf "any"
    set server-type https
    set extport 443
    set ssl-certificate "Fortinet_SSL"
  next
end
```

2. Configure the address object for the SSH server:

```
config firewall address
  edit "SSH_server"
    set subnet 192.168.20.1 255.255.255.255
  next
end
```

3. Configure the host-key that will be used to authenticate the SSH server. The public-key was retrieved when pre-configure the Linux SSH server (step 1b).

```
config firewall ssh host-key
  edit "ed25519"
    set type ECDSA
    set usage access-proxy
    set public-key "AAAAE2*****IpEik="
  next
end
```

4. Configure the access proxy SSH client certificate:

A CA certificate is assigned to sign the SSH certificate that will be used in the SSH authentication. The SSH certificate will have the username embedded in the certificate principal.

```
config firewall access-proxy-ssh-client-cert
  edit "ssh-access-proxy"
    set source-address enable
    set auth-ca "Fortinet_SSH_CA"
  next
end
```

5. Configure the access-proxy server setting:

```

config firewall access-proxy
  edit "ZTNA_SSH"
    set vip "ZTNA_SSH"
    set client-cert enable
    config api-gateway
      edit 1
        set url-map "tcp"
        set service tcp-forwarding
        config realservers
          edit 1
            set address "SSH_server"
            set type ssh
            set ssh-client-cert "ssh-access-proxy"
            set ssh-host-key-validation enable
            set ssh-host-key "ed25519"
          next
        end
      next
    end
  next
end

```

6. Configure the RADIUS setting, user setting, and user group to apply user authentication to the access proxy connection using RADIUS:

```

config user radius
  edit "Win2k16-Radius"
    set server "192.168.20.6"
    set secret ENC <secret>
  next
end
config user local
  edit "radCurtis"
    set type radius
    set radius-server "Win2k16-Radius"
  next
end
config user group
  edit "radius_group"
    set member "radCurtis" "Win2k16-Radius"
  next
end

```

7. Create the authentication scheme and rule to perform the authentication:

```

config authentication scheme
  edit "basic_auth"
    set method basic
    set user-database "Win2k16-Radius"
  next
end
config authentication rule
  edit "ztna-basic"
    set srcaddr "all"
    set ip-based disable
    set active-auth-method "basic_auth"
    set web-auth-cookie enable
  next
end

```

```

    next
end

```

8. Configure the ZTNA rule to allow traffic to the SSH server, and apply user authentication, posture check, and a security profile where necessary:

```

config firewall proxy-policy
    edit 5
        set name "SSH-proxy"
        set proxy access-proxy
        set access-proxy "ZTNA_SSH"
        set srcintf "port1"
        set srcaddr "all"
        set dstaddr "all"
        set ztna-ems-tag "FCTEMS8821001056_ems138_av_tag"
        set action accept
        set schedule "always"
        set groups "radius_group"
        set utm-status enable
        set ssl-ssh-profile "custom-deep-inspection"
    next
end

```

To check the results:

1. On the remote client, open FortiClient, go to the *Zero Trust Telemetry* tab, and make sure that it is connected to the EMS server.
2. Go to the *ZTNA Connection Rules* tab and click *Add Rule*.
3. Configure the rule, then click *Create*:

Rule Name	SSH-Linux
Destination Host	192.168.20.1:22
Proxy Gateway	192.168.2.87:443
Mode	Transparent
Encryption	Disabled (recommended)

When Encryption is disabled, the connection between the client and FortiGate access proxy is not encapsulated in HTTPS after the client and FortiGate connection is established. This allows for less overhead, because SSH is already a secure connection. This option is available in FortiClient 7.0.1 and later releases.

4. Open an SSH client, such as PuTTY, and make an SSH connection to *radCurtis@192.168.20.1* on port 22.
5. After device authentication is performed and passes in the background, FortiClient prompts the user to sign in. Enter the username, *radCurtis*, and password, then click *Sign in*.

After successful user authentication, the SSH connection is established without an additional log in.

```

PuTTY
Using username "radCurtis".
Welcome to Ubuntu 18.04.4 LTS (GNU/Linux 5.4.0-80-generic x86_64)

 * Documentation:  https://help.ubuntu.com
 * Management:    https://landscape.canonical.com
 * Support:       https://ubuntu.com/advantage

 * Super-optimized for small spaces - read how we shrank the memory
 footprint of MicroK8s to make it the smallest full K8s around.

 https://ubuntu.com/blog/microk8s-memory-optimisation

 * Canonical Livepatch is available for installation.
 - Reduce system reboots and improve kernel security. Activate at:
 https://ubuntu.com/livepatch

135 packages can be updated.
2 updates are security updates.

New release '20.04.2 LTS' available.
Run 'do-release-upgrade' to upgrade to it.

Your Hardware Enablement Stack (HWE) is supported until April 2023.
Last login: Wed Aug 11 17:40:37 2021 from 192.168.20.5
radCurtis@keith-OptiPlex-5040:~$

```

6. On the FortiGate, check the logged in user:
 - a. Go to *Dashboard > Users & Devices* and expand the *Firewall Users* widget.
 - b. Check the WAD proxy user list:

```

# diagnose wad user list
ID: 2, VDOM: root, IPv4: 10.10.10.25
  user name   : radCurtis
  worker      : 0
  duration    : 614
  auth_type   : Session
  auth_method : Basic
  pol_id      : 5
  g_id        : 12
  user_based  : 0
  expire      : 53
  LAN:
    bytes_in=3403 bytes_out=5699
  WAN:
    bytes_in=3681 bytes_out=3132

```

7. The successful connection is logged in the forward traffic logs after the SSH connection has disconnected:

```

# execute log display
25 logs found.
10 logs returned.

1: date=2021-08-11 time=17:59:56 eventtime=1628729996110159120 tz="-0700"

```

ZTNA access proxy with SAML and MFA using FortiAuthenticator example

ZTNA access proxy supports device verification using device certificates that are issued by EMS. To authenticate users, administrators can use either basic or SAML authentication. An advantage of SAML authentication is that multi-factor authentication (MFA) can be provided by the SAML Identity Provider (IdP).

In these examples, a FortiAuthenticator is used as the IdP, and MFA is applied to user authentication for remote users accessing the web, RDP, and SSH resources over the ZTNA access proxy. It is assumed that the FortiGate EMS fabric connector has already been successfully connected.

- [Configuring the FortiAuthenticator on page 1102](#)
- [Configuring the FortiGate SAML settings on page 1104](#)
- [Example 1 - Applying SAML and MFA to ZTNA HTTPS access proxy on page 1107](#)
- [Example 2 - Applying SAML and MFA to a ZTNA TCP forwarding access proxy for RDP connections on page 1109](#)
- [Example 3 - Applying SAML and MFA to a ZTNA SSH access proxy on page 1112](#)

DNS resolutions:

- ztna.fortidemo.fortinet.com:20443 -> 10.100.64.201:20443
- entcore.fortidemo.fortinet.com:20443 -> 10.100.64.201:20443
- fac.fortidemo.fortinet.com -> 10.100.64.103

The FortiAuthenticator (FAC) integrates with Active Directory (AD) on the Windows Domain Controller, which is also acting as the EMS server. Users are synchronized from the AD to the FAC, and remote users are configured with token-based authentication. SAML authentication is configured on the FortiGate, pointing to the FAC as the SAML IdP. The SAML server is applied to the ZTNA access proxy authentication scheme and rule, to provide the foundation for applying user authentication on individual ZTNA rules.

Configuring the FortiAuthenticator

First configure the FortiAuthenticator to synchronize users from AD using LDAP, apply MFA to individual remote users, and be the IdP.

To create a remote authentication server pointing to the Windows AD:

1. Go to *Authentication > Remote Auth. Servers > LDAP* and click *Create New*.
2. Configure the following:

Name	AD
Primary server name / IP	10.100.88.5
Port	389 (or another port if using LDAPS)
Based distinguished name	DC=FORTI-ARBUTUS,DC=LOCAL
Bind type	Regular
Username	<user account used for LDAP bind>
Password	<password of user>
User object class	person (default)
Username attribute	sAMAccountName (default)
Group object class	group (default)
Obtain group membership from	Group attribute
Group membership attribute	memberOf (default)
Secure connection	Enable if using LDAPS or STARTTLS

3. Click *OK*.
4. In the *Remote LDAP Users* section click *Go*.
5. Select the users to import then click *OK*.
6. Click *OK*.
For more details, see [LDAP](#) in the [FortiAuthenticator Administration Guide](#).

To configure a remote LDAP user to use MFA:

1. Go to *Authentication > User Management > Remote Users*, and edit a user.
2. Enable *Token-based authentication* then select the method of token code delivery.
For this example, select *FortiToken > Mobile*, select the Token from the drop-down list, and set the *Activation delivery method* to email.
3. In the *User Information* section, add the email address that will be used for the FortiToken activation.
4. Click *OK*.
An activation email is sent to the user that they can use to install the token to their FortiToken Mobile app.
For more details, see [Remote users](#) in the [FortiAuthenticator Administration Guide](#).

To configure SAML IdP:

1. Go to *Authentication > SAML IdP > General* and enable *Enable SAML Identity Provider portal*.
2. The *Server address* is the device FQDN or IP address (configured in the System Information widget at *System > Dashboard > Status*). In this example, it is *fac.fortidemo.fortinet.com*.
3. Set *Username input format* to *username@realm*.
4. Click *Add a realm* in the *Realms* table:

- a. Set *Realm* to the just created LDAP realm (*AD*).
- b. Optionally, enable *Filter* and select the required users groups. In this example, *Customer Support* and *Marketing* are configured.
5. Set *Default IdP certificate* to the certificate that will be used in the HTTPS connection to the IdP portal.
6. Click *OK*.
7. Go to *Authentication > SAML IdP > Service Providers*, and click *Create New* to create a service provider (SP) for the FortiGate SP.
8. Configure the following, which must match what will be configured on the FortiGate:

SP name	Enterprise Core
IdP prefix	ztna
Server certificate	Same certificate as the default IdP certificate used in SAML IdP > General
SP entity ID	https://entcore.fortidemo.fortinet.com:20443/ztna/saml/metadata/
SP ACS (login) URL	https://entcore.fortidemo.fortinet.com:20443/ztna/saml/login/
SP SLS (logout) URL	https://entcore.fortidemo.fortinet.com:20443/ztna/saml/logout/
Participate in single logout	Enable

Where the *SP entity ID*, *SP ACS (login) URL*, and *SP SLS (logout) URL* break down as follows:

- *entcore.fortidemo.fortinet.com* - The FQDN that resolves to the FortiGate SP.
- *20443* - The port that is used to map to the FortiGate's SAML SP service.
- */ztna/saml* - The custom, user defined fields.
- */metadata*, */login*, and */logout* - The standard convention used to identify the SP entity, log in portal, and log out portal.

9. Click *OK*.
10. Edit the just created SP object and, under *SAML Attribute*, click *Create New*.
11. Set *SAML attribute* to the username and set *User attribute* to *Username*, then click *OK*.
12. Click *OK*.

For more details, see [Configuring SAML settings](#) in the [SAML Interoperability Guide](#).

Configuring the FortiGate SAML settings

On the FortiGate, a SAML user is used to define the SAML SP and IdP settings. This user is then applied to the ZTNA proxy using an authentication scheme, rule, and settings. A ZTNA server is then created to allow access to the SAML SP server so that end users can reach the FortiGate SP's captive portal. The SAML user must then be added to a ZTNA rule to trigger authentication when accessing the ZTNA access proxy.

To create a new SAML user/server:

1. Create the SAML user object:

```
config user saml
  edit "su-ztna"
    set cert "FortiDemo"
    set entity-id "https://entcore.fortidemo.fortinet.com:20443/ztna/saml/metadata/"
    set single-sign-on-url
```

```

"https://entcore.fortidemo.fortinet.com:20443/ztna/saml/login/"
    set single-logout-url
"https://entcore.fortidemo.fortinet.com:20443/ztna/saml/logout/"
    set idp-entity-id "http://fac.fortidemo.fortinet.com/saml-idp/ztna/metadata/"
    set idp-single-sign-on-url "https://fac.fortidemo.fortinet.com/saml-
idp/ztna/login/"
    set idp-single-logout-url "https://fac.fortidemo.fortinet.com/saml-
idp/ztna/logout/"
    set idp-cert "REMOTE_Cert_1"
    set user-name "username"
    set digest-method sha1
    next
end

```

Where:

- The `FortiDemo` certificate is a local certificate that is used to sign SAML messages that are exchanged between the client and the FortiGate SP. In this example, it is used to sign `entcore.fortidemo.fortinet.com`.
- The `REMOTE_Cert_1` certificate is a remote certificate that is used to identify the IdP. In this example, `fac.fortidemo.fortinet.com`.
- The URLs used in the SAML user settings are the same as the ones defined on the FortiAuthenticator.

2. Add the SAML user object to a new user group:

```

config user group
    edit "ztna-users"
        set member "su-ztna"
    next
end

```

To apply the SAML server to proxy authentication:**1. Apply the SAML server to an authentication scheme:**

```

config authentication scheme
    edit "saml-scheme"
        set method saml
        set saml-server "su-ztna"
    next
end

```

2. Apply the authentication scheme to an authentication rule:

```

config authentication rule
    edit "saml-rule"
        set srcintf "any"
        set srcaddr "all"
        set ip-based disable
        set active-auth-method "saml-scheme"
        set web-auth-cookie enable
    next
end

```

3. Configure the active authentication scheme, and a captive portal to serve the log in page for the SAML requests:

```

config firewall address
    edit "entcore.fortidemo.fortinet.com"
        set type fqdn

```

```

        set fqdn "entcore.fortidemo.fortinet.com"
    next
end

config authentication setting
    set active-auth-scheme "saml-scheme"
    set captive-portal "entcore.fortidemo.fortinet.com"
end

```

To configure a ZTNA access proxy to allow SAML authentication requests to the SP:

1. Configure the ZTNA server:
 - a. Go to *Policy & Objects > ZTNA*, select the *ZTNA Servers* tab, and click *Create New*.
 - b. Configure the following:

Name	ZTNA-access
External interface	Any
External IP	10.100.64.201
External port	20443
SAML	Enabled
SAML SSO Server	su-ztna
Default certificate	FortiDemo

- c. Click *OK*.
2. Define the ZTNA rule to allow access to the ZTNA server:
 - a. Go to *Policy & Objects > ZTNA*, select the *ZTNA Rules* tab, and click *Create New*.
 - b. Configure the following:

Name	ZTNA-Rule
Source (Address)	all
Source (User)	ztna-users
ZTNA Server	ZTNA-access
Action	Accept

- c. Click *OK*.

To configure a VIP and a firewall policy to forward IdP authentication traffic to the FortiAuthenticator:

Remote clients connect to the FortiAuthenticator IdP behind the FortiGate using a VIP. In this example, users connect to the FQDN `fac.fortidemo.fortinet.com` that resolves to the VIP's external IP address.

1. Configure the VIP to forward traffic to the FortiAuthenticator:
 - a. Go to *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP*.
 - b. Configure the following:

Name	FortiAuthenticator
Interface	Any
External IP address	10.100.64.103
Map to > IPv4 address/range	10.100.88.9
Port Forwarding	Enabled
Protocol	TCP
External service port	443
Map to IPv4 port	443

- c. Click OK.
2. Configure a firewall policy to allow VIP:
 - a. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
 - b. Configure the following:

Name	WAN to FAC
ZTNA	Disabled
Incoming Interface	Any
Outgoing Interface	Any
Source	All
ZTNA Server	FortiAuthenticator
Schedule	always
Service	ALL
Action	Accept
NAT	disabled

- c. Click OK.

Example 1 - Applying SAML and MFA to ZTNA HTTPS access proxy

In this HTTPS access proxy example, two real servers are implemented with round robin load balancing performed between them. The HTTPS access proxy is configured on the same ZTNA server as was configured in the authentication step. The same ZTNA rule and firewall policy also apply.

To configure the ZTNA server for HTTPS access proxy with load balancing:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Servers* tab.
2. Edit the ZTNA-access server.
3. In the *Service/server mapping* table, click *Create New*:
 - a. Set *Service* to *HTTPS*.
 - b. Set *Virtual Host* to *Any Host*.

- c. In the *Servers* table click *Create New*:
 - i. Set *IP* to 10.100.77.200
 - ii. Set *Port* to 443.
 - iii. Set *Status* to *Active*.
 - iv. Click *OK*.
 - d. Create a second server with *IP 10.100.77.202*.
 - e. Click *OK*.
4. Enable *Load balancing*, and select the *Round Robin* algorithm.
 5. Click *OK*.

Testing and verification:

From the remote endpoint, user John Locus attempts to connect to the Finance server over ZTNA:

1. On the remote Windows computer, open FortiClient and register to the EMS server.

It is not necessary to configure a *ZTNA Destination* on the FortiClient for the HTTPS access proxy use case. In fact, configuring a *ZTNA Destination* rule for the website may interfere with its operation.

2. Open a browser and attempt to connect to the web server at <https://ztna.fortidemo.fortinet.com:20443>.
3. Device authentication prompts the user for their device certificate. Select the certificate issued by EMS and click *OK*.
4. FortiGate receives the SAML request and redirects the user to the IdP login screen. Enter the username and password for John Locus and click *Login*.
5. A second prompt opens asking for the *Token Code*. Enter the code then click *Verify*.

Not JohnLocus? Sign in as a different user

6. The FortiAuthenticator IdP verifies the login, then sends the SAML assertion back to the user.
7. The browser redirects the assertion to the FortiGate SP, which decides if the user is allowed access.
8. On a successful log in, FortiGate redirects the user to the web page that they are trying to access.

Logs and debugs:

On the FortiGate, a successful connection can be seen in *Log & Report > Forward Traffic log*, or by using the CLI:

```
# execute log filter category 0
# execute log filter field srcip 10.100.66.103
# execute log display
...
```

```

1: date=2021-08-25 time=23:34:15 eventtime=1629959656098675227 tz="-0700" logid="0000000024"

```

Log number four shows that the session was first allowed through the ZTNA firewall policy. Log numbers one and two show the traffic allowed through the ZTNA proxy-policy over two successive sessions. Note that they have different destination IP addresses (dstip), indicating that ZTNA was performing server load balancing.

Use the following command to show if the FortiGate's WAD process has an active record of the SAML user login:

```

# diagnose wad user list

ID: 6, VDOM: root, IPv4: 10.100.66.103
  user name   : johnlocus
  worker      : 0
  duration    : 611
  auth_type   : Session
  auth_method : SAML
  pol_id      : 1
  g_id        : 3
  user_based  : 0
  expire      : 283
  LAN:
    bytes_in=38016 bytes_out=16166
  WAN:
    bytes_in=12422 bytes_out=7217

```

Example 2 - Applying SAML and MFA to a ZTNA TCP forwarding access proxy for RDP connections

In this TCP forwarding access proxy example, RDP connections are allowed to be forwarded to the Windows/EMS server. Traffic to TCP/3389 is allowed through the ZTNA proxy.

To configure the ZTNA server for TCP forwarding on TCP/3389:

1. Create a firewall address for the Windows/EMS server:
 - a. Go to *Policy & Objects > Addresses* and click *Create New > Address*.
 - b. Configure the following:

Name	EMS-Server
Type	Subnet
IP/Netmask	10.100.88.5/32
Interface	any

- c. Click *OK*.
2. Go to *Policy & Objects > ZTNA* and select the *ZTNA Servers* tab.
3. Edit the ZTNA-access server.
4. In the *Service/server mapping* table, click *Create New*:
 - a. Set *Service* to *TCP Forwarding*.
 - b. In the *Servers* table click *Create New*:
 - i. Set *Address* to *EMS-Server*.
 - ii. Set *Ports* to *3389*.
 - iii. Click *OK*.
 - c. Click *OK*.
5. Click *OK*.

Testing and verification:

On the remote endpoint, manually configure ZTNA connection rules to forward RDP traffic to the ZTNA access proxy. The rules can also be pushed from the EMS server; for details see [Provisioning ZTNA TCP forwarding rules via EMS](#).

Configure the ZTNA connection rule:

1. On the remote Windows computer, open FortiClient.
2. Register to the EMS server.
3. On the *ZTNA Connection Rules* tab, click *Add Rule* to add a TCP forwarding rule.
4. Configure the following:

Rule Name	RDP-server
Destination Host	10.100.88.5:3389
Proxy Gateway	ztna.fortidemo.fortinet.com:20443
Mode	Transparent
Encryption	Disabled <i>Encryption</i> can be enabled or disabled. When it is disabled, the client to access proxy connection is not encrypted in HTTPS. Because RDP is encrypted by default, disabling <i>Encryption</i> does not reduce security.

5. Click *Create*.

Connect over RDP:

1. On the remote PC, open a new RDP connection.
2. Enter the IP address 10.100.588.5. By default, RDP session use port 3389.
When the connection to the ZTNA access proxy is established, FortiGate will redirect the SAML login request to the FortiAuthenticator IdP.
A FortiClient prompt will open with the FortiAuthenticator login screen.
3. Enter the username and password then click *Login*.
4. A second prompt opens asking for the *Token Code*. Enter the code from your FortiToken app, then click *Verify*.
5. FortiAuthenticator verifies the token code, determines if the login is successful, then sends the SAML assertion back to the client.
6. The client redirects the response back to the FortiGate SP.
7. If the log in was successful, the user can now log on to the RDP session.

Logs and debugs:

On the FortiGate, a successful connection can be seen in *Log & Report > Forward Traffic log*, or by using the CLI:

```
# execute log filter category 0
# execute log filter field srcip 10.100.66.103
# execute log display
...
3: date=2021-08-25 time=23:05:52 eventtime=1629957952722272222 tz="-0700" logid="0000000024"

```

Use the following command to show if the FortiGate's WAD process has an active record of the SAML user login:

```
# diagnose wad user list

ID: 6, VDOM: root, IPv4: 10.100.66.103
  user name   : johnlocus
  worker      : 0
  duration    : 611
  auth_type   : Session
  auth_method : SAML
  pol_id      : 1
  g_id        : 3
  user_based  : 0
  expire      : no
  LAN:
    bytes_in=51471 bytes_out=233862
```

WAN:

```
bytes_in=211247 bytes_out=24410
```

Example 3 - Applying SAML and MFA to a ZTNA SSH access proxy

In this SSH access proxy example, SSH connections can be forwarded to the web server.

To configure the ZTNA server for SSH access proxy:

1. Create a firewall address for the web server:
 - a. Go to *Policy & Objects > Addresses* and click *Create New > Address*.
 - b. Configure the following:

Name	Web-Server1
Type	Subnet
IP/Netmask	10.100.77.101/32
Interface	any

- c. Click *OK*.
2. Go to *Policy & Objects > ZTNA* and select the *ZTNA Servers* tab.
3. Edit the ZTNA-access server.
4. In the *Service/server mapping* table, edit the *TCP Forwarding* entry:
 - a. In the *Servers* table click *Create New*:
 - i. Set *Address* to *Web-Server1*.
 - ii. Set *Ports* to *22*.
 - iii. Optionally, enable *Additional SSH Options* to configure other SSH options as needed.
 - iv. Click *OK*.
 - b. Click *OK*.
5. Click *OK*.

Testing and verification:

On the remote endpoint, manually configure ZTNA connection rules to forward SSH traffic to the ZTNA access proxy. The rules can also be pushed from the EMS server; for details see [Provisioning ZTNA TCP forwarding rules via EMS](#).

Configure the ZTNA connection rule:

1. On the remote Windows computer, open FortiClient.
2. Register to the EMS server.
3. On the *ZTNA Connection Rules* tab, click *Add Rule* to add a TCP forwarding rule.

4. Configure the following:

Rule Name	SSH-webserver
Destination Host	10.100.77.101:22
Proxy Gateway	ztna.fortidemo.fortinet.com:20443
Mode	Transparent
Encryption	Disabled

5. Click *Create*.

Connect over SSH:

1. On the remote PC, open a new SSH connection.

2. Enter the host `root@10.100.77.101` on port 22.

When the connection to the ZTNA access proxy is established, FortiGate will redirect the SAML login request to the FortiAuthenticator IdP.

A FortiClient prompt will open with the FortiAuthenticator login screen.

3. Enter the username and password then click *Login*.

4. A second prompt opens asking for the *Token Code*. Enter the code from your FortiToken app, then click *Verify*.

5. FortiAuthenticator verifies the token code, determines if the login is successful, then sends the SAML assertion back to the client.

6. The client redirects the response back to the FortiGate SP.

7. If the log in was successful, the user can now log on to the SSH session.

Logs and debugs:

On the FortiGate, a successful connection can be seen in *Log & Report > Forward Traffic log*, or by using the CLI:

```
# execute log filter category 0
# execute log filter field srcip 10.100.66.103
# execute log display
...
2: date=2021-08-25 time=23:20:03 eventtime=1629958804111962686 tz="-0700" logid="0000000024"
type="traffic" subtype="forward" level="notice" vd="root" srcip=10.100.66.103 srcport=60043

```

Use the following command to show if the FortiGate's WAD process has an active record of the SAML user login:

```
# diagnose wad user list

ID: 6, VDOM: root, IPv4: 10.100.66.103
  user name   : johnlocus
  worker      : 0
  duration    : 192
  auth_type   : Session
  auth_method : SAML
  pol_id      : 1
  g_id        : 3
  user_based  : 0
  expire      : 475
  LAN:
    bytes_in=19647 bytes_out=10063
  WAN:
    bytes_in=2886 bytes_out=1860
```

ZTNA access proxy with SSL VPN web portal example

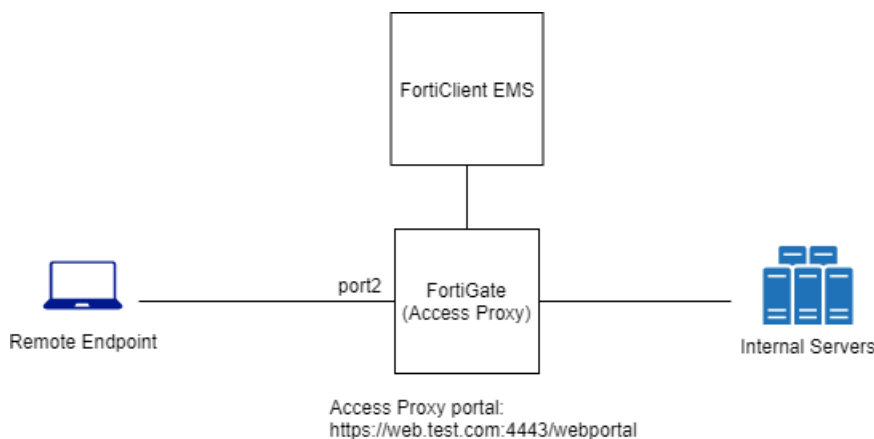

SSL VPN web portals can be defined in ZTNA access proxy settings. The ZTNA access proxy handles the access control processes (client certificate authentication, posture check, user authentication and authorization), and establishes the HTTPS connection between the end user and the access proxy. Then, it forwards the user to the web portal where they can use predefined bookmarks to access TCP based services like HTTPS, RDP, VNC, FTP, SFTP, SSH, Telnet, and SMB. Existing SSL VPN portal configurations can be used.

The web portal service can only be configured in the CLI.

Example

In this example, a remote client connects to the ZTNA access proxy and completes the client certificate check. If successful, the remaining access control procedures are automatically completed, and the user is forwarded to the web portal. The web portal is configured with predefined bookmarks that connect to internal servers and external websites. The user can access any resource that is defined in the bookmarks to create an end-to-end connection.

To configure the SSL VPN web portal:

1. Go to *VPN > SSL-VPN Portals* and click *Create New*.
2. Enter the name, *test_ssl*.
3. Disable *Tunnel Mode*.
4. Enable *Web Mode*.
5. Create the bookmarks:
 - a. Under *Predefined Bookmarks*, click *Create New*.
 - b. Enter the name of the service.
 - c. Select the service *Type*.
 - d. Enter the *URL* to access the service.
 - e. Click *OK*.
 - f. Repeat these steps to create other bookmarks.
6. Click *OK*.

To configure the ZTNA access proxy:

1. Configure a VIP for the ZTNA access proxy. The `ssl-certificate` can be replaced with a server certificate:

```
config firewall vip
  edit "ztna_webportal"
    set type access-proxy
    set extip 172.18.62.68
    set extintf "any"
    set server-type https
    set extport 4443
    set ssl-certificate "*.test.com"
  next
end
```

2. Configure the virtual host to be used to connect to the ZTNA access proxy. The host should resolve to the VIP's address:

```
config firewall access-proxy-virtual-host
  edit "webportal"
    set ssl-certificate "*.test.com"
    set host "web.test.com"
  next
end
```

3. Configure the ZTNA access proxy to be in web portal mode:

```
config firewall access-proxy
  edit "ztna_webportal"
    set vip "ztna_webportal"
    set client-cert enable
    config api-gateway
      edit 1
        set url-map "/webportal"
        set service web-portal
        set virtual-host "webportal"
        set ssl-vpn-web-portal "test_ssl"
      next
    end
```

```
    next
end
```

4. Apply the access proxy to a proxy policy (specify the ZTNA tags as needed):

```
config firewall proxy-policy
  edit 1
    set name "ztna_rule"
    set proxy access-proxy
    set access-proxy "ztna_webportal"
    set srcintf "any"
    set srcaddr "all"
    set dstaddr "all"
    set ztna-ems-tag "FCTEMS8821000000_High"
    set action accept
    set schedule "always"
    set logtraffic all
    set srcaddr6 "all"
    set dstaddr6 "all"
    set utm-status enable
    set profile-type group
    set profile-group "profile group1"
    set logtraffic-start enable
  next
end
```

The SSL VPN bookmarks are learned by the WAD daemon and are ready to use.

5. Verify the bookmarks:

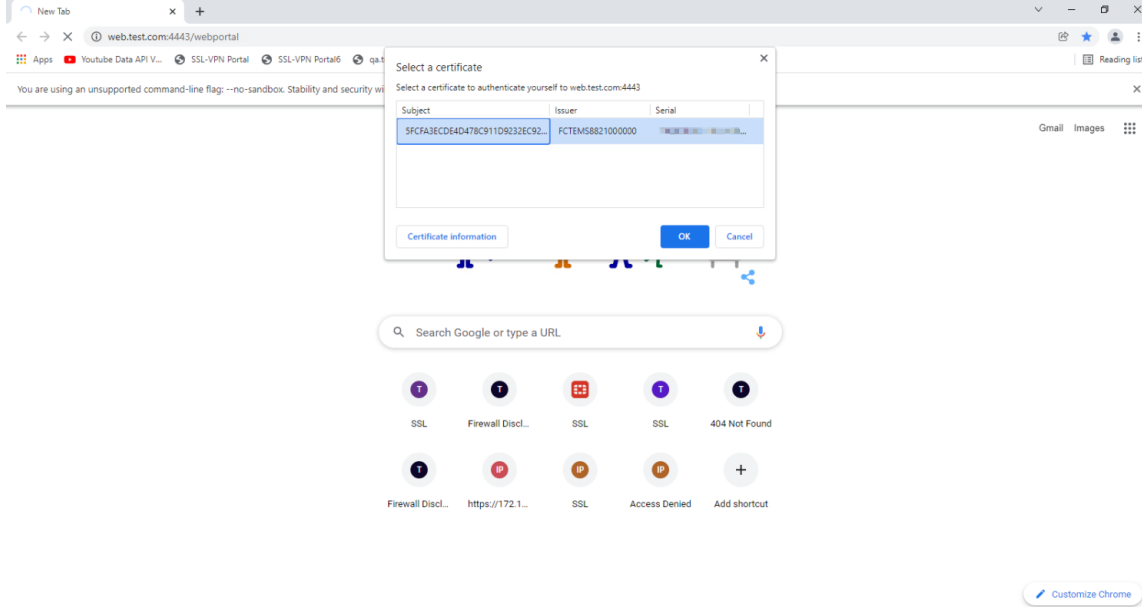

```
# diagnose test app wad 351
[bookmark: (portal/group/name=test_ssl/gui-bookmarks/2nd HTTP)]:
  type :1
  url  :http://httpbin.org
  host :
  folder:
  domain:
  port :0
[bookmark: (portal/group/name=test_ssl/gui-bookmarks/FTP)]:
  type :4
  url  :
  host :
  folder:172.16.200.215
  domain:
  port :0
[bookmark: (portal/group/name=test_ssl/gui-bookmarks/HTTPS-fortinet)]:
  type :1
  url  :https://www.fortinet.com
  host :
  folder:
  domain:
  port :0
[bookmark: (portal/group/name=test_ssl/gui-bookmarks/RDP)]:
  type :9
  url  :
  host :172.18.62.213
  folder:
  domain:
```

port :3389

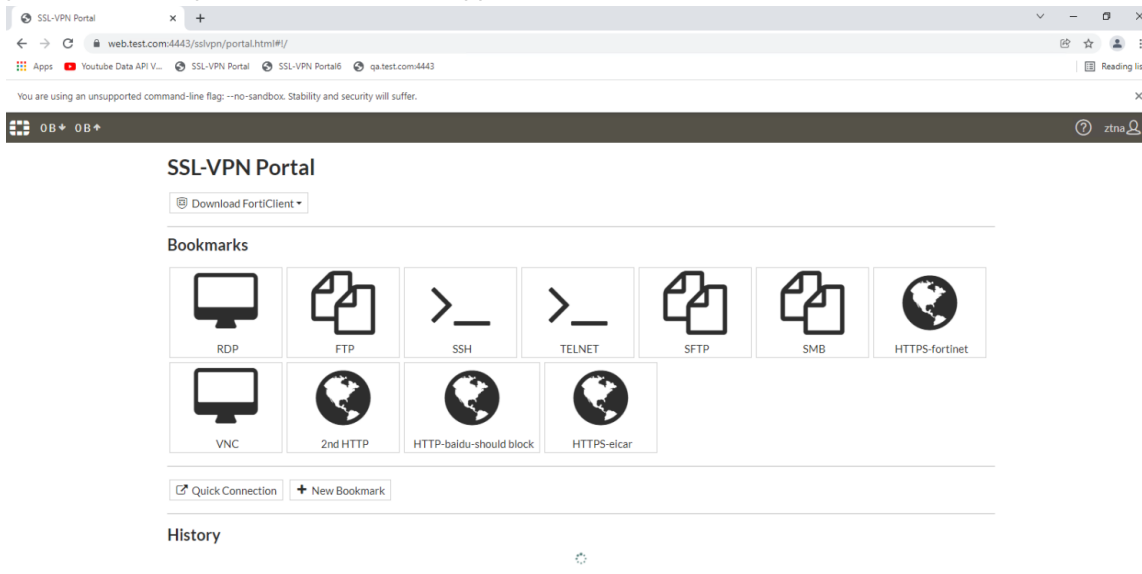

...

To test the connection:

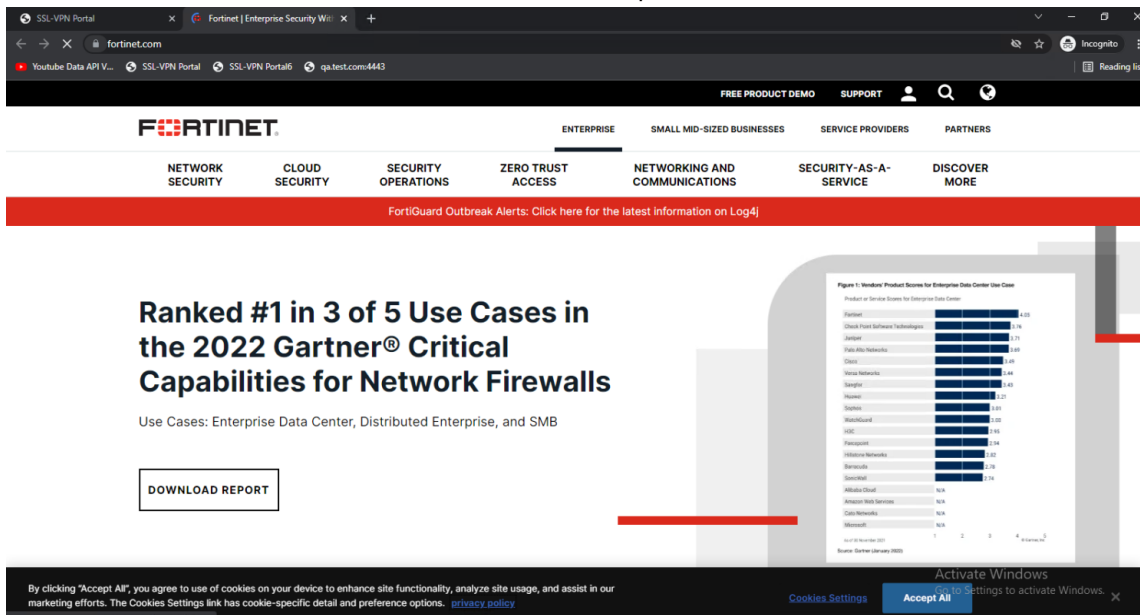

1. From the client browser, go to <https://web.test.com:4443/webportal> to access the ZTNA access proxy web portal.

2. Once the client passes the certificate check, posture check, and access is granted, the user is redirected to the web portal. The list of predefined bookmarks appears.

3. Click a bookmark, such as *HTTPS-fortinet*. The website opens.

4. From the web portal, click another bookmark, such as *SSH*. The page opens with the credential login screen to access the server.

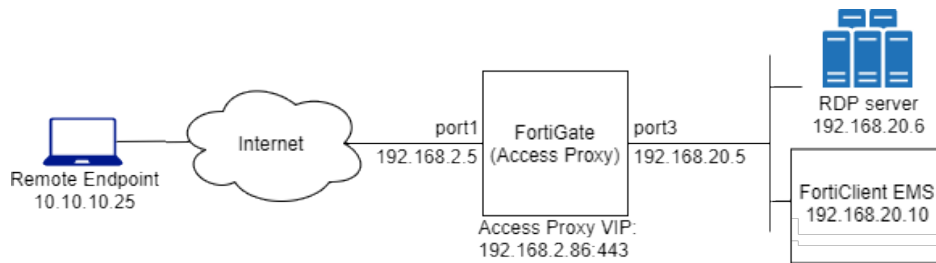

Posture check verification for active ZTNA proxy session examples

Endpoint posture changes trigger active ZTNA proxy sessions to be re-verified and terminated if the endpoint is no longer compliant with the ZTNA policy.

The FortiGate monitors changes to the endpoint tags that are updated by EMS with the `fnacd` process. When a change is detected, the endpoint's active ZTNA sessions must match the ZTNA policy again before data can pass.

Changes to the ZTNA policy, such as changing the ZTNA tag matching logic, will also trigger re-verification of the client device against the policy.

The remote endpoint accesses the RDP server through the TCP forwarding access proxy. The proxy is managed by the FortiClient EMS server, which has a ZTNA tagging rule that assigns the *AV-enabled* tag to endpoints that have Windows antivirus enabled, and the *Low risk host* tag to endpoints that are low risk.

These examples assume that the FortiGate EMS fabric connector has already connected successfully, and a ZTNA server named WIN2K16-P1-RDP that forwards traffic to the RDP server has been configured.

Example 1 - The ZTNA tag status changes on the endpoint

In this example, a ZTNA rule is configured to allow access for endpoints that have the *AV-enabled* tag. After an RDP session is established, Windows antivirus is disabled on the remote endpoint. The FortiGate re-verifies the session and the active RDP session is removed from the FortiGate session table, causing the RDP session to be disconnected.

To configure the ZTNA rule in the GUI:

1. Go to *Policy & Objects > ZTNA*, select the *ZTNA Rules* tab, and click *Create New*.
2. Set *Name* to *TCP-forward-WIN2K16*.
3. Set *Incoming Interface* to *port1*.
4. Set *Source* to *all*.
5. In *ZTNA Tag* add *AV-enabled*
6. In *ZTNA Server* add *WIN2K16-P1-RDP*.
7. Set *Destination* to *all*.
8. Set *Action* to *ACCEPT*.
9. Configure the remaining options as needed.
10. Click *OK*.

To configure the ZTNA rule in the CLI:

```
config firewall proxy-policy
  edit 4
    set name "TCP-forward-WIN2K16"
    set proxy access-proxy
    set access-proxy "WIN2K16-P1-RDP"
    set srcintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set ztna-ems-tag "FCTEMS0000109188_AV-enabled"
    set action accept
    set schedule "always"
    set logtraffic all
  next
end
```

To test the example:

1. On the remote endpoint, open FortiClient.
2. On the *Zero Trust Telemetry* tab, make sure that you are connected to the EMS server.
3. Add a ZTNA rule:
 - a. On the *ZTNA Connection Rules* tab, click *Add Rule*.
 - b. Configure the ZTNA rule:

Rule Name	RDP-WIN2K16
Destination Host	192.168.20.6:3389
Proxy Gateway	192.168.2.86:443
Encryption	Disabled

- c. Click *Create*.
4. Ensure that the endpoint has Windows antivirus enabled.
5. Open an RDP session to connect to the RDP server at 192.168.20.6.
6. After a successful connection, on the FortiGate:
 - a. The endpoint is detected and marked with the *AV-enabled* tag:

```
# diagnose test application fcnacd 7

ZTNA Cache V2:
Entry #1:

- UID: F4F3263AEBE54777A6509A8FCCDF9284
- Domain:

srcfamily="Firewall" osname="FortiOS" srchwversion="FortiWiFi-30E" appcat="unscanned"

```

7. On the remote endpoint, disable Windows antivirus.

FortiClient EMS detects a change in ,and removes the *AV-enabled* tag on the FortiClient endpoint.

8. Due to the change in posture, the RDP session is disconnected:

a. The endpoint is no longer marked with the *AV-enabled* tag:

```

# diagnose test application fcnacd 7

ZTNA Cache V2:
Entry #1:

- UID: F4F3263AEBE54777A6509A8FCCDF9284
- Domain:
- User: keithli
- Owner:
- Certificate SN: 1626C2C10E6AD97D71FA9E2D9C314C1F5C03D68B
- EMS SN: FCTEMS0000109188
- online: true
- Tags (2):
  -- Tag (#0): all_registered_clients
  -- Tag (#1): Low
lls_idx_mask = 0x00000001,

```

b. The previous session is removed:

```

# diagnose sys session filter dst 192.168.2.86
# diagnose sys session filter src 10.10.10.25
# diagnose sys session list
total session 0

```

c. The forward traffic log indicates that traffic is denied:

```
# execute log display
7: date=2021-10-18 time=11:31:45 eventtime=1634581905530844852 tz="-0700"

```

Example 2 - The ZTNA rule tag checking logic changes

In this example, a ZTNA rule is configured to allow access to endpoints that have at least one of the *AV-enabled* or *Low* ZTNA tags. A remote user who has Windows antivirus disabled, but is low risk, successfully establishes an RDP session over the ZTNA access proxy. An administrator changes the ZTNA rule's tag matching logic from *Any* to *All*, causing the RDP session to be disconnected.

To configure the ZTNA rule in the GUI:

1. Go to *Policy & Objects > ZTNA*, select the *ZTNA Rules* tab.
2. Edit the *TCP-forward-WIN2K16* rule.
3. In *ZTNA Tag*, add *Low*.
4. Ensure that *Match ZTNA Tags* is set to *Any*.
5. Click *OK*.

To configure the ZTNA rule in the CLI:

```
config firewall proxy-policy
  edit 4
    set name "TCP-forward-WIN2K16"
    set proxy access-proxy
    set access-proxy "WIN2K16-P1-RDP"
    set srcintf "port1"
    set srcaddr "all"
    set dstaddr "all"
    set ztna-ems-tag "FCTEMS0000109188_AV-enabled" "FCTEMS0000109188_Low"
```

```

        set ztna-tags-match-logic or
        set action accept
        set schedule "always"
        set logtraffic all
    next
end

```

To test the example:

1. On the remote Windows PC, disable antivirus protection.
2. Open an RDP session to connect to the RDP server at 192.168.20.6.
3. After a successful connection, on the FortiGate:
 - a. The endpoint is detected and marked with the *Low* tag, but not the *AV-enabled* tag:

```

# diagnose test application fcnacd 7

ZTNA Cache V2:
Entry #1:

- UID: F4F3263AEBE54777A6509A8FCCDF9284
- Domain:
- User: keithli
- Owner:
- Certificate SN: 1626C2C10E6AD97D71FA9E2D9C314C1F5C03D68B
- EMS SN: FCTEMS0000109188
- online: true
- Tags (2):
  -- Tag (#0): all_registered_clients
  -- Tag (#1): Low
lls_idx_mask = 0x00000001,

```

- b. A session is created:

```

# diagnose sys session filter dst 192.168.2.86
# diagnose sys session filter src 10.10.10.25
# diagnose sys session list

session info: proto=6 proto_state=01 duration=29 expire=3598 timeout=3600
flags=00000000 socktype=0 sockport=1012 av_idx=0 use=3

rpdb_link_id=00000000 rpdb_svc_id=0 ngfwid=n/a

```

- c. The forward traffic log indicates that traffic is allowed:

```
# execute log filter category 0
# execute log display
...
1: date=2021-10-18 time=12:46:01 eventtime=1634586361077487880 tz="-0700"
logid="0000000024" type="traffic" subtype="forward" level="notice" vd="root"
srcip=10.10.10.25 srcport=55140 srcintf="port1" srcintfrole="wan"
dstcountry="Reserved" srccountry="Reserved" dstip=192.168.20.6 dstport=3389
dstintf="root" dstintfrole="undefined" sessionid=12542 srcuid="5445be2e-5d7b-51ea-
e2c3-ae6b7855c52f" service="RDP" proto=6 action="accept" policyid=4
policytype="proxy-policy" poluid="ce8f82d0-8fb3-51eb-0a17-5e6a6a51ff27"
policyname="TCP-forward-WIN2K16" duration=138 wanin=140349 rcvdbyte=140349
wanout=47118 lanin=48799 sentbyte=48799 lanout=142521 appcat="unscanned"
```

4. On the FortiGate, edit the ZTNA rule *TCP-forward-WIN2K16*:

- In the GUI, set *Match ZTNA Tags* to *All*.
- In the CLI, set *ztna-tags-match-logic* to *and*.

5. Due to the ZTNA rule update, the FortiGate re-verifies the session, and the RDP session is disconnected:

- a. The previous session is removed:

```
# diagnose sys session filter dst 192.168.2.86
# diagnose sys session filter src 10.10.10.25
# diagnose sys session list
total session 0
```

- b. The ZTNA log indicates that traffic is denied:

```
# execute log filter category 21
# execute log display
1: date=2021-10-18 time=12:53:57 eventtime=1634586837921889075 tz="-0700"
logid="2101060510" type="utm" subtype="ztna" eventtype="ztna-policy-match"
level="warning" vd="root" msg="Connection is blocked due to unable to match a proxy-
policy" policyid=0 sessionid=13865 srcip=10.10.10.25 dstip=192.168.2.86 srcport=55162
dstport=443 srcintf="port1" srcintfrole="wan" dstintf="root" dstintfrole="undefined"
proto=6 action="blocked" service="HTTPS" gatewayid=1 vip="WIN2K16-P1-RDP"
accessproxy="WIN2K16-P1-RDP" clientdeviceid="F4F3263AEBE54777A6509A8FCCDF9284"
clientdevicetags="MAC_FCTEMS0000109188_Low/FCTEMS0000109188_all_registered_
clients/MAC_FCTEMS0000109188_all_registered_clients/FCTEMS0000109188_Low"
```

ZTNA TCP forwarding access proxy with FQDN example

When defining ZTNA connection rules on FortiClient for TCP forwarding, it is sometimes desirable to configure the destination host address as an FQDN address instead of an IP address. Since the real servers are often servers in the corporate network, this layer of obfuscation prevents internal IPs from easily leaking to the public, and also makes the destination more easily recognizable by the end users.

One obstacle to overcome is getting remote hosts to resolve an internal FQDN that is typically only resolvable by an internal DNS in the corporate network. This can be solved with the following:

1. When an FQDN address is added as a destination host in a ZTNA connection rule, FortiClient creates a virtual IP for this FQDN address and adds this to the computer's host file (Windows). The same is true when a ZTNA connection rule entry is pushed from EMS.
2. The virtual IP mapped to the FQDN address is not the real address of the server. It allows applications to resolve the FQDN address to this virtual IP. FortiClient listens to any traffic destined for it and forwards the traffic using the TCP

forwarding URL with FQDN to the ZTNA access proxy.

3. The FortiGate access proxy will resolve the FQDN using the internal DNS on the corporate network, matching the traffic to the ZTNA real server configuration with the same domain and address.
4. If a valid ZTNA real server entry is found, traffic is forwarded to the real server.

Example

In this example, two servers in the internal network are added to the FortiGate access proxy for TCP forwarding. The remote client configures two ZTNA connection rules, with the destination host field pointing to the FQDN addresses of the internal servers. These FQDN addresses are configured in the FortiGate's DNS database so they can be resolved by the FortiGate. It is recommended to use an internal DNS server for production environments.

This example assumes that the FortiGate EMS Fabric connector is already successfully connected.

This feature requires a minimum FortiClient and FortiClient EMS version of 7.0.3.

To configure the TCP forwarding access proxy:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Set *Name* to *ZTNA_S1*.
4. Configure the network settings:
 - a. Set *External interface* to *any*.
 - b. Set *External IP* to *172.18.62.32*.
 - c. Set *External port* to *443*.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.
6. Add server mapping:
 - a. In the *Service/server mapping* table, click *Create New*.
 - b. For *Service*, select *TCP Forwarding*.
 - c. Add a server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Create a new FQDN address for the HTTPS server at *s27.qa.fortinet.com*, then click *OK*.

- iii. Apply the new address object as the address for the new server.
 - iv. Click *OK*.
 - d. Add another server using the same steps for s29.qa.fortinet.com.
7. Click *OK*. Now that the ZTNA server is complete, the domain settings must be configured in the CLI to map domains to the real servers.

To map domains to the real servers:

```
config firewall access-proxy
  edit "ZTNA_S1"
    set vip "ZTNA_S1"
    set client-cert enable
    config api-gateway
      edit 2
        set url-map "/tcp"
        set service tcp-forwarding
        config realservers
          edit 4
            set address "s27.qa.fortinet.com"
            set domain "qa.fortinet.com"
          next
          edit 5
            set address "s29.qa.fortinet.com"
            set domain "qa.fortinet.com"
          next
        end
      next
    end
  next
end
```

To configure the ZTNA rule:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Rules* tab.
2. Click *Create New*.
3. Set *Name* to *ZTNA_TCP*.
4. Set *Incoming Interface* to *port2*.
5. Set *Source* to *all*.
6. Select the ZTNA server *ZTNA_S1*.
7. Configure the remaining options as needed.
8. Click *OK*.

To configure the DNS entries for each server:

1. Enable the DNS database visibility:
 - a. Go to *System > Feature Visibility*.
 - b. Enable *DNS Database*.
 - c. Click *Apply*.
2. Go to *Network > DNS Servers*. Under *DNS Database*, click *Create New*.
3. Set *DNS Zone* to *ZTNA*.

4. Set *Domain Name* to *qa.fortinet.com*.
5. Add the DNS entries:
 - a. Under *DNS Entries*, click *Create New*.
 - b. Set *Hostname* to *s27*.
 - c. Set *IP Address* to the HTTPS server address.
 - d. Click *OK*.
 - e. Add another DNS entry using the same steps for the *s29.qa.fortinet.com* HTTP server.
6. Click *OK*.

Testing the connection to the access proxy

Before connecting, users must have a ZTNA connection rule in FortiClient.

ZTNA TCP forwarding rules can be provisioned from the EMS server. See [Provisioning ZTNA TCP forwarding rules via EMS](#) for more details.

To create the ZTNA rules in FortiClient and connect:

1. From the *ZTNA Connection Rules* tab, click *Add Rule*.
2. Create a rule for the HTTPS server:
 - a. Set *Rule Name* to *server27*.
 - b. Set *Destination Host* to *s27.qa.fortinet.com:443*.
 - c. Set *Proxy Gateway* to *172.18.62.32:443*.
 - d. Disable *Encryption*.
 - e. Click *Create*.
3. Create a rule for the HTTP server:
 - a. Set *Rule Name* to *server29*.
 - b. Set *Destination Host* to *s29.qa.fortinet.com:80*.
 - c. Set *Proxy Gateway* to *172.18.62.32:443*.
 - d. Disable *Encryption*.
 - e. Click *Create*.
4. Upon creating the ZTNA rules, two new entries are added to the Windows PC's host file in folder *C:\Windows\System32\drivers\etc*. View the file, and observe the new entries for the virtual IP and FQDN pairing for each ZTNA connection rule.

```
# ----- FORTICLIENT ZTNA VIP START -----  
10.235.0.1 s27.qa.fortinet.com  
10.235.0.2 s29.qa.fortinet.com  
# ----- FORTICLIENT ZTNA VIP END -----
```

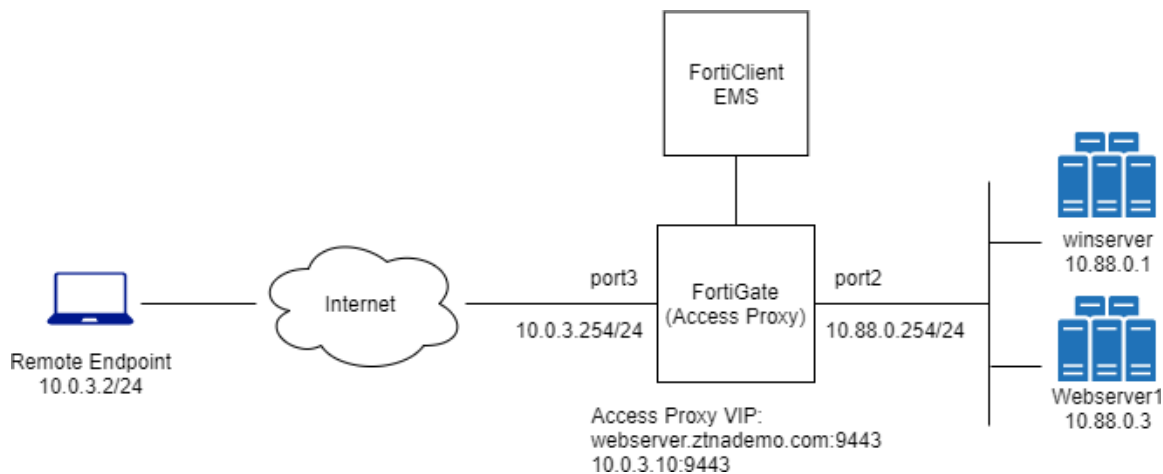

5. The Windows PC now resolves the FQDNs to the virtual IPs, and FortiClient will listen to the traffic to these IPs and forward them to the TCP access proxy.
6. Have the remote user connect to the HTTPS and HTTP servers on a browser. After device verification, the user is able to successfully connect to the remote servers.

ZTNA session-based form authentication

Session-based form authentication for ZTNA allows users to log in through an authentication portal with support for multi-factor authentication (MFA). This added advantage over the basic type authentication method allows FortiToken MFA to be applied directly to FortiGate users. FortiToken MFA can be applied to local users or remote users. Session-based form authentication can also be applied to explicit and transparent web proxies.

Example

In this example, the FortiGate is configured with a ZTNA HTTPS access proxy to protect access to the web server. It uses session-based form authentication with cookies and `auth-portal` enabled. It connects to the internal Windows Active Directory using LDAPS for user authentication, and assigns FortiToken MFA to individual users.

This example assumes that the FortiGate EMS Fabric connector is already successfully connected.

To configure the LDAP server:

1. Go to *User & Authentication > LDAP Servers* and click *Create New*.
2. Configure the following settings:

Name	<i>LDAP-fortiad</i>
Server IP/Name	<i>10.88.0.1</i>
Server Port	<i>389</i>
Common Name Identifier	<i>sAMAccountName</i>
Distinguished Name	<i>dc=fortiad,dc=info</i>
Exchange server	Disable this setting.
Bind Type	<i>Regular</i> Enter the <i>Username</i> and <i>Password</i> for LDAP binding and lookup.
Secure Connection	Enable and set the <i>Protocol</i> to <i>LDAPS</i> .
Certificate	Enable and select the <i>CA</i> certificate to validate the server certificate.

Server identity check

Optionally, enable to verify the domain name or IP address against the server certificate.

3. Click *Test Connectivity* to verify the connection to the server.
4. Click *OK*.

To configure a user with FortiToken MFA:

1. Go to *User & Authentication > User Definition* and click *Create New*.
2. Set *User Type* to *Remote LDAP User* and click *Next*.
3. Set *LDAP Server* to *LDAP-fortiad* and click *Next*.
4. For *Remote Users*, right-click on a user from the list under the corresponding OU and click *Add Selected*. In this example, the user *tsmith* under the *Marketing* OU is selected.
5. Click *Submit*.
6. Double-click the new user, *tsmith*, to edit the settings.
7. Enable *Two-factor Authentication*. Select either *FortiToken Cloud* or *FortiToken*. In this example, *FortiToken* is selected with a mobile FortiToken available on this FortiGate.
8. Enter an *Email Address* for the user to get a token activation notification.
9. Click *OK*.

To configure a user group:

1. Go to *User & Authentication > User Groups* and click *Create New*.
2. Enter the name of the group, *FortiAD-MFA-group*.
3. Set *Type* to *Firewall*.
4. Click the *+* in the *Members* field and add the user, *tsmith*.
5. Click *OK*.

To configure the authentication scheme:

1. Go to *Policy & Objects > Authentication Rules* and click *Create New > Authentication Scheme*.
2. Enter the name, *ZTNA-Auth-scheme*.
3. Set *Method* to *Form-based*.
4. Set *User database* to *Other* and select the *LDAP-fortiad* LDAP server.
5. Enable *Two-factor authentication*.
6. Click *OK*.

To configure the authentication rule:

```
config authentication rule
  edit "ztna_form_rule"
    set srcaddr "all"
    set ip-based disable
    set active-auth-method "ZTNA-Auth-scheme"
    set web-auth-cookie enable
  next
end
```

By disabling `ip-based`, the rule is session-based, so web authentication cookies must be enabled.

To configure the ZTNA basic server settings in the GUI:

Configuring the ZTNA server requires some settings that can only be configured in the CLI. The basic settings are configured in the GUI first, then the advanced CLI-only configurations are added after.

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Enter the server name, *ZTNA_S1*.
4. Configure the network settings:
 - a. Set *External interface* to *port3*.
 - b. Set *External IP* to *10.0.3.10*.
 - c. Set *External port* to *9443*.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP. In this example, the custom certificate, *ztna-wildcard* is selected.
6. Add server mapping:
 - a. In the *Service/server mapping* table, click *Create New*.
 - b. Set *Service* to *HTTPS*.
 - c. Set *Virtual Host* to *Any Host*.
 - d. Configure the path as needed.
 - e. Add a server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Set *IP* to *10.88.0.3*.
 - iii. Set *Port* to *9443*.
 - iv. Click *OK* to complete the server settings.
 - f. Click *OK* to complete the HTTPS service mapping.
7. Click *OK*.

To configure the advanced authentication settings in the CLI:

The following steps are required to create a virtual host and to enable the authentication portal.

1. Create an access proxy virtual host that points to the ZTNA access proxy. The FQDN of the host must be able to resolve to the external address 10.0.3.10. The client will be redirected to this page for form authentication:

```
config firewall access-proxy-virtual-host
  edit "auth-portal-vhost"
    set ssl-certificate "ztna-wildcard"
    set host "authportal.ztnademo.com"
  next
end
```

2. Enable `auth-portal` on the access proxy and point it to the virtual host:

```
config firewall access-proxy
  edit "ZTNA_S1"
    set auth-portal enable
    set auth-virtual-host "auth-portal-vhost"
  next
end
```

When `auth-virtual-host` is configured in the access proxy, it acts as a single sign-on (SSO) point. This means users will be authenticated once when accessing any domains or services in `ZTNA_S1`.

When `auth-virtual-host` is not configured, users will be re-authenticated for each domain or service in `ZTNA_S1`.

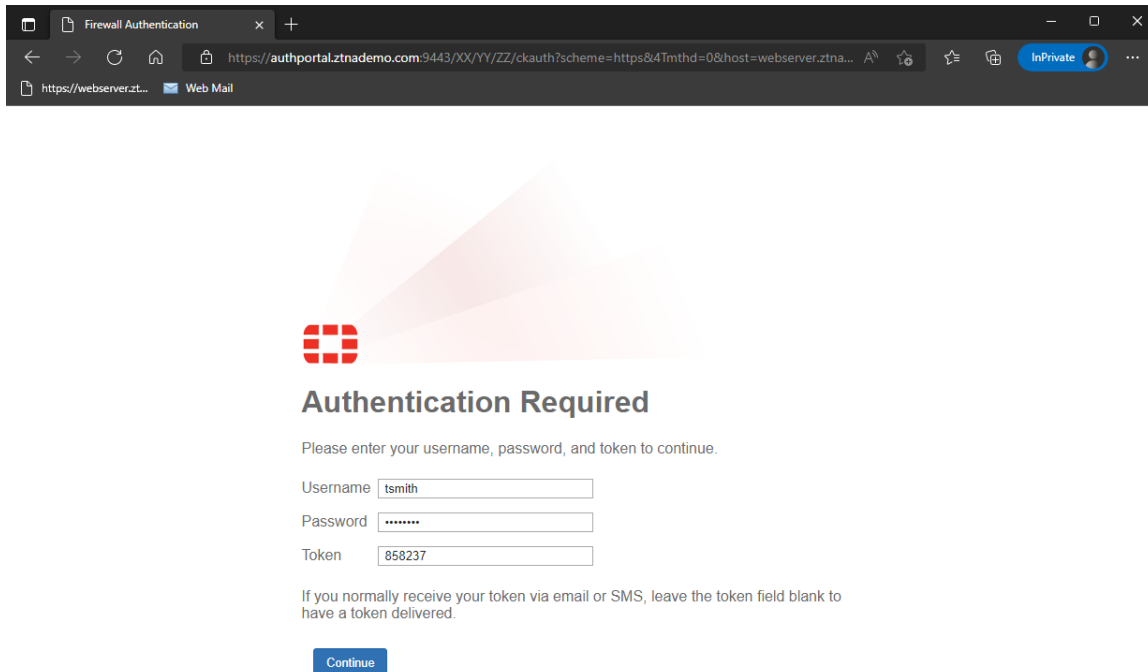

To apply the authentication to the ZTNA rule:

1. Go to *Policy & Objects* > *ZTNA* and select the *ZTNA Rules* tab.
2. Click *Create New*.
3. Enter the name, `ZTNA_R1`.
4. Set *Incoming Interface* to `port3`.
5. Set *Source* to *all*. This can also be set to specific IP addresses to only allow those addresses to connect to this HTTPS access proxy.
6. Click the + in the *Source* and from the *User* tab, select the *FortiAD-MFA-group* user group.
7. Click the + in the *ZTNA Tag* field and select the *Low* tag.
8. Set *ZTNA Server* to `ZTNA_S1`.
9. Set *Destination* to *Webserver1*, which is an address object for 10.88.0.3/32.
10. Configure the remaining options as needed.
11. Click *OK*.

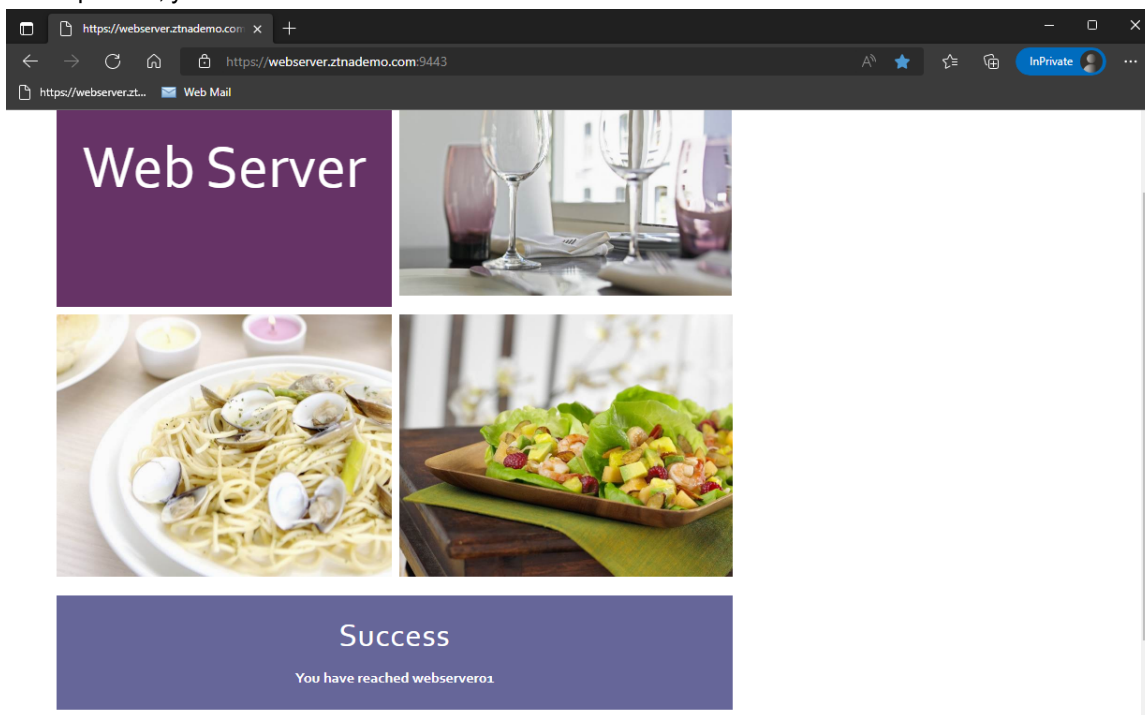

Testing the connection

To test the remote access to the HTTPS access proxy with user authentication:

1. On the remote Windows PC, open FortiClient.
2. From the *Zero Trust Telemetry* tab, make sure that you are connected to the EMS server.
3. Open a browser and enter the address or FQDN of the server and the access port. In this example, `https://webserver.ztnademo.com:9443` resolves to `https://10.0.3.10:9443`.
4. The browser prompts for the client certificate to use. Select the EMS signed certificate, then click *OK*.
5. The client is verified by the FortiGate to authenticate your identity.
6. Form authentication redirects you to the captive portal defined by the `auth-virtual-host`, `authportal.ztnademo.com:9443`. Enter your user credentials and FortiToken code.

7. After the user authentication passes, the FortiGate performs a posture check on the endpoint. When the posture check passes, you are allowed access to the website.

To verify the logs:

1. Verify the logged in users in the WAD daemon:

```
# diagnose wad user list
ID: 2, VDOM: root, IPv4: 10.0.3.2
```

```

user name      : tsmith
worker        : 1
duration      : 42
auth_type     : Session
auth_method   : Form
pol_id        : 1
g_id          : 4
user_based    : 0
expire        : no
LAN:
  bytes_in=5117 bytes_out=302717
WAN:
  bytes_in=304915 bytes_out=4407

```

2. Verify the endpoint information:

```

# diagnose endpoint record list
Record #1:
    IP Address = 10.0.3.2
    MAC Address = 02:09:0f:00:03:03
    MAC list = 02:09:0f:00:04:03;02:09:0f:00:03:03;
    VDOM = (-1)
    EMS serial number: FCTEMS8822000000
    Client cert SN: 5BDEE2D7B7FCA460D9CEC67BBF4D1FA33E3D281A
    Public IP address: 67.249.72.215
    Quarantined: no
    Online status: online
    Registration status: registered
    On-net status: on-net
    Gateway Interface:
    FortiClient version: 7.0.2
    AVDB version: 1.0
    FortiClient app signature version: 13.364
    FortiClient vulnerability scan engine version: 2.31
    FortiClient UID: 9A016B5A6E914B42AD4168C066EB04CA
    Host Name: WIN10-01
    OS Type: WIN64
    OS Version: Microsoft Windows 10 Professional Edition, 64-bit (build
19042) (version 2009)
    Host Description:
    Domain: fortiad.info
    Last Login User: tsmith
    ...
    Number of Routes: (0)
online records: 1; offline records: 0; quarantined records: 0

```

3. Verify the detected tags on the endpoint:

```

# diagnose test app fcnacd 7
ZTNA Cache V2:
Entry #1:
- UID: 9A016B5A6E914B42AD4168C066EB04CA
- EMS SN: FCTEMS88220010000
- Domain: fortiad.info
- User: tsmith
- Owner:
- Certificate SN: 5BDEE2D7B7FCA460D9CEC67BBF4D1FA33E3D281A

```

```

- online: true
- Tags (2):
  -- Tag (#0): all_registered_clients
  -- Tag (#1): Low
lls_idx_mask = 0x00000001,

```

4. Verify the ZTNA logs.

- In the GUI, go to *Log & Report > ZTNA Traffic*.
- In the CLI:

```

# execute log filter category 0
# execute log filter field subtype ztna
# execute log display
17 logs found.
10 logs returned.

```

```

1: date=2022-05-19 time=13:04:41 eventtime=1652990680922903215 tz="-0700"

Migrating from SSL VPN to ZTNA

ZTNA can be used to replace VPN-based teleworking solutions to enhance the user experience and to increase security. A typical teleworking configuration may utilize SSL VPN tunnel or web portal mode with LDAP user authentication. Common objects defined for this setup can be reused when migrating to ZTNA, such as the remote LDAP server, user group, and address objects.

SSL VPN teleworking scenarios

SSL VPN tunnel mode access with LDAP user authentication

Remote users that are in the *ALLOWED-VPN* active directory group have access to a specific web server when they connect through the SSL VPN tunnel. The FortiGate enables split tunneling to the web server so that only traffic to that destination is routed through the tunnel. The web server hosts internal websites that are only accessible by employees.

SSL VPN web mode access with LDAP user authentication

Remote users that are in the *ALLOWED-VPN* active directory group have access to a specific web server when they connect through the SSL VPN web portal. The web server hosts internal websites that are only accessible by employees. The pre-defined bookmark to the internal website is the only site that allows remote access.

Common configurations

This section includes configurations for common objects used in the SSL VPN configuration that can be reused in the ZTNA deployment:

- [LDAP server](#)
- [User group](#)
- [Firewall address for protected server](#)

LDAP server

To configure an LDAP server:

```
config user ldap
  edit "WIN2K16-KLHOME-LDAPS"
    set server "192.168.20.6"
    set server-identity-check disable
    set cnid "sAMAccountName"
    set dn "dc=KLHOME,dc=local"
    set type regular
    set username "KLHOME\Administrator"
    set password *****
    set secure ldaps
    set ca-cert "CA_Cert_1"
    set port 636
  next
end
```

User group

To configure the user group:

```
config user group
  edit "KLHOME-ALLOWED-VPN"
    set member "WIN2K16-KLHOME-LDAPS"
    config match
      edit 1
        set server-name "WIN2K16-KLHOME-LDAPS"
        set group-name "CN=ALLOWED-VPN,DC=KLHOME,DC=local"
      next
    end
  end
```

```

next
end

```

Firewall address for protected server

Firewall addresses can be reused in the server settings for TCP forwarding configurations.

To configure the firewall address:

```

config firewall address
  edit "winserver"
    set subnet 192.168.20.6 255.255.255.255
  next
end

```

Migrating to ZTNA

The preceding simple [SSL VPN tunnel and web mode teleworking solutions](#) can be migrated to ZTNA configurations, providing device authentication using client certificates and additional security posture checks.

Instead of connecting to the SSL VPN tunnel or web portal, the remote user connects to the HTTPS access proxy that forwards traffic to the web server after authentication and security posture checks are completed. This provides granular control over who can access the web resource using role-based access control. It also gives the user transparent access to the website using only their browser.

Migrating to ZTNA includes the following steps:

1. [Connecting to FortiClient EMS](#)
2. [Configuring ZTNA tags on FortiClient EMS](#)
3. [Configuring a VIP to allow remote users access to FortiClient EMS](#)
4. [Configuring the ZTNA server](#)
5. [Configuring the authentication scheme and rule](#)
6. [Configuring the ZTNA rules](#)

Connecting to FortiClient EMS

The first step to configure ZTNA is to connect to and authorize a FortiClient EMS using the EMS connector. There are different ways to connect to an on-premise FortiClient EMS server and a FortiClient EMS Cloud. Refer to the first step of [Configure a FortiClient EMS connector on page 1038](#) for instructions.

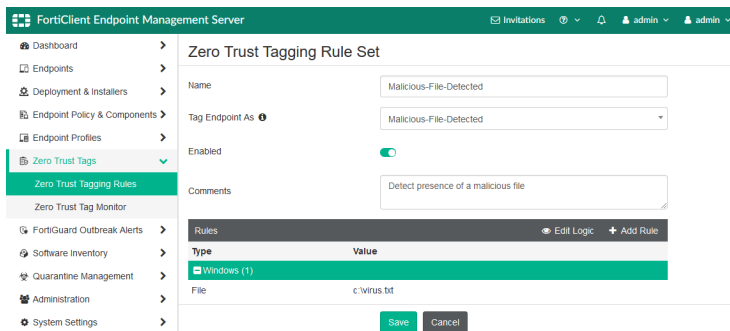

Configuring ZTNA tags on FortiClient EMS

ZTNA tags and tagging rules define security posture checks that connecting devices must pass before they are allowed to access protected resources and applications. In the following example, a Zero Trust tagging rule is configured to

detect if a virus file exists on an endpoint.

To configure a Zero Trust tagging rule on the FortiClient EMS:

1. Log in to the FortiClient EMS.
2. Go to *Zero Trust Tags > Zero Trust Tagging Rules*, and click *Add*.
3. In the *Name* field, enter *Malicious-File-Detected*.
4. In the *Tag Endpoint As* dropdown list, select *Malicious-File-Detected*.
EMS uses this tag to dynamically group together endpoints that satisfy the rule, as well as any other rules that are configured to use this tag.
5. Click *Add Rule* then configure the rule:
 - a. For OS, select *Windows*.
 - b. From the *Rule Type* dropdown list, select *File* and click the + button.
 - c. Enter a file name, such as *C:\virus.txt*.
 - d. Click *Save*.

6. Click *Save*.

Configuring a VIP to allow remote users access to FortiClient EMS

A ZTNA solution requires users to be registered and connected to the FortiClient EMS server. When an EMS server is behind the FortiGate, a VIP needs to be defined to allow remote users access to register to the FortiClient EMS. The only port required to be forwarded is TCP/8013. This VIP also needs to be applied in a firewall policy to allow this traffic.

To configure a VIP to allow traffic to the EMS server:

1. Go to *Policy & Objects > Virtual IPs* and click *Create New > Virtual IP*.
2. Set *Name* to *VIP-EMS*.
3. Configure the VIP settings:
 - a. Set *Interface* to *port1*.
 - b. Set *External IP address/range* to *192.168.2.5*.
 - c. Set *Map to* to *192.168.20.10*.
 - d. Enable *Port Forwarding*.
 - e. Set *External service port* to *8013*.
 - f. Set *Map to IPv4 port* to *8013*.
4. Click *OK*.

To configure the firewall policy:

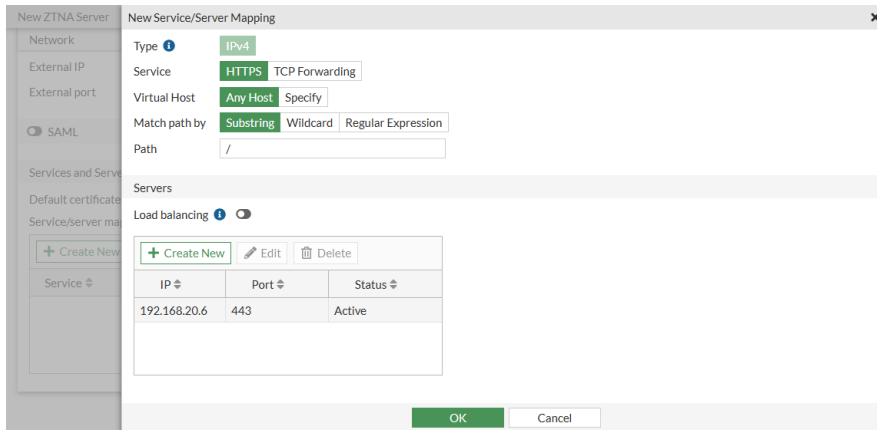

1. Go to *Policy & Objects > Firewall Policy* and click *Create New*.
2. Set *Name* to *ZTNA-VIP*.
3. Configure the policy settings:
 - a. Set *Incoming Interface* to *port1*.
 - b. Set *Outgoing Interface* to *port3*.
 - c. Set *Source* to *all*.
 - d. Set *Destination* to *VIP-EMS*.
 - e. For *Service*, select an option that is for TCP/8013.
 - f. Disable *NAT*.
 - g. Configure the remaining options as needed.
4. Click *OK*.

Configuring the ZTNA server

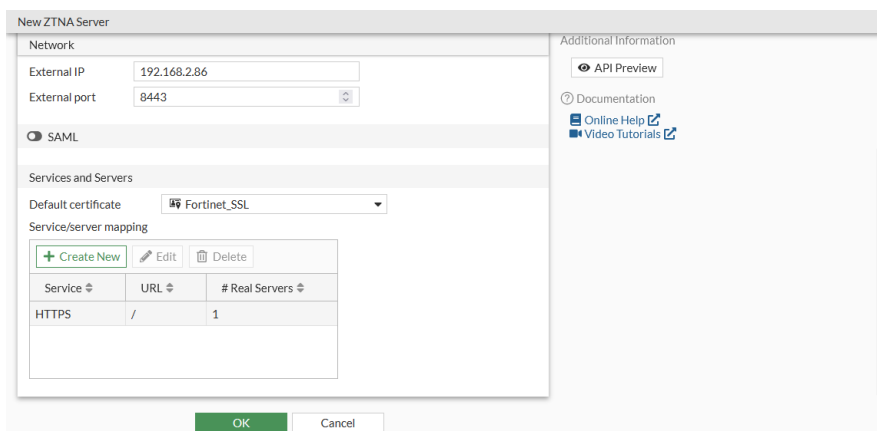

The ZTNA server defines the external IP and port used for the FortiGate access proxy. It also defines the protected resources that can be accessed through the HTTPS access proxy or TCP forwarding access proxy. The following configuration defines a HTTPS access proxy for accessing the web server on 192.168.20.6.

To configure a ZTNA server for HTTPS access proxy:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Servers* tab.
2. Click *Create New*.
3. Set *Name* to *WIN2K16-P1*.
4. Configure the network settings:
 - a. Set *External interface* to *port1*.
 - b. Set *External IP* to *192.168.2.86*.
 - c. Set *External port* to *8443*.
5. Select the *Default certificate*. Clients will be presented with this certificate when they connect to the access proxy VIP.
6. Add server mapping:
 - a. In the *Service/server mapping* table, click *Create New*.
 - b. Set *Service* to *HTTPS*.
 - c. Set *Virtual Host* to *Any Host*.
 - d. Configure the path as needed. For example, to map to *winserver.fgdocs.com/fortigate*, enter */fortigate*.
 - e. Add a server:
 - i. In the *Servers* table, click *Create New*.
 - ii. Set *IP* to *192.168.20.6*.
 - iii. Set *Port* to *443*.
 - iv. Click *OK*.

f. Click **OK**.

7. Click **OK**.

Configuring the authentication scheme and rule

The authentication scheme defines the authentication method that is applied. In this example, basic HTTP authentication is used so that users are prompted for a username and password the first time that they connect to a website through the HTTPS access proxy. The [LDAP server](#) defined for the SSL VPN configurations can be reused here.

To configure an authentication scheme:

1. Go to *Policy & Objects > Authentication Rules* and click *Create New > Authentication Scheme*.
2. Set the name to *ZTNA-Auth-scheme*.
3. Set *Method* to *Basic*.
4. Set *User database* to *Other* and select *WIN2K16-KLHOME-LDAPS* as the LDAP server.
5. Click **OK**.

The authentication rule defines the proxy sources and destination that require authentication, and what authentication scheme is applied. In this example, active authentication through the basic HTTP prompt is used and applied to all sources.

To configure an authentication rule:

1. Go to *Policy & Objects > Authentication Rules* and click *Create New > Authentication Rule*.
2. Set the name to *ZTNA-Auth-rule*.
3. Set *Source Address* to *all*.
4. Set *Protocol* to *HTTP*.
5. Enable *Authentication Scheme* and select *ZTNA-Auth-scheme*.
6. Click *OK*.

Configuring the ZTNA rules

A user or user group must be applied to the ZTNA rule used to control user access. The authenticated user from the authentication scheme and rule must match the user or user group in the ZTNA rule. The [user group](#), *KLHOME-ALLOWED-VPN*, defined in the SSL VPN configurations is reused in this example. The ZTNA tag, *Malicious-File-Detected*, is used to define a rule to deny access when the connecting device has the malicious file detected.

To configure ZTNA rules to allow and deny traffic based on ZTNA tags:

1. Go to *Policy & Objects > ZTNA* and select the *ZTNA Rules* tab.
2. Create a rule to deny traffic:
 - a. Click *Create New*.
 - b. Set *Name* to *ZTNA-Deny-malicious*.
 - c. Set *Incoming Interface* to *port1*.
 - d. Set *Source* to *all*, then click the + and from the *User* tab, select the *KLHOME-ALLOWED-VPN* group.
 - e. Add the ZTNA tag *Malicious-File-Detected*.
This tag is dynamically retrieved from EMS when the Zero Trust tagging rule is first created.
 - f. Select the ZTNA server *WIN2K16-P1*.
 - g. Set *Action* to *DENY*.
 - h. Enable *Log Violation Traffic*.

- i. Click *OK*.
3. Create a rule to allow traffic:

- a. Click *Create New*.
 - b. Set *Name* to *proxy-WIN2K16-P1*.
 - c. Set *Incoming Interface* to *port1*.
 - d. Set *Source* to *all*, then click the + and from the *User* tab, select the *KLHOME-ALLOWED-VPN* group. The *Source* can also be set to specific IP addresses to only allow those addresses to connect to this HTTPS access proxy.
 - e. Add the ZTNA tag *Low*.
 - f. Select the ZTNA server *WIN2K16-P1*.
 - g. Set *Action* to *ACCEPT*.
 - h. Configure the remaining options as needed.
 - i. Click *OK*.
4. In the *ZTNA Rules* list, make sure that the deny rule (*ZTNA-Deny-malicious*) is above the allow rule (*proxy-WIN2K16-P1*).

Testing the connection

Once ZTNA is configured, connect to the FortiGate access proxy using an endpoint that is registered to EMS. The user should be prompted for their device certificate, username, and password the first time they connect. Once they have authenticated and they pass the security posture checks, they will be allowed to access the website.

See [ZTNA HTTPS access proxy example on page 1053](#) and [ZTNA HTTPS access proxy with basic authentication example on page 1060](#) for sample verifications and results.

Disabling the SSL VPN

Once testing is complete and the ZTNA servers and policies are configured, the users can be migrated to using ZTNA. Use the following checklist to verify if the remote users are ready to migrate:

1. The users have installed a supported FortiClient version and have installed the ZTNA module.
2. The endpoints can register to FortiClient EMS.
3. If using a TCP forwarding access proxy, ensure that ZTNA rules are either pushed from FortiClient EMS, or the users know how to configure them manually.

Next, SSL VPN access can be disabled in a phased approach by disabling SSL VPN firewall policies that allow access to resources that are accessible using ZTNA.

Once all applications and resources have been migrated, the SSL VPN can be disabled entirely by going to *VPN > SSL-VPN Settings*, and deselecting the *Enable SSL-VPN* toggle.

ZTNA scalability support for up to 50 thousand concurrent endpoints

ZTNA scalability supports up to 50 thousand concurrent endpoints. Communication between FortiOS and FortiClient EMS has efficient queries that request incremental updates. Retrieved device information can be written to the FortiClient NAC daemon cache.

FortiOS can receive tag information from the EMS common tags API. This feature requires FortiClient EMS 7.0.3 or later.

The APIs `api/v1/report/fct/uid_tags` and `api/v1/report/fct/tags` replace the API `api/v1/report/fct/host_tags`.

To use the common tags API capability:

1. Enable the common tags API when connecting the EMS:

```
config endpoint-control fctems
  edit "local.ems"
    set server "10.6.30.213"
    set capabilities fabric-auth silent-approval websocket websocket-malware push-
ca-certs common-tags-api
    next
end
```

2. The FortiGate uses the new APIs to obtain device information from the EMS:

```
[ec_ems_context_submit_work:414] Call submitted successfully.
  obj-id: 11, desc: REST API to get updates of tag endpoints., entry:
api/v1/report/fct/tags.
[ec_ems_context_submit_work:414] Call submitted successfully.
  obj-id: 12, desc: REST API to get updates of tags associated with FCT UID., entry:
api/v1/report/fct/uid_tags.
[ec_ez_worker_process:334] Processing call for obj-id: 11, entry:
"api/v1/report/fct/tags"
[dynamic_addr_ha_act:215] called (EMS SN N/A).
[dynamic_addr_ha_act:215] called (EMS SN N/A).
[ec_ez_worker_process:441] Call completed successfully.
  obj-id: 11, desc: "REST API to get updates of tag endpoints.", entry:
"api/v1/report/fct/tags".
[ec_ez_worker_process:334] Processing call for obj-id: 12, entry:
"api/v1/report/fct/uid_tags"
[ec_record_sync_tags_info_store:1419] Received 1 tags for
3D86DF70B85E16CBAD67908A897B4494 with sn FCTEMS8888888888
[ec_record_sync_tags_info_store:1419] Received 1 tags for
DA12930442F13F84D2441F03FCB6A10E with sn FCTEMS8888888888
[ec_record_sync_tags_info_store:1419] Received 1 tags for
25C59C275F257F4C5FBC7F6F5F56788E with sn FCTEMS8888888888
[ec_ez_worker_process:441] Call completed successfully.
  obj-id: 12, desc: "REST API to get updates of tags associated with FCT UID.", entry:
"api/v1/report/fct/uid_tags".
[ec_ems_context_submit_work:414] Call submitted successfully.
  obj-id: 7, desc: REST API to get updates about system info., entry:
api/v1/report/fct/sysinfo.
[ec_ems_context_submit_work:414] Call submitted successfully.
  obj-id: 11, desc: REST API to get updates of tag endpoints., entry:
api/v1/report/fct/tags.
[ec_ez_worker_process:334] Processing call for obj-id: 11, entry:
"api/v1/report/fct/tags"
[ec_ez_worker_process:441] Call completed successfully.
  obj-id: 11, desc: "REST API to get updates of tag endpoints.", entry:
"api/v1/report/fct/tags".
(.....)
```

3. Confirm that the device information from the EMS is written to the FortiClient NAC daemon cache:

```
# diagnose endpoint record list
...
Avatar source: OS
Phone number:
Number of Routes: (1)
Gateway Route #0:
- IP:10.1.91.6, MAC: 4f:8d:c2:73:dd:fe, Indirect: no
- Interface:port2, VFID:1, SN: FG5H1E5999999999
online records: 37174; offline records: 0; quarantined records: 0; out-of-sync records:
0
```

4. Use the tags that are pulled from the EMS in a firewall address:

```
config firewall address
edit "FCTEMS8888888888_ZT_AD_MGMT"
set type dynamic
set sub-type ems-tag
set obj-tag "ZT_AD_MGMT"
set tag-type "zero_trust"
next
end
```

5. Check the tags' resolved IP and MAC addresses:

```
# diagnose firewall fqdn getinfo-ip FCTEMS8888888888_ZT_AD_MGMT
getinfo FCTEMS8888888888_ZT_AD_MGMT id:114 generation:106 count:187 data_len:6160 flag 0

# diagnose firewall fqdn getinfo-mac MAC_FCTEMS8888888888_ZT_AD_MGMT
getinfo MAC_FCTEMS8888888888_ZT_AD_MGMT id:163 generation:105 count:371 data_len:2226
flag 0

# diagnose firewall dynamic address FCTEMS8888888888_ZT_AD_MGMT
CMDB name: FCTEMS8888888888_ZT_AD_MGMT
TAG name: ZT_AD_MGMT
FCTEMS8888888888_ZT_AD_MGMT: ID(114)
ADDR(10.1.10.4)
(.....)
ADDR(10.1.99.195)
Total IP dynamic range blocks: 190.
Total IP dynamic addresses: 281.

# diagnose firewall dynamic address MAC_FCTEMS8888888888_ZT_AD_MGMT
CMDB name: MAC_FCTEMS8888888888_ZT_AD_MGMT
TAG name: ZT_AD_MGMT
MAC_FCTEMS8888888888_ZT_AD_MGMT: ID(163)
MAC(52:f1:9d:06:1c:db)
MAC(4b:77:2b:db:82:15)

Total MAC dynamic addresses: 393.
```

ZTNA troubleshooting and debugging commands

The following debug commands can be used to troubleshoot ZTNA issues:

Command	Description
# diagnose endpoint fctems test-connectivity <EMS>	Verify FortiGate to FortiClient EMS connectivity.
# execute fctems verify <EMS>	Verify the FortiClient EMS's certificate.
# diagnose test application fcnacd 2	Dump the EMS connectivity information.
# diagnose debug app fcnacd -1 # diagnose debug enable	Run real-time FortiClient NAC daemon debugs.
# diagnose endpoint record list <ip>	Show the endpoint record list. Optionally, filter by the endpoint IP address.
# diagnose endpoint lls-comm send ztna find-uid <uid> <EMS_serial_number> <EMS_tenant_id>	Query endpoints by client UID, EMS serial number, and EMS tenant ID.
# diagnose endpoint lls-comm send ztna find-ip-vdom <ip> <vdom>	Query endpoints by the client IP-VDOM pair.
# diagnose wad dev query-by uid <uid> <EMS_serial_number> <EMS_tenant_id>	Query from WAD diagnose command by UID, EMS serial number, and EMS tenant ID.
# diagnose wad dev query-by ipv4 <ip>	Query from WAD diagnose command by IP address.
# diagnose firewall dynamic list	List EMS ZTNA tags and all dynamic IP and MAC addresses.
# diagnose test application fcnacd 7 # diagnose test application fcnacd 8	Check the FortiClient NAC daemon ZTNA and route cache.
# diagnose wad worker policy list	Display statistics associated with access proxy rules.
# diagnose wad debug enable category all # diagnose wad debug enable level verbose # diagnose debug enable	Run real-time WAD debugs.
# diagnose debug reset	Reset debugs when completed

The WAD daemon handles proxy related processing. The FortiClient NAC daemon (fcnacd) handles FortiGate to EMS connectivity.

Troubleshooting usage and output

1. Verify the FortiGate to EMS connectivity and EMS certificate:

```
# diagnose endpoint fctems test-connectivity WIN10-EMS
Connection test was successful:

# execute fctems verify WIN10-EMS
Server certificate already verified.
```

```
# diagnose test application fcnacd 2
EMS context status:
FortiClient EMS number 1:
    name: WIN10-EMS confirmed: yes
    fetched-serial-number: FCTEMS0000109188
Websocket status: connected
```

2. If fcnacd does not report the proper status, run real-time fcnacd debugs:

```
# diagnose debug app fcnacd -1
# diagnose debug enable
```

3. Verify the following information about an endpoint:

- Network information
- Registration information
- Client certificate information
- Device information
- Vulnerability status
- Relative position with the FortiGate

```
# diagnose endpoint record list 10.6.30.214
Record #1:
    IP Address = 10.6.30.214
    MAC Address = 00:0c:29:ba:1e:61
    MAC list = 00:0c:29:ba:1e:61;00:0c:29:ba:1e:6b;
    VDOM = root (0)
    EMS serial number: FCTEMS8821001322
    EMS tenant id: 00000000000000000000000000000000
    Client cert SN: 17FF6595600A1AF53B87627AB4EBEDD032593E64
    Quarantined: no
    Online status: online
    Registration status: registered
    On-net status: on-net
    Gateway Interface: port2
    FortiClient version: 7.0.0
    AVDB version: 84.778
    FortiClient app signature version: 18.43
    FortiClient vulnerability scan engine version: 2.30
    FortiClient UID: 5FCFA3ECDE4D478C911D9232EC9299FD
    Host Name: ADPC
    ...
    Number of Routes: (1)
        Gateway Route #0:
            - IP:10.1.100.214, MAC: 00:0c:29:ba:1e:6b, Indirect: no
            - Interface:port2, VFID:0, SN: FG5H1E5819902474
online records: 1; offline records: 0; quarantined records: 0
```

4. Query the endpoint information, include ZTNA tags, by UID or IP address:

```
# diagnose endpoint lls-comm send ztna find-uid 5FCFA3ECDE4D478C911D9232EC9299FD
FCTEMS8821001322 00000000000000000000000000000000
UID: 5FCFA3ECDE4D478C911D9232EC9299FD
EMS Fabric ID: FCTEMS8821001322:00000000000000000000000000000000
    status code:ok
    Domain: qa.wangd.com
    User: user1
```

```

```

6. List all the dynamic ZTNA IP and MAC addresses learned from EMS:

```

# diagnose firewall dynamic list
List all dynamic addresses:
FCTEMS0000109188_all_registered_clients: ID(51)
  ADDR(172.17.194.209)
  ADDR(192.168.40.8)
...
FCTEMS0000109188_Low: ID(78)
  ADDR(172.17.194.209)

```

```

        ADDR(192.168.40.8)
...
FCTEMS0000109188_Malicious-File-Detected: ID(190)
        ADDR(172.17.194.209)
        ADDR(192.168.40.8)
...

```

7. Check the FortiClient NAC daemon ZTNA and route cache:

```

# diagnose test application fcnacd 7
ZTNA Cache:
-uid 5FCFA3ECDE4D478C911D9232EC9299FD: { "tags": [ "ZT_OS_WIN", "all_registered_
clients", "Medium" ], "domain": "qa.wangd.com", "user_name": "user1", "client_cert_sn":
"17FF6595600A1AF53B87627AB4EBEDD032593E64", "owner": "FOSQA@qa.wangd.com", "gateway_
route_list": [ { "gateway_info": { "fgt_sn": "FG5H1E5819902474", "interface": "port2",
"vdom": "root" }, "route_info": [ { "ip": "10.1.100.214", "mac": "00-0c-29-ba-1e-6b",
"route_type": "direct" } ] } ], "ems_sn": "FCTEMS8821001322" }

# diagnose test application fcnacd 8
IP-VfID Cache:
IP: 10.1.100.206, vfid: 0, uid: 3DED29B54386416E9888F2DCBD2B9D21
IP: 10.1.100.214, vfid: 0, uid: 5FCFA3ECDE4D478C911D9232EC9299FD

```

8. Troubleshoot WAD with real-time debugs to understand how the proxy handled a client request:

```

# diagnose wad debug enable category all
# diagnose wad debug enable level verbose
# diagnose debug enable

[0x7fbd7a46bb60] Received request from client: 10.10.10.20:56312
GET / HTTP/1.1 Host: 192.168.2.86:8443 Connection: keep-alive Cache-Control: max-age=0
Upgrade-Insecure-Requests: 1 User-Agent: Mozilla/5.0 (Windows NT 10.0; Win64; x64)
